Preliminary Draft Environmental Impact Statement
Shasta Lake Water Resources Investigation

United States Department of the Interior
Bureau of Reclamation, Mid-Pacific Region
2800 Cottage Way, MP-700
Sacramento, CA 95825

This Preliminary Draft Environmental Impact Statement (EIS) for the Shasta Lake Water Resources Investigation (SLWRI) has been prepared by the U.S. Department of the Interior, Bureau of Reclamation (Reclamation), Mid-Pacific Region, consistent with requirements of the National Environmental Policy Act (NEPA). Cooperating agencies pursuant to NEPA include the U.S. Forest Service, Bureau of Indian Affairs, Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians, and U.S. Army Corps of Engineers. A companion document to the Preliminary Draft EIS, the Draft Feasibility Report, has been published under separate cover.

This Preliminary Draft EIS evaluates the potential environmental effects of alternative plans to enlarge Shasta Dam and Reservoir to (1) increase anadromous fish survival in the upper Sacramento River, primarily upstream from Red Bluff Diversion Dam, (2) increase water supplies and water supply reliability for agricultural, municipal and industrial, and environmental purposes, and (3) address related water resource problems, needs, and opportunities. In addition to the No-Action Alternative, this Preliminary Draft EIS considers five action alternatives, which include potential dam raises ranging from 6.5 to 18.5 feet and related reservoir enlargements ranging from 256,000 to 634,000 acre feet.

The SLWRI is a feasibility study that is one of five studies for potential surface water storage projects included in the 2000 CALFED Bay-Delta Programmatic Record of Decision, and is being conducted under the general authority of Public Laws 96-375, which was reaffirmed under Public Law 108-361, also known as the CALFED Bay-Delta Authorization Act. Reclamation is releasing the Preliminary Draft EIS and Draft Feasibility Report to share the information generated since completion of the Plan formulation Report in 2007.

Release of these documents is intended to inform interested agencies, organizations, and individuals of the potential impacts, costs, and benefits of the alternative analyzed to-date. A complete Draft EIS will be prepared and processed for formal public review and comment, consistent with NEPA, following additional refinements to the action alternatives with changes in regulatory conditions in the Sacramento-San Joaquin Delta affecting operations of the State and Federal water projects.

For further information, please contact Katrina Chow, Project Manager, at the address above, by telephone at (916) 978-5067, or by e-mail at KChow@usbr.gov.

Shasta Lake Water Resources Investigation, California

Preliminary Draft
Environmental Impact Statement

Prepared by:

United States Department of the Interior
Bureau of Reclamation
Mid-Pacific Region

U.S. Department of the Interior
Bureau of Reclamation

November 2011

Summary

S.1 Introduction

This Preliminary Draft Environmental Impact Statement (PDEIS) has been prepared to evaluate the potential environmental, cultural, and socioeconomic effects of implementing the proposed action to modify the existing Shasta Dam and Reservoir as part of the ongoing Shasta Lake Water Resources Investigation (SLWRI). The SLWRI is a feasibility study being conducted by the U.S. Department of the Interior, Bureau of Reclamation (Reclamation), Mid-Pacific Region, and includes this PDEIS and the accompanying Draft of the *Shasta Lake Water Resources Investigation Feasibility Report* (Feasibility Report) and appendices. Reclamation is serving as the Federal lead agency for compliance with the National Environmental Policy Act (NEPA). Cooperating agencies for the SLWRI, pursuant to NEPA, include U.S. Forest Service (USFS), Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians, U.S. Army Corps of Engineers, and U.S. Bureau of Indian Affairs. This document has also been prepared in accordance with the California Environmental Quality Act (CEQA).

The purpose of the proposed action is to improve operational flexibility of the Sacramento-San Joaquin Delta (Delta) watershed system through modifying the existing Shasta Dam and Reservoir to increase water supply reliability for agricultural, municipal and industrial, and agricultural purposes, and increase anadromous fish survival in the upper Sacramento River, and address other related resource needs.

Public Law 96-375 (October 3, 1980) provides feasibility study authority for the SLWRI and allows the Secretary of the Interior to do the following:

> …*engage in feasibility studies relating to enlarging Shasta Dam and Reservoir, Central Valley Project, California or to the construction of a larger dam on the Sacramento River, California, to replace the present structure.*

Section 103(c), "Authorizations for Federal Activities Under Applicable Law," of the CALFED Bay-Delta Authorization Act (Public Law 108-361, October 25, 2004), authorizes the Secretary of the Interior to carry out the activities described in paragraphs (1) through (10) of Subsection (d), which include the following:

> *…(1)(A)(i) planning and feasibility studies for projects to be pursued with project-specific study for enlargement of (1) the Shasta Dam in Shasta County.*

Also, Section 103(a)(1) of Public Law 108-361 (October 25, 2004) states the following:

> *The Record of Decision is approved as a general framework for addressing the CALFED Bay-Delta Program, including its components relating to water storage, ecosystem restoration, water supply reliability (including new firm yield), conveyance, water use efficiency, water quality, water transfers, watersheds, the Environmental Water Account, levee stability, governance, and science.*

The CALFED Bay-Delta Program (CALFED) Programmatic Record of Decision (ROD) called for the Secretary of the Interior to do the following:

> *…engage in feasibility studies for the purpose of determining the potential costs, benefits, environmental impacts, and feasibility of using the Sacramento River for conveying water from the enlarged Shasta Dam and Reservoir or the larger dam to points of use downstream from the dam.*

Other Federal legislation influences the SLWRI. Two laws of special note are Public Law 89-336 (November 8, 1965) and Public Law 102-575 (October 30, 1992). Public Law 89-336 created the Whiskeytown-Shasta-Trinity National Recreation Area, which includes Shasta Dam and Reservoir. Public Law 102-575, the Central Valley Project Improvement Act, directed numerous changes to the operation of the Central Valley Project (CVP). Among these changes was adding fish and wildlife protection, restoration, and enhancement as a project purpose, which resulted in substantial changes to water supply deliveries, river flows, and related environmental conditions in the study area.

S.1.1 Intended Use of This Preliminary Draft Environmental Impact Statement

Release of this Preliminary Draft EIS, the Draft Feasibility Report, and their appendices presents SLWRI findings to date, and provides another opportunity for public and stakeholder input.

S.1.2 Intended Use of Final Environmental Impact Statement

An environmental impact statement (EIS) identifies and evaluates alternatives that meet the project purpose and can also avoid project-related impacts, analyzes the environmental effects of an action, and indicates additional measures to reduce or avoid potential environmental effects resulting from the action alternatives (i.e., mitigation measures). An EIS must also disclose significant environmental effects that cannot be avoided, growth-inducing effects, significant cumulative impacts, and effects found not to be significant.

The purpose of an EIS is not to recommend approval or rejection of a project, but to provide information to aid the public and decision makers/permitting agencies in the decision-making process.

This EIS, when finalized, is intended to be used by the Federal lead agency when considering approval of the proposed action or an alternative to the proposed action. All cooperating agencies, responsible agencies, and other Federal, State, and local agencies with permitting or approval authority over any aspect of the proposed action are expected to use the information contained in the Final SLWRI EIS to meet most, if not all, of their information needs to make decisions and/or issue permits with respect to the proposed action.

S.2 Purpose and Need for Proposed Action and Project Objectives

NEPA regulations require a statement of "the underlying purpose and need to which the agency is responding in proposing the alternatives, including the proposed action," described below. The State CEQA Guidelines require a clearly written statement of objectives, including the underlying purpose of a project (Section 15124(b)), also described below.

S.2.1 Purpose and Need

The purpose of the proposed action is to improve operational flexibility of the Sacramento-San Joaquin Delta (Delta) watershed system through modifying the existing Shasta Dam and Reservoir to increase water supply reliability and anadromous fish populations in the upper Sacramento River. Specifically, the purpose of the proposed action is to accomplish all of the following:

- Promote increased survival of anadromous fish populations in the upper Sacramento River, primarily upstream from the location of the Red Bluff Diversion Dam (RBDD).
- Increase water supplies and water supply reliability for agricultural, municipal and industrial, and environmental purposes to help meet current and future water demands.
- To the extent possible, through meeting these objectives, include features that conserve and restore ecosystem resources in the Shasta Lake area and along the upper Sacramento River, reduce flood damage along the Sacramento River, increase hydropower capabilities at Shasta Dam, maintain and increase recreation opportunities at Shasta Lake, and maintain or improve water quality conditions in the Sacramento River downstream from Shasta Dam and in the Delta.

The need for the proposed action is described below and summarized from the 2007 Reclamation *Shasta Lake Water Resources Investigation Plan*

Formulation Report, the 2004 Reclamation *Shasta Lake Water Resources Investigation Initial Alternatives Information Report*, and the Plan Formulation Appendix.

S.2.1.1 Anadromous Fish Survival

The Sacramento River system is unique in California in that it supports four separate runs of Chinook salmon: fall-, late fall-, winter-, and spring-run. The adult populations of the four runs of salmon and other important fish species that spawn in the upper Sacramento River have considerably declined over the last 40 years. Several fish species in the upper Sacramento River have been listed under the Federal Endangered Species Act: Sacramento River winter-run Chinook salmon (endangered), Central Valley spring-run Chinook salmon (threatened), Central Valley steelhead (threatened), and the Southern Distinct Population Segment of North American green sturgeon (threatened). Two of these species are also listed under the California Endangered Species Act: Sacramento River winter-run Chinook salmon (endangered) and Central Valley spring-run Chinook salmon (threatened).

Unsuitable water temperatures in the upper Sacramento River, especially in dry and critically dry years, is a critical factor affecting the abundance of Chinook salmon and steelhead in the river. Releases of cold water stored behind Shasta Dam can improve seasonal water temperatures in the Sacramento River for anadromous fish, particularly winter-run Chinook salmon, during critical periods. Prolonged droughts depleting the cold-water storage in Shasta Reservoir could extirpate the entire Sacramento River winter-run Chinook salmon population. Under current conditions, even 2 consecutive years of drought could reduce Shasta Reservoir cold-water storage to levels insufficient to support the Sacramento River winter-run Chinook spawning and incubation season. This could result in complete year-class failure, virtually eliminating all of a single year's spawning and incubating winter-run Chinook in the Sacramento River. Various actions have been taken to address these problems, ranging from minimum instream flow requirements to structural changes at Shasta Dam. Despite these steps, additional actions are needed to address anadromous fish survival in the upper Sacramento River.

S.2.1.2 Water Supply Reliability

Demands for water in the state of California exceed available supplies. Reclamation's 2008 *Water Supply and Yield Study* describes dramatic increases in statewide population, land use changes, regulatory requirements, and limitations on storage and conveyance facilities have resulted in unmet water demands and subsequent increases in competition for water supplies among urban, agricultural, and environmental uses. The 2009 *California Water Plan Update* concludes that California is facing one of the most significant water crises in its history; drought impacts are growing, ecosystems are declining, water quality is diminishing, and climate change is affecting statewide hydrology. Challenges are greatest during drought years, when water supplies are less available.

As the population of California grows, and the demand for adequate water supplies becomes more acute, the ability to maintain a healthy and viable industrial and agricultural economy while protecting aquatic species will be increasingly difficult. Compounding these issues, potential effects of climate change such as changed precipitation patterns, less snowfall, and earlier snowmelt may considerably increase the demands on available water supplies in the future. As owner and operator of the CVP, one of the largest water storage and conveyance systems in the world, Reclamation has identified the need to increase the reliability of CVP water deliveries to its water contractors, particularly during dry and critically dry water years. Similar needs and challenges are faced by the SWP and other water projects throughout the State. As one of many efforts to improve the reliability of California's water supply, the SLWRI was established to evaluate the potential to improve water supply reliability primarily by modifying Shasta Dam and enlarging Shasta Lake.

S.2.1.3 Other Resources

Reclamation has identified other resource needs that could be addressed through potential modification of Shasta Dam and Reservoir. Escalating demands on statewide electricity production, continuing modification of natural aquatic and riparian habitats in the Sacramento River system, increasing threats of potential flooding in the Sacramento River system, and greater demands for recreational opportunities are all potential local, regional, or statewide problems exacerbated by California's population growth in general and particularly in the Sacramento Valley. The SLWRI provides opportunities to address these other resource needs, as well as the primary SLWRI objectives of increased anadromous fish survival and water supply reliability.

S.2.2 Project Objectives

To address the identified purpose and need described above, two primary project (i.e., planning) objectives were developed for the SLWRI. Five secondary project objectives were developed to take advantage of other beneficial project opportunities.

S.2.2.1 Primary Project Objectives

Primary project objectives are those which specific alternatives are formulated to address. Primary project objectives developed for the SLWRI are as follows:

- Increase the survival of anadromous fish populations in the Sacramento River, primarily upstream from the RBDD.

- Increase water supply and water supply reliability for agricultural, municipal and industrial, and environmental purposes to help meet current and future water demands, with a focus on enlarging Shasta Dam and Reservoir.

The primary project objectives are considered to have coequal priority, with each pursued to the maximum practicable extent without adversely affecting the other.

S.2.2.2 Secondary Project Objectives

Secondary project objectives are actions, operations, or features that should be considered in the plan formulation process, but only to the extent possible through pursuit of the primary objectives. Five secondary project objectives were developed for the SLWRI:

- Conserve, restore, and enhance ecosystem resources in the Shasta Lake area and along the upper Sacramento River.
- Reduce flood damage along the Sacramento River.
- Develop additional hydropower generation capabilities at Shasta Dam.
- Maintain and increase recreation opportunities at Shasta Lake.
- Maintain or improve water quality conditions in the Sacramento River downstream from Shasta Dam and the Delta.

S.3 Study Area

Shasta Dam and Shasta Lake are located on the upper Sacramento River in Northern California, approximately 9 miles northwest of Redding in Shasta County. Because of the potential influence of the proposed modification of Shasta Dam and Reservoir and subsequent system operations and water deliveries on resources over a large geographic area, the SLWRI includes both a primary study area and an extended study area. The primary study area includes Shasta Dam and Reservoir, the lower portions of all contributing major and minor tributaries flowing into Shasta Lake, Trinity and Lewiston reservoirs, and the Sacramento River between Shasta Dam and the RBDD facilities, including tributaries at their confluence. The RBDD is directly adjacent to the Red Bluff Pumping Plant (RBPP), which is currently under construction. The extended study area includes the Sacramento River downstream from the RBDD, including portions of the American and Feather river basins downstream from CVP/State Water Project (SWP) facilities, San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta), lower portions of the San Joaquin River basin downstream from CVP facilities (Friant and New Melones reservoirs), and facilities and water service areas of the CVP and SWP.

S.4 Summary Description of Alternatives

The following sections summarize the no-action and five action alternatives evaluated in the PDEIS.

S.4.1 No-Action Alternative

For the SLWRI, under the No-Action Alternative, the Federal Government would continue to implement reasonably foreseeable actions, including actions with current authorization, secured funding for design and construction, and environmental permitting and compliance activities that are substantially complete, but would not take additional actions toward implementing a plan to raise Shasta Dam to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water supply and reliability issues in California. The following discussions highlight the consequences of implementing the No-Action Alternative, as they relate to the objectives of the SLWRI.

Anadromous Fish Survival

Much has been done to address anadromous fish survival problems in the upper Sacramento River. Solutions have ranged from changes in the timing and magnitude of releases from Shasta Dam to constructing and operating the temperature control device (TCD) at the dam. Actions also include site-specific projects, such as introducing spawning gravel to the Sacramento River, and work to improve or restore spawning habitat in tributary streams. However, some actions have had an adverse effect on Sacramento River habitat, including implementing requirements of the Trinity River ROD, as amended in 2000. Increased demand for water for agricultural, municipal and industrial, and environmental uses is also expected to reduce the reliability of cold water for anadromous fish. According to 2009 National Marine Fisheries Service *Public Draft Recovery Plan*, under the No-Action Condition, a drought lasting several years would likely result in the extirpation of winter run Chinook salmon. Under the No-Action Alternative, it is assumed that actions to protect fisheries and benefit aquatic environments would continue, including maintaining the TCD and satisfying other existing regulatory requirements.

Water Supply Reliability

Demands for water in California will continue to exceed available supplies, and the need for additional supplies is expected to grow. Competition for available water supplies would intensify as water demands increase to support population growth. Water conservation and reuse efforts are expected to significantly increase, and forced conservation as the result of increasing water shortages would continue. It is likely that with continued and deepening shortages in available water supplies, adverse economic impacts would increase over time in the Central Valley and elsewhere in California.

Ecosystem Resources, Flood Management, Hydropower, Recreation, and Water Quality

As opportunities arise, some locally sponsored efforts will likely continue to improve environmental conditions on tributaries to Shasta Lake and along the upper Sacramento River. However, overall, future environmental-related conditions in these areas will likely be similar to existing conditions. The quantity, quality, diversity, and connectivity of riparian, wetland, and riverine habitats along the Sacramento River have been limited by confinement of the river system by levees, reclamation of adjacent lands for farming, bank protection, channel stabilization, and land development.

Under the No-Action Alternative, the threat of flooding would continue, and may increase as population growth continues. California's demand for electricity is also expected to increase substantially in the future. Under the No-Action Alternative, no actions would be taken to help meet this growing demand.

To address the impact of water quality deterioration on the Sacramento River basin and Delta ecosystems, several environmental flow goals have been established through legal mandates. Despite these efforts, under the No-Action Alternative, these resources would continue to decline and ecosystems would continue to be impacted. In addition, Delta water quality may continue to decline.

S.4.2 Management Measures Common to All Action Alternatives

Eight of the management measures identified during the alternatives development process would be included in all action alternatives to some degree:

- Enlarge the cold-water pool of Shasta Lake
- Modify the TCD
- Increase water conservation storage
- Reduce water demand
- Modify flood operations
- Modify hydropower facilities
- Maintain and increase recreation opportunities
- Maintain or improve water quality

These eight common management measures are described below.

All action alternatives would involve, at a minimum, enlarging the cold-water pool by raising Shasta Dam to enlarge Shasta Reservoir. Minimum modifications to the TCD under all action alternatives would include raising the existing structure and modifying the shutter control. All action alternatives

would also increase the conservation storage in Shasta Reservoir by raising Shasta Dam. To reduce water demand, all action alternatives would include an additional water conservation program for new water supplies created by the project. This program would augment current water use efficiency practices. Enlarging Shasta Reservoir would require adjustment of the existing flood operation guidelines, or rule curves, to reflect physical modifications such as an increase in dam/spillway elevation; the rule curves would be revised with the goal of reducing flood damage and enhancing other objectives to the extent possible. Enlarging Shasta Dam would probably also require various modifications to the dam's existing hydropower facilities to enable their continued efficient use. Recreation is important to the Shasta Lake region; therefore, existing recreation opportunities would be maintained and/or increased. All action alternatives would maintain and potentially improve water quality by increasing Delta outflow during drought years and reducing salinity during critical periods, and may also provide operational flexibility for Delta emergency response.

S.4.3 Alternative CP1

Comprehensive Plan (CP) 1 focuses on both anadromous fish survival and water supply reliability. CP1 consists of enlarging Shasta Dam by raising the crest 6.5 feet and implementing the set of eight common management measures described above. By raising Shasta Dam from a crest at elevation 1,077.5 feet above mean sea level (elevation 1,077.5) to elevation 1,084.0, this alternative would increase the height of the reservoir's full pool by 8.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications, including replacing the three drum gates with six sloping, fixed-wheel gates. This increase in full pool height would add approximately 256,000 acre-feet of additional storage to the overall reservoir capacity. Accordingly, the overall full pool storage would increase from 4.55 million acre-feet (MAF) to 4.81 MAF.

Under CP1, operations for water supply, hydropower, and environmental requirements would be similar to existing operations, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. As mentioned, this alternative (and all action alternatives) includes extending the existing TCD for efficient use of the expanded cold-water pool.

CP1 would also include the potential to revise the operational rules for flood control for Shasta Dam and Reservoir, which could reduce the potential for flood damage, and benefit recreation. Reservoir reoperation may provide recreation benefits by raising the bottom of the flood control pool elevation and, thus, allowing higher winter and spring water levels and increasing Shasta Lake's surface area. In addition, reservoir reoperation may provide more operational flexibility in reservoir drawdown requirements in response to storms, resulting in a net increase in the rate of spring reservoir filling during some years.

S.4.4 Alternative CP2

CP2 also focuses on both anadromous fish survival and water supply reliability. CP2 consists of enlarging Shasta Dam by raising the crest 12.5 feet and implementing the set of eight common management measures described above. A dam raise of 12.5 feet was chosen because it represents a midpoint between the likely smallest dam raise considered and the largest practical dam raise that would not require relocating the Pit River Bridge. By raising Shasta Dam from a crest at elevation 1,077.5 to elevation 1,090.0, CP2 would increase the height of the reservoir's full pool by 14.5 feet. This increase in full pool height would add approximately 443,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would increase from 4.55 MAF to 5.0 MAF.

Under CP2, operations for water supply, hydropower, and environmental requirements would be similar to existing operations, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. The existing TCD would be extended for efficient use of the expanded cold-water pool.

As described for CP1, this alternative would also include the potential to revise flood control operational rules, which could reduce the potential for flood damage and benefit recreation.

S.4.5 Alternative CP3

As for CP1 and CP2, CP3 focuses on both anadromous fish survival and water supply reliability. CP3 consists of enlarging Shasta Dam and Reservoir by raising the dam crest 18.5 feet and implementing the set of eight common management measures described above.

By raising Shasta Dam from a crest at elevation 1,077.5 to elevation 1,096.0, CP3 would increase the height of the reservoir's full pool by 20.5 feet. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would be increased from 4.55 MAF to 5.19 MAF. Although higher dam raises are technically and physically feasible, 18.5 feet is the largest dam raise that would not require extensive and costly reservoir area relocations, such as relocating the Pit River Bridge, Interstate-5, and the Union Pacific Railroad tracks.

Under CP3, operations for water supply, hydropower, and environmental requirements would be similar to existing operations, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. The existing TCD would be extended for efficient use of the expanded cold-water pool.

As described for the above alternatives, this alternative would also include the potential to revise flood control operational rules, which could reduce the potential for flood damage and benefit recreation.

S.4.6 Alternative CP4

CP4 focuses on increasing anadromous fish survival by raising Shasta Dam 18.5 feet, while also increasing water supply reliability. In addition to raising the dam and implementing the set of eight common management measures described above, CP4 would dedicate part of the increased storage in Shasta Lake to maintaining cold-water volumes.

The additional storage created by the 18.5-foot dam raise would be used to both improve the ability to meet water temperature objectives for winter-run Chinook salmon during drought years and increase water supply reliability. The reservoir's capacity would increase by 634,000 acre-feet to a total of 5.19 MAF. Of the increased reservoir storage space, about 378,000 acre-feet would be dedicated to increasing the supply of cold water for anadromous fish survival purposes.

Operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as for CP1, while the cold-water pool would be subject to an adaptive management plan that may include operational changes to the timing and magnitude of release from Shasta Dam to benefit anadromous fish. The existing TCD would be extended to achieve efficient use of the expanded cold-water pool.

As described for the above alternatives, this alternative would also include the potential to revise flood control operational rules, which could reduce the potential for flood damage and benefit recreation.

Two additional ecosystem restoration features under CP4 would include augmenting spawning gravel in the upper Sacramento River at targeted locations to provide either immediate spawning habitat or long-term recruitment, and restoring riparian, floodplain, and side channel habitat in the upper Sacramento River to provide rearing habitat for juvenile salmonids.

S.4.7 Alternative CP5

CP5 focuses on anadromous fish survival, increased water supply reliability, ecosystem enhancements in the Shasta Lake area and the upper Sacramento River upstream from the RBDD facilities, and increased recreation opportunities around Shasta Lake. CP5 consists of raising Shasta Dam 18.5 feet; constructing additional resident fish habitat in Shasta Lake and along the lower reaches of its tributaries (the Sacramento River, the McCloud River, and Squaw Creek); constructing shoreline fish habitat around Shasta Lake; augmenting spawning gravel in the upper Sacramento River; restoring riparian, floodplain, and side channel habitat in the upper Sacramento River; increasing recreation

opportunities at Shasta Lake; and implementing the set of eight common management measures described above.

The additional storage created by the 18.5-foot dam raise would be used primarily to increase water supply reliability, while also improving the ability to meet water temperature objectives for winter-run Chinook salmon during drought years. The reservoir's capacity would increase by 634,000 acre-feet to a total of 5.19 MAF.

Under CP5, operations for water supply, hydropower, and environmental requirements would be similar to existing operations, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. The existing TCD would be extended to achieve efficient use of the expanded reservoir.

As described the above alternatives, this alternative would also include the potential to revise flood control operational rules, which could reduce the potential for flood damage and benefit recreation.

S.5 Alternatives Considered and Eliminated

Formulation of a range of comprehensive alternatives for evaluation in this PDEIS began with a review of problems, needs, and opportunities identified and defined previously, study authorities, and other pertinent direction, including information contained in the 2000 CALFED ROD, followed by development of primary and secondary planning objectives, and, finally, development of comprehensive alternatives to meet the project purpose and need. Some project alternatives suggested during this process were not retained because they did not adequately meet, or were beyond the scope of, the purpose and need statement, did not contribute to both primary planning objectives, or had high social or environmental impacts.

S.6 Major Conclusions of Environmental Analysis

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is a determining factor in whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the significance of the environmental effects of a proposed project. As stated in State CEQA Guidelines, Section 15382, a "[s]ignificant effect on the environment means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project."

S.6.1 Methods and Assumptions

The PDEIS analyzes the direct and indirect effects of the No-Action Alternative and comprehensive plans (i.e., action alternatives) for each environmental resource area. Direct effects are those that would be caused by the action and would occur at the same time and place. Indirect effects are reasonably foreseeable consequences that may occur at a later time or at a distance from the project area. Examples of indirect effects are growth inducement and other effects related to changes in land use patterns, population density, or growth rate, and related effects on the physical environment.

The effects of the No-Action Alternative and action alternatives were determined by comparing estimates of resulting conditions with baseline conditions. These baseline conditions differ between NEPA and CEQA. Under NEPA, the No-Action Alternative (i.e., expected future conditions without the project) is the baseline to which the action alternatives are compared; the No-Action Alternative is also compared to existing conditions. Under CEQA, existing conditions are the baseline to which alternatives are compared.

Uncertainties Affecting Definition of Reasonably Foreseeable/Without-Project Conditions

Federal water resources planning and NEPA procedures require the application of best available information, sound science, and definition of a reasonably foreseeable future condition as the basis for comparing the potential effects of alternative plans, which leads to identification of a recommended plan and/or action and supports decision making. A variety of physical, environmental, socioeconomic, regulatory, and operational conditions and uncertainties in the Bay-Delta and related watersheds is impacting the SLWRI's ability to establish a reasonably foreseeable future condition. These same challenges are affecting other water resource studies, operations, and management actions in the Bay-Delta and related watersheds.

Plan formulation efforts and analysis of the No-Action Alternative and action alternatives discussed in this chapter are based on CVP and SWP operational conditions described Reclamation's 2004 *Long-Term CVP and SWP Operations Criteria and Plan* (OCAP) *Biological Assessment*. Modeling studies will be updated to reflect changes in water operations resulting from ongoing OCAP reconsultation and other relevant water resources projects and programs, including, potentially, Bay-Delta Conservation Plan/Delta Habitat Conservation and Conveyance Plan efforts. The results of these updated studies will be incorporated into the Draft EIS and other future SLWRI documents.

Effects of Project Implementation with Climate Change

Council on Environmental Quality guidance, issued February 18, 2010, suggests that Federal agencies consider opportunities to reduce greenhouse gas (GHG) emissions caused by proposed Federal actions, adapt their actions to climate change impacts throughout the NEPA process, and address these issues in the

agencies' NEPA procedures. Following are the two main factors to consider when addressing climate change in environmental documentation:

- Effects of a proposed action and alternative actions on GHG emissions
- Impacts of climate change on a proposed action or alternatives

Council on Environmental Quality notes that "significant" national policy decisions with "substantial" GHG impacts require analysis of their GHG effects. That is, the GHG effects of a Federal agency's proposed action must be analyzed if the action would cause "substantial" annual direct emissions; would implicate energy conservation or reduced energy use or GHG emissions; or would promote cleaner, more efficient renewable-energy technologies. Qualitative or quantitative information on GHG emissions that is useful and relevant to the decision should be used when deciding among alternatives.

Each resource area analyzed in the PDEIS evaluates the effects of comprehensive plans combined with predicted effects of climate change. The ways SLWRI comprehensive plans could affect GHG production are also addressed. The Climate Change Projection Appendix provides a summary of global climate forecasts and climate change implications for California water resources are discussed, particularly those of Shasta Lake, including predictions about changes in monthly and annual natural runoff, reservoir storage and temperature, flood management, power generation, fish conservation, and water supply and quality. The discussion of climate change implications provided in the Climate Change Projection Appendix provides the context for consideration of cumulative conditions.

S.6.2 Summary of Impacts

The action alternatives would affect environmental resources in the primary and extended study areas. The primary study area is the area surrounding Shasta Dam and Reservoir, and the Sacramento River corridor from Shasta Dam downstream to the RBDD facilities. The extended study area consists of the lower Sacramento River and the lower portion of major tributaries, the Delta, and the CVP/SWP water service areas, which includes a substantial portion of California, such as much of Southern California. Some of the impacts would be temporary, construction-related effects that would be less than significant or would be reduced to less-than-significant levels through mitigation. Other impacts would be permanent, some of which would remain significant and unavoidable despite proposed mitigation measures. In addition, some effects of the project would be beneficial.

Table S-1, included at the end of this summary, summarizes the environmental impacts of the action alternatives, the duration and quantification of each impact, the level of significance of each impact before mitigation, recommended mitigation measures and the level of significance of each impact after mitigation.

S.6.3 Significant and Unavoidable Impacts

As shown in Table S-1, the action alternatives would likely result in the following significant and unavoidable direct and indirect impacts:

- **Botanical Resource** – Loss of Multi-Species Conservation Strategy (MSCS) covered species; loss of USFS sensitive, U.S. Bureau of Land Management (BLM) sensitive, or California Rare Plant Rank (CRPR) species; loss of jurisdictional waters; and loss of general vegetation habitats (all action alternatives).

- **Wildlife Resources** – Take and loss of habitats for the Shasta salamander, bald eagle, northern spotted owl, and Pacific fisher; impact on the foothill yellow-legged frog, tailed frog, northwestern pond turtle, purple martin, special-status bats, American marten, ringtail, terrestrial mollusks, and their habitat; impact on willow flycatcher, Vaux's swift, yellow warbler, yellow-breasted chat, long-eared owl, northern goshawk, Cooper's hawk, great blue heron, and osprey, and their foraging and nesting habitat; permanent loss of general wildlife habitat; take and loss of foraging and nesting habitat for other birds of prey and migratory bird species; and loss of critical deer winter and fawning range (all action alternatives).

- **Geology, Geomorphology, Minerals, and Soils** – Loss or diminished availability of known mineral resources; loss or diminished soil biomass productivity; and soil erosion or loss of topsoil due to shoreline processes (all action alternatives).

- **Air Quality and Climate** – Short-term emissions of criteria air pollutants and precursors during project construction (all action alternatives).

- **Agriculture and Important Farmlands** – Direct and indirect conversion of forest land to nonforest uses in the vicinity of Shasta Lake (all action alternatives).

- **Land Use and Planning** – Conflicts with existing land use goals and policies of affected jurisdictions (Shasta Lake and vicinity and upper Sacramento River), and disruption of existing land uses (Shasta Lake and vicinity and upper Sacramento River) (all action alternatives).

- **Cultural Resources** – Inundation of traditional cultural properties and sacred sites (all action alternatives).

- **Aesthetics and Visual Resources** – Consistency with guidelines for visual resources in the USFS 1995 *Shasta-Trinity National Forest Land and Resource Management Plan*; degradation and/or obstruction of a

scenic view from key observation points; and generation of increased daytime glare and/or nighttime lighting (all action alternatives).

- **Wild and Scenic River Considerations for McCloud River** – Effect on McCloud River's eligibility for listing as a Federal Wild and Scenic River; conflicts with the USFS 1995 *Shasta-Trinity National Forest Land and Resource Management Plan* or USFS 1995 *Coordinated Resource Management Plan*; and conflicts with the California Public Resources Code, Section 5093.542 (all action alternatives).

The action alternatives could also result in the following significant and unavoidable cumulative impacts (i.e., an impact would make a considerable contribution to a significant cumulative effect):

- **Hydrology, Hydraulics, and Water Management** – Cumulative effects on south Delta water levels, X2 position, and Delta outflow (all action alternatives).

- **Botanical Resources and Wetlands** – Cumulative effects from increased water delivery in the service areas and growth-related loss of sensitive plant communities and special-status plant species (all action alternatives).

- **Wildlife Resources** – Cumulative effects from inundation at Shasta Lake, leading to take and loss of habitat for numerous special-status species at Shasta Lake and vicinity (all action alternatives).

- **Geology, Geomorphology, Minerals, and Soils** – Cumulative effects from use of soil and mineral resources, leading to diminished regional availability of cement, concrete sand, and aggregate and loss of soil productivity (all action alternatives).

- **Aesthetics and Visual Resources** – Changes to aesthetic values and resources at Shasta Lake (all action alternatives).

- **Environmental Justice** – Cumulative effects from disproportionate placement of environmental impacts on Native American populations, leading to disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance in the vicinity of Shasta Lake (all action alternatives).

- **Air Quality and Climate** – Cumulative effects from emissions of NO_X during project construction (all action alternatives).

S.6.4 Environmental Commitments

As part of project planning and environmental assessment, Reclamation and/or its contractors would incorporate certain environmental commitments and best management practices into the action alternatives to avoid or minimize potential impacts. Reclamation will also coordinate planning, engineering, design and construction, operation, and maintenance phases of the project with applicable resource agencies.

The following environmental commitments would be incorporated into any action alternative for any project-related construction activities:

- Develop and implement a construction management plan to avoid or minimize potential impacts to public health and safety during project construction.
- Comply with applicable laws, policies, and plans for this project.
- Develop and implement an erosion and sediment control plan to control short-term and long-term erosion and sedimentation effects, and to stabilize soils and vegetation in areas affected by construction activities.
- Develop and implement a stormwater pollution prevention plan to prevent or minimize the discharge of sediments and other contaminants with the potential to affect beneficial uses or lead to violations of water quality objectives of surface waters.
- Develop and implement a feasible spill prevention and hazardous materials management plan to minimize effects from spills of hazardous, toxic, or petroleum substances for project-related activities occurring in or near waterways.
- Implement in-water construction work windows to occur when sensitive fish species are not present, or would be least susceptible to disturbance (e.g., July through September).
- Monitor potential impacts to important fishery resources throughout all phases of project construction.
- Perform fish rescue/salvage for fish entrapped within construction structures and cofferdam enclosures, and stop construction activities for spawning activities for sensitive fish species.
- Prepare a comprehensive revegetation plan to be implemented in conjunction with other management plans (e.g., erosion and sediment control plan).

- Develop and require implementation of a control plan to prevent the introduction of zebra/quagga mussels and other invasive species to project areas.

- Recycle or reuse demolished construction materials where practical.

- Demolish and remove all asphaltic roadways and parking lots inundated by the proposed Shasta Dam raise, per California Department of Fish and Game Code 5650 Section (a).

S.7 Areas of Controversy and Issues to Be Resolved

Several areas of controversy and issues to be resolved have been identified in the SLWRI to date.

S.7.1 Areas of Controversy

Federal, State, and local stakeholders have identified several areas of controversy during the SLWRI scoping process and agency meetings and workshops. Key topics include potential adverse effects on cultural resources in the Shasta Lake area; recreation and recreation providers in the Whiskeytown-Shasta-Trinity National Recreation Area; terrestrial special-status species around Shasta Lake, including State-designated fully protected species, aquatic special-status species in the Sacramento River and Delta (including delta smelt); the lower McCloud River and its special designation under California Public Resources Code 5093.542(c); Delta water quality and south Delta water levels; Central Valley hydrology below CVP and SWP facilities and resulting effects on water supplies for water contractors and other water users; impacts on reservoir area property owners; reservoir reoperation for flood control; and consistency with the 2000 CALFED ROD.

S.7.2 Issues to Be Resolved

As the SLWRI progresses, various issues will need to be addressed and resolved. Subject areas that have been identified to date are described below.

Native American Concerns and Cultural Resources

This PDEIS and accompanying Draft Feasibility Report are consistent with the National Historic Preservation Act Section 106, and describe supporting analyses, studies, coordination, impacts, and mitigation, as necessary. Reclamation has invited Federally recognized tribes and non-Federally recognized tribal groups to be consulting parties to the SLWRI. Although no Federally recognized tribes reside in the immediate Shasta Lake area, members of the Winnemem band of the Wintu Indians have raised concerns about potential impacts of enlarging Shasta Dam on sites they value for historic and cultural significance. Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians is a cooperating agency for the SLWRI, pursuant to NEPA. The Winnemem Wintu will continue to have the opportunity to

participate and are anticipated to continue to provide input, through the Section 106 process as an invited consulting party, as well as through the NEPA process.

Impacts on Biological Resources

The physical environment and associated landscapes within and adjacent to the primary study area provide for a wide array of habitat used by a diverse assemblage of wildlife with varying habitat needs and home ranges. To date, species-specific survey efforts as part of the SLWRI have only included focused investigations for a number of special-status species in the inundation and relocation areas described previously. The scale of these surveys has been limited, and because of a variety of external factors, have not addressed habitat for species with a large home range or at a watershed scale. Therefore, for species that have large home ranges (e.g., Pacific fisher), or that use a wide range of habitats for some aspect of their life history, analyses presented in this document assume presence over a conservatively large geographic area to cover the full range of impacts anticipated for these species.

Off-Site Mitigation for Impacts on Biological Resources

Details about off-site opportunities to mitigate impacts on biological resources in the primary study area are not yet available. Potential mitigation lands containing wetland and special-status species habitat comparable to those that would be affected by the proposed action have been identified near the study area. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in future documents. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in future documents.

Water Rights

Improving the reliability of water supplies is a primary objective of the SLWRI. The water supply reliability benefits of the project alternatives are described in Chapter 2. Water rights for the expanded Shasta Reservoir, which are appropriated by the State Water Resources Control Board (SWRCB), must be in place before the project can operate. Evaluation of water rights will remain a focus of the SLWRI.

Coordinated CVP and SWP Operational Conditions

Planning assumptions and information on water operations used to develop alternatives during the SLWRI were developed in 2006, and reflect the coordinated CVP and SWP operations described in Reclamation's 2004 *Long-Term CVP Operations Criteria and Plan* (2004 OCAP). In addition, the model package used to evaluate potential effects of the alternatives included in this PDEIS was based on operations described in Reclamation's 2004 *Long-Term CVP and SWP OCAP Biological Assessment* (2004 OCAP BA).

Reclamation consulted with the National Oceanic and Atmospheric Administration National Marine Fisheries Service (NMFS) and U.S. Fish and

Wildlife Service (USFWS) on the 2004 OCAP, and the two agencies issued the 2004 *Biological Opinion on the Long-Term CVP and SWP OCAP* (2004 NMFS BO) and 2005 *Reinitiation of Formal and Early Section 7 ESA Consultation on the Coordinated Operations of the CVP and SWP and the OCAP to Address Potential Critical Habitat Issues* (2005 USFWS BO), respectively. In 2007, the District Court for the Eastern District of California (District Court), in *Natural Resources Defense Council v. Kempthorne*, found the 2005 USFWS BO to be unlawful and inadequate. In May 2008, in *Pacific Coast Federation of Fishermen's Associations v. Gutierrez*, the District Court found the 2004 NMFS BO to be unlawful and inadequate. The District Court remanded both BOs to the fishery agencies.

In August 2008, Reclamation reinitiated consultation with the fishery agencies based on Reclamation's 2008 *Biological Assessment on the Continued Long-Term Operations of the CVP and SWP*. USFWS issued the *Formal ESA Consultation on the Proposed Coordinated Operations of the CVP and SWP* in December 2008, finding that the long-term operations of the CVP and SWP, as described in the 2004 OCAP BA, would jeopardize the continued existence of the delta smelt. In June 2009, NMFS issued the *BO and Conference Opinion on the Long-Term Operations of the CVP and SWP* (2009 NMFS BO), finding that the same operations would jeopardize populations of listed salmonids, steelhead, green sturgeon, and orcas. Because both agencies made jeopardy determinations, both agencies included a Reasonable and Prudent Alternative (RPA) in their respective BOs.

Several lawsuits were filed challenging the validity of the 2008 USFWS BO and 2009 NMFS BO and Reclamation's acceptance of the RPA included with each BO (*Consolidated Salmonid Cases, Delta Smelt Consolidated Cases*). On November 13, 2009, and March 5, 2010, the District Court concluded that Reclamation had violated NEPA by failing to perform any NEPA analysis before provisionally adopting the 2008 USFWS RPA and 2009 NMFS RPA. On December 14, 2010, the District Court found the 2008 USFWS BO to be unlawful and remanded the BO to USFWS. The District Court issued a similar ruling for the 2009 NMFS BO on September 20, 2011. On May 4, 2011, in the *Delta Smelt Consolidated Cases*, the District Court ordered USFWS to prepare a draft BO by October 1, 2011, which was subsequently extended to an unspecified date to be agreed upon by involved parties. Reclamation and USFWS must prepare a final BO and final NEPA document by November 1, 2013, and December 1, 2013, respectively.

Reclamation and DWR use CalSim-II to study operations, benefits, and effects of new facilities and operational parameters for the CVP and SWP. A set of operational assumptions was developed in 2006 based on water operations described in the 2004 OCAP BA and the Coordinated Operations Agreement between Reclamation and DWR for the CVP and SWP, as ratified by Congress. These assumptions were used to guide development, modeling, and evaluation of potential effects of the No-Action Alternative and action alternatives

included in this PDEIS. Rationale for the decision to use these existing evaluations as the basis of analysis in the PDEIS and accompanying Draft Feasibility Report is provided in Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences." Modeling studies and associated analyses will be updated and included in the Draft EIS and other future SLWRI documents.

S.8 Public Involvement and Next Steps

This PDEIS will be published for public, stakeholder, and agency review. During this period, stakeholder workshops will be held to present key findings and solicit input.

A Draft EIS will be prepared considering input from stakeholders and the public and results of updated modeling studies. In accordance with NEPA review requirements, the Draft EIS will be circulated for public and agency review and comment for at least 60 days following the date when the U.S. Environmental Protection Agency publishes the notice of availability of weekly receipt of environmental impact statements in the *Federal Register*. Similar to the approach to public scoping, public meetings will be held in various locations statewide to solicit and receive public input on the Draft EIS. These meetings will be held during the public comment period so that any comments received at the meetings can be addressed in the FEIS. In addition, written comments from the public, reviewing agencies, and stakeholders will be accepted during the public comment period.

An FEIS will be prepared and circulated in accordance with NEPA requirements and will include responses to all comments. Reclamation will circulate the FEIS for at least 60 days before issuing its ROD. In the ROD, which is the final step in the EIS process, Reclamation will document its decision on which actions, if any, to take to address the primary objectives. It will also describe other risk reduction plans it considered, identify any mitigation plans, and describe factors and comments taken into consideration when making its decision.

To date, CEQA scoping has not been initiated. This process will not commence until a State lead agency is identified.

Table S-1. Summary of Impacts and Mitigation Measures

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Geology, Geomorphology, Minerals, and Soils						
Impact Geo-1: Exposure of Structures and People to Geologic Hazards, Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruptions	N-A	NA	–	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Geo-2: Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats	N-A	NA	–	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	S	Mitigation Measure Geo-2: Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact.	LTS
Impact Geo-3: Loss or Diminished Availability of Known Mineral Resources that Would Be of Future Value to the Region	N-A	NA	–	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	SU	No feasible mitigation available to reduce impact.	SU
Impact Geo-4: Lost or Diminished Soil Biomass Productivity	N-A	NA	–	NI	No mitigation measures required.	NI
	CP1	Long-term	Loss of 1,954.6 acres of moderate productivity land; 1604.5acres of low productivity land; 565 acres of nonproductive land	SU	No feasible mitigation available to reduce impact.	SU
	CP2	Long-term	Loss of 2,128 acres of moderate productivity land; 1,751 acres of low productivity land; 638 acres of nonproductive land	SU	No feasible mitigation available to reduce impact.	SU
	CP3–CP5	Long-term	Loss of 2,301 acres of moderate productivity land; 2,092 acres of low productivity land; 760 acres of nonproductive land	SU	No feasible mitigation available to reduce impact.	SU

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Geo-5: Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes	N-A	NA	–	NI	No mitigation measures required.	NI
	CP1	Short-term and long-term	–	SU	No feasible mitigation available to reduce impact.	SU
	CP2–CP3	Short-term and long-term	Similar to CP1, but greater	SU	No feasible mitigation available to reduce impact.	SU
	CP4	Short-term and long-term	Similar to CP1 & CP2, but greater	SU	No feasible mitigation available to reduce impact.	SU
	CP5	Short-term and long-term	Similar to CP1 & CP2, but greater	SU	No feasible mitigation available to reduce impact.	SU
Impact Geo-6: Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes	N-A	NA	–	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Geo-7: Be Located on a Geologic Unit or Soil that is Unstable, or that Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence	N-A	NA	–	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Geo-8: Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste	N-A	NA	–	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact WQ-17: Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-18: Long-Term Metals Effects That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	PS	Mitigation Measure WQ-18: Implement Mitigation Measure WQ-6: Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines.	LTS
Impact WQ-19a: Delta Salinity on the Sacramento River at Collinsville	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	<10% increases in salinity in extended study area (Collinsville)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-19b: Delta Salinity on the San Joaquin River at Jersey Point	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	No increase in electrical conductivity in extended study area (Jersey Point)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-19c: Delta Salinity on the Sacramento River at Emmaton	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	No more than 0.2% increase in electrical conductivity in extended study area (Emmaton)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-19d: Delta Salinity on the Old River at Rock Slough	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	Chlorides not increased more than 1.2% in extended study area (Rock Slough)	LTS	No mitigation needed; thus, none proposed.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact WQ-19e: Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	Electrical conductivity not changed, chlorides increased <1.0% in extended study area (Jones Pumping Plant)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-19f: Delta Water Quality on the West Canal at the Mouth of the Clifton Court Forebay	N-A	NA	NA	LTS	No mitigation measures required.	LTS
	CP1–CP5	Long-term	Electrical conductivity not changed, chlorides increased <1.0% in extended study area (Clifton Court Forebay)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-19g: Delta Salinity on the San Joaquin River at Vernalis	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	No increase in electrical conductivity in extended study area (Vernalis)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-19h: Delta Salinity on the San Joaquin River at Brandt Bridge	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	No increase in electrical conductivity in extended study area (Brandt Bridge)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-19i: Delta Salinity on the Old River near the Middle River	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	No increase in electrical conductivity in extended study area (Old River)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-19j: Delta Salinity on the Old River at Tracy Road Bridge	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	No increase in electrical conductivity in extended study area (Tracy Road Bridge)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-20: X2 Position	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	No increase in number of months in which X2 is out of compliance in extended study area (Delta)	LTS	No mitigation needed; thus, none proposed.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Noise and Vibration						
Impact Noise-1: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise	N-A	NA	NA	LTS	No mitigation measures required.	LTS
	CP1–CP3	Short-term	Blasting activities at the dam – noise levels of 60 dBA at sensitive receptors downstream on the Sacramento River (7,000 feet away) On-site heavy duty construction equipment at other project sites – exterior noise levels at noise-sensitive receptors located within 75 – 7,000 feet of construction activity could exceed applicable standards (>50 dBA $L_{eq)}$	S	Mitigation Measure Noise-1: Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites.	LTS
	CP4	Short-term	Similar to CP1–CP3, but greater noise related to gravel augmentation	S	Mitigation Measure Noise-1: Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites.	LTS
	CP5	Short-term	Similar to CP4, but greater noise related to restoration at Reading Island	S	Mitigation Measure Noise-1: Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites.	LTS
Impact Noise-2: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction	N-A	NA	NA	LTS	No mitigation measures required.	LTS
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Noise-3: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile Source Noise During Operations	N-A	NA	NA	LTS	No mitigation measures required.	LTS
	CP1–CP5	Short-term and long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Hazards and Hazardous Materials and Waste						
Impact Haz-1: Wildland Fire Risk (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Short-term	– (36-month construction period)	PS	Mitigation Measure Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.	LTS
	CP2	Short-term	Similar to CP1, but greater and longer duration (48-month construction period)	PS	Mitigation Measure Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.	LTS
	CP3–CP5	Short-term	Similar to CP1 & CP2, but greater and longer duration (60-month construction period)	PS	Mitigation Measure Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Haz-2: Release Potentially Hazardous Materials or Hazardous Waste (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Short-term	– (36-month construction period)	PS	Mitigation Measure Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.	LTS
	CP2	Short-term	Similar to CP1, but greater and longer duration (48-month construction period)	PS	Mitigation Measure Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.	LTS
	CP3–CP5	Short-term	Similar to CP1 & CP2, but greater and longer duration (60-month construction period)	PS	Mitigation Measure Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.	LTS
Impact Haz-3: Expose Workers to Hazardous Materials (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Short-term	– (36-month construction period)	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	Short-term (48-month construction period)	Similar to CP1, but greater and longer duration (48-month construction period)	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3–CP5	Short-term (60-month construction period)	Similar to CP1 & CP2, but greater and longer duration (60-month construction period)	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Haz-4: Expose Sensitive Receptors to Hazardous Materials (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Short-term (con-struction period)	–	PS	Mitigation Measure Haz-4: Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Haz-5: Wildland Fire Risk (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Haz-6: Release Potentially Hazardous Materials or Hazardous Waste (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Haz-7: Expose Workers to Hazardous Materials (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Haz-8: Expose Sensitive Receptors to Hazardous Materials (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Agriculture and Important Farmlands						
Impact Ag-1: Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake	N-A	Permanent conversion	–	PS	No mitigation measures required.	SU
	CP1–CP5	NA	–	NI	No mitigation needed; thus, none proposed.	NI

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Ag-2: Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Permanent conversion	1,051 acres of forest land affected by inundation and 107 acres of forest land affected by infrastructure relocation	S	No feasible mitigation is available to reduce impact.	SU
	CP2	Permanent conversion	1,440 acres of forest land affected by inundation and 116 acres of forest land affected by infrastructure relocation	S	No feasible mitigation is available to reduce impact.	SU
	CP3–CP5	Permanent conversion	2,068 acres of forest land affected by inundation and 133 acres of forest land affected by infrastructure relocation	S	No feasible mitigation is available to reduce impact.	SU
Impact Ag-3: Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River	N-A	Permanent conversion	–	PS	No mitigation measures required.	SU
	CP1	NA	–	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	NA	Similar to CP1, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3–CP5	NA	Similar to CP1 & CP2, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Ag-4: Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River	N-A	Permanent conversion	NA	LTS	No mitigation measures required.	LTS
	CP1	Permanent conversion	–	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	NA	Similar to CP1, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3–CP5	NA	Similar to CP1 & CP2, but greater	LTS	No mitigation needed; thus, none proposed.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Ag-5: Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area	N-A	Permanent conversion	–	PS	No mitigation measures required.	SU
	CP1–CP5	NA	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Ag-6: Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area	N-A	Permanent conversion	NA	LTS	No mitigation measures required.	LTS
	CP1–CP5	Permanent conversion	–	LTS	No mitigation needed; thus, none proposed.	LTS
Fisheries and Aquatic Ecosystems						
Impact Aqua-1: Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations	N-A	Permanent	–	PS	No mitigation measures required.	PS
	CP1–CP5	Permanent	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Aqua-2: Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction	N-A	Temporary	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Temporary	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Aqua-3: Effects on Cold-Water Habitat in Shasta Lake	N-A	Long-term	–	PS	No mitigation measures required.	PS
	CP1–CP5	Long-term	–	B	No mitigation needed; thus, none proposed.	B

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Aqua-4: Effects on Special-Status Aquatic Mollusks	N-A	Long-term	–	LTS	No mitigation measures required.	LTS
	CP1–CP5	Permanent		PS	Mitigation Measure Aqua-4: Implement Mitigation Measure Geo-2: Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact.	LTS
Impact Aqua-5: Effects on Special-Status Fish Species	N-A	–	–	LTS	No mitigation measures required.	LTS
	CP1–CP5	–	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Aqua-6: Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Permanent	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Aqua-7: Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Permanent	5.4 miles of low-gradient reaches	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	Permanent	7.4 miles of low-gradient reaches	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3–CP5	Permanent	11 miles of low-gradient reaches	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Aqua-8: Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Permanent	12.6 miles of non-fish-bearing tributary habitat	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	Permanent	17.3 miles of non-fish-bearing tributary habitat	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3–CP5	Permanent	24.0 miles of non-fish-bearing tributary habitat	LTS	No mitigation needed; thus, none proposed.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Aqua-9: Effects on Water Quality at Livingston Stone Hatchery	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	NA	NA	NI	No mitigation needed; thus, none proposed.	NI
Impact Aqua-10: Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Temporary, long-term, or both	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Aqua-11: Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Temporary, long-term, or both	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Aqua-12: Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation—Chinook Salmon	N-A	NA	NA	PS	No mitigation measures required.	PS
	CP1 & CP4	Long-term	–	B	No mitigation needed; thus, none proposed.	B
	CP2	Long-term	Similar to CP1 & CP4, but greater in magnitude	B	No mitigation needed; thus, none proposed.	B
	CP3 & CP5	Long-term	Similar to CP1, CP2 & CP4, but greater in magnitude	B	No mitigation needed; thus, none proposed.	B

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Aqua-13: Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operations—Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass	N-A	NA	–	PS	No mitigation measures required.	PS
	CP1	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	Long-term	Similar to CP1, but greater in magnitude	LTS	No mitigation needed; thus, none proposed.	LTS

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Aesthetics and Visual Resources						
Impact Vis-1: Consistency with Guidelines for Visual Resources in the STNF LRMP (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	Short-term and long-term	NA	NI	No mitigation measures required.	NI
	CP1–CP5	Short-term and long-term	Degraded visual character and quality of primary study area	SU	No feasible mitigation is available to reduce impact.	SU
Impact Vis-2: Degradation and/or Obstruction of a Scenic View from Key Observation Points (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	Short-term	NA	NI	No mitigation measures required.	NI
	CP1	Short-term	Scenic views obstructed or degraded in primary study area	SU	No feasible mitigation available to reduce impact.	SU
	CP2	Short-term	Similar to CP1, but greater (acres, miles, duration)	SU	No feasible mitigation available to reduce impact.	SU
	CP3–CP5	Short-term	Similar to CP1& CP2, but greater (acres, miles, duration)	SU	No feasible mitigation available to reduce impact.	SU
Impact Vis-3: Generation of Increased Daytime Glare and/or Nighttime Lighting (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	Short-term and long-term	NA	NI	No mitigation measures required.	NI
	CP1	Short-term and long-term	Increased glare in primary study area	S	Mitigation Measure Vis-3: Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting.	SU
	CP2	Short-term and long-term	Similar to CP1, but greater (amount, duration)	S	Mitigation Measure Vis-3: Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting.	SU
	CP3–CP5	Short-term and long-term	Similar to CP1 & CP2, but greater (amount, duration)	S	Mitigation Measure Vis-3: Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting.	SU

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Vis-4: Consistency with Federal and State Scenic Highway Requirements (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	Permanent	NA	NI	No mitigation measures required.	NI
	CP1	Permanent	Visible from SR 151.	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	Permanent	Similar to CP1, but greater vegetation removal would be visible	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3–CP5	Permanent	Similar to CP1 & CP2, but greater vegetation removal would be visible	LTS	No mitigation needed; thus, none proposed.	LTS
Transportation and Traffic						
Impact Trans-1: Short-Term and Long-Term Increases in Traffic in the Primary Study Area in Relation to the Existing Traffic Load and Capacity of the Street System	N-A	NA	NA	LTS	No mitigation measures required.	LTS
	CP1	Long-term	Increase of 148 one-way trips per day throughout the primary study area	LTS	Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS
		Short-term	Approximately 83 round trips per day by haul trucks and 900 round trips per day (36-month construction period)	PS	Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS
	CP2	Long-term	Increase of 251 one-way trips per day throughout the primary study area	LTS	Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS
		Short-term	Similar to CP1, but over a longer period (48-month construction period)	PS	Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS
	CP3–CP5	Long-term	Increase of 398 one-way trips per day throughout the primary study area	LTS	Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS
		Short-term	Similar to CP1 & CP2, but over a longer period (60-month construction period)	PS	Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Trans-2: Adverse Effects on Access to Local Streets or Adjacent Uses in the Primary Study Area	N-A	NA	NA	LTS	No mitigation measures required.	LTS
	CP1	Permanent and/or temporary	Road closures and detours or partial road closures, or a combination of both, at Shasta Lake	PS	Mitigation Measure Trans-2: Implement Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS
	CP2	Permanent and/or temporary	Similar to CP1, but over a longer period	PS	Mitigation Measure Trans-2: Implement Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS
	CP3–CP5	Permanent and/or temporary	Similar to CP1 and CP2, but over a longer period	PS	Mitigation Measure Trans-2: Implement Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan.	LTS
Impact Trans-3: Hazards in the Primary Study Area Caused by a Design Feature	N-A	NA	NA	LTS	No mitigation measures required.	LTS
	CP1	Permanent	Relocated road segments and vehicular and railroad bridges would be designed to current engineering design standards	B	No mitigation needed; thus, none proposed.	B
	CP2	Permanent	Similar to CP1, but more road segments and bridges would be replaced	B	No mitigation needed; thus, none proposed.	B
	CP3–CP5	Permanent	Similar to CP1 and CP2, but more road segments & bridges would be replaced	B	No mitigation needed; thus, none proposed.	B

Public Services						
Impact PS-1: Disruption of Public Services (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Short-term	(36-month construction period)	PS	Mitigation Measure PS-1: Coordinate and Assist Public Services Agencies.	LTS
	CP2	Short-term	Similar to CP1, but greater duration & area (48-month construction period)	PS	Mitigation Measure PS-1: Coordinate and Assist Public Services Agencies.	LTS
	CP3–CP5	Short-term	Similar to CP1 & CP2, but greater duration & area (60-month construction period)	PS	Mitigation Measure PS-1: Coordinate and Assist Public Services Agencies.	LTS
Impact PS-2: Degraded Level of Public Services (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Short-term	– (36-month construction period)	PS	PS-2: Provide Support to Public Services Agencies.	LTS
	CP2	Short-term	Similar to CP1, but greater duration (48-month construction period)	PS	PS-2: Provide Support to Public Services Agencies.	LTS
	CP3–CP5	Short-term	Similar to CP1 & CP2, but greater duration (60-month construction period)	PS	PS-2: Provide Support to Public Services Agencies.	LTS
Impact PS-3: Relocation of Public Service Facilities (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	No impact	NI	No mitigation measures required.	NI
	CP1	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	Long-term	Greater than CP1	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3–CP5	Long-term	Greater than CP1 & CP2	LTS	No mitigation needed; thus, none proposed.	LTS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact PS-4: Short-Term Disruption of Public Services (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	No impact	NI	No mitigation measures required.	NI
	CP1–CP3	Short-term	–	NI	No mitigation needed; thus, none proposed.	NI
	CP4-CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact PS-5: Degraded Levels of Public Services (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	No impact	NI	No mitigation measures required.	NI
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact PS-6: Relocation of Public Services Facilities (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	No impact	NI	No mitigation measures required.	NI
	CP1–CP5	Long-term	–	NI	No mitigation needed; thus, none proposed.	NI
Power and Energy						
Impact Hydro-1: Decrease in Shasta Powerplant Energy Generation	N-A, CP1–CP5	Long-term	>5% decrease in long-term monthly average hydropower generation in primary study area at a level of recurrence that would substantially affect the power market	PS	No feasible mitigation proposed to reduce impact.	PS
Impact Hydro-2: Decrease in CVP and SWP Powerplant Energy Generation	N-A, CP1–CP5	Long-term	>5% decrease in long-term monthly average hydropower generation in CVP and SWP service areas at a level of recurrence that would substantially affect the power market	PS	No feasible mitigation proposed to reduce impact.	PS
Impact Hydro-3: Increase in CVP and SWP Pumping Plant Energy	N-A, CP1–CP5	Long-term	>5% increase in long-term monthly average power consumption in CVP and SWP service areas at a level of recurrence that would substantially affect the power market	PS	No feasible mitigation proposed to reduce impact.	PS

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact Hydro-4: Decrease in CVP and SWP Net Energy Generation	N-A, CP1–CP5	Long-term	>5% decrease in long-term monthly average net energy generation in CVP and SWP Service Areas at a level of recurrence that would substantially affect the power market.	PS	No feasible mitigation proposed to reduce impact.	PS
Impact Hydro-5: Decrease in Pit 7 Powerplant Net Energy Generation	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Long-term	<5% decrease in net energy generation in Pit 7 Powerplant	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2–CP5	Long-term	>5% decrease in net energy generation in Pit 7 Powerplant	PS	No feasible mitigation proposed to reduce impact.	PS
Environmental Justice						
Impact EJ-1: Potential Disproportionate Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake	N-A	NA	NA	NDHA	No mitigation measures required.	NDHA
	CP1–CP5	Short-term	–	NDHA	No mitigation needed; thus, none proposed.	NDHA
Impact EJ-2: Potential Disproportionate Effect on Native American Populations in the Vicinity of Shasta Lake	N-A	NA	NA	NDHA	No mitigation measures required.	NDHA
	CP1–CP5	Short-term and long-term	–	DHA	No feasible mitigation available to reduce impact.	DHA
Impact EJ-3: Potential Disproportionate Effect on Minority and Low-Income Populations in the Upper Sacramento River Area	N-A	Long-term	NA	NDHA	No mitigation measures required.	NDHA
	CP1–CP5	Long-term	–	NDHA	No mitigation needed; thus, none proposed.	NDHA

Table S-1. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure	LOS After Mitigation[4]
Impact WASR-3: Conflict with the California Public Resources Code, Section 5093.542	N-A	NA	NA	NI	No mitigation measures required.	NI
	CP1	Long-term	Would affect about 2 percent of the lower McCloud River	SU	No feasible mitigation available to reduce impact.	SU
	CP2	Long-term	Would affect about 2.3 percent of the lower McCloud River	SU	No feasible mitigation available to reduce impact.	SU
	CP3–CP5	Long-term	Would affect about 3 percent of the lower McCloud River	SU	No feasible mitigation available to reduce impact.	SU

Notes:

[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.

[2] NA = not applicable. Short-term = construction-related or otherwise persisting from one to several years. Long-term = persisting for years to decades. Permanent = persisting at least years to decades and effectively irreversible.

[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.

[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable. NDHA = not disproportionately high and adverse. DHA = disproportionately high and adverse. RS = remote and speculative.

Key:

BLM = U.S. Bureau of Land Management
BMP = best management practice
cfs = cubic feet per second
CO = carbon monoxide
CO_2e = carbon dioxide equivalent
CP = Comprehensive Plan
CRMP = Coordinated Resources Management Plan
CRPR = California Rare Plant Rank
CVP = Central Valley Project
dBA = A-weighted decibels
Delta = Sacramento–San Joaquin Delta
DFG = California Department of Fish and Game
GHG = greenhouse gas
ITA = Indian Trust Assets
lb = pound
L_{eq} = equivalent noise level
LRMP = land and resource management plan
MSCS = Multi-Species Conservation Strategy
NHPA = National Historic Preservation Act
NO_X = oxides of nitrogen
PM = particulate matter
PM_{10} = respirable particulate matter with an aerodynamic resistance diameter of 10 micrometers or less
$PM_{2.5}$ = respirable particulate matter with an aerodynamic resistance diameter of 2.5 micrometers or less
ROG = reactive organic gas
SR = State Route
STNF = Shasta-Trinity National Forest
SWP = State Water Project
TBD = to be determined
USFS = U.S. Forest Service
X2 = distance in kilometers from the Golden Gate Bridge to the location where salinity concentration is 2 parts per thousand

Contents

Chapter 1 Introduction 1-1

1.1 Background 1-1
1.1.1 SLWRI Authorization 1-2
1.1.2 Major Previous Studies and Reports 1-3

1.2 Purpose and Need for Proposed Action and Project Objectives 1-3
1.2.1 Purpose and Need for Proposed Action 1-3
1.2.2 Project Objectives 1-8

1.3 Setting and Location 1-9
1.3.1 Primary Study Area 1-11
1.3.2 Extended Study Area 1-14

1.4 NEPA Requirements 1-18
1.4.1 NEPA Process 1-18

1.5 Intended Use of EIS 1-18
1.5.1 Intended Use of Preliminary Draft EIS 1-18
1.5.2 Intended Use of Final EIS 1-19

1.6 Areas of Controversy/Issues to Be Resolved 1-21
1.6.1 Areas of Controversy 1-21
1.6.2 Issues to Be Resolved 1-24

1.7 Documents Used to Prepare Preliminary Draft EIS 1-26
1.7.1 CVPIA EIS 1-26
1.7.2 CALFED EIS/EIR 1-27

1.8 Organization of Preliminary Draft EIS 1-27

Chapter 2 Alternatives 2-1

2.1 Alternatives Development Process 2-1
2.1.1 Plan Formulation Process 2-2
2.1.2 Project Objectives 2-4
2.1.3 Management Measures 2-5
2.1.4 Initial Alternatives Phase 2-10
2.1.5 Development and Refinement of Comprehensive Plans 2-12

2.2 Alternatives Considered and Eliminated from Further Analysis 2-15
2.2.1 Initial Alternatives Phase 2-15
2.2.2 Comprehensive Plans Phase 2-19

2.3 No-Action Alternative 2-20
2.3.1 Anadromous Fish Survival 2-21
2.3.2 Water Supply Reliability 2-22

2.3.3 Ecosystem Resources, Flood Management, Hydropower Generation, Recreation, and Water Quality 2-22

2.4 Action Alternatives 2-23
2.4.1 Management Measures Common to All Action Alternatives 2-23
2.4.2 Construction Activities Common to All Action Alternatives....2-26
2.4.3 Environmental Commitments Common to All Action Alternatives....2-40
2.4.4 Environmental Commitments Common to All Action Alternatives....2-42
2.4.5 Comprehensive Plan 1 (CP1) – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability....2-47
2.4.6 Comprehensive Plan 2 (CP2) – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability....2-59
2.4.7 Comprehensive Plan (CP3) – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability....2-67
2.4.8 Comprehensive Plan 4 (CP4) – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability 2-75
2.4.9 Comprehensive Plan 5 (CP5) – 18.5-Foot Dam Raise, Combination Plan....2-85

2.5 Comparison of Alternatives 2-91
2.5.1 Completeness 2-91
2.5.2 Effectiveness 2-93
2.5.3 Efficiency 2-94
2.5.4 Acceptability 2-94

2.6 Preferred Alternative and Rationale for Selection 2-94
2.6.1 Summary of Comparison....2-94
2.6.2 Rationale for Plan Selection 2-94

Chapter 3 Considerations for Describing Affected Environment and Environmental Consequences.... 3-1

3.1 Introduction.... 3-1

3.2 Chapter Contents and Definition of Terms.... 3-1
3.2.1 NEPA Requirements....3-2
3.2.2 Approach to Affected Environment 3-3
3.2.3 Methods and Assumptions....3-4
3.2.4 Significance Criteria 3-6
3.2.5 Impact Comparisons and Definitions....3-7
3.2.6 Impact Levels....3-7
3.2.7 Mitigation Development Process and Objectives....3-9
3.2.8 Significance after Mitigation 3-9
3.2.9 Cumulative Effects....3-9

3.3 Resources Eliminated from Further Consideration.... 3-45

3.4 Regulatory Framework 3-46
3.4.1 Federal....3-46
3.4.2 State 3-58
3.4.3 Regional and Local 3-64

Chapter 4 Geology, Geomorphology, Minerals, and Soils 4-1

4.1 Affected Environment 4-1
4.1.1 Geology 4-2
4.1.2 Geologic Hazards 4-14
4.1.3 Geomorphology 4-22
4.1.4 Mineral Resources 4-28
4.1.5 Soils 4-30

4.2 Regulatory Framework 4-41
4.2.1 Federal 4-41
4.2.2 State 4-44
4.2.3 Regional and Local 4-47

4.3 Environmental Consequences and Mitigation Measures 4-48
4.3.1 Methods and Assumptions 4-48
4.3.2 Criteria for Determining Significance of Effects 4-51
4.3.3 Topics Eliminated from Further Discussion 4-52
4.3.4 Direct and Indirect Effects 4-53
4.3.5 Mitigation Measures 4-82
4.3.6 Cumulative Effects 4-89

Chapter 5 Air Quality and Climate 5-1

5.1 Affected Environment 5-1
5.1.1 Regional Climate in the Primary Study Area 5-3
5.1.2 Criteria Air Pollutants 5-3
5.1.3 Monitoring Station Data and Criteria Pollutant Attainment Area Designations 5-4
5.1.4 Toxic Air Contaminants in the Primary Study Area 5-6
5.1.5 Global Study Area 5-9

5.2 Regulatory Framework 5-10
5.2.1 Federal 5-10
5.2.2 State 5-13
5.2.3 Regional and Local 5-21

5.3 Environmental Consequences and Mitigation Measures 5-24
5.3.1 Methods and Assumptions 5-24
5.3.2 Criteria for Determining Significance of Effects 5-25
5.3.3 Topics Eliminated from Further Consideration 5-29
5.3.4 Direct and Indirect Effects 5-29
5.3.5 Mitigation Measures 5-51
5.3.6 Cumulative Effects 5-57

Chapter 6 Hydrology, Hydraulics, and Water Management 6-1

6.1 Affected Environment 6-1
6.1.1 Storage Facilities 6-1
6.1.2 Diversion Facilities 6-2
6.1.3 Hydrology and Hydraulics 6-2

6.1.4 Surface Water Supply 6-5
6.1.5 Flood Management 6-6
6.1.6 South Delta Water Levels 6-10
6.1.7 Groundwater Resources 6-10

6.2 Regulatory Setting 6-13
6.2.1 Federal 6-13
6.2.2 State 6-19
6.2.3 Regional and Local 6-25

6.3 Environmental Consequences and Mitigation Measures 6-29
6.3.1 Methods and Assumptions 6-29
6.3.2 Criteria for Determining Significance of Effects 6-32
6.3.3 Direct and Indirect Effects 6-37
6.3.4 Mitigation Measures 6-108
6.3.5 Cumulative Effects 6-111

Chapter 7 Water Quality 7-1

7.1 Affected Environment 7-1
7.1.1 Overview of Water Quality Conditions 7-1
7.1.2 Sediment 7-7
7.1.3 Temperature 7-10
7.1.4 Metals 7-12
7.1.5 Salinity 7-16

7.2 Regulatory Framework 7-17
7.2.1 Federal 7-18
7.2.2 State 7-26
7.2.3 Local 7-33

7.3 Environmental Consequences and Mitigation Measures 7-34
7.3.1 Methods and Assumptions 7-34
7.3.2 Criteria for Determining Significance of Effects 7-38
7.3.3 Topics Eliminated from Further Consideration 7-42
7.3.4 Direct and Indirect Effects 7-42
7.3.5 Mitigation Measures 7-166
7.3.6 Cumulative Effects 7-181

Chapter 8 Noise and Vibration 8-1

8.1 Affected Environment 8-1
8.1.1 Acoustic Fundamentals 8-1
8.1.2 Existing Noise Sources and Levels 8-7
8.1.3 Existing Noise-Sensitive Land Uses 8-11

8.2 Regulatory Framework 8-11
8.2.1 Federal 8-11
8.2.2 State 8-12
8.2.3 Regional and Local 8-14

8.3 Environmental Consequences and Mitigation Measures 8-21
8.3.1 Methods and Assumptions 8-21
8.3.2 Criteria for Determining Significance of Effects 8-22
8.3.3 Topics Eliminated from Further Consideration 8-23
8.3.4 Direct and Indirect Effects 8-23
8.3.5 Mitigation Measures 8-35
8.3.6 Cumulative Effects 8-37

Chapter 9 Hazards and Hazardous Materials and Waste 9-1

9.1 Affected Environment 9-1
9.1.1 Hazards 9-2
9.1.2 Hazardous Materials and Waste 9-7

9.2 Regulatory Framework 9-12
9.2.1 Federal 9-12
9.2.2 State 9-17
9.2.3 Regional and Local 9-20

9.3 Environmental Consequences and Mitigation Measures 9-20
9.3.1 Methods and Assumptions 9-20
9.3.2 Criteria for Determining Significance of Effects 9-20
9.3.3 Topics Eliminated from Further Consideration 9-21
9.3.4 Direct and Indirect Effects 9-21
9.3.5 Mitigation Measures 9-37
9.3.6 Cumulative Effects 9-43

Chapter 10 Agriculture and Important Farmland 10-1

10.1 Affected Environment 10-1
10.1.1 Agriculture 10-1
10.1.2 Important Farmland 10-6
10.1.3 Williamson Act 10-11
10.1.4 Forest Land 10-11

10.2 Regulatory Framework 10-16
10.2.1 Federal 10-16
10.2.2 State 10-16
10.2.3 Regional and Local 10-20

10.3 Environmental Consequences and Mitigation Measures 10-21
10.3.1 Methods and Assumptions 10-21
10.3.2 Criteria for Determining Significance of Effects 10-22
10.3.3 Topics Eliminated from Further Consideration 10-22
10.3.4 Direct and Indirect Effects 10-23
10.3.5 Mitigation Measures 10-43
10.3.6 Cumulative Effects 10-47

Chapter 11 Fisheries and Aquatic Ecosystems 11-1

11.1 Affected Environment 11-1
11.1.1 Aquatic Habitat 11-1
11.1.2 Fish Species 11-7
11.1.3 Aquatic Macroinvertebrates 11-21

11.2 Regulatory Framework 11-24
11.2.1 Federal 11-24
11.2.2 State 11-37
11.2.3 Regional and Local 11-39
11.2.4 Federal, State, and Local Programs and Projects 11-40

11.3 Environmental Consequences and Mitigation Measures 11-44
11.3.1 Methods and Assumptions 11-44
11.3.2 Criteria for Determining Significance of Effects 11-64
11.3.3 Direct and Indirect Effects 11-66
11.3.4 Mitigation Measures 11-263
11.3.5 Cumulative Effects 11-277

Chapter 12 Botanical Resources and Wetlands 12-1

12.1 Affected Environment 12-1
12.1.1 Vegetation Communities 12-5
12.1.2 Special-Status Species 12-32
12.1.3 Invasive Species 12-57
12.1.4 Waters of the United States, Including Wetlands, in Shasta Lake and Vicinity 12-62

12.2 Regulatory Framework 12-67
12.2.1 Federal 12-67
12.2.2 State 12-74
12.2.3 Local 12-76
12.2.4 Federal, State, and Local Programs and Projects 12-77

12.3 Environmental Consequences and Mitigation Measures 12-82
12.3.1 Methods and Assumptions 12-82
12.3.2 Criteria for Determining Significance of Effects 12-86
12.3.3 Topics Eliminated from Further Consideration 12-88
12.3.4 Direct and Indirect Effects 12-88
12.3.5 Mitigation Measures 12-146
12.3.6 Cumulative Effects 12-171

Chapter 13 Wildlife Resources 13-1

13.1 Affected Environment 13-1
13.1.1 Wildlife 13-5
13.1.2 Special-Status Species 13-26
13.1.3 Other Wildlife Resources 13-63

13.2 Regulatory Framework 13-64

13.2.1 Federal 13-64
13.2.2 State 13-71
13.2.3 Regional and Local 13-74
13.2.4 Federal, State, and Local Programs and Projects 13-75

13.3 Environmental Consequences and Mitigation Measures 13-80
13.3.1 Methods and Assumptions 13-80
13.3.2 Criteria for Determining Significance of Effects 13-82
13.3.3 Topics Eliminated from Further Consideration 13-83
13.3.4 Direct and Indirect Effects 13-83
13.3.5 Mitigation Measures 13-185
13.3.6 Cumulative Effects 13-224

Chapter 14 Cultural Resources 14-1

14.1 Affected Environment 14-1
14.1.1 Regional Setting 14-2
14.1.2 Archaeological Resources and Historical Structures 14-6

14.2 Regulatory Framework 14-11
14.2.1 Federal 14-11
14.2.2 State 14-12
14.2.3 Regulatory Compliance 14-12

14.3 Environmental Consequences and Mitigation Measures 14-14
14.3.1 Impact Assessment Methods and Assumptions 14-14
14.3.2 Criteria for Determining Significance of Effects 14-17
14.3.3 Direct and Indirect Effects 14-19
14.3.4 Mitigation Measures 14-29
14.3.5 Cumulative Effects 14-35

Chapter 15 Indian Trust Assets 15-1

15.1 Affected Environment 15-1

15.2 Regulatory Framework 15-5

15.3 Environmental Consequences and Mitigation Measures 15-6
15.3.1 Methods and Assumptions 15-6
15.3.2 Direct and Indirect Effects 15-6

Chapter 16 Socioeconomics, Population, and Housing 16-1

16.1 Affected Environment 16-1
16.1.1 Socioeconomics 16-1
16.1.2 Population 16-6
16.1.3 Housing 16-7

16.2 Regulatory Framework 16-8
16.2.1 Federal 16-9
16.2.2 State 16-10
16.2.3 Regional and Local 16-10

16.3 Environmental Consequences and Mitigation Measures 16-13
16.3.1 Methods and Assumptions 16-13
16.3.2 Criteria for Determining Significance of Effects 16-16
16.3.3 Topics Eliminated from Further Discussion 16-17
16.3.4 Direct and Indirect Effects 16-17
16.3.5 Mitigation Measures 16-58
16.3.6 Cumulative Effects 16-63

Chapter 17 Land Use and Planning 17-1

17.1 Affected Environment 17-1
17.1.1 Land Use 17-1
17.1.2 Planning 17-8

17.2 Regulatory Framework 17-15
17.2.1 Federal 17-15
17.2.2 State 17-17
17.2.3 Regional and Local 17-19

17.3 Environmental Consequences and Mitigation Measures 17-21
17.3.1 Methods and Assumptions 17-21
17.3.2 Criteria for Determining Significance of Effects 17-22
17.3.3 Topics Eliminated from Further Consideration 17-22
17.3.4 Direct and Indirect Effects 17-23
17.3.5 Mitigation Measures 17-32
17.3.6 Cumulative Effects 17-36

Chapter 18 Recreation and Public Access 18-1

18.1 Affected Environment 18-1
18.1.1 Recreation 18-1

18.2 Regulatory Framework 18-17
18.2.1 Federal 18-17
18.2.2 State 18-20
18.2.3 Regional and Local 18-21

18.3 Environmental Consequences and Mitigation Measures 18-24
18.3.1 Methods and Assumptions 18-24
18.3.2 Criteria for Determining Significance of Effects 18-26
18.3.3 Topics Eliminated from Further Consideration 18-27
18.3.4 Direct and Indirect Effects 18-27
18.3.5 Mitigation Measures 18-83
18.3.6 Cumulative Effects 18-93

Chapter 19 Aesthetics and Visual Resources 19-1

19.1 Affected Environment 19-1
19.1.1 Visual Environment 19-1

19.2 Regulatory Framework 19-73

19.2.1 Federal 19-73
19.2.2 State 19-75
19.2.3 Regional and Local 19-75

19.3 Environmental Consequences and Mitigation Measures 19-76
19.3.1 Methods and Assumptions 19-76
19.3.2 Criteria for Determining Significance of Effects 19-77
19.3.3 Topics Eliminated from Further Consideration 19-78
19.3.4 Direct and Indirect Effects 19-78
19.3.5 Mitigation Measures 19-87
19.3.6 Cumulative Effects 19-90

Chapter 20 Transportation and Traffic 20-1

20.1 Affected Environment 20-1
20.1.1 Roadways 20-1
20.1.2 Public Transit 20-3
20.1.3 Railroads 20-3
20.1.4 Water Navigation 20-4
20.1.5 Airports 20-5

20.2 Regulatory Framework 20-5
20.2.1 Federal 20-5
20.2.2 State 20-5
20.2.3 Regional and Local 20-6

20.3 Environmental Consequences and Mitigation Measures 20-6
20.3.1 Methods and Assumptions 20-7
20.3.2 Criteria for Determining Significance of Effects 20-23
20.3.3 Topics Eliminated from Further Consideration 20-24
20.3.4 Direct and Indirect Effects 20-24
20.3.5 Mitigation Measures 20-44
20.3.6 Cumulative Effects 20-52

Chapter 21 Utilities and Service Systems 21-1

21.1 Affected Environment 21-1
21.1.1 Water Supply 21-2
21.1.2 Wastewater Infrastructure 21-11
21.1.3 Stormwater Drainage and Infrastructure 21-15
21.1.4 Solid Waste Management 21-16
21.1.5 Electrical Service and Infrastructure 21-17
21.1.6 Natural Gas Service and Infrastructure 21-19
21.1.7 Telecommunications 21-19

21.2 Regulatory Framework 21-20
21.2.1 Federal 21-20
21.2.2 State 21-22
21.2.3 Regional and Local 21-24

21.3 Environmental Consequences and Mitigation Measures 21-24

21.3.1 Methods and Assumptions 21-24
21.3.2 Criteria for Determining Significance of Effects 21-25
21.3.3 Topics Eliminated from Further Consideration 21-26
21.3.4 Direct and Indirect Effects 21-26
21.3.5 Mitigation Measures 21-46
21.3.6 Cumulative Effects 21-51

Chapter 22 Public Services 22-1

22.1 Affected Environment 22-1
22.1.1 Fire Protection Services 22-2
22.1.2 Emergency Services 22-4
22.1.3 Law Enforcement 22-6
22.1.4 Schools 22-7

22.2 Regulatory Framework 22-8
22.2.1 Federal 22-8
22.2.2 State 22-9
22.2.3 Regional and Local 22-10

22.3 Environmental Consequences and Mitigation Measures 22-10
22.3.1 Methods and Assumptions 22-10
22.3.2 Criteria for Determining Significance of Effects 22-10
22.3.3 Topics Eliminated from Further Consideration 22-11
22.3.4 Direct and Indirect Effects 22-11
22.3.5 Mitigation Measures 22-23
22.3.6 Cumulative Effects 22-27

Chapter 23 Power and Energy 23-1

23.1 Affected Environment 23-1
23.1.1 Shasta Lake and Vicinity 23-1
23.1.2 Upper Sacramento River (Shasta Dam to Red Bluff) 23-2
23.1.3 Lower Sacramento River and Delta 23-2
23.1.4 CVP/SWP Service Areas 23-3

23.2 Regulatory Framework 23-6
23.2.1 Federal 23-6
23.2.2 State 23-6
23.2.3 Regional and Local 23-6

23.3 Environmental Consequences and Mitigation Measures 23-7
23.3.1 Methods and Assumptions 23-7
23.3.2 Criteria for Determining Significance of Effects 23-9
23.3.3 Direct and Indirect Effects 23-11
23.3.4 Mitigation Measures 23-56
23.3.5 Cumulative Effects 23-57

Chapter 24 Environmental Justice 24-1

24.1 Affected Environment 24-1
24.1.1 Minority and Low-Income Populations 24-1

24.2 Regulatory Framework 24-7
24.2.1 Federal 24-7
24.2.2 State 24-8
24.2.3 Regional and Local 24-8

24.3 Environmental Consequences and Mitigation Measures 24-8
24.3.1 Methods and Assumptions 24-8
24.3.2 Criteria for Determining Disproportionately High and Adverse Effects 24-10
24.3.3 Topics Eliminated from Further Consideration 24-10
24.3.4 Direct and Indirect Effects 24-10
24.3.5 Mitigation Measures 24-28
24.3.6 Cumulative Effects 24-31

Chapter 25 Wild and Scenic River Considerations for McCloud River 25-1

25.1 Background 25-1

25.2 Regulatory Framework 25-6
25.2.1 Federal 25-6
25.2.2 State 25-7

25.3 Affected Environment 25-8
25.3.1 The McCloud River 25-9
25.3.2 The McCloud River's Wild and Scenic Values 25-11

25.4 Environmental Consequences and Mitigation Measures 25-22
25.4.1 Methods and Assumptions 25-22
25.4.2 Criteria for Determining Significance of Effects 25-24
25.4.3 Direct and Indirect Effects 25-24
25.4.4 Mitigation Measures 25-36
25.4.5 Topics Eliminated from Further Consideration 25-37
25.4.6 Cumulative Effects 25-37

Chapter 26 Other Required Disclosures 26-1

26.1 Significant Adverse Effects that Cannot be Avoided If a Project is Implemented 26-1

26.2 Relationship of Short-Term Uses and Long-Term Productivity 26-2

26.3 Irreversible and Irretrievable Commitments of Resources 26-3

26.4 Growth-Inducing Impacts 26-4
26.4.1 Increased Construction Work 26-6
26.4.2 Increased Flood Protection 26-6
26.4.3 Increased Water Supply Reliability 26-7

26.5 Identification of Environmental Preferences for Alternatives 26-9
26.5.1 Least Environmentally Damaging Practicable Alternative 26-9

26.5.2 Environmentally Preferable Alternative/Environmentally Superior Alternative 26-9

26.6 Compliance with Applicable Laws, Policies, and Plans 26-10
26.6.1 Federal Requirements 26-10
26.6.2 State Requirements 26-16
26.6.3 Local Plans and Policies 26-20

Chapter 27 Public Involvement, Consultation, and Coordination 27-1

27.1 Public Involvement Through Project Scoping 27-1
27.1.1 Notice of Intent to Propose an Environmental Impact Statement 27-1
27.1.2 Public Scoping Meetings 27-2

27.2 Other Public Outreach 27-3

27.3 Consultation and Coordination 27-4
27.3.1 Consultation and Coordination with Agencies 27-4
27.3.2 Consultation and Coordination with Tribal Governments 27-4
27.3.3 Coordination with Native American Tribal Groups 27-5

27.4 Major Topics of Interest 27-5

27.5 Additional Steps in the Environmental Review Process 27-6

Chapter 28 References 28-1

Chapter 29 PDEIS Distribution List 29-1

29.1 Document Availability 29-1

29.2 Agencies and Organizations Receiving Copies of the PDEIS 29-1
29.2.1 Federal and State Agencies 29-1
29.2.2 Regional and Local Entities 29-2
29.2.3 Other Interested Parties 29-3

Chapter 30 List of EIS Preparers 30-1

Chapter 31 Index 31-1

Chapter 1
Introduction

This Preliminary Draft Environmental Impact Statement (PDEIS) has been prepared as part of the Shasta Lake Water Resources Investigation (SLWRI) to evaluate the potential environmental, cultural, and socioeconomic effects of implementing the proposed action to modify the existing Shasta Dam and Reservoir. The SLWRI is led by the U.S. Department of the Interior, Bureau of Reclamation (Reclamation), Mid-Pacific Region, and includes this PDEIS and the accompanying Draft of the *Shasta Lake Water Resources Investigation Feasibility Report* (Feasibility Report) and appendices. Reclamation is serving as the Federal lead agency for compliance with the National Environmental Policy Act (NEPA). Under NEPA, a cooperating agency is any Federal agency, other than the lead agency, that has jurisdiction by law or special expertise with respect to any environmental impact involved in an action requiring an environmental impact statement (EIS). Cooperating agencies for the SLWRI, pursuant to NEPA, are U.S. Forest Service (USFS), Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians, U.S. Army Corps of Engineers, and U.S. Department of the Interior, Bureau of Indian Affairs. This document has also been prepared in accordance with the California Environmental Quality Act (CEQA) and may be used by State of California (State) permitting agencies that would be involved in reviewing and approving the project.

In conducting the SLWRI, Reclamation determined that expanding the capacity of Shasta Lake by modifying Shasta Dam would (1) increase survival of anadromous fish in the Sacramento River, and (2) improve water supply reliability for agricultural, municipal and industrial (M&I), and environmental water users; these are the two primary purposes of the SLWRI. In addition, implementing the proposed action would address other related resource needs.

1.1 Background

Reclamation was established in 1902 to assist in meeting the increasing water demands of the West. Today, Reclamation is the largest water provider in the country and the second largest producer of hydroelectric power in the western United States. Reclamation's Mid-Pacific Region is responsible for managing the Central Valley Project (CVP), which stores and delivers about 20 percent of the State's developed water — 7 million acre-feet (MAF) — to more than 250 water contractors throughout California.

Shasta Dam and Shasta Lake were constructed from September 1938 to June 1945. Shasta Dam was fully operable in April 1949, following World War II. During this period (circa 1945 – 1949), approximately 37 miles of the Union Pacific Railroad main line and 21 miles of U.S. Highway 99 (now Interstate 5 (I-5)) were relocated around the reservoir. Reclamation currently operates Shasta Dam and Shasta Lake in conjunction with other facilities to manage floodwater, irrigation water supply, M&I water supply, hydropower generation, and maintenance of navigation flows. The Central Valley Project Improvement Act (CVPIA) added "fish and wildlife mitigation, protection, and restoration" as a priority equal to water supply, and added "fish and wildlife enhancement" as a priority equal to hydropower generation.

1.1.1 SLWRI Authorization

Public Law 96-375 (October 3, 1980) provides feasibility study authority for the SLWRI and allows the Secretary of the Interior to do the following:

> *…engage in feasibility studies relating to enlarging Shasta Dam and Reservoir, Central Valley Project, California or to the construction of a larger dam on the Sacramento River, California, to replace the present structure.*

Section 103(c), "Authorizations for Federal Activities Under Applicable Law," of the CALFED Bay-Delta Authorization Act (Public Law 108-361, October 25, 2004), authorizes the Secretary of the Interior to carry out the activities described in paragraphs (1) through (10) of Subsection (d), which include the following:

> *...(1)(A)(i) planning and feasibility studies for projects to be pursued with project-specific study for enlargement of (1) the Shasta Dam in Shasta County.*

Also, Section 103(a)(1) of Public Law 108-361 (October 25, 2004) states the following:

> *The Record of Decision is approved as a general framework for addressing the CALFED Bay-Delta Program, including its components relating to water storage, ecosystem restoration, water supply reliability (including new firm yield), conveyance, water use efficiency, water quality, water transfers, watersheds, the Environmental Water Account, levee stability, governance, and science.*

The CALFED Bay-Delta Program (CALFED) Programmatic Record of Decision (ROD) (CALFED 2000a) called for the Secretary of the Interior to do the following:

> *…engage in feasibility studies for the purpose of determining the potential costs, benefits, environmental impacts, and feasibility of using the Sacramento River for conveying water from the enlarged Shasta Dam and Reservoir or the larger dam to points of use downstream from the dam.*

Other Federal legislation influences the SLWRI. Two laws of special note are Public Law 89-336 (November 8, 1965) and Public Law 102-575 (October 30, 1992). Public Law 89-336 created the Whiskeytown-Shasta-Trinity National Recreation Area, which includes Shasta Dam and Reservoir. Public Law 102-575, the CVPIA, directed numerous changes to operation of the CVP. Among these changes was adding fish and wildlife protection, restoration, and enhancement as a project purpose, which resulted in substantial changes to water supply deliveries, river flows, and related environmental conditions in the study area. To minimize impacts to CVP water contractors, the CVPIA also directed the Secretary of the Interior to develop a least-cost plan to increase the yield of the CVP by the amount dedicated to fish and wildlife purposes.

1.1.2 Major Previous Studies and Reports

Major previous Reclamation studies and reports investigating potential enlargement of Shasta Dam and Reservoir include the *Enlarged Shasta Lake Investigation Preliminary Findings Report* (1983), *Shasta Dam and Reservoir Enlargement, Appraisal Assessment of the Potential for Enlarging Shasta Dam and Reservoir* (1999), *Strategic Agency and Public Involvement Plan* (2003), *Mission Statement Milestone Report* (2003), *Initial Alternatives Information Report* (2004), *Environmental Scoping Report* (2006), and *Plan Formulation Report* (2007).

1.2 Purpose and Need for Proposed Action and Project Objectives

NEPA regulations require a statement of "the underlying purpose and need to which the agency is responding in proposing the alternatives, including the proposed action" (40 Code of Federal Regulations 1502.13), described in Section 1.2.1. The State CEQA Guidelines require a clearly written statement of objectives, including the underlying purpose of a project (Section 15124(b)), described in Section 1.2.2.

1.2.1 Purpose and Need for Proposed Action

The purpose of the proposed action is to improve operational flexibility of the Sacramento-San Joaquin Delta (Delta) watershed system through modifying the existing Shasta Dam and Reservoir to increase water supply reliability and anadromous fish populations in the upper Sacramento River. Specifically, the purpose of the proposed action is to accomplish all of the following:

- Promote increased survival of anadromous fish populations in the upper Sacramento River, primarily upstream from the location of the Red Bluff Diversion Dam (RBDD).

- Increase water supplies and water supply reliability for agricultural, M&I, and environmental purposes to help meet current and future water demands.

- To the extent possible, through meeting these objectives, include features that conserve and restore ecosystem resources in the Shasta Lake area and along the upper Sacramento River, reduce flood damage along the Sacramento River, increase hydropower capabilities at Shasta Dam, maintain and increase recreation opportunities at Shasta Lake, and maintain or improve water quality conditions in the Sacramento River downstream from Shasta Dam and in the Delta.

The need for the proposed action is described below and summarized from the 2007 Reclamation *Shasta Lake Water Resources Investigation Plan Formulation Report*, the 2004 Reclamation *Shasta Lake Water Resources Investigation Initial Alternatives Information Report*, and the Plan Formulation Appendix.

Anadromous Fish Survival

The Sacramento River system is unique in California in that it supports four separate runs of Chinook salmon: fall-, late fall-, winter-, and spring-run. The adult populations of the four runs of salmon and other important fish species that spawn in the upper Sacramento River have considerably declined over the last 40 years (DFG 2010). Several fish species in the upper Sacramento River have been listed under the Federal Endangered Species Act: Sacramento River winter-run Chinook salmon (endangered), Central Valley spring-run Chinook salmon (threatened), Central Valley steelhead (threatened), and the Southern Distinct Population Segment of North American green sturgeon (threatened). Two of these species are also listed under the California Endangered Species Act: Sacramento River winter-run Chinook salmon (endangered) and Central Valley spring-run Chinook salmon (threatened).

Unsuitable water temperatures in the upper Sacramento River, especially in dry and critically dry years, is a critical factor affecting the abundance of Chinook salmon and steelhead in the river. Releases of cold water stored behind Shasta Dam can improve seasonal water temperatures in the Sacramento River for anadromous fish, particularly winter-run Chinook salmon, during critical periods. Prolonged droughts depleting the cold-water storage in Shasta Reservoir could extirpate the entire Sacramento River winter-run Chinook salmon population (NMFS 2009a). Under current conditions, even 2 consecutive years of drought could reduce Shasta Reservoir cold-water storage to levels insufficient to support the Sacramento River winter-run Chinook spawning and incubation season. This could result in complete year-class

failure, virtually eliminating all of a single year's spawning and incubating winter-run Chinook in the Sacramento River (NMFS 2009a).

Various Federal, State, and local projects are addressing factors contributing to declines in anadromous fish populations. Recovery actions range from changing the timing and magnitude of reservoir releases to changing the temperature of released water. In May 1990, the State Water Resources Control Board issued Order 90-5, which included temperature objectives for the Sacramento River to protect winter-run Chinook salmon. The 1993 and 2004 National Marine Fisheries Service (NMFS) Biological Opinions (BO) for Sacramento River winter-run Chinook salmon reinforced this order and established certain operating parameters for Shasta Reservoir. The State Water Resources Control Board action and the NMFS BOs set surrogate or minimum flows in the river downstream from Keswick Dam primarily to affect water temperatures during key periods. In addition to flow requirements, structural changes have been made at Shasta Dam to change the temperature of released water, such as construction of the temperature control device, which was completed in 1997.

However, implementing requirements in the Trinity River ROD (as amended) may reduce water temperature improvements provided by the temperature control device at Shasta Dam. One of the major elements of the Trinity River ROD is reducing the average annual export of Trinity River water from 74 percent to 52 percent of the flow (Reclamation 2000). This reduces flow from the Trinity River basin into Keswick Reservoir, and then into the Sacramento River. Because water diverted from the Trinity River is generally cooler than flows released from Shasta Dam, implementing the Trinity River ROD offsets some of the benefits derived from the temperature control device.

Despite the efforts described above, a residual need remains for generally cooler water in the Sacramento River, especially in dry and critically dry water years. Additional actions are needed to continue reducing water temperatures in the Sacramento River at critical life stages of and improve habitat conditions for anadromous fish species.

Also, future effects of climate change on operations and conditions at Shasta Lake, and in the upper Sacramento River, could potentially result in changes to water temperature, flow, and ultimately, fish survival. Most importantly, it is expected that climate change may result in increased water temperatures downstream from Shasta Dam, particularly in summer months, and more frequent wet and drought (particularly extended drought) years. Increased water temperatures and extended drought periods may compound the threats to anadromous fish in the Sacramento River. Climate change could also result in reduced end-of-September carryover storage volumes, resulting in lower lake levels for a portion of the year, and a smaller cold-water pool, resulting in warmer water temperature and reduced water quality within Shasta Reservoir.

Water Supply Reliability

California's water supply system faces critical challenges with demands exceeding supplies for agricultural, M&I, and environmental water uses across the State. The 2009 California Department of Water Resources (DWR) *California Water Plan Update* concludes that California is facing one of the most significant water crises in its history; drought impacts are growing, ecosystems are declining, water quality is diminishing, and climate change is affecting statewide hydrology. Compounding these issues, Reclamation's *Water Supply and Yield Study* (2008a) describes dramatic increases in statewide population, land use changes, regulatory requirements, and limitations on storage and conveyance facilities, further straining available water supplies and infrastructure to meet water demands. Furthermore, projected unmet water demands are expected to increase competition for water supplies among agricultural, M&I, and environmental uses.

Projecting accurate and quantified water supply and shortages in California is complex; there are numerous variables and, just as important, numerous opinions regarding these variables. Reclamation's *Water Supply and Yield Study* (2008a) estimates current statewide water supply shortages at 2.3 MAF and 4.2 MAF for average and dry years, respectively. Without further investment in water management and infrastructure, future statewide shortages are expected to increase to approximately 4.9 MAF and 6.1 MAF in average and dry years, respectively, by 2030 (Reclamation 2008a). Representative demands for dry and average years were based on water use data from the 2005 *California Water Plan Update* (DWR), adjusted for population growth, increasing urban water use, and reductions in irrigated acreage and environmental flow due to insufficient water supplies.

A major factor in California's future water picture is population growth. California's population is expected to increase by just over 60 percent by 2050 (DOF 2010) and could force some of the existing water supplies currently identified for agricultural uses to be redirected to urban uses. Because some portion of increased population growth in the Central Valley would occur on lands currently used for irrigated agriculture, water that would have been needed for these lands for irrigation would instead be used to meet urban demands. However, this would only partially offset the required agricultural-to-urban water conversion needed to sustain projected urban water demands, since much of the growth would occur on nonirrigated agricultural lands. Even if all of the urban growth in the Central Valley would occur on lands currently under irrigation, this would only account for up to about 40 percent of expected future conversion needs, and additional agricultural-to-urban water conversion would be required to help sustain urban growth primarily in other areas of the State.

Another potentially significant factor affecting water supply reliability is climate change. Potential impacts due to climate change are many and complex (DWR 2006), varying through time and geographic location across the State (Reclamation 2011). Changes in geographic distribution, timing, and intensity

of precipitation are projected for the Central Valley (Reclamation 2011), which could broadly impact rainfall runoff relationships important for flood management and water supply. A reduction in total system storage is also anticipated as a result of climate change. Precipitation held in snowpack makes up a significant quantity of total annual supplies needed for urban, M&I, and many environmental uses. It is expected that in the future, climate change may significantly reduce water held in snowpack in the Sierra Nevada Mountains (DWR 2009). Additionally, when climate change is considered in projections of change in water demand, annual water demand is higher than under a repeat of historical climate (DWR 2009). During drought periods, expected supplies could be further reduced, and expected shortages would be significantly greater.

Also, CVP and State Water Project (SWP) flexibility has diminished with population growth and increased environmental and ecosystem commitments and requirements (Reclamation 2008a). For example, the CVPIA, implemented in 1993, dedicated 800 thousand acre-feet of CVP water supplies to the environment as well as additional water supplies for wildlife refuges. This had the greatest impact on dry year agricultural water deliveries, with CVP delivery capability for agricultural users, both north and south of the Delta, reduced by about 50 percent (Reclamation 2008a). Complicating this issue is the variability associated with water resources in California. Precipitation in California is seasonably, temporally, and spatially variable and agricultural, M&I, and environmental water users have variable needs for quantity, quality, timing, and place of use.

California's water systems face the threat of too much water during floods, and too little water to meet demands during dry and critical water years. Chronic water shortages have led to increases in groundwater usage, which has led to groundwater overdraft in many regions across the State. Groundwater overdraft can cause permanent declines in groundwater levels, long-term reductions in groundwater supplies, land subsidence, decreases in water quality, a greater potential for salt water intrusion, and lasting environmental impacts. Challenges are greatest during drought years, when water supplies are less available (DWR 2009).

An integrated portfolio of solutions, regional and statewide, is needed to meet future water supply needs. Even with major efforts by multiple agencies to address the complex water resources issues in the State, demands are expected to exceed supplies in the future. The 2008 *Water Supply and Yield Study* (Reclamation) stated that a "variety of storage and conveyance projects and water management actions have the potential to help fill [the] gap" between water supply and demand in California. The *2009 California Water Plan Update* (DWR) concluded that California must invest in reliable, high-quality, and affordable water conservation, efficient water management, and development of water supplies to protect public health, and improve California's economy, environment, and standard of living. Water management flexibility and adaptability will become even more necessary in the future to

meet the challenges associated with increasing population, environmental needs, and climate change. Even so, to avoid major impacts to the economy, overall environment, and standard of living in California, actions to conserve existing supplies and optimize the use of existing facilities will be needed. Additionally, development of additional water sources and increased storage and delivery capability are critical for providing reliable water supplies for expanding M&I uses and to maintain adequate supplies for agricultural and environmental purposes.

Other Resources

Reclamation has identified other resource needs that could be addressed through modification of Shasta Dam and Reservoir. Escalating demands on statewide electricity production, continuing modification of natural aquatic and riparian habitats in the Sacramento River system, increasing threats of potential flooding in the Sacramento River system, and greater demands for recreational opportunities are all potential local, regional, or statewide problems exacerbated by California's population growth in general and particularly in the Sacramento Valley. The SLWRI provides opportunities to address these other resource needs, as well as the primary SLWRI objectives of increased anadromous fish survival and water supply reliability.

1.2.2 Project Objectives

To address the identified purpose and need described above, two primary project (i.e., planning) objectives were developed for the SLWRI. Five secondary project objectives were developed to take advantage of other beneficial project opportunities.

Primary Project Objectives

Primary project objectives are those which specific alternatives are formulated to address. Primary project objectives developed for the SLWRI are as follows:

- Increase the survival of anadromous fish populations in the Sacramento River, primarily upstream from the RBDD.

- Increase water supply and water supply reliability for agricultural, M&I, and environmental purposes to help meet current and future water demands, with a focus on enlarging Shasta Dam and Reservoir.

The primary project objectives are considered to have coequal priority, with each pursued to the maximum practicable extent without adversely affecting the other.

Secondary Project Objectives

Secondary project objectives are actions, operations, or features that should be considered in the plan formulation process, but only to the extent possible through pursuit of the primary project objectives. Five secondary project objectives were developed for the SLWRI:

- Conserve, restore, and enhance ecosystem resources in the Shasta Lake area and along the upper Sacramento River
- Reduce flood damage along the Sacramento River
- Develop additional hydropower generation capabilities at Shasta Dam
- Maintain and increase recreation opportunities at Shasta Lake
- Maintain or improve water quality conditions in the Sacramento River downstream from Shasta Dam and in the Delta

1.3 Setting and Location

Shasta Dam and Shasta Lake are located on the upper Sacramento River in Northern California, approximately 9 miles northwest of Redding in Shasta County (Figure 1-1). The SLWRI includes both a primary and extended study area because of the potential influence of the proposed modification of Shasta Dam and Reservoir and subsequent system operations and water deliveries on resources over a large geographic area. The primary study area includes the following:

- Shasta Dam and Shasta Lake
- Lower reaches of three primary tributaries flowing into Shasta Lake (Sacramento, McCloud, and Pit rivers) and all smaller tributaries flowing into the lake
- Trinity and Lewiston Reservoirs
- Sacramento River between Shasta Dam and the RBDD facilities, including tributaries at their confluence

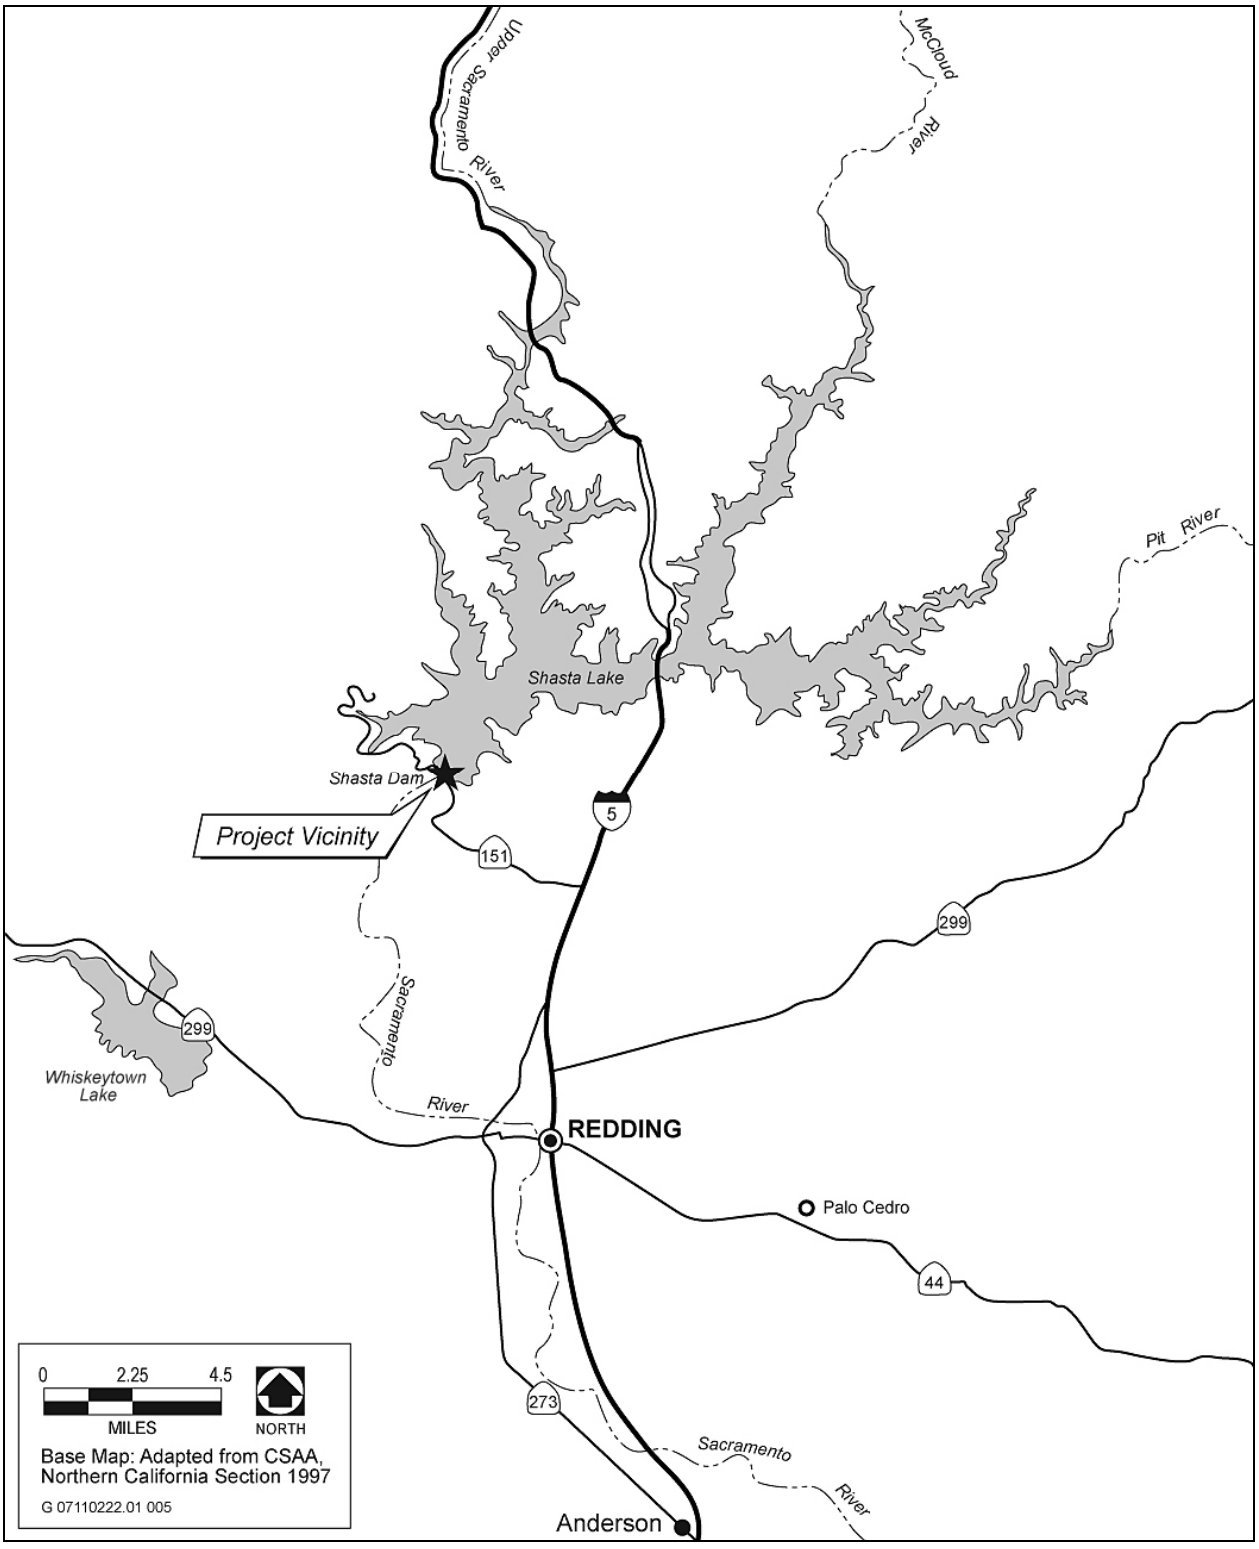

Figure 1-1. Shasta Dam and Shasta Lake Vicinity

The extended study area includes the following:

- Sacramento River downstream from the RBDD facilities, including portions of major tributaries, namely the American and Feather river basins downstream from CVP/SWP facilities
- Delta
- San Joaquin River basin at and downstream from CVP facilities (Friant and New Melones reservoirs)
- Facilities and water service areas of the CVP and SWP

The SLWRI study area includes other areas of California with resource programs or projects that could potentially be directly or indirectly influenced by modifying Shasta Dam and Reservoir. As discussed above, this area is represented by the Sacramento and San Joaquin rivers and the Delta system, plus the entirety of the CVP and SWP facilities and water service areas. For analyses of each resource that may be directly or indirectly affected by the project, this study area is subdivided into specific geographic areas, as described in the following sections.

1.3.1 Primary Study Area

The primary study area includes Shasta Dam and Reservoir, the lower portions of all contributing major and minor tributaries affected by increasing storage in Shasta Lake, and the Sacramento River downstream to the location of the RBDD. The RBDD is directly adjacent to the Red Bluff Pumping Plant (RBPP), which is currently under construction. Figure 1-2 shows the portion of the primary study area downstream from Shasta Dam.

Shasta Dam

Shasta Dam and Shasta Lake deliver about 55 percent of the total annual water supply used by the CVP. Shasta Dam is 602 feet tall (533 feet above the streambed). Upon construction, Shasta Dam was the second tallest and second largest concrete dam in the world. It was exceeded only by Hoover Dam (located in Clark County, Nevada) in height and by Grand Coulee Dam (located in Grant County, Washington) in volume and surface area (Reclamation 2004a).

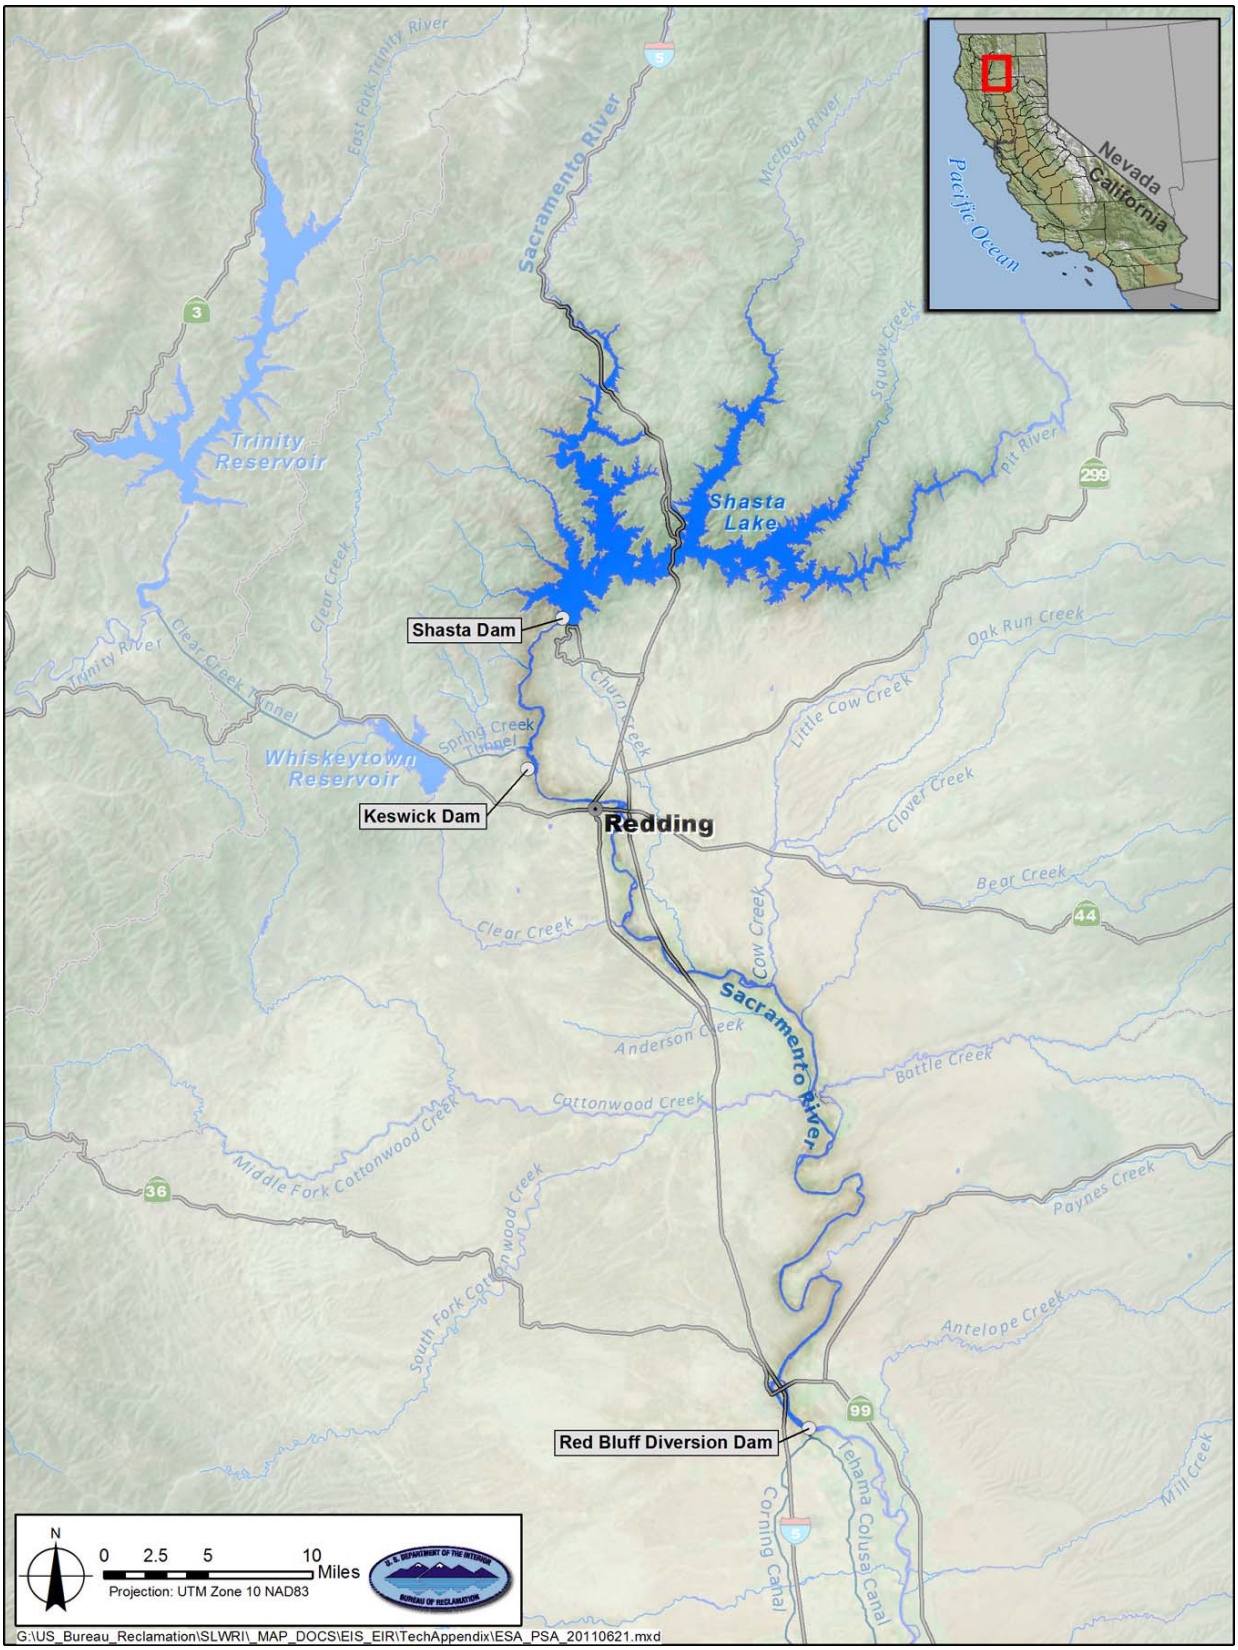

Figure 1-2. Primary Study Area – Shasta Lake Area and Sacramento River from Shasta Dam to Red Bluff Diversion Dam

Shasta Lake and Vicinity

Created by Shasta Dam, Shasta Lake is the largest reservoir in California with a surface area of approximately 29,500 acres, a volume of 4.55 MAF, and approximately 400 miles of shoreline. Offering a wide variety of water-based recreational opportunities, Shasta Lake is considered a premier lake for houseboating. Eleven resorts and numerous Shasta-Trinity National Forest campgrounds and boat ramps provide boating and fishing access; bank and boat fishing occurs year-round. Recreation at the reservoir is managed by the USFS consistent with the *Shasta-Trinity Land and Resource Management Plan* (USFS 1995) and guidelines established for the Whiskeytown-Shasta-Trinity National Recreation Area. Shasta Lake is also home to a wide variety of wildlife species, including resident bald eagles and osprey.

The reservoir's watershed receives a substantial amount of precipitation relative to the rest of California; only a limited region in the State's far northwest corner receives more. The three major tributaries to Shasta Lake are the Sacramento, McCloud, and Pit rivers. Many smaller tributary creeks and streams (both seasonal and perennial) flow into these major tributaries and the reservoir itself. The major tributaries are described in more detail below.

Sacramento River The Sacramento River drains an area of approximately 430 square miles. Its headwaters include portions of Mount Shasta and the Trinity and Klamath mountains. The Sacramento River flows south from its headwaters for about 40 miles before entering Shasta Lake.

McCloud River The McCloud River drains an area of approximately 600 square miles. Its headwaters are at Colby Meadows near Bartle, California. The McCloud River flows southwesterly from its headwaters for about 50 miles to its terminus at Shasta Lake.

Pit River The Pit River watershed is located in northeastern California and southeastern Oregon. The north and south forks of the Pit River drain the northern portion of the watershed. The North Fork Pit River originates at the outlet of Goose Lake, and the South Fork originates in the south Warner Mountains at Moon Lake in Lassen County. The Pit River is joined by the Fall River in Shasta County and has 21 named tributaries, totaling approximately 1,050 miles of perennial streams and encompassing approximately 4,700 square miles.

Trinity and Lewiston Reservoirs Trinity and Lewiston reservoirs impound the upper Trinity River approximately 60 and 67 miles, respectively, southwest of the headwaters near Mount Eddy (USFS 2005). Trinity Reservoir has a watershed of approximately 105,600 acres and a usable storage capacity of approximately 2,438,000 acre-feet. Flow into Lewiston Reservoir, with a capacity of approximately 14,700 acre-feet, is completely regulated by releases from Trinity Dam (USFS 2005). At Lewiston Dam, a portion of Trinity River

flows are diverted to the Sacramento River basin through the Clear Creek Tunnel.

Upper Sacramento River — Shasta Dam to Red Bluff Diversion Dam

This portion of the study area includes an approximately 65-mile-long stretch of the Sacramento River corridor from Shasta Dam to the RBDD facilities, including tributaries at their confluence. The Sacramento River corridor within this reach also includes Reading Island and areas proposed for gravel augmentation. Communities located along this stretch of the river are Redding, Anderson, and Red Bluff. The northern portion of this reach is located in Shasta County and the southern portion is in Tehama County.

Shasta Dam, Keswick Dam, Anderson-Cottonwood Irrigation District Dam, and the RBDD are located on the Sacramento River in this area. Urban, residential, industrial, and agricultural land uses predominate along the upper Sacramento River between Shasta Dam and the RBDD.

1.3.2 Extended Study Area

The extended study area for the project includes the RBDD south (downstream along the Sacramento River) to the Delta. It also includes the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) area and portions of the American and Feather river basins, the San Joaquin River basin, and the CVP and SWP facilities and water service areas (Figure 1-3).

Sacramento River from Red Bluff Diversion Dam to Delta

The segment of the extended study area between the RBDD facilities and the Delta includes the Sacramento River, tributaries at their confluence, and portions of major tributaries that may be affected by the project, namely, the Feather and American rivers. The Yuba River is a major tributary to the Feather River, but the Yuba River is not considered part of this segment of the extended study area for two reasons: it is geographically separated from the Sacramento River, and its watershed has no CVP or SWP facilities that could be indirectly affected by increased storage at Shasta Lake. Lake Oroville is a major DWR SWP facility on the Feather River, and Folsom Lake is a major Reclamation CVP facility on the American River.

The reach of the middle Sacramento River between Red Bluff and Colusa is approximately 100 miles.

The Sacramento River Hydrologic Region, as defined by DWR, is the main water supply for much of California's urban and agricultural areas. Annual runoff averages about 22.4 MAF, which is nearly one-third of California's total runoff. M&I and agricultural supplies to the Sacramento Valley region are about 8 MAF, with groundwater providing approximately 2.5 MAF of that total. Much of the remainder of the runoff in the Sacramento River watershed goes to dedicated in-channel flows that support various environmental requirements, including instream flow and Delta salinity requirements (DWR 2003).

Figure 1-3. Central Valley Project and State Water Project Water Service Areas

Sacramento-San Joaquin Delta

Surface water resources in the Delta are influenced by the interaction of tributary inflows, tides, Delta hydrodynamics, local Delta diversions and exports, and water transfers. The Delta receives runoff from a watershed that includes more than 40 percent of California's land area and covers approximately 750,000 acres. Tributaries that discharge directly into the Delta include the Sacramento, San Joaquin, Mokelumne, Cosumnes, and Calaveras rivers. Existing surface water conditions in the Delta are the result of the many changes that have occurred as the Delta and its watershed have been developed over the past 150 years.

Tides move water twice daily from San Francisco Bay into the Delta. The location of the mixing zone between freshwater from the Delta and saline water from the bay varies with the amount of Delta outflow and tides. Saltwater intrusion into the Delta during summer is controlled by tides, freshwater inflows from reservoir releases, and Delta pumping. Average incoming and outgoing Delta tidal flow is approximately 170,000 cubic feet per second and average net Delta outflow is about 30,000 cubic feet per second, or about 21 MAF per year, measured at Chipps Island.

San Joaquin River Basin to Delta

The San Joaquin River basin includes the Central Valley south of the Delta. This area is drier than the Sacramento Valley, and flows into the Delta from the San Joaquin River are considerably less than those from the Sacramento River. The river is also subject to extreme variations in flow and water quality.

The San Joaquin River watershed above Vernalis (the point at which the river enters the Delta) is 13,356 square miles. Inflows from the Merced (farthest upstream), Tuolumne, and Stanislaus rivers contribute more than 60 percent of the flows in the San Joaquin River, as measured at Vernalis.

The major rivers of the San Joaquin system have contributed an average of about 5.5 MAF to Delta inflow, with an annual range of 1.1 to 15 MAF. Historical unimpaired flows on the Stanislaus, Tuolumne, Merced, and San Joaquin rivers averaged a total of 5.6 MAF. Numerous dams, reservoirs, and diversions are located on these rivers and others in the San Joaquin system. New Melones Reservoir is located on the Stanislaus River and is part of Reclamation's CVP system.

Central Valley Project Facilities and Water Service Areas

The CVP supplies irrigation water to the Sacramento and San Joaquin valleys; domestic water to cities and industries in Sacramento County and the east and South San Francisco Bay area; and water to fish hatcheries and wildlife refuges throughout the Central Valley. The CVP delivers approximately 7 MAF of water per year. CVP facilities include 20 dams and reservoirs with a combined storage capacity of more than 11 MAF, 39 pumping plants, 2 pumping-generating plants, 11 powerplants, and more than 500 miles of major canals and

aqueducts. CVP divisions comprise Trinity River, Shasta Lake, Sacramento River, American River, Delta, West San Joaquin, San Felipe, East Side, and Friant.

The CVP has three primary storage facilities in Northern California: Shasta Dam and Shasta Lake, Trinity Dam and Clair Engle Lake, and Folsom Dam and Folsom Lake. Major storage facilities south of the Delta are New Melones Reservoir on the Stanislaus River, Millerton Lake on the San Joaquin River, and San Luis Reservoir, which is a pumped-storage reservoir on the west side of the San Joaquin Valley, and is shared with the SWP.

The Delta-Mendota Canal is the main conveyance facility of the CVP. This canal conveys water from the C. W. "Bill" Jones Pumping Plant (formerly known as the Tracy Pumping Plant) in the south Delta near Byron to agricultural lands in the San Joaquin Valley. Water not delivered directly is diverted from the Delta-Mendota Canal at the O'Neill Pumping Plant into O'Neill Forebay. The water then flows along the San Luis Canal to CVP contractors in the San Joaquin Valley or is lifted into San Luis Reservoir through the Gianelli Pumping/Generating Plant for later use. The majority of the remaining water continues to the southern Central Valley, with some water being diverted to Santa Clara County.

State Water Project Facilities and Water Service Areas

The SWP is the largest state-built, multipurpose water project in the country. DWR operates and maintains the SWP, which conveys an annual average of 2.5 MAF of water through 20 pumping plants, 4 pumping-generating plants, 5 hydroelectric powerhouses, 34 storage facilities, and about 701 miles of open canals and pipelines.

DWR operates the SWP to export Delta flows and store and transfer water from the Feather River basin to the San Joaquin Valley, South San Francisco Bay, areas north of Suisun Bay, coastal counties, and ultimately to Southern California. The State Legislature authorized the SWP in 1951 for water supply, flood control, hydropower generation, recreation, and fish and wildlife purposes. Approximately 25 million of California's estimated 37 million residents benefit from SWP water, which also irrigates about 750,000 acres of farmland, mainly in the south San Joaquin Valley. Of the contracted water supply, M&I users have received about half of the total water delivered over the last 20 years; the remainder is supplied for agricultural use. A total of 29 contracting agencies receive water from the SWP.

In the southern Delta, the SWP diverts water from Clifton Court Forebay for delivery south of the Delta. The Harvey O. Banks Pumping Plant lifts water from Clifton Court Forebay into Bethany Reservoir. The water delivered to Bethany Reservoir flows into the California Aqueduct, the main conveyance facility of the SWP. Along the western San Joaquin Valley, the California Aqueduct transports water through the Gianelli Pumping/Generating Plant for

storage in San Luis Reservoir until it is needed for later use. The 444-mile-long California Aqueduct conveys water to the agricultural lands of the San Joaquin Valley and the urban regions of Southern California. The west branch of the aqueduct ends in Castaic Lake, and the east branch terminates at Lake Perris in Southern California.

1.4 NEPA Requirements

NEPA is a planning process to inform stakeholders, public agencies, and decision makers of the significance of potential environmental effects that may result from taking an action or implementing a Federal action. These processes disclose the significance of the effects of a proposed action on the natural and human environment. The environmental effects of a range of reasonable alternatives, including a no-action alternative, are also analyzed as required under NEPA.

1.4.1 NEPA Process

Reclamation is the Federal lead agency for NEPA compliance (42 U.S. Code 4321 et seq.). Based on a review of technical data and the scope of the SLWRI, Reclamation determined that the proposed action would result in significant impacts and that an EIS is the appropriate NEPA document to be prepared. Consequently, this PDEIS has been made available for public review, and a Draft EIS, Final EIS, and ROD will be published subsequently.

The EIS, when finalized, will satisfy NEPA requirements for formulating and evaluating alternatives, disclosing environmental impacts, and indentifying potential mitigation measures. Section 1.5.2, “Intended Use of Final EIS,” describes the roles and responsibilities of Federal, State, and local agencies and includes a list of agencies that may use the EIS, when finalized, for NEPA compliance, or to inform decisions regarding resources within their jurisdictions.

1.5 Intended Use of EIS

This section described how this PDEIS will be used now and when it is finalized.

1.5.1 Intended Use of Preliminary Draft EIS

Release of this Preliminary Draft EIS, the Draft Feasibility Report, and their appendices presents SLWRI findings to date, and provides another opportunity for public and stakeholder input. When additional information and studies are incorporated into the SLWRI, Reclamation will distribute a formal Draft EIS for public review and comment.

1.5.2 Intended Use of Final EIS

An EIS identifies and evaluates alternatives that meet the project purpose and can also avoid project-related impacts, analyzes the environmental effects of an action, and indicates additional measures to reduce or avoid potential environmental effects resulting from the action alternatives (i.e., mitigation measures). An EIS must also disclose significant environmental effects that cannot be avoided, growth-inducing effects, significant cumulative impacts, and effects found not to be significant. The purpose of an EIS is not to recommend approval or rejection of a project, but to provide information to aid the public and decision makers/permitting agencies in the decision-making process.

This EIS, when finalized, is intended to be used by the Federal lead agency when considering approval of the proposed action or an alternative to the proposed action. All cooperating agencies, responsible agencies, and other Federal, State, and local agencies with permitting or approval authority over any aspect of the proposed action are expected to use the information contained in the Final SLWRI EIS to meet most, if not all, of their information needs to make decisions and/or issue permits with respect to the proposed action. Table 1-1 presents Federal, State, and local agencies that may use the EIS for their decision-making needs.

This PDEIS also serves as a companion document to the Draft Feasibility Report, published concurrently. The Draft Feasibility Report builds on the information contained in the *Shasta Lake Water Resources Investigation Plan Formulation Report* (Reclamation 2007) and incorporates information contained in the SLWRI PDEIS by reference. The Feasibility Report, when finalized, will be used to determine the type and extent of Federal interest in enlarging Shasta Dam and Reservoir.

Table 1-1. Agency Roles and Responsibilities

Agency	Role/Responsibility
Federal	
U.S. Army Corps of Engineers (cooperating agency)	Permitting under Section 404 of the Clean Water Act; Permitting under Sections 9, 10, and 13 of the Rivers and Harbors Act
U.S. Department of the Interior, Bureau of Indian Affairs (cooperating agency)	Participating in SLWRI feasibility study
U.S. Department of the Interior, Bureau of Land Management	Reviewing SLWRI studies for consistency of project facilities with management of the Sacramento River Bend Management Area
U.S. Department of the Interior, Bureau of Reclamation	Serving as NEPA lead agency
U.S. Fish and Wildlife Service	Completing Federal Endangered Species Act consultation and incidental take authorization; verifying compliance with the Fish and Wildlife Coordination Act
National Marine Fisheries Service	Completing Federal Endangered Species Act consultation and incidental take authorization; verifying compliance with the Magnuson-Stevens Act

Table 1-1. Agency Roles and Responsibilities (contd.)

Agency	Role/Responsibility
State	
U.S. Forest Service (cooperating agency)	Verifying consistency of project facilities with management of the Shasta-Trinity National Forest and Whiskeytown-Shasta-Trinity National Recreation Area; regulating occupancy and use of National Forest lands under the Federal Land Policy Management Act
U.S. Environmental Protection Agency	Reviewing effects on air quality for compliance with the Clean Air Act and State Implementation Plan; verifying compliance with the Safe Drinking Water Act; reviewing and filing EIS
California Air Resources Board	Verifying compliance with criteria pollutant standards
California Department of Boating and Waterways	Verifying compliance with the California Harbors and Navigation Code
California Department of Conservation	Designating Important Farmland for the State
California Department of Fish and Game (trustee agency)	Completing California Endangered Species Act consultation and incidental take authorization; permitting under Section 1602 of the Fish and Game Code (streambed alteration agreement); completing consultation as a trustee agency
California Department of Forestry and Fire Protection	Providing fire protection services to unincorporated areas
California Department of Parks and Recreation	Verifying consistency with management of State Park lands
California Department of Transportation	Issuing encroachment permit and/or approving transportation management plan
California Department of Water Resources	Operating the State Water Project; participating in the SLWRI feasibility study
California Department of Toxic Substances Control	Verifying compliance with regulations for generation, transportation, treatment, storage, and disposal of hazardous waste
California Energy Commission	Verifying compliance with State energy policies
California Highway Patrol	Verifying that the project would not interfere with any emergency response plan or emergency response times
California Resources Agency	Verifying that California's natural and cultural resources are protected
Central Valley Flood Protection Board (formerly The Reclamation Board)	Issuing levee and floodway encroachment permits
California Office of Historic Preservation	Verifying compliance with Section 106 of the National Historic Preservation Act
State Lands Commission	Verifying consistency with the management of lands managed by the commission; possibly issuing a State Lands lease
Native American Heritage Commission	Identifying sacred sites and most likely descendants for Native American burials; providing Native American contact information
State Water Resources Control Board, Regional Water Quality Control Boards	National Pollutant Discharge Elimination System permitting under Section 402 of the Clean Water Act; issuing certification under Section 401 of the Clean Water Act; issuing water right permits

Table 1-1. Agency Roles and Responsibilities (contd.)

Agency	Role/Responsibility
Shasta County	Verifying compliance with the State's Surface Mining and Reclamation Act; issuing other possible construction authorizations/ encroachment permits
Tehama County	Verifying compliance with the State's Surface Mining and Reclamation Act; issuing other possible construction authorizations/ encroachment permits
Local	
Shasta County Air Quality Management District	Reviewing effects on air quality and authority to construct/permit to operate
Resource Conservation Districts	Verifying consistency with protected agricultural lands in the primary and extended study areas

Key:
EIS = environmental impact statement
NEPA = National Environmental Policy Act
SLWRI = Shasta Lake Water Resources Investigation
State = State of California

1.6 Areas of Controversy/Issues to Be Resolved

Several areas of controversy and issues to be resolved have been identified in the SLWRI to date.

1.6.1 Areas of Controversy

Federal, State, and local stakeholders identified several areas of controversy during the SLWRI scoping process and SLWRI agency meetings and workshops. Major concerns are listed below:

- **Impacts on Cultural Resources** — Sites of cultural and religious significance exist in and around Shasta Lake, including sites related to historical activities of Native Americans. The Winnemem Wintu have raised concerns about inundation effects on sites they value for historical and cultural significance that would result from enlarging Shasta Lake through a dam raise.

- **Impacts on Recreation** — Shasta Lake is the principal recreation destination in Shasta County, which realizes annually well over $160 million related to outdoor recreation. Shasta Lake has attracted development of 11 private marinas with 1,075 houseboats and 18 public campgrounds. Stakeholders are concerned about possible adverse effects on recreation at Shasta Lake, such as impacts on concessionaires and their facilities and potential impacts on the regional economy.

- **Impacts on McCloud River's Free-Flowing Condition or Wild Trout Fishery** — No formally designated components of the National or State wild and scenic rivers programs are present in the primary

study area. However, although the McCloud River is not formally designated, Section 5093.542 of the California Public Resources Code specifies that the McCloud River should be maintained in its free-flowing condition, and its wild trout fishery protected from 0.25 miles below McCloud Dam downstream to the McCloud River Bridge. Section 5093.542 was established through enactment of the Wild and Scenic Rivers Act, as amended (Sections 5093.50 – 5093.70). Up to about 3,500 feet of the lower McCloud River above the McCloud River Bridge and within the special designation would be occasionally inundated if Shasta Dam were modified. DWR and other State agencies, landowners, and various environmental groups have expressed concerns about potential impacts on McCloud River resources resulting from enlarging Shasta Dam and Lake.

Another area of controversy concerns whether State agencies can participate in projects that could have an adverse effect on the McCloud River's free-flowing conditions or its wild-trout fishery. Section 5093.542(c) of the California Public Resources Code states the following:

> *Except for participation by DWR in studies involving the technical and economic feasibility of enlargement of Shasta Dam, no department or agency of the state shall assist or cooperate with, whether by loan, grant, license, or otherwise, any agency of the federal, state, or local government in the planning or construction of any dam, reservoir, diversion, or other water impoundment facility that could have an adverse effect on the free-flowing condition of the McCloud River, or on its wild trout fishery.*

Furthermore, Section 5093.542(d) states the following:

> *All state agencies exercising powers under any other provision of law with respect to the protection and restoration of fishery resources shall continue to exercise those powers in a manner to protect and enhance the fishery [of the protected segments of the McCloud River].*

Participation by various State agencies in planning and potential construction activities associated with modifying Shasta Dam and Reservoir, including related permitting and approval processes, varies by an agency's mandate and PRC Section 5093.542. DFG has taken the position that it must participate in preparing the EIS to comply with Section 5093.542(d). Other State agencies, including DWR and the State Water Resources Control Board, have participated to a limited extent or expressed their intent to participate in the SLWRI. The CALFED Program Plan (CALFED 2000b) concluded that although

Section 5093.542 sought to protect the free-flowing condition of the McCloud River, it also provided for investigations of enlarging Shasta Dam.

- **Impacts on Reservoir-Area Property Owners** — Raising Shasta Dam would affect privately owned real estate. The raise would (1) inundate additional lands around Shasta Lake; (2) affect existing structures, requiring acquisition of private property or relocation of displaced parties; and (3) require replacement of bridges and segments of existing paved and unpaved roads. These potential effects concern property owners around Shasta Lake.

- **Impacts on Environment, Especially Biological Resources** — Raising Shasta Dam or modifying project operations would affect a broad range of environmental resources, some adversely and some beneficially. Concern has been expressed about potential impacts on all of the following:

  - Wildlife habitat, special-status plant and animal species, and State-designated fully protected species at the reservoir rim

  - Fishery habitat on several creeks and streams that flow into Shasta Lake

  - Fishery and riparian habitat resources along the upper Sacramento River below Shasta Dam

  - Delta smelt and other sensitive aquatic species in the Delta

  - Delta water quality and South Delta water levels

  - Central Valley hydrology below CVP and SWP facilities, and resulting effects on water supplies for water contractors and other water users.

- **Reservoir Reoperation** — Residents and businesses around Shasta Lake have expressed interest in revising the operation of Shasta Dam to reduce the potential for extreme seasonal drawdown for flood control, such as occurred in early 2004. The flood control diagram has not been changed since July 1977 (USACE 1997), and new and evolving technology could reduce Shasta Lake water surface fluctuations associated with drawdown operations for flood control.

1.6.2 Issues to Be Resolved

Issues to be resolved for the SLWRI are described below.

Native American Concerns and Cultural Resources

This PDEIS and accompanying Draft Feasibility Report are consistent with the National Historic Preservation Act Section 106, and describe supporting analyses, studies, coordination, impacts, and mitigation, as necessary. Reclamation has invited Federally recognized tribes and non-Federally recognized tribal groups to be consulting parties to the SLWRI. Although no Federally recognized tribes reside in the immediate Shasta Lake area, members of the Winnemem band of the Wintu Indians have raised concerns about potential impacts of enlarging Shasta Dam on sites they value for historical and cultural significance. Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians is a cooperating agency for the SLWRI, pursuant to NEPA. The Winnemem Wintu will continue to have the opportunity to participate, and are anticipated to continue to provide input, through the Section 106 process as an invited consulting party, as well as through the NEPA process.

Impacts on Biological Resources

The physical environment and associated landscapes within and adjacent to the primary study area provide for a wide array of habitat used by a diverse assemblage of wildlife with varying habitat needs and home ranges. To date, species-specific survey efforts as part of the SLWRI have only included focused investigations for a number of special-status species in the inundation and relocation areas described previously. The scale of these surveys has been limited, and because of a variety of external factors, have not addressed habitat for species with a large home range or at a watershed scale. Therefore, for species that have large home ranges (e.g., Pacific fisher), or that use a wide range of habitats for some aspect of their life history, analyses presented in this document assume presence over a conservatively large geographic area to cover the full range of impacts anticipated for these species.

Off-Site Mitigation for Impacts on Biological Resources

Details about off-site opportunities to mitigate impacts on biological resources in the primary study area are not yet available. Potential mitigation lands containing wetland and special-status species habitat comparable to those that would be affected by the proposed action have been identified near the study area. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in future documents. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in future documents.

Water Rights

Improving the reliability of water supplies is a primary objective of the SLWRI. The potential water supply reliability benefits of the project alternatives are described in Chapter 2. Water rights for the expanded Shasta Reservoir, which

are appropriated by the State Water Resources Control Board, must be in place before the project can operate. Evaluation of water rights will remain a focus of the SLWRI.

Coordinated CVP and SWP Operational Conditions

Planning assumptions and information on water operations used to develop comprehensive alternatives for the SLWRI were developed in 2006, and reflect the coordinated CVP and SWP operations described in the 2004 *Long-Term CVP Operations Criteria and Plan* (2004 OCAP) (Reclamation). In addition, the model package used to evaluate potential effects of the alternatives included in this PDEIS was based on operations described in the 2004 *Long-Term CVP and SWP OCAP Biological Assessment* (2004 OCAP BA) (Reclamation).

Reclamation consulted with the National Oceanic and Atmospheric Administration NMFS and U.S. Fish and Wildlife Service (USFWS) on the 2004 OCAP, and the two agencies issued the 2004 *Biological Opinion on the Long-Term CVP and SWP OCAP* (2004 NMFS BO) and 2005 *Reinitiation of Formal and Early Section 7 ESA Consultation on the Coordinated Operations of the CVP and SWP and the OCAP to Address Potential Critical Habitat Issues* (2005 USFWS BO), respectively. In 2007, the District Court for the Eastern District of California (District Court), in *Natural Resources Defense Council v. Kempthorne*, found the 2005 USFWS BO to be unlawful and inadequate. In May 2008, in *Pacific Coast Federation of Fishermen's Associations v. Gutierrez*, the District Court found the 2004 NMFS BO to be unlawful and inadequate. The District Court remanded both BOs to the fishery agencies.

In August 2008, Reclamation reinitiated consultation with the fishery agencies based on the 2008 *Biological Assessment on the Continued Long-Term Operations of the CVP and SWP* (Reclamation 2008b). USFWS issued the *Formal ESA Consultation on the Proposed Coordinated Operations of the CVP and SWP* in December 2008 (2008 USFWS BO), finding that the long-term operations of the CVP and SWP, as described in the 2004 OCAP BA, would jeopardize the continued existence of the delta smelt. In June 2009, NMFS issued the *BO and Conference Opinion on the Long-Term Operations of the CVP and SWP* (2009 NMFS BO), finding that the same operations would jeopardize populations of listed salmonids, steelhead, green sturgeon, and orcas. Because both agencies made jeopardy determinations, both agencies included a Reasonable and Prudent Alternative (RPA) in their respective BOs.

Several lawsuits were filed challenging the validity of the 2008 USFWS BO and 2009 NMFS BO and Reclamation's acceptance of the RPA included with each BO (*Consolidated Salmonid Cases, Delta Smelt Consolidated Cases*). On November 13, 2009, and March 5, 2010, the District Court concluded that Reclamation had violated NEPA by failing to perform any NEPA analysis before provisionally adopting the 2008 USFWS RPA and 2009 NMFS RPA. On December 14, 2010, the District Court found the 2008 USFWS BO to be unlawful and remanded the BO to USFWS. The District Court issued a similar

ruling for the 2009 NMFS BO on September 20, 2011. On May 4, 2011, in the *Delta Smelt Consolidated Cases*, the District Court ordered USFWS to prepare a draft BO by October 1, 2011, which was subsequently extended to an unspecified date to be agreed upon by involved parties. Reclamation and USFWS must prepare a final BO and final NEPA document by November 1, 2013, and December 1, 2013, respectively.

Reclamation and DWR use CalSim-II to study operations, benefits, and effects of new facilities and operational parameters for the CVP and SWP. A set of operational assumptions was developed in 2006 based on water operations described in the 2004 OCAP BA and the Coordinated Operations Agreement between Reclamation and DWR for the CVP and SWP, as ratified by Congress. These assumptions were used to guide development, modeling, and evaluation of potential effects of the No-Action Alternative and action alternatives included in this PDEIS. Rationale for the decision to use these existing evaluations as the basis of analysis in the PDEIS and accompanying Draft Feasibility Report is provided in Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences." Modeling studies and associated analyses will be updated and included in the Draft EIS and other future SLWRI documents.

1.7 Documents Used to Prepare Preliminary Draft EIS

1.7.1 CVPIA EIS

The CVPIA is a Federal statute enacted in 1992 with the following purposes:

> *To protect, restore, and enhance fish, wildlife, and associated habitats in the Central Valley and Trinity River basins of California; to address impacts of the CVP on fish, wildlife and associated habitats; to improve the operational flexibility of the CVP; to increase water-related benefits provided by the CVP to the state of California through expanded use of voluntary water transfers and improved water conservation; to contribute to the state of California's interim and long-term efforts to protect the Bay-Delta; and to achieve a reasonable balance among competing demands for use of CVP water, including the requirements of fish and wildlife, agricultural, municipal and industrial and power contractors.*

A programmatic EIS was prepared by Reclamation and USFWS in October 1999 to address the potential impacts of implementing the CVPIA. Although not tiering from that document, this SLWRI PDEIS uses information contained in the CVPIA EIS, updated to reflect current and project-specific conditions.

1.7.2 CALFED EIS/EIR

CALFED is a collaboration of 25 Federal and State agencies with regulatory and management responsibilities in the Bay-Delta to develop and implement a long-term comprehensive plan to restore ecological health and improve water management for beneficial uses of the Bay-Delta system. The objective of the collaborative planning process is to identify comprehensive solutions to the problems of ecosystem quality, water delivery reliability, water quality, and Delta levee integrity.

In July 2000, the CALFED agencies released the *Final Programmatic EIS/Environmental Impact Report* (EIR) (CALFED 2000b), which analyzed a range of alternatives to solve Bay-Delta system problems. In August 2000, the CALFED agencies issued a programmatic ROD that identified 12 action plans. Specifically, plans were identified for the Governance, Ecosystem Restoration, Watersheds, Water Supply Reliability, Storage, Conveyance, Environmental Water Account, Water Use Efficiency, Water Quality, Water Transfer, Levees, and Science programs (CALFED 2000a). The CALFED agencies then began implementing Stage 1 of the ROD, including the first 7 years of a 30-year program to establish a foundation for long-term actions. The SLWRI and associated EIS would be consistent with the CALFED *Programmatic EIS/EIR*, but the SLWRI EIS does not tier from that EIS/EIR.

1.8 Organization of Preliminary Draft EIS

Chapter 1, "Introduction," summarizes the purpose, need, objectives, authorization, and location of the proposed action; provides an overview of the environmental review process and background for the project; summarizes intended use of the FEIS and areas of controversy and issues to be resolved; and discusses documents used to prepare this PDEIS.

Chapter 2, "Alternatives," summarizes the methods used for selecting project alternatives, describes the project alternatives, discusses alternatives that have been eliminated from further discussion, and presents the likely preferred alternative and rationale for selection.

Chapter 3, "Considerations for Describing Affected Environment and Environmental Consequences," describes the approach to describing the affected environment and environmental consequences, defines impact levels, and describes the methodology for cumulative effects, including cumulative projects. This chapter also presents the regulatory framework for the resources chapters that follow.

Chapters 4 – 25 describe the existing environmental and resource-specific regulatory frameworks for each resource area analyzed in this PDEIS, in the following order:

- Geology, geomorphology, minerals, and soils
- Air quality and climate
- Hydrology, hydraulics, and water management
- Water quality
- Noise and vibration
- Hazards and hazardous materials and waste
- Agriculture and important farmland
- Fisheries and aquatic ecosystems
- Botanical resources and wetlands
- Wildlife resources
- Cultural resources
- Indian Trust Assets
- Socioeconomics, population, and housing
- Land use and planning
- Recreation and public access
- Aesthetics and visual resources
- Transportation and traffic
- Utilities and service systems
- Public services
- Power and energy
- Environmental justice
- Wild and scenic river considerations for McCloud River

Each resource chapter listed above also describes project-level impacts of the No-Action Alternative and action alternatives on the resource or issue area, mitigation measures for those impacts, and cumulative effects of all of the alternatives.

Chapter 26, "Other Required Disclosures," describes any significant adverse effects of the proposed project that cannot be avoided, irreversible and irretrievable commitments of resources, growth-inducing effects, and compliance with applicable laws.

Chapter 27, "Public Involvement, Consultation, and Coordination," describes the public scoping process, agencies and organizations consulted, and areas of controversy, and identifies issues to be resolved.

Chapter 28, "References," lists the sources of information used to prepare this PDEIS.

Chapter 29, "DEIS Distribution List," lists the elected officials; government departments; Federal, State, and local agencies; and special-interest groups that received notice of the availability of this PDEIS.

Chapter 30, "List of EIS Preparers," lists individuals who participated in preparation of this PDEIS, and provides qualifications for those individuals, in order of organization and agency.

Chapter 31, "Index," lists important terms and topics and gives page numbers of relevant discussions.

This page left blank intentionally.

Chapter 2
Alternatives

NEPA and CEQA require consideration of a range of alternatives to a proposed action that would feasibly attain the majority of a project's basic objectives and accomplish the project purpose and need, while avoiding or minimizing environmental impacts. The purpose of including alternatives in an EIS is to offer a clear basis for choice by decision makers and the public about whether to proceed with a proposed action or project.

NEPA requires that alternatives be evaluated at a comparable level of detail (40 Code of Federal Regulations 1502.14(b)). Similarly, the Council on Environmental Quality regulations for implementing NEPA (40 Code of Federal Regulations 1502.14) require all reasonable alternatives to be objectively evaluated in an EIS so that each alternative is evaluated at an equal level of detail. Alternatives that cannot reasonably meet the project purpose and need do not require detailed analysis.

CEQA requires that the lead agency consider alternatives that would avoid or reduce one or more of the significant impacts identified for a project in an EIR. The State CEQA Guidelines state that an EIR needs to describe and evaluate only those alternatives necessary to permit a reasonable choice and to foster informed decision making and informed public participation (Section 15126.6(f)). Consideration of alternatives focuses on those that can either eliminate significant adverse environmental impacts, or reduce them to less-than-significant levels; alternatives considered in this context may include those that are more costly, and those that could impede, to some degree, the attainment of all the project objectives (Section 15126.6(b)). CEQA does not require the alternatives to be evaluated at the same level of detail as a proposed project.

This chapter documents compliance with NEPA requirements for alternatives analysis and the alternatives development process, and describes the six alternatives evaluated in detail in this PDEIS. This chapter is also generally consistent with CEQA requirements.

2.1 Alternatives Development Process

This section describes the alternatives development process for the SLWRI. A more detailed description of this process is included in the Plan Formulation Appendix.

2.1.1 Plan Formulation Process

The plan formulation process for Federal water resources studies and projects begins with identifying existing and projected future resources conditions likely to occur in a study area. This is followed by defining water resources problems, needs, and opportunities to be addressed, and developing planning objectives, constraints, and criteria.

For the SLWRI, the above process was separated into five phases, of which the first three have been completed. These planning phases are shown in Figure 2-1 and described below:

- **Mission Statement Phase –** This study phase consisted of projecting without-project future conditions, defining resulting resource problems and needs, defining a specific set of planning objectives, and identifying constraints and criteria for addressing the planning objectives.

- **Initial Alternatives Phase –** This phase included developing a number of potential management measures, or project actions or features designed to address planning objectives. These measures were then used to formulate a set of plans that were conceptual in scope (concept plans). These initial plans were evaluated and compared to the planning objectives to identify the most suitable plans for further development.

- **Comprehensive Plans Phase –** The measures and concept plans carried forward were further refined and developed with more specificity to formulate comprehensive alternative plans to address the planning objectives. These plans were then evaluated and compared.

- **Plan Refinement Phase –** This phase focuses on further refinement of the comprehensive plans to identify a plan suitable to be recommended for implementation. This phase includes preparing and circulating a Draft Feasibility Report and Draft EIS.

- **Recommended Plan Phase –** The next phase of the SLWRI planning process will focus on identifying a recommended plan, preparing a Biological Assessment, and confirming Federal and non-Federal responsibilities. This phase will conclude with the preparation and processing of a Final Feasibility Report to support a Federal decision, and a Final EIS.

Public and stakeholder outreach was performed concurrently with the above phases, as shown in Figure 2-1. Major reports include the *Strategic Agency Public Involvement Plan*, published in 2003 (Reclamation), and the *Environmental Scoping Report*, published in 2006 (Reclamation).

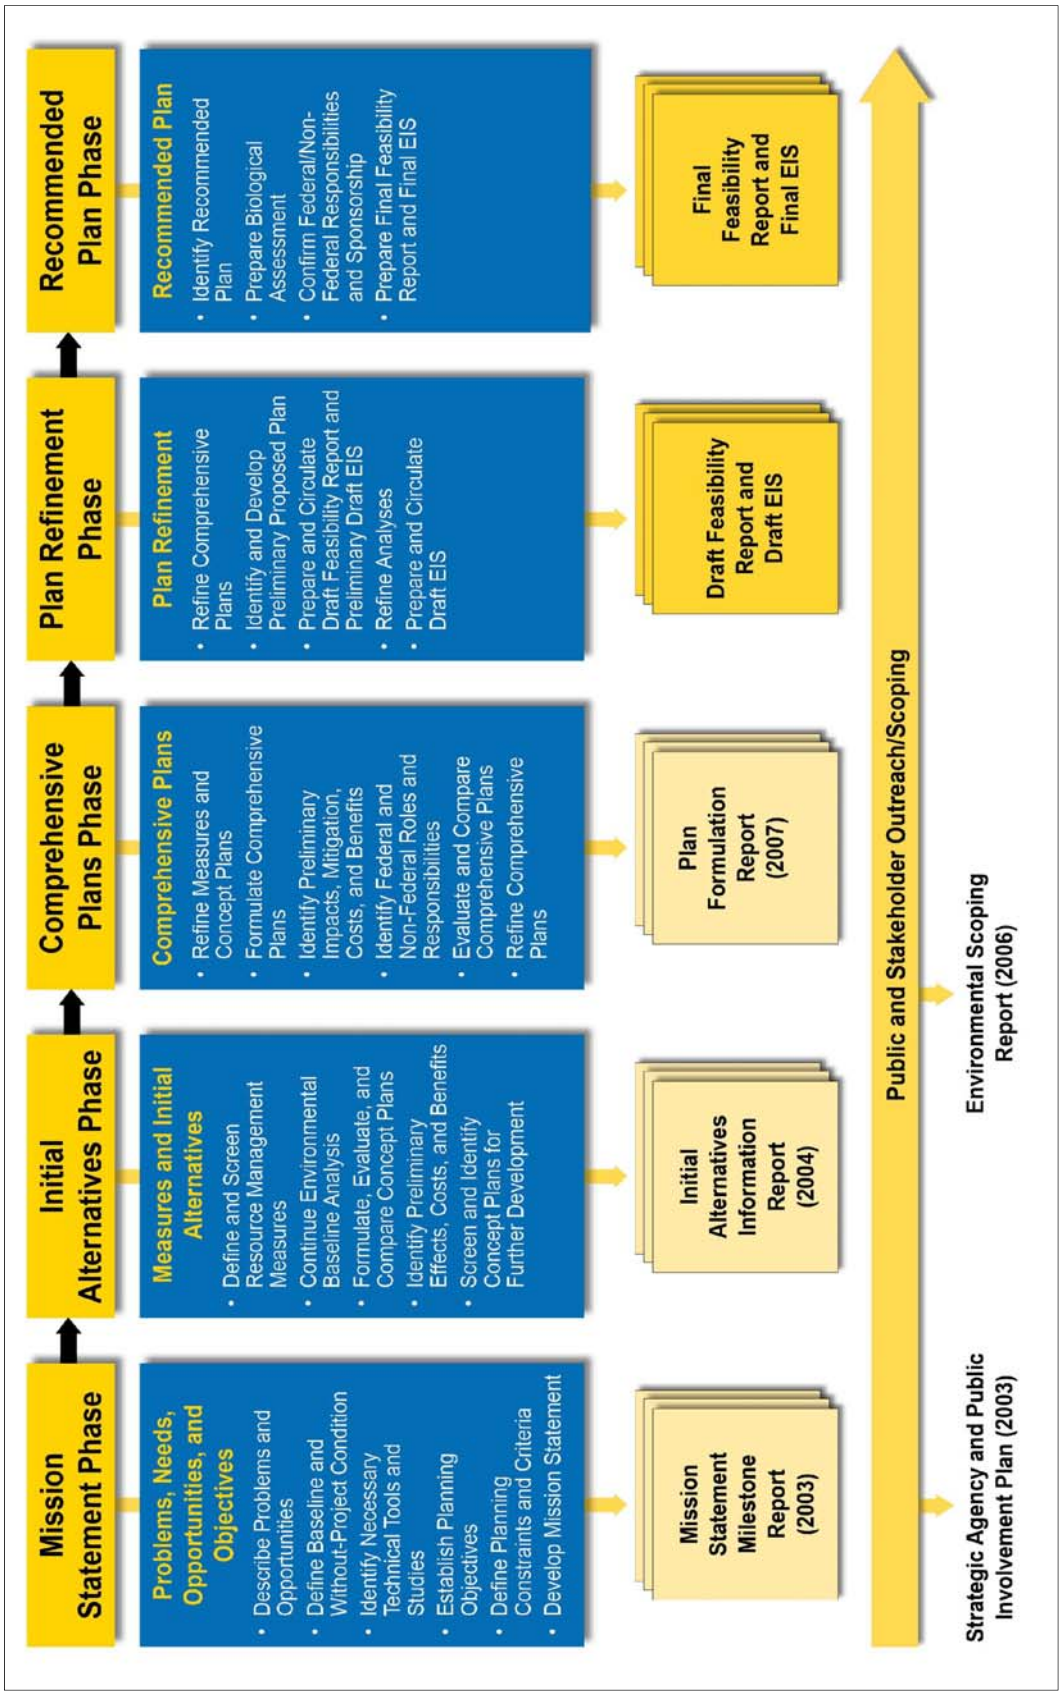

Figure 2-1. Plan Formulation Phases

2.1.2 Project Objectives

On the basis of the problems, needs, and opportunities identified in the plan formulation process, study authorities, and other pertinent direction, including information contained in the CALFED Bay-Delta Program Record of Decision (ROD) (CALFED 2000), primary and secondary objectives were developed. Primary objectives are those which specific alternatives are formulated to address. The primary objectives are considered to have coequal priority, with each pursued to the maximum practicable extent without adversely affecting the other. Secondary objectives are actions, operations, or features that should be considered in the plan formulation process, but only to the extent possible through pursuit of the primary objectives.

- **Primary Objectives**:
  - Increase the survival of anadromous fish populations in the Sacramento River, primarily upstream from the Red Bluff Diversion Dam (RBDD)
  - Increase water supply and water supply reliability for agricultural, municipal and industrial (M&I), and environmental purposes to help meet current and future water demands, with a focus on enlarging Shasta Dam and Reservoir
- **Secondary Objectives**:
  - Conserve, restore, and enhance ecosystem resources in the Shasta Lake area and along the upper Sacramento River
  - Reduce flood damage along the Sacramento River
  - Develop additional hydropower generation capabilities at Shasta Dam
  - Maintain and increase recreation opportunities at Shasta Lake
  - Maintain or improve water quality conditions in the Sacramento River downstream from Shasta Dam and in the Delta

Criteria, constraints, and additional planning considerations used to guide alternatives formulation are described in the Plan Formulation Appendix.

Following development of objectives, constraints, and criteria for the SLWRI, the next major step in formulating concept plans was to identify and evaluate potential management measures.

2.1.3 Management Measures

A management measure is any structural or nonstructural project action or feature that could address the objectives and satisfy the other applicable planning considerations. Numerous potential management measures were identified based on previous studies, programs, and projects to address the objectives. These measures were developed through study team meetings, field inspections, outreach, and environmental scoping for the SLWRI. Management measures are listed in Table 2-1 and described in detail in the Plan Formulation Appendix.

In the context of SLWRI management measures and project actions, the term "enhancement" specifically refers to restoration actions that improve environmental conditions above the baseline (without-project condition). Correspondingly, the term "mitigation" refers to restoration actions that improve environmental conditions toward the baseline to compensate for project impacts. The relationship between restoration, enhancement, and mitigation is illustrated in Figure 2-2.

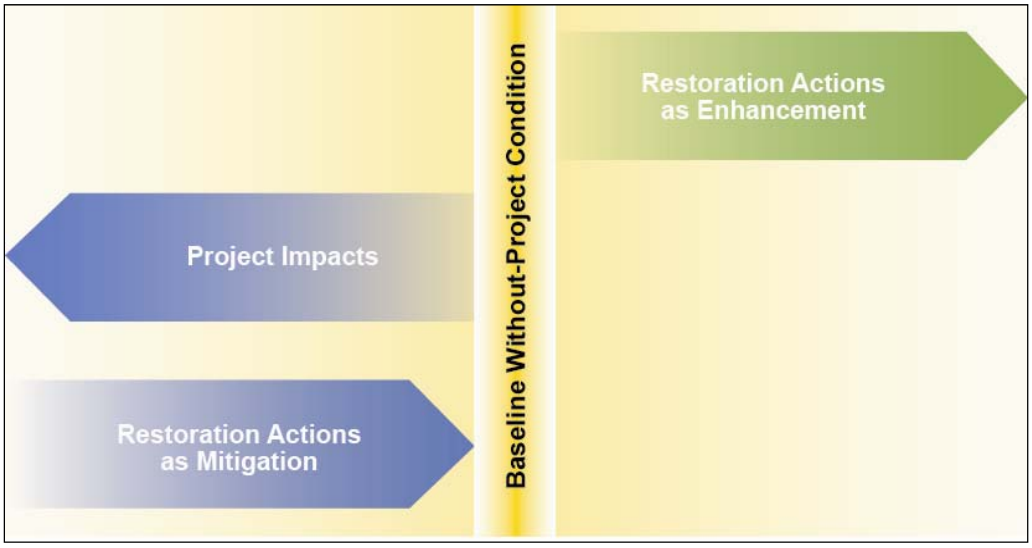

Figure 2-2. Conceptual Schematic of Restoration Actions as Enhancement Versus Restoration Actions as Mitigation

Table 2-1. Management Measures to Address Objectives

Objectives		Management Measure	Retained	Deleted
Primary Objectives				
Increase Anadromous Fish Survival	Improve Fish Habitat	Restore abandoned gravel mines along the Sacramento River		X
		Construct instream aquatic habitat downstream from Keswick Dam	X	
		Replenish spawning gravel in the Sacramento River	X	
		Construct instream fish habitat on tributaries to the Sacramento River		X
		Remove instream sediment along Middle Creek		X
		Rehabilitate inactive instream gravel mines along Stillwater and Cottonwood creeks		X
	Improve Water Flows and Quality	Make additional modifications to Shasta Dam for temperature control	X	
		Enlarge Shasta Lake cold-water pool	X	
		Modify storage and releases operations at Shasta Dam	X	
		Modify ACID diversions to reduce flow fluctuations		X
		Increase instream flows on Clear, Cow, and Bear creeks		X
		Construct a storage facility on Cottonwood Creek to augment spring instream flows		X
		Transfer existing Shasta Reservoir storage from water supply to cold-water releases		X
		Remove Shasta Dam and Reservoir		X
	Improve Fish Migration	Improve fish trap below Keswick Dam		X
		Screen diversions on Old Cow and South Cow creeks		X
		Remove or screen diversions on Battle Creek		X
		Construct a migration corridor from the Sacramento River to the Pit River		X
		Cease operating or remove the Red Bluff Diversion Dam		X
		Reoperate the CVP to improve overall fish management		X
		Construct a fish ladder on Shasta Dam		X
		Reintroduce anadromous fish to areas upstream from Shasta Dam		X
Increase Water Supply Reliability	Increase Surface Water Storage	Increase conservation storage space in Shasta Reservoir by raising Shasta Dam	X	
		Construct new conservation storage reservoir(s) upstream from Shasta Reservoir		X
		Construct new conservation storage on tributaries to the Sacramento River downstream from Shasta Dam		X
		Construct new conservation offstream surface storage near the Sacramento River downstream from Shasta Dam		X
		Construct new conservation surface water storage south of the Delta		X
		Increase total or seasonal conservation storage at other CVP facilities		X
		Dredge bottom of Shasta Reservoir		X

Table 2-1. Management Measures to Address Objectives (contd.)

Objectives		Management Measure	Retained	Deleted
Increase Water Supply Reliability (continued)	Reoperate Reservoir	Increase effective conservation storage space in Shasta Reservoir by increasing efficiency of reservoir operation for water supply reliability	X	
		Increase the conservation pool in Shasta Reservoir by encroaching on dam freeboard		X
		Increase conservation storage space in Shasta Reservoir by reallocating space from flood control		X
	Improve Conjunctive Water Management	Develop conservation offstream surface storage near the Sacramento River downstream from Shasta Dam		X
		Develop conservation groundwater storage near the Sacramento River downstream from Shasta Dam		X
		Develop additional conservation groundwater storage south of the Delta		X
	Coordinate Operation and Precipitation Enhancement	Improve Delta export and conveyance capability through coordinated CVP and SWP operations		X
		Implement additional precipitation enhancement		X
	Reduce Demand	Implement water use efficiency methods	X	
		Retire agricultural lands		X
	Improve Water Transfers and Purchases	Transfer water between users		X
	Expand Delta Export and Conveyance Facilities	Expand Banks Pumping Plant		X
		Construct Delta-Mendota Canal/California Aqueduct intertie		X
	Improve Surface Water Treatment	Implement treatment/supply of agricultural drainage water		X
		Construct desalination facility		X

Table 2-1. Management Measures to Address Objectives (contd.)

Objectives		Management Measure	Retained	Deleted
Secondary Objectives				
Conserve, Restore, and Enhance Ecosystem Resources	Improve Cold-Water and Warm-Water Fishery Habitat	Construct shoreline fish habitat around Shasta Lake	X	
		Construct instream fish habitat on tributaries to Shasta Lake	X	
		Increase instream flows on the lower McCloud River		X
		Reduce acid mine drainage entering Shasta Lake		X
		Reduce motorcraft access to upper reservoir arms		X
		Increase instream flows on the Pit River		X
	Restore and Conserve Riparian and Wetland Habitat	Restore riparian and floodplain habitat along the Sacramento River	X	
		Restore wetlands along the Fall River and Hat Creek		X
		Conserve upper Pit River riparian areas		X
		Restore riparian and floodplain habitat on lower Clear Creek		X
		Promote Great Valley cottonwood regeneration along the Sacramento River		X
		Conserve riparian corridor along Cow Creek		X
		Remove and control nonnative vegetation in the Cow Creek and Cottonwood Creek watersheds		X
	Improve Other Fish and Wildlife Habitat	Create a parkway along the Sacramento River		X
		Enhance forest management practices to conserve bald eagle nesting habitat		X
		Remove and control nonnative plants around Shasta Lake		X
		Control erosion and restore affected habitat in the Shasta Lake area		X
		Develop geographic information system for Shasta to Red Bluff reach		X
		Implement erosion control in tributary watersheds		X
Reduce Flood Damage		Update Shasta Dam and Reservoir flood management operations	X	
		Increase flood management storage space in Shasta		X
		Implement nonstructural flood damage reduction measures		X
		Implement traditional flood damage reduction measures		X
		Route PMF from top of conservation pool		X

Table 2-1. Management Measures to Address Objectives (contd.)

Objectives	Management Measure	Retained	Deleted
Develop Additional Hydropower Generation	Modify existing/construct new generation facilities at Shasta Dam to take advantage of increased hydraulic head	X	
	Construct new hydropower generation facilities		X
Maintain and Increase Recreation Opportunities	Maintain and enhance recreation capacity, facilities, and opportunities	X	
	Develop new NRA recreation plan		X
	Reoperate reservoir for recreation	X	
Maintain or Improve Water Quality	Improve operational flexibility for Delta water quality by increasing storage in Shasta Reservoir	X	

Key:
ACID = Anderson-Cottonwood Irrigation District
Banks Pumping Plant = Harvey O. Banks Pumping Plant
CVP = Central Valley Project
Delta = Sacramento-San Joaquin Delta
NRA = National Recreation Area
PMF = probable maximum flood
SWP = State Water Project

The SLWRI study team and stakeholders reviewed the management measures for their ability to address the primary and secondary objectives. Retained management measures were combined to formulate concept plans. As detailed in the Plan Formulation Appendix, measures are retained for possible inclusion in an alternative plan or deleted from further consideration for various reasons. One important factor for retention in alternative plans is the potential for a measure to directly address an objective without adversely impacting other objectives.

Of the management measures listed in Table 2-1, eight measures addressing primary objectives were selected for further consideration and potential inclusion in alternative plans. Eight measures addressing secondary objectives were also selected for potential inclusion in alternative plans. Measures that have been carried forward are believed to best address the objectives of the SLWRI, with consideration of planning constraints and criteria. It should be noted that measures that have been deleted from consideration in this phase may be reconsidered in the future as mitigation measures.

2.1.4 Initial Alternatives Phase

The retained measures were used to formulate a preliminary set of plans that were conceptual in scope. Each concept plan was reviewed for impacts, costs, and benefits and compared to objectives to determine whether the plan should be eliminated or carried forward into the comprehensive plans phase. The purpose of this phase of the formulation process was to (1) explore an array of different strategies to address the primary objectives, constraints, and criteria, and (2) identify concept plans that would warrant further development in the comprehensive plans phase.

First, two sets of plans were developed that focused on either anadromous fish survival (AFS) or water supply reliability (WSR) as the single primary objective. Three AFS plans and four WSR plans were developed. Although the AFS and WSR plans focused on single objectives, each generally contributed to both primary objectives. In the three AFS plans, for example, emphasis was placed on combinations of measures that could best address the fish survival goals while considering incidental benefits to water supply reliability, if possible. Second, five plans were developed that included measures to address both primary and, to a lesser degree, secondary objectives, termed combined objective (CO) plans. All 12 concept plans are listed in Table 2-2, and are explained in detail in the Plan Formulation Appendix.

Table 2-2. Summary of Concept Plan Features

Plan	Features													
		Primary Objective Focus							Secondary Objectives Addressed[4]					
	Dam Raise	Water Supply Reliability[2]			Anadromous Fish Survival				Environmental Restoration			Flood Control and Hydropower		Recreation
	Raise Shasta Dam[1] (feet)	Increase Conservation Storage	Perform Conjunctive Water Management[3]	Reoperate Shasta Dam	Modify TCD	Replenish Spawning Gravel	Enlarge Shasta Lake Cold-Water Pool	Increase Minimum Flows[3]	Restore Shoreline Aquatic Habitat	Restore Tributary Aquatic Habitat	Restore Riparian Habitat	Modify Flood Control Operations and Implement Shasta Public Safety[3] Features	Modify Hydropower Facilities	Maintain and Increase Recreation Opportunities
AFS-1	6.5	*		Changes to water supply operations and modification of the TCD would likely be included, to some extent, in any alternative that includes raising Shasta Dam.			X					Changes to flood control operations at Shasta Dam, Public Safety,[3] and hydropower facilities would likely be part of any alternative that includes physically modifying Shasta Dam; the degree and details of these changes will be included in feasibility level alternative plans.		Included in feasibility level alternative plans.
AFS-2	6.5	*					*	X						
AFS-3	6.5	*				X	*	X						
WSR-1	6.5	X					*							
WSR-2	18.5	X					*							
WSR-3	202.5	X					*							
WSR-4	18.5	X	X				*							
CO-1	6.5	X				X	X							
CO-2	18.5	X				X	X							
CO-3	18.5	X				X	X	X						
CO-4	6.5	X	X			X	X		X	X	X			
CO-5	18.5	X	X			X	X		X	X	X			

Notes:

[1] Raising Shasta Dam provides both water supply and temperature benefits, regardless of how the additional storage is exercised. While the AFS measures focus on use of the additional space for anadromous fish survival, they also provide water supply benefits. Similarly, the WSR measures focus on water supply reliability but the reservoir enlargements also provide benefits to anadromous fish.

[2] All concept plans will include attention to water demand reduction.

[3] These measures were used for evaluation because they were retained at the time of plan formulation. However, they have since been removed from consideration.

[4] Water quality was added as a management measure after development of concept plans, and is not considered in this table.

Key:

* Coincidental benefit, although not a primary focus of the concept plan.

AFS = anadromous fish survival

CO = combined objectives

TCD = temperature control device

WSR = water supply reliability

X = Primary focus of concept plan

The 12 concept plans were compared considering two basic planning criteria: effectiveness and efficiency. Effectiveness is the extent to which an alternative alleviates problems and achieves objectives; efficiency is the measure of how efficiently an alternative alleviates identified problems and meets specified objectives to protect the Nation's environment. These, along with completeness and acceptability, are the four general criteria identified in the *Federal Water Resources Council Principles and Guidelines for Water and Related Land Resources Implementation Studies* (WRC 1983). Based on this comparison, and the relative ability of plans to address both primary objectives, five of the concept plans were initially recommended for further development as comprehensive plans (CP): WSR-1, WSR-2, WSR-4, CO-2, and CO-5. CO-2 was subsequently eliminated from further consideration because continued evaluation concluded that restoration of existing gravel mines would have a low likelihood of successfully benefiting salmon resources. Subsequent analysis of WSR-4 and the conjunctive use component of CO-5 indicated tradeoffs between conjunctive use water supply benefits and critical gains in fisheries benefits. The resulting reduction in benefits to fisheries operations in dry and critical years was deemed unacceptable in terms of meeting primary project objectives. Thus, WSR-4 and the conjunctive use component of CO-5 were eliminated from further consideration.

The eight concept plans eliminated from further consideration are described in Section 2.2, "Alternatives Considered and Eliminated from Further Consideration." Although these concept plans were not further considered as stand-alone plans, major features of some of these plans were refined for further development into alternatives. Concept plans eliminated from further consideration, and rationale for their elimination, are discussed in detail in the Plan Formulation Appendix.

2.1.5 Development and Refinement of Comprehensive Plans

Through continued refinement of management measures and concept plans carried forward, the following plan types were identified for further development into comprehensive plans:

- Plan(s) to raise Shasta Dam between 6.5 feet and 18.5 feet, focusing on both water supply reliability and anadromous fish survival but with benefits to various secondary objectives (subsequently developed into CP1, CP2, and CP3)

- Plan(s) to raise Shasta Dam by about 18.5 feet, focusing on anadromous fish survival, but also including water supply reliability and other various secondary objectives (subsequently developed into CP4)

- Plan(s) to raise Shasta Dam by about 18.5 feet, focusing on all objectives (subsequently developed into CP5)

Considering results of initial plan formulation efforts, the approach was to first formulate plans focusing on different dam raise heights within the range of 6.5 to 18.5 feet to address the first plan type listed above. A dam raise of 12.5 feet in CP2 was chosen because it represented a midpoint between the smallest and largest likely and practical dam raises. Next, the approach was to identify the most efficient and effective of the identified dam raise heights, and formulate comprehensive plans to focus on anadromous fish survival and other objectives at this height.

Using the general rationale described above, and incorporating input from the public scoping process and continued coordination with resource agencies and other interested parties, five comprehensive plans were developed in addition to the No-Action Alternative:

- **Comprehensive Plan 1 (CP1)** — 6.5-foot dam raise, enlarging the reservoir by 256,000 acre-feet, focusing on both anadromous fish survival and water supply reliability.

- **Comprehensive Plan 2 (CP2)** — 12.5-foot dam raise, enlarging the reservoir by 443,000 acre-feet, focusing on both anadromous fish survival and water supply reliability.

- **Comprehensive Plan 3 (CP3)** — 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, focusing on both anadromous fish survival and water supply reliability.

- **Comprehensive Plan 4 (CP4)** — 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, focusing on anadromous fish survival while increasing water supply reliability.

- **Comprehensive Plan 5 (CP5)** — 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, a combination plan focusing on all objectives.

The five comprehensive plans were designated as the action alternatives for the purpose of this PDEIS, and are described in Section 2.4.

Because of the large number of possibilities for increasing anadromous fish survival, additional analyses were conducted to determine the combination of actions that would provide the greatest overall benefits within CP4. These analyses are described below.

Refinement of Plan for Anadromous Fish Survival Focus with Water Supply Reliability

Primarily using the SALMOD model, and based on output from the water operations (CalSim-II), reservoir temperature, and river temperature models, a suite of flow- and temperature-focused actions (scenarios) were investigated to

assess which combination of actions would likely result in the maximum increase in fish populations.

To formulate CP4, three dam height raises were considered (6.5 feet, 12.5 feet, and 18.5 feet), resulting in 256,000 acre-feet, 443,000 acre-feet, and 634,000 acre-feet of increased storage, respectively. For each of these proposed dam raises, several combinations for allocating the increased storage were analyzed. For instance, assuming a dam raise of 12.5 feet, three options were considered: (1) no increase in the minimum pool, (2) an increase in the minimum pool similar to a 6.5-foot dam raise, and (3) all of the increased space dedicated to increased fisheries. The combinations considered represent scenarios developed to focus on increasing the cold-water pool, and are listed in Table 2-3.

Table 2-3. Scenarios Considered for Cold-Water Storage – Anadromous Fish Survival Focus with Water Supply Reliability

Scenario	Dam Raise (feet)	Enlarged Reservoir	Description
A (CP1)	6.5	256,000 acre-feet	No increase in minimum pool.
B	6.5	256,000 acre-feet	Dedicate 256,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.
C (CP2)	12.5	443,000 acre-feet	No increase in minimum pool.
D	12.5	443,000 acre-feet	Dedicate 187,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.
E	12.5	443,000 acre-feet	Dedicate 443,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.
F (CP3/CP5)	18.5	634,000 acre-feet	No increase in minimum pool.
G	18.5	634,000 acre-feet	Dedicate 191,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.
H (CP4)	18.5	634,000 acre-feet	Dedicate 378,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.
I	18.5	634,000 acre-feet	Dedicate 634,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.

Key:
CP = comprehensive plan

Additional scenarios focusing on increasing Sacramento River flows with an 18.5-foot raise were also analyzed. The flow combinations were based primarily on flows identified as part of the Anadromous Fish Restoration Plan (USFWS 2001). These scenarios are listed in Table 2-4.

Table 2-4. Scenarios Considered to Augment Flows – Anadromous Fish Survival Focus Plan

Flow Augmentation Scenario	Dam Raise (feet)	Enlarged Reservoir	Description
1	18.5	634,000 acre-feet	October – March AFRP flows or 500 cfs increase, whichever is less.
2	18.5	634,000 acre-feet	October – March AFRP flows or 750 cfs increase, whichever is less.
3	18.5	634,000 acre-feet	October – March AFRP flows or 1,000 cfs increase, whichever is less.
4	18.5	634,000 acre-feet	Increase August flows to 10,000 cfs and September flows to 6,000 cfs for temperature control.

Key:
AFRP = Anadromous Fish Restoration Plan (USFWS 2001)
cfs = cubic foot per second

Quantitative analysis indicated that increasing the minimum pool in Shasta Reservoir would have the greatest net fishery benefit. By increasing the minimum pool, the allowable carryover pool storage would increase in the reservoir. This carryover would act to conserve cold water that could be managed to better benefit anadromous fish. Scenarios 1, 2, 3, and 4 (flow augmentation scenarios) showed limited benefits to anadromous fish compared with other scenarios, and were eliminated from further analysis. Scenarios B, E, and I would not contribute to increased water supply reliability. Although CP4 focuses on anadromous fish survival, because these three scenarios would not contribute to a primary objective, they were deleted from further consideration. Of the remaining scenarios, Scenarios D and H were deemed to be the most cost-effective. Based on further analysis, Scenario H was chosen to represent reservoir operations in CP4 because this scenario would provide the greatest benefit to anadromous fish and still meet the primary objective of water supply reliability. Scenario comparison and selection are discussed further in the Plan Formulation Appendix.

2.2 Alternatives Considered and Eliminated from Further Analysis

Alternatives considered but eliminated from further analysis are described below. Plans are described that were developed during the initial plans phase, and the comprehensive plans phase, consistent with the alternatives development process discussed above. Management measures deleted from further consideration were summarized previously and are also described in the Plan Formulation Appendix.

2.2.1 Initial Alternatives Phase

The following concept plans were eliminated from further consideration as stand-alone plans.

- **AFS-1**– Increase Cold Water Assets with Shasta Operating Pool Raise (6.5 feet). AFS-1 focused on maintaining cooler water temperatures in the upper Sacramento River by increasing the minimum end-of-October carryover storage target. This would allow additional cold water to be stored for use in the following year. No changes would be made to the existing seasonal temperature targets for anadromous fish on the upper Sacramento River, but the ability to meet these targets would be improved. It was found that this plan had a significant potential to benefit anadromous fish in the upper Sacramento River, but there would be no additional increase in water supply reliability. Major plan components included (1) raising Shasta Dam by 6.5 feet for the primary purpose of enlarging the cold-water pool and regulating water temperature in the upper Sacramento River and (2) increasing the size of the minimum operating pool to 880,000 acre-feet. This plan was not retained for further development as a stand-alone plan because, although it had considerable benefits for anadromous fish survival, it did not meet the primary planning objective of increasing water supply reliability.

- **AFS-2** – Increase Minimum Anadromous Fish Flow with Shasta Enlargement (6.5 feet). AFS-2 focused on the primary planning objective of anadromous fish survival by using the additional reservoir storage to increase minimum seasonal flows in the upper Sacramento River from the current 3,250 cubic feet per second (cfs) to about 4,200 cfs. The primary component of AFS-2 included raising Shasta Dam by 6.5 feet for the primary purpose of enlarging the volume of water available to meet minimum flows for winter-run Chinook salmon on the upper Sacramento River. No changes would be made to the carryover target volume or minimum operating pool. Subsequent evaluation indicated that although at various stages of development the concept of increasing minimum flows would be beneficial for fish, at other life stages increasing minimum flows would be detrimental. Accordingly, this plan was deleted from further development.

- **AFS-3** – Increase Minimum Anadromous Fish Flow with Shasta Enlargement (6.5 feet) and Restore Aquatic Habitat. AFS-3 was similar to AFS-2, except that it also includes acquiring, restoring, and reclaiming one or more inactive gravel mine along the upper Sacramento River to restore about 150 acres of aquatic and floodplain habitat. Major plan components included (1) raising Shasta Dam by 6.5 feet for the primary purpose of enlarging the volume of water available to meet minimum flows for winter-run Chinook salmon on the upper Sacramento River and (2) acquiring, restoring, and reclaiming one or more inactive gravel mining operations along the upper Sacramento River to restore about 150 acres of aquatic and floodplain habitat. Increasing minimum flows was not found to significantly benefit to anadromous fish, and concerns were expressed

regarding significant uncertainties about offstream areas being able to successfully support viable fish spawning and rearing. Further, during public scoping activities in late 2005, little to no interest was demonstrated for restoring inactive gravel mines along the Sacramento River above the RBDD. Accordingly, this plan element was deleted from further consideration at this time.

- **WSR-3** – Increase Water Supply Reliability with Shasta Enlargement (High Level). WSR-3 focused on water supply reliability by increasing the volume of water stored in Shasta Lake by the maximum amount technically feasible. Major components of this plan included (1) raising Shasta Dam by about 202.5 feet for the primary purpose of creating 9.3 million acre feet (MAF) of additional storage available for water supply and (2) major modifications to, or replacing, dam appurtenances, including hydropower facilities and the temperature control device (TCD). Raising the dam to this level would require extensive and very costly reservoir area relocations such as moving the Pit River Bridge, Interstate-5 (I-5), and the Union Pacific Railroad, and would require modifying Keswick Dam and its powerplant. This plan would provide a major increase in water supply reliability, anadromous fish, hydropower, flood damage reduction, and recreation resources. However, the plan is not financially feasible at this time because the construction cost is estimated at over $6 billion (at October 2008 price levels). Accordingly, this plan was deleted from further development.

- **WSR-4** – Increase Water Supply Reliability with Shasta Enlargement (18.5 feet) and Conjunctive Water Management. WSR-4 focused on the primary objective of water supply reliability by raising Shasta Dam 18.5 feet in combination with conjunctive water management. Major components of this plan included (1) raising Shasta Dam by 18.5 feet for the primary purpose of creating 636,000 acre-feet of additional storage available for water supply and (2) implementing a conjunctive water management program, consisting largely of contracts between Reclamation and certain Sacramento River basin water users. The conjunctive water management component included downstream facilities, such as additional river diversions and transmission and groundwater pumping facilities, to facilitate exchanges. Reclamation would provide additional surface supplies in wet and normal water years to participating CVP users, in exchange for reducing deliveries in dry and critically dry years, when users would rely more on groundwater supplies. Preliminary estimates of the conjunctive water management component associated this alternative indicated that water supply yield could be increased between 10 to 20 percent. However, few to no fishery benefits would result and no strong indication of non-Federal participation in a conjunctive water management component was identified. Accordingly, this plan element was deleted from further consideration.

- **CO-1 and CO-2** – Increase Anadromous Fish Habitat and Water Supply Reliability with Shasta Enlargement (6.5 feet and 18.5 feet). CO-1 and CO-2 addressed both primary objectives by restoring anadromous fish habitat and raising Shasta Dam. Both CO-1 and CO-2 would dedicate some of the added reservoir space from the dam raise to increasing the minimum carryover storage in Shasta Reservoir to make more cold-water releases for regulating water temperature in the upper Sacramento River. Major components of this plan included (1) raising Shasta Dam by 6.5 feet and 18.5 feet, respectively, for the purposes of expanding the cold-water pool and creating 260,000 acre-feet and 630,000 acre-feet, for CO-1 and CO-2, respectively, of additional storage available for water supply, (2) acquiring, restoring, and reclaiming one or more inactive gravel mining operations along the upper Sacramento River to create about 150 acres of aquatic and floodplain habitat, and (3) revising flood control operations to benefit water supply reliability by managing floods more efficiently. For reasons similar to those described for AFS-3, both CO-1 and CO-2 were eliminated as stand-alone plans and the gravel mine restoration components of both plans were deleted from further consideration.

- **CO-3** – Increase Anadromous Fish Flow/Habitat and Water Supply Reliability with Shasta Enlargement (18.5 feet). CO-3 is similar to CO-2, except a portion of the additional storage would be dedicated to managing flows for winter-run Chinook salmon on the upper Sacramento River. Under this preliminary plan, approximately 320,000 acre-feet would be dedicated to increasing minimum flows from approximately 3,250 cfs to about 4,200 cfs between October 1 and April 30. However, subsequent evaluation indicated that although at various stages of development the concept of increasing minimum flows would be beneficial for fish, at other life stages increasing minimum flows would be detrimental. Accordingly, this plan was deleted from further development.

- **CO-4** – Multipurpose with Shasta Enlargement (6.5 feet). This plan addressed both primary and secondary objectives through a combination of measures, including raising Shasta Dam, restoring habitat, and adding recreation facilities in the Shasta Lake area. Enlargement of the reservoir and limited reservoir reoperation would also help improve operations for flood management and recreation. Major components of this plan included increasing water supply reliability with a 6.5-foot dam raise, increasing anadromous fish survival by increasing cold-water pool depth and volume in Shasta Reservoir, and restoring inactive gravel mines and floodplain habitat along the Sacramento River. In addition, the plan included further investigation of and potential modifications to the existing TCD at Shasta Dam for enhanced temperature management, and increasing the operational efficiencies of Shasta Dam and Reservoir for water supply

reliability and flood control. Finally, the plan included implementing conjunctive water management, as in WSR-4, shoreline and tributary fish habitat improvements in the Shasta Lake area, and restoring one or more riparian habitat areas between Redding and Red Bluff on the Sacramento River. CO-4 was eliminated from further consideration primarily because of low effectiveness and efficiency and redundancies with WSR-1 and CO-5, both of which were recommended for further development.

2.2.2 Comprehensive Plans Phase

The scenarios presented in Tables 2-5 and 2-6 were eliminated from further consideration during the comprehensive plans phase. These scenarios are described further in the Plan Formulation Appendix.

Table 2-5. Eliminated Scenarios Considered to Augment Flows – Anadromous Fish Survival Focus Plan

Scenario	Description	Reason for Elimination
1	Dam raise of 18.5 feet. Additional 634,000 acre-feet of storage. October – March AFRP flows or 500 cfs increase, whichever is less.	Analysis indicated limited benefits to fish compared with overall cost of the project.
2	Dam raise of 18.5-feet. Additional 634,000 acre-feet of storage. October – March AFRP flows or 750 cfs increase, whichever is less.	Analysis indicated limited benefits to fish compared with overall cost of the project.
3	Dam raise of 18.5-feet. Additional 634,000 acre-feet of storage. October – March AFRP flows or 1,000 cfs increase, whichever is less.	Analysis indicated limited benefits to fish compared with overall cost of the project.
4	Dam raise of 18.5-feet. Additional 634,000 acre-feet of storage. Increase August flows to 10,000 cfs and September flows to 6,000 cfs for temperature control.	Analysis indicated limited benefits to fish compared with overall cost of the project.

Source: USFWS 2001
Key:
AFRP = Anadromous Fish Restoration Plan
cfs = cubic feet per second

Table 2-6. Eliminated Scenarios Considered for Cold-Water Storage – Anadromous Fish Survival Focus Plan

Scenario	Description	Reason for Elimination
B	Dam raise of 6.5 feet. Additional 256,000 acre-feet of storage. Dedicating 256,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it did not considerably contribute to other objectives.
D	Dam raise of 12.5 feet. Additional 443,000 acre-feet of storage. Dedicating 187,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it was not as cost-effective as an 18.5-foot raise.
E	Dam raise of 12.5 feet. Additional 443,000 acre-feet of storage. Dedicating 443,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it did not considerably contribute to other objectives.
G	Dam raise of 18.5 feet. Additional 634,000 acre-feet of storage. Dedicating 191,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it was redundant with Scenario H and provided less benefit.
I	Dam raise of 18.5 feet. Additional 634,000 acre-feet of storage. Dedicating 634,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it did not considerably contribute to other objectives.

2.3 No-Action Alternative

NEPA and CEQA require the analysis of a baseline alternative, representing a scenario in which the project is not implemented. For all Federal feasibility studies of potential water resources projects, the NEPA No-Action Alternative is intended to account for existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area. Reasonably foreseeable actions include actions with current authorization, secured funding for design and construction, and environmental permitting and compliance activities that are substantially complete.

Under CEQA, the No-Project Alternative is similar to NEPA's No-Action Alternative, but it involves the review of two scenarios: the existing condition baseline, which represents only current conditions at the time the Notice of Preparation is published, and "reasonably foreseeable" future conditions without the project (which is equivalent to the NEPA No-Action Alternative). Table 2-1 of the Modeling Appendix describes the existing condition, and shows which actions were assumed to be part of the future condition (or No-Action /No-Project Alternative).

For the PDEIS, the No-Action Alternative is considered to be the basis for comparison with potential action alternatives, consistent with the *Federal Water Resources Council Principles and Guidelines for Water and Related Land*

Resources Implementation Studies (WRC 1983) and NEPA guidelines. Thus, if no proposed action is determined to be feasible, the No-Action Alternative is the default option.

Plan formulation efforts and analysis of the No-Action Alternative and action alternatives discussed in this chapter are based on CVP and SWP operational conditions described in the 2004 Operations Criteria and Plan Biological Assessment (Reclamation 2004). Modeling studies will be updated to reflect changes in water operations resulting from ongoing Operations Criteria and Plan reconsultation and other relevant water resources projects and programs, including, potentially, Bay-Delta Conservation Plan/Delta Habitat Conservation and Conveyance Plan efforts. The results of these updated studies will be incorporated into the Draft EIS and other future SLWRI documents.

Under the No-Action Alternative, the Federal Government would continue to implement reasonably foreseeable actions, as defined above, but would not take additional actions toward implementing a plan to raise Shasta Dam to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water supply and reliability issues in California. The following discussions highlight the consequences of implementing the No-Action Alternative, as they relate to the objectives of the SLWRI.

2.3.1 Anadromous Fish Survival

Much has been done to address anadromous fish survival problems in the upper Sacramento River. Solutions have ranged from changes in the timing and magnitude of releases from Shasta Dam to constructing and operating the TCD at the dam. Actions also include site-specific projects, such as introducing spawning gravel to the Sacramento River, and work to improve or restore spawning habitat in tributary streams. However, some actions have had an adverse effect on Sacramento River habitat, including implementing requirements of the Trinity River ROD, as amended (Reclamation 2000), which reduced flows from the Trinity River basin into Keswick Reservoir and then into the Sacramento River. Water diverted from the Trinity River is generally cooler than flows released from Shasta Dam. Accordingly, since implementation of the Trinity ROD, some of the benefits derived from flow changes and the Shasta TCD have been offset by the reduction in cooler water from the Trinity River. Increased demand for water for agricultural, M&I, and environmental uses is also expected to reduce the reliability of cold water for anadromous fish. Prolonged drought that depletes the cold-water pool in Shasta Reservoir could put populations of anadromous fish at risk of severe population decline or extirpation in the long-term (NMFS 2009). The risk associated with a prolonged drought is especially high in the Sacramento River because Shasta Reservoir is operated to maintain only 1 year of carryover storage. Under the No-Action Alternative, after 2 years of drought, Shasta Reservoir storage would be insufficient to provide cold water throughout the winter-run Chinook salmon spawning season. A drought lasting several years would likely result in the extirpation of winter-run Chinook salmon (NMFS 2009).

Under the No-Action Alternative, it is assumed that actions to protect fisheries and benefit aquatic environments would continue, including maintaining the TCD and satisfying existing regulatory requirements.

2.3.2 Water Supply Reliability

Demands for water in the Central Valley and throughout California exceed available supplies, and the need for additional supplies is expected to grow. There is growing competition for limited system resources between various users and uses, including agricultural, M&I, and environmental. M&I water demands and environmental water requirements have each increased, resulting in greater competition for limited water supplies. As mentioned, the population of California is expected to increase by more than 60 percent above 2005 levels by 2050. Significant increases in population also are expected to occur in the Central Valley, nearly 130 percent above 2005 levels by 2050. As these population increases occur, and are coupled with the need to maintain a healthy and vibrant industrial and agricultural economy, the demand for water would continue to significantly exceed available supplies. Competition for available water supplies would intensify as water demands increase to support this population growth.

Water conservation and reuse efforts are expected to significantly increase, and forced conservation resulting from increasing water shortages would continue. Without developing cost-effective new sources, however, the growing urban population would increasingly rely on shifting water supplies from such areas as agricultural production to satisfy M&I demands. It is likely that with continued and deepening shortages in available water supplies, adverse economic impacts would increase over time in the Central Valley and elsewhere in California. One example could include higher water costs, resulting in a further shift in agricultural production to areas outside California and/or outside the United States. Under the No-Action Alternative, Shasta Dam would not be modified and the CVP would continue operating similarly to existing conditions.

The No-Action Alternative would continue to meet water supply demands at levels similar to existing conditions, but would not be able to meet the expected increased demand in California.

2.3.3 Ecosystem Resources, Flood Management, Hydropower Generation, Recreation, and Water Quality

As opportunities arise, some locally sponsored efforts would likely continue to improve environmental conditions on tributaries to Shasta Lake and along the upper Sacramento River. However, overall, future environmental-related conditions in these areas would likely be similar to existing conditions. The quantity, quality, diversity, and connectivity of riparian, wetland, and riverine habitats along the Sacramento River have been limited by confinement of the river system by levees, reclamation of adjacent lands for farming, bank protection, channel stabilization, and land development.

Shasta Dam and Reservoir have greatly reduced flood damage along the Sacramento River. Shasta Dam and Reservoir were constructed at a total cost of about $36 million. During flood events in 1983, 1986, and 1997, Shasta Dam, in combination with the Sacramento River Flood Control Project, prevented an estimated $14 billion in property losses due to flooding. Accordingly, from a flood damage perspective only, Shasta Dam has far more than paid for itself. However, residual risks to human life, health, and safety along the Sacramento River remain. Development in flood-prone areas has exposed the public to the risk of flooding. Storms producing peak flows, and volumes greater than the existing flood management system was designed for, can occur, and result in extensive flooding along the upper Sacramento River. Under the No-Action Alternative, the threat of flooding would continue, and may increase as population growth continues.

California's demand for electricity is expected to significantly increase in the future. Under the No-Action Alternative, no actions would be taken to help meet this growing demand.

As California's population continues to grow, demands would grow significantly for water-oriented recreation at and near the lakes, reservoirs, streams, and rivers of the Central Valley. This increase in demand would be especially pronounced at Shasta Lake.

To address the impact of water quality deterioration on the Sacramento River basin and Delta ecosystems and endangered and threatened fish populations, several environmental flow goals and objectives in the Central Valley (including the Delta) have been established through legal mandates aimed at maintaining and recovering endangered and threatened fish and wildlife, and protecting designated critical habitat. Despite these efforts, under the No-Action Alternative, these resources would continue to decline and ecosystems would continue to be impacted. In addition, Delta water quality may continue to decline.

2.4 Action Alternatives

The five comprehensive plans designated as the action alternatives for the purpose of this PDEIS are discussed below. Management measures, construction activities, and environmental commitments common to these alternatives are described first.

2.4.1 Management Measures Common to All Action Alternatives

Eight of the management measures retained during the alternatives development process are included, to some degree, in all of the action alternatives. These measures were included because they (1) would either be incorporated or required with any dam raise, (2) were logical and convenient additions that would significantly improve any alternative, or (3) should be considered with

any new water increment developed in California. The eight measures include enlarging the Shasta Lake cold-water pool, modifying the TCD, increasing conservation storage, reducing demand, modifying flood operations, modifying hydropower facilities, maintaining or increasing recreation opportunities, and maintaining or improving water quality.

Enlarge Shasta Lake Cold-Water Pool

Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBDD. At a minimum, all comprehensive plans include enlarging the cold-water pool by raising Shasta Dam to enlarge Shasta Reservoir. Some alternatives also increase the seasonal carryover storage in Shasta Lake.

Modify Temperature Control Device

For all action alternatives, the TCD would be modified to account for an increased dam height and to reduce leakage of warm water into the structure. Minimum modifications to the TCD include raising the existing structure and modifying the shutter control. This measure would increase the ability of operators at Shasta Dam to meet downstream temperature requirements, and provide more operational flexibility to achieve desirable water temperatures during critical periods for anadromous fish.

Increase Conservation Storage

All action alternatives include increasing the amount of space available for water conservation storage in Shasta Reservoir by raising Shasta Dam. Conservation storage is the portion of the reservoir capacity available to store water for subsequent release to increase water supply reliability for agricultural, M&I, and environmental purposes. All action alternatives include a range of dam enlargements and increases in conservation space.

Reduce Demand

All action alternatives include a water conservation program for new water supplies that are created by the project. This program would augment current water use efficiency practices. The proposed program would consist of a 10-year initial program to which Reclamation would allocate approximately $2.3 million to $3.8 million to fund water conservation efforts. Funding would be proportional to additional water supplies delivered and would focus on assisting project beneficiaries (agencies receiving increased water supplies because of the project), with developing new or expanded urban water conservation, agricultural water conservation, and water recycling programs. Program actions would be a combination of technical assistance, grants, and loans to support a variety of water conservation projects such as recycled wastewater projects, irrigation system retrofits, and urban utilities retrofit and replacement programs. The program could be established as an extension of existing Reclamation programs, or as a new program through teaming with SLWRI cost-sharing partners. Combinations and types of water use efficiency actions funded would be tailored to meet the needs of identified cost-sharing partners, including

consideration of cost-effectiveness at a regional scale for agencies receiving funding.

Modify Flood Operations

Physical enlargement of Shasta Reservoir would require alterations to existing flood operation guidelines or rule curves, to reflect physical modifications, such as an increase in dam/spillway elevation. The rule curves would be revised with the goal of reducing flood damage and enhancing other objectives to the extent possible. Potential modification of flood operations would be considered for all action alternatives.

Modify Hydropower Facilities

Under each action alternative, physical enlargement of Shasta Dam would likely require various minimum modifications, commensurate with the magnitude of the enlargement, to the existing hydropower facilities at the dam to enable their continued efficient use. These modifications, in conjunction with increased lake surface elevations, may provide incidental benefits to hydropower generation. Although modifications could also be included to further increase the power production capabilities of the reservoir (e.g., additional penstocks and generators), they are believed to be a detail beyond the scope of this investigation and are not considered further at this level of planning.

Maintain and Increase Recreation Opportunities

In addition to the measures described above, all action alternatives address, to some extent, the secondary objective of maintaining or increasing recreation opportunities at Shasta Lake. Outdoor recreation, and especially recreation at Shasta Lake, represents a major source of enjoyment to millions of people annually and is a major source of income to the northern Sacramento Valley. Shasta Dam and Reservoir are within the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). Recreation within these lands is managed by USFS. As part of this administration, USFS either directly operates and maintains, or manages through leases, numerous public campgrounds, marinas, boat launching facilities, and related water-oriented recreation facilities. Enlarging Shasta Dam and Reservoir would affect some of these facilities. Consistent with the position of USFS, and planning conditions described in this chapter, all of the action alternatives include features to, at a minimum, maintain the overall recreation capacity of the existing facilities. All action alternatives also provide for modernization of recreation facilities.

Maintain or Improve Water Quality

All action alternatives could contribute to improved Delta water quality conditions and Delta emergency response. Additional storage in Shasta Reservoir would provide improved operational flexibility. Shasta Dam has the ability to provide increased releases and high-flow releases to reestablish Delta water quality. Improved Delta water quality conditions could provide benefits for both water supply reliability and ecosystem restoration by potentially

increasing Delta outflow during drought years and reducing salinity during critical periods.

2.4.2 Construction Activities Common to All Action Alternatives

Common construction activities would include land-based construction activities associated with the following:

- Clearing vegetations from portions of the inundated reservoir area.
- Constructing the dam, appurtenant structures, reservoir area dikes, and railroad embankments.
- Relocating roadways, bridges, recreation facilities, utilities, and miscellaneous minor infrastructure.

Construction activities common to all action alternatives are described below.

Clearing Portions of Inundated Reservoir Area

A portion of the acreage inundated at the new full pool would need to be cleared. This would include removing trees and other vegetation from around the reservoir. Willows, cottonwoods, and buttonbush would not be removed in and along riparian areas. Manzanita removed in cleared areas would be stockpiled and used for fish habitat structures placed in designated locations. Structures, utilities, and other infrastructure would also need to be removed and/or relocated, as described below in more detail.

Fifteen vegetation management areas have been delineated to facilitate efficient removal of vegetation around the reservoir perimeter, including 11 areas of complete vegetation removal and 4 areas of overstory removal (see Figure 2-3). The acreages of each vegetation management area affected by identified reservoir clearing treatments are included below in the detailed description of each action alternative.

Vegetation management activities would need to be complete before inundation of new areas created by a dam raise. A single staging area (landing) would serve each vegetation management area. Access for vegetation removal activities would most likely be limited to late summer and fall, when water levels were low and recreation use had decreased. Removal by helicopter is generally limited to spring and fall because of the limited availability of helicopters during the summer fire season. Vegetation removal would also be limited during bird nesting season, typically spring through summer. Reservoir area breeding surveys would be performed to determine the appropriate time frame for vegetation removal activities. Because of distance and/or safety constraints, helicopters would not be used in the following vegetation management areas: Bridge Bay, Lakeshore East, Pit Arm, and McCloud Arm. Slash burning could take place during the winter following vegetation treatment and would comply with all regulations set forth by the Shasta County Air Quality Management District. Methods for clearing the reservoir area are summarized below.

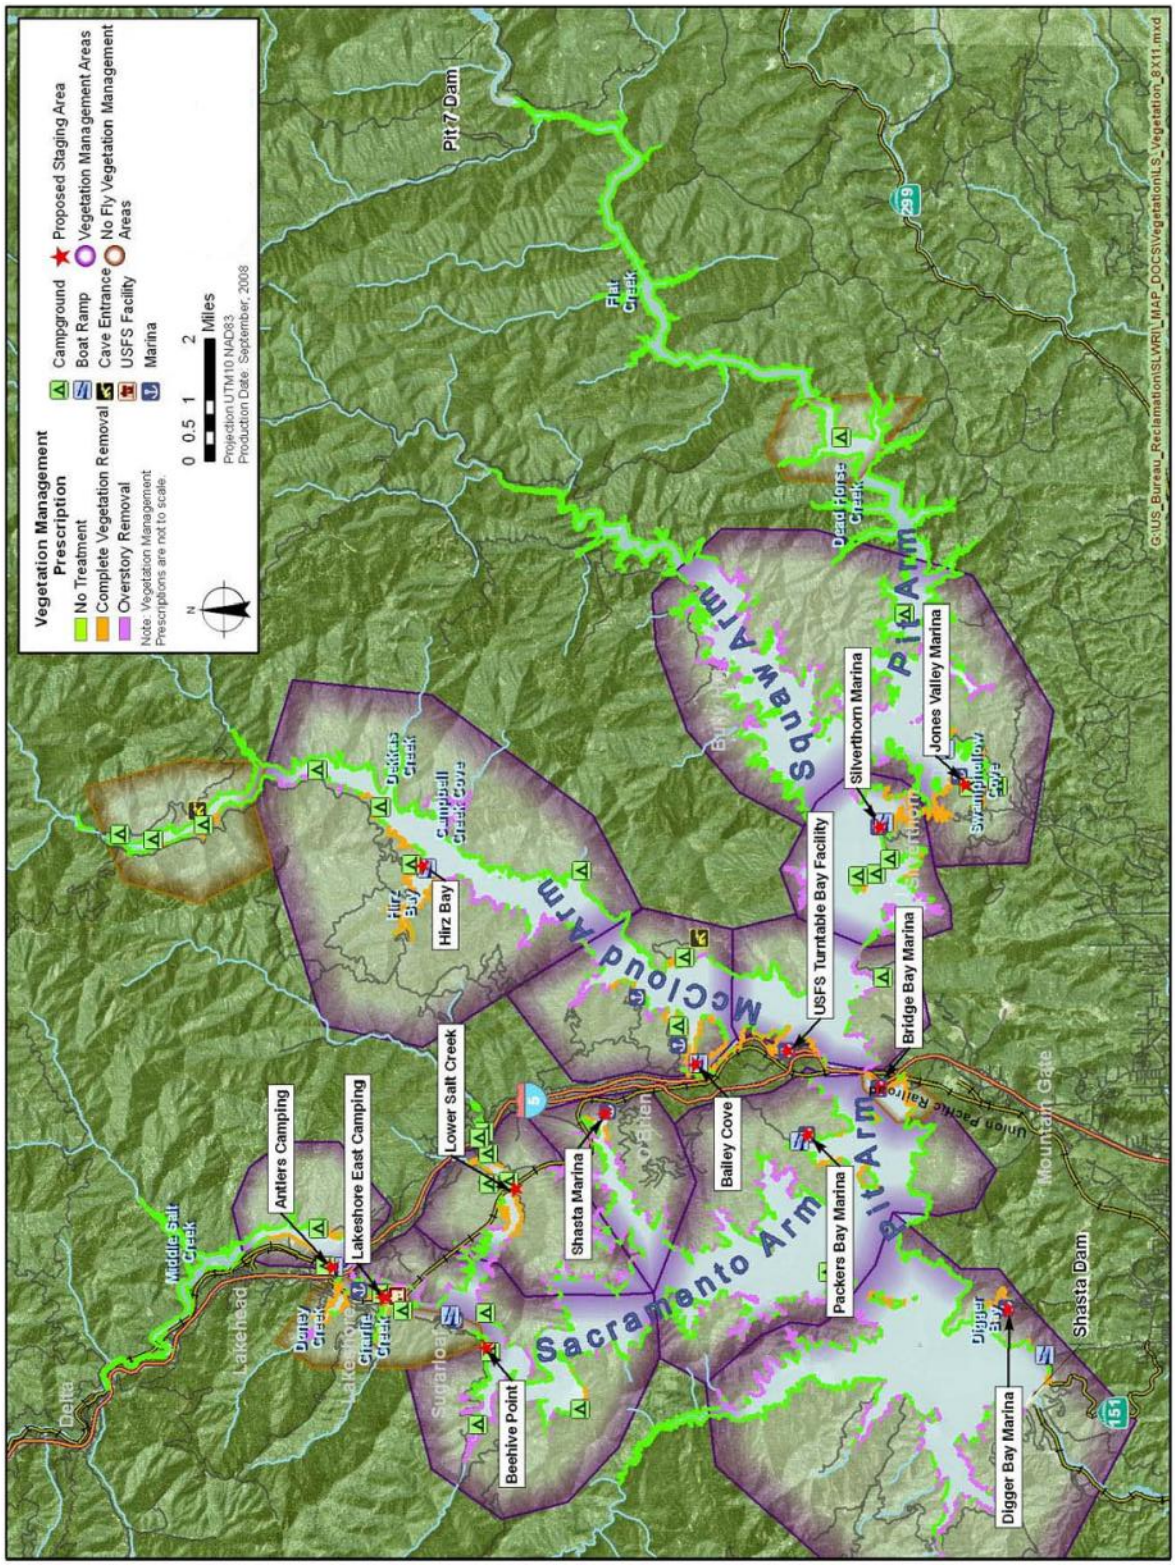

Figure 2-3. Vegetation Management Areas

Complete Vegetation Removal Complete vegetation removal would clear all existing vegetation from the designated treatment area and would generally be applied to locations along and adjacent to developed recreation areas, including boat ramps, day use areas, campgrounds, marinas, and resorts. Exceptions would be made in areas with high shoreline erosion potential, or in habitat for special-status species.

Timber would be harvested and removed to landings by ground-skidding equipment if road access were present and slopes were less than 35 percent; otherwise, trees would be yarded by helicopter and residual vegetation and activity-created slash would be piled and burned by hand. Where possible, trees would be felled into the reservoir during removal to minimize damage to reservoir walls. Tree stumps would be cut to within 24 inches of the ground surface and brush stumps would be cut flush to the ground. Stumps would be left in place to reduce shoreline erosion. Complete vegetation removal is intended to maximize shoreline access and minimize the risk to visitors from snags and water hazards.

Overstory Removal Overstory removal involves removing all trees from the treatment area that are greater than 10 inches in diameter at breast height, or 15 feet in height, generally in houseboat mooring areas or narrow arms of the reservoir where snags pose the greatest risk to boaters. Trees would be harvested and removed to landings by ground-skidding equipment if road access were present and slopes were less than 35 percent; otherwise, trees would be yarded by helicopter and activity-created slash would be piled and burned by hand. The remaining understory vegetation would be left in place. As for complete vegetation removal, where possible, trees would be felled into the reservoir during removal to minimize damage to reservoir walls. Tree stumps would be cut to within 24 inches of the ground surface. Stumps would be left in place to reduce shoreline erosion. Overstory removal is intended to minimize the risk to visitors from snags and water hazards.

No Treatment Designated areas of the inundation zone would be left untreated with no vegetation removed. This prescription would generally be applied to stream inlets, the upper end of major drainages, the shoreline of wider arms of the reservoir, and special habitat areas. This treatment is intended to maximize the habitat benefits of inundated and residual vegetation.

Construction of Dam and Appurtenant Structures

This section summarizes major features associated with enlarging Shasta Dam and Reservoir and modifying its appurtenances for all action alternatives. Total surface area that would be required for work limits and permanent features, and an estimate of materials needed to modify Shasta Dam and its appurtenances, are included in the detailed description of each action alternative. For more detailed explanations of design considerations, please refer to the Engineering Summary Appendix.

Dam Crest Structure Removal Before any enlargement of Shasta Dam, existing structures on the dam crest would need to be removed. These structures include the gantry crane, existing spillway drum gates and frames, the spillway bridge, concrete in the spillway crest and abutments, upstream parapet walls, sidewalks, curbing, crane rails, and control equipment.

Modification of the main dam would require the demolition, removal, and transportation to waste of top-of-dam materials. This would include the demolition and removal of the upstream reinforced-concrete parapet wall and curb. Sawcuts would be used to aid in removing the upstream reinforced-concrete parapet wall and curb. In addition, sawcuts would be required along the upstream face and crest of the dam before the excavation of a 2-foot by 2-foot end area at the upstream face of the dam to embed a 12-inch polyvinyl chloride waterstop. The existing dam crest would be prepared by using a high-pressure water jet on the concrete surface. Existing roadway drains would be backfilled with cement grout.

Four-inch-diameter drain holes on 10-foot centers would be drilled from two different locations: from the existing dam crest to drain the surface contact, with each hole 2.5 feet long (248 holes), and from the existing dam crest for surface drainage at the downstream overhang, with one hole per block and each hole 6.5 feet long (50 holes). A 3-foot-diameter vertical shaft would be excavated through the concrete from the existing dam crest to the hoist gallery to install electrical conduit.

The existing spillway drum gates and piers would require removal according to a phased construction plan that would minimize impacts to reservoir operations during construction. Two drum gates and one pier would be removed to construct three new piers and install three new sloping fixed-wheel gates. This would be followed by removal of the remaining drum gate and pier to construct two new piers and install three new sloping fixed-wheel gates. This work would require two construction seasons to complete.

Removing the existing spillway bridge should be phased and/or scheduled to allow vehicular access across the dam for the longest time possible. The cantilever parapet wall sections at the dam crest would be removed by wire saw.

Control equipment for the TCD would be removed, stored, and reinstalled when the TCD structure is modified. The elevator on the dam would be removed, stored, and reinstalled for any of the dam raises. Storage would most likely be on site, within the parking lot of the left wing dam.

Main Gravity Dam Shasta Dam would be raised by placing mass concrete corresponding in width to the existing dam monolith blocks on the existing dam crest (concrete gravity section and spillway crest section). Structural concrete would be placed for the top of the dam, including for the roadway, the upstream and downstream parapets, and the walkway 1092.5 feet above mean sea level

(elevation 1,092.5). Reinforcing bars would be used around the utility gallery, and nominal temperature steel would be used for the exposed structural concrete surfaces. Two 6-inch-diameter steel top-of-dam drains would be furnished and installed in each block to drain to the upstream face. Surface area and features of the new dam crest would be similar to the existing dam crest, including gantry crane rails and surface drains. A new upstream parapet wall would provide flood protection. The dam raise would include a new utility gallery and 5-inch-diameter formed drains on 10-foot centers.

Wing Dams Zoned embankment wing dams were originally constructed on both abutments of the main dam to protect the contact between the concrete and the excavated foundation surface. The left wing dam would be raised 20.5 feet to elevation 1,098.0 to maintain the same height above the top of joint-use storage, as for existing conditions. This would involve extending the existing reinforced-concrete core wall to the raised dam crest, and placing a thick layer of large rockfill downstream from the core wall. The upstream face would consist of a reinforced concrete or mechanically stabilized earth wall, and a concrete parapet wall to elevation 1,101.5. The road from the concrete dam crest would be ramped up through the left wing dam to the new embankment crest. Roadways and security features on the existing dam crest would be relocated to the new dam crest. The existing rotunda on the left abutment of the dam would be removed and reconstructed.

A building housing a visitor center and Reclamation offices, a parking lot, picnic areas, and vista points have been incorporated into the abutment design. The existing roadways, lawns, sidewalks, trees, and other features on the left wing dam crest would be restored to preraise configurations. Existing facilities would be removed from the site before construction, and replaced after the raise is completed.

The right wing dam would be raised to meet the dam crest. Concrete was selected for the right wing dam in lieu of embankment to facilitate construction. The new right wing dam crest would provide surface area and features similar to the existing dam crest, including gantry crane rails and surface drains. A new upstream parapet wall would provide flood protection. The right wing dam would include a new utility gallery and a foundation drainage curtain. Right abutment access roads would be modified to match the new dam crest.

Spillway Structural concrete would be used to raise the existing spillway crest and to shape the raised spillway crest. The existing spillway bridge, two existing spillway piers, cantilever wall sections, and three existing drum gates and operating equipment would be removed. Five new spillway piers would be constructed at locations within the spillway, designed to avoid existing overflow block contraction joints, and a new concrete spillway crest would be constructed between them. The locations of the new piers would result in different widths of spillway gates. The three existing 110-foot by 28-foot drum gates would be replaced with six sloping, fixed-wheel gates (four 48-foot by 38-foot and two

54-foot by 38-foot gates). The total spillway crest length would decrease from 330 feet to 300 feet, as a result. A new bridge would be required over the spillway to allow for vehicular traffic and for a gantry crane to travel from one end of the dam to the other.

Temperature Control Device Modifications to the TCD would be needed for dam full pool elevation raises. Modifications would primarily include extending the main steel structure to the new full pool elevation; raising the TCD operating equipment, including gate hoists, electrical equipment, miscellaneous metalwork, and hoist platform above the new top of joint-use elevation; and lengthening/replacing shutter operating cables.

Shasta Powerplant Penstock Intake and Penstock Modifications The centerline of the existing penstock intakes would remain at the current level, but the gate hoists would require relocation with a higher dam crest. Additional penstock foundations providing seismic restraint would be constructed on the exposed portion of the penstocks downstream from the dam, regardless of the size of the dam raise, to address identified existing seismic deficiencies.

Pit 7 Dam Powerhouse The only expected modifications to the Pit 7 Powerhouse associated with the proposed action include installation of a tailwater depression system. During high flows, a tailwater depression system would introduce compressed air into the turbine runner pit to depress the tailwater to a level that does not interfere with turbine operation, thereby allowing continued turbine operation.

The tailwater depression system would include air compressors, air discharge piping with control valves, water-level sensors, power supply, and electrical controls. Air compressors would be of the high-volume, low-pressure type, referred to as "blowers." Blowers would be driven by electric motors supplied with available power from the Pit 7 Powerhouse.

Reservoir Area Dikes and Railroad Embankments

The proposed dikes would be constructed using common earthmoving equipment and methods. Additional excavation to provide working surfaces and keys for the embankment fill would be required along the slope of the upstream foundation for some of the proposed dikes. Ground treatment and/or over-excavation may be necessary in some areas to remove and/or treat pervious material. It is expected that approximately 1 foot of organic-rich soil and vegetation would be excavated from the foundation of the proposed dikes, and a shear key on the upstream sides of the dikes. Riprap would be placed on the upstream face of each dike to the crest of the dike to protect against wave run-up and erosion. The volume of riprap required for each dike is summarized below in the detailed description of each action alternative. Reservoir dikes are further described in the Engineering Summary Appendix.

Relocations

As a result of the proposed Shasta Dam raise, the following major features would be inundated by the increase in full pool elevation. Existing infrastructure affected by enlarging Shasta Dam and Reservoir would need to be removed and/or relocated.

Roadways Criteria were established for four typical road replacement scenarios. Road design criteria and construction characteristics are discussed in detail in the Engineering Summary Appendix.

Roadway construction activities would involve, but not be limited to, demolition of existing roadways as required; clearing, grubbing, and site preparation of work areas, as required; grading road alignments to meet finished grades; placing road subgrade; installing storm drain culverts; constructing retaining wall systems; installing road appurtenances such as guardrails; performing construction-related traffic control; and establishing and maintaining a Stormwater Pollution Prevention Plan (SWPPP). Noisy equipment, such as pile drivers, are anticipated for road construction work. Typical noise would result from trucks and diesel-powered equipment.

Replacement roadways would be constructed by excavating the existing up-grade slope to provide fill material for the embankment fill portion of road construction; bench-excavating into the up-grade slope above the existing roadway to establish the new road finished grade; building the new road on an engineered fill embankment from imported borrow material; or building the new road directly above the existing road on an engineered fill embankment from imported borrow material. A road alignment may use either a single method of construction for the entire alignment, or it may use all four methods at different locations along an alignment. To limit impacts to existing roadways, road closures would be avoided whenever possible.

Estimated work limits for road segment relocation are described in the Engineering Summary Appendix. Estimated work limits depend on the surrounding terrain, and vary from a minimum of 5 feet to 30 feet wide, measured from the extent of earthwork. Where the road would be constructed as an embankment fill against an existing steep hillside, a 5-foot-wide minimum work area would be used. Where the terrain beyond the limit of earthwork was flat enough to be used as work areas for construction equipment, the work limits would range from 15 feet to 30 feet wide. Features associated with proposed roadway relocations for all action alternatives are summarized below in the detailed description of each action alternative.

Vehicle Bridges As a result of raising Shasta Dam for any of the action alternatives, the following local road vehicle bridges would be replaced:

- Charlie Creek Bridge
- Doney Creek Bridge

- McCloud River Bridge
- Didallas Creek Bridge

Criteria and assumptions considered in determining structure type and length for the replacement structures are included in the Engineering Summary Appendix. Based on the design criteria and assumptions, and considering preliminary horizontal alignments and profile grades developed for the relocated roadways, Table 2-7 summarizes proposed bridge characteristics for the four road bridges requiring replacement under all action alternatives.

Table 2-7. Features of Proposed Bridge Relocations Common to All Action Alternatives

Bridge Feature	Charlie Creek Bridge	Doney Creek Bridge	McCloud River Bridge	Didallas Creek Bridge
Bridge Length (lf)	782	760	490	115
Number of Abutments	2	2	2	2
Number of Piers	4	4	4	0
Pier Diameter (lf)	14	14	6	N/A
Volume of Backfill (cy)	480	400	530	180
Volume of Concrete (cy)	3,530	3,320	2,320	760
Quantity of Steel (tons)	575	516	380	104
Number of Class 140 Piles	24	24	24	24
Number of 24-inch Cast-In-Steel-Shell Piles	72	72	32	N/A
Volume of Excavated Material (cy)	1,200	550	820	440
Quantity of Demolished Material (cy)	3,500	3,300	2,300	800

Key:
cy = cubic yards
lf = linear feet
N/A = not applicable
sf = square feet
SLWRI = Shasta Lake Water Resources Investigation

Construction would take place during the low-water season, and is expected to last between 6 and 8 months. The waterway would remain clear for navigation during construction. Bridge construction would begin with piers and abutments. To allow underwater construction of pier foundations, steel pile shells would be driven into the lake bed to create a temporary cofferdam. It may be necessary to dewater the shells during drilling if water seeps in. A hole would then be drilled to the specified foundation depth. Reinforcing steel would be installed within the shells before concrete was poured. After completion of the piers and abutments, construction of the superstructure and bridge deck would begin via the balanced cantilever method. This process entails forming and constructing the horizontal structure outward from the piers in each direction, in equal (balanced) proportions, until the superstructure/deck segments meet at midspan.

Traffic would continue on the existing bridges during construction. It is likely that barges would be used extensively for bridge foundation construction, bridge assembly, transport of materials, workers, and equipment, and demolition of the existing bridges. Concrete would be poured from barges. A

staging area would be required on the lakeshore, from which barges could be loaded and unloaded.

Although Fender's Ferry Bridge would not need to be replaced as a result of the Shasta Dam raises, modifications to the bridge would be necessary. The Fender's Ferry Bridge is a three-span structure with a steel plate girder superstructure supported on riveted steel tower bents and reinforced concrete piers with spread footings. As a result of differences in east and west riverbank topography, the western pier steel tower is supported at a much lower elevation than the eastern pier tower. Thus, at the proposed full pool elevations, the eastern pier steel tower would be inundated.

The existing reinforced concrete pier and footing would be enlarged and extended, and the existing steel tower modified to prevent inundation as a result of the higher full pool levels associated with the dam raise scenarios under consideration. Proposed modifications include the following:

- Enlarging the existing reinforced concrete footing.
- Enlarging and extending the existing reinforced concrete columns and pier wall to elevation 1096.16.
- Removing approximately 24 feet of the lower portion of the eastern pier steel tower (based on location of existing cross bracing).
- Reusing the existing steel bearing assemblies.

Quantities for the major items of work are estimated in the Engineering Summary Appendix.

Construction activities would likely be completed from the existing embankment without constructing cofferdams around the pier because average water surface elevations are below the existing eastern pier bottom-of-footing elevation for all months, with the exception of April and May. Construction of temporary bents to support the superstructure would be necessary to facilitate construction of the pier modifications. During construction activities, temporary traffic controls may be needed to facilitate delivery of materials and construction of temporary support bents.

Railroad Bridges

Pit River Bridge Pier Modification The new full pool elevations would inundate the existing bridge bearings and low-chord steel truss members. To prevent the existing steel bearings and lower portions of the steel truss members from being submerged, a watertight concrete tub structure would be required. The reinforced concrete structure would be attached to the top of two existing concrete piers. The structure footprint would be rectangular and approximately 151 feet long by 52.5 feet wide.

Because the existing bridge superstructure and top-of-pier are exposed to the elements, a structure cover would not be required; however, two submersible sump pumps would be installed to keep the water level in the new concrete protective structure from rising near the bearings. Each pump would discharge into 2-inch-diameter copper tubing, and the two lines would tee into a 2.5-inch-diameter line that would follow the slope upward to the discharge point. Check valves and ball valves would prevent pumped water from draining out of the line back into the sump. Protective grates would prevent large objects from entering the sump area.

Union Pacific Railroad Bridges The existing Sacramento River Second Crossing and Doney Creek railroad bridge superstructures consist of deck truss bridges with a single track. The piers and abutments were designed to accommodate a future parallel single-track superstructure. Portions of both bridges would be submerged for any reservoir raise and would need to be replaced with new, higher superstructures. Structural analyses of the existing bridge piers under design earthquake loads indicated that new bridge piers would be required. Minimal changes would be required for the railroad vertical alignment. The feasibility designs would permit uninterrupted rail service during construction.

The proposed new bridge superstructure would be a composite superstructure consisting of steel plate girders and a reinforced concrete deck. In general, the bridge superstructures would be designed to be continuous over the piers. However, with a requirement for 16 feet of vertical clearance between the two westernmost piers (underneath Span 2) for the Sacramento River Second Crossing railroad bridge (with a minimum width of 30 feet), to allow for the passage of houseboats, Span 2 is a simply supported span. No minimum clearance for houseboat traffic would be required for the Doney Creek railroad bridge; large-diameter concrete columns with drilled shafts would support the superstructure and be founded on bedrock. The Sacramento River Second Crossing railroad bridge would require nine spans, with a total length of 982 feet between concrete abutments. The Doney Creek railroad bridge would require five spans, with a total length of 537.5 feet between concrete abutments. The proposed relocation of the railroad bridges would require the railroad tracks to be realigned between the two bridges. This realignment would parallel the existing tracks with a 25-foot offset to the east.

Recreation Facilities Any raise of Shasta Dam would have some effect on the many recreation features found along the reservoir shoreline. These features include marinas/boat ramps, resorts, campgrounds/day use areas, cabins, trails, and USFS facilities. Areas for potential recreation mitigation (referred to as windows) and corresponding relocation plans for each window have been developed. Figure 2-4 details the location of these windows and existing recreation sites with proposed modification, expansion, or relocation. After authorization of the project, further detailed designs would need to be developed.

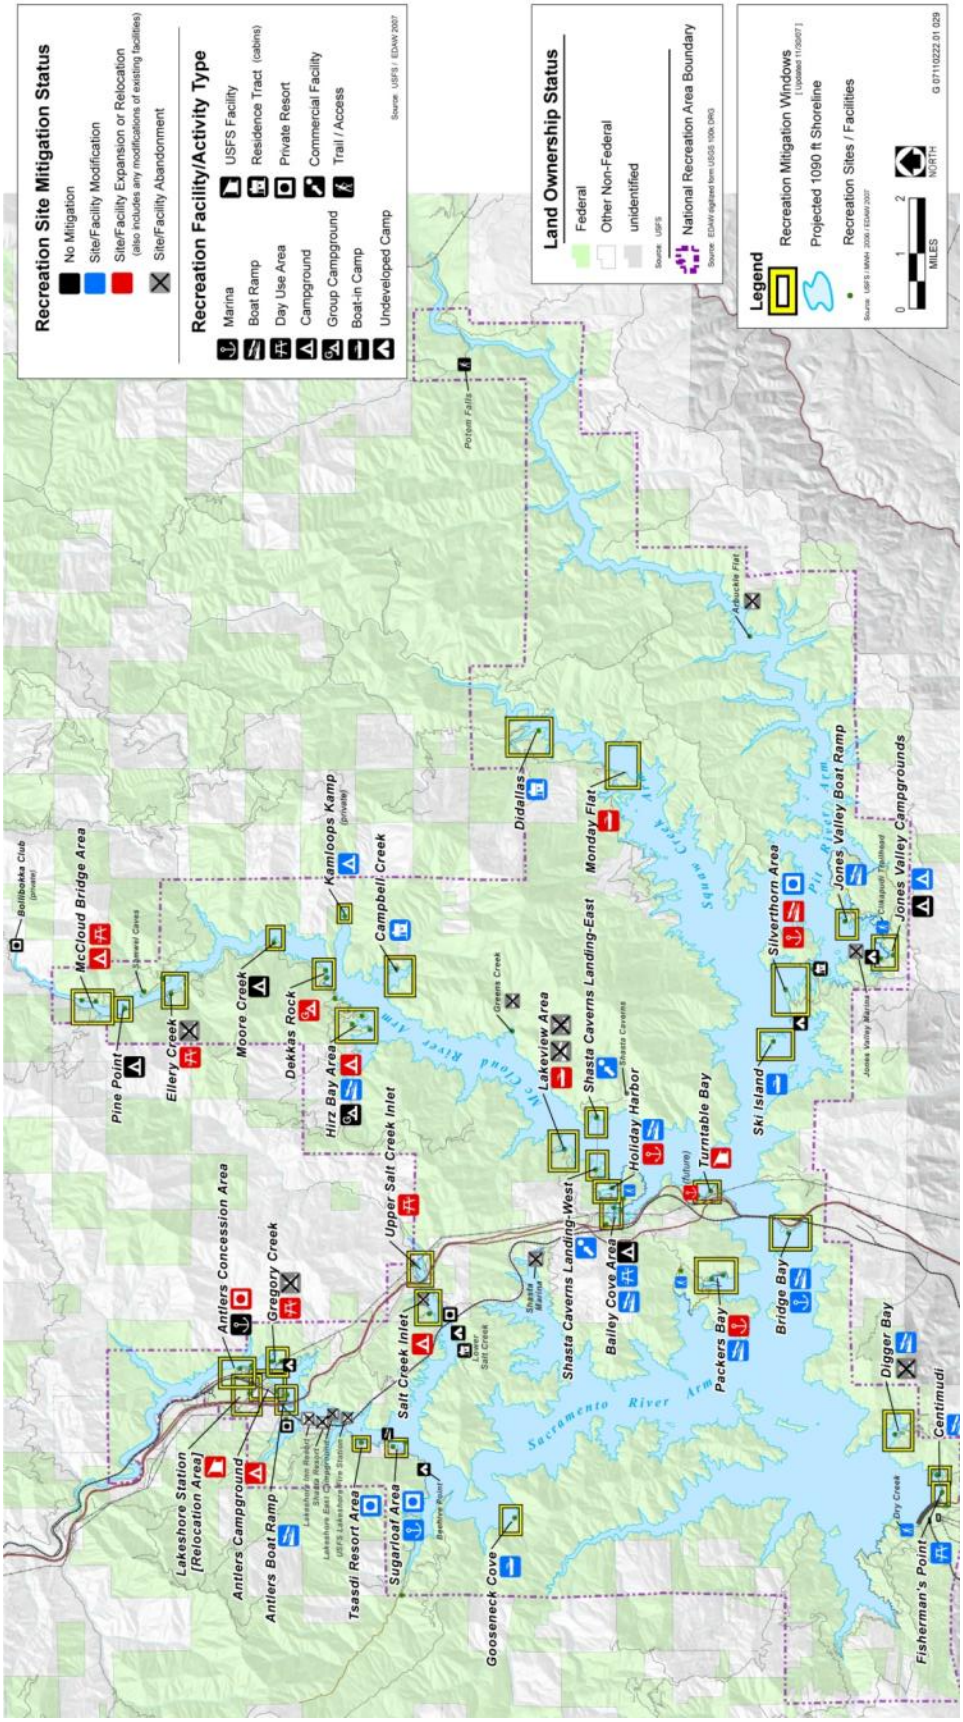

Figure 2-4. Recreation Mitigation Study Windows

The primary goal of the relocation plans is to verify that with any dam raise, the existing recreation capacity could be maintained. Reclamation and USFS would continue to work together to revise a recreation plan that is suitable for the NRA.

Inundated recreation facilities and associated utilities would be relocated before demolition, with the exception of facilities identified for abandonment. Action alternatives would, at minimum, maintain the existing recreation capacity at Shasta Lake. Recreation facilities proposed for relocation are included below in the detailed description of each action alternative. Construction-specific information regarding relocating and demolishing recreation facilities is under development and will be completed after project authorization.

Marina/Boat Ramp Modifications Several marinas around Shasta Lake would be affected by raising Shasta Dam. Typically, marinas consist of a parking area, a boat ramp, various structures (retail, restrooms, maintenance facilities, storage, administration, etc.), and utilities (power, water, and septic). Most of the effects of the dam raise would be due to the inundation of boat ramps, parking lots, structures, and utilities. Boat ramps would be modified in place, on fill, where possible. Parking areas would be replaced on fill, or relocated above the new reservoir elevation. Existing structures that would be inundated would be demolished, and either replaced above the reservoir elevation (upslope or on placed fill), or moved to a floating structure on the water to provide better access for recreational users. Any access roads would be relocated above the new full pool for continued access around the marinas. Existing septic systems that would be inundated would be demolished and removed from the area or relocated. New facilities could also be connected to new localized wastewater treatment facilities. Power lines would be installed to accommodate new structures.

Marinas and boat ramps that could not be modified in place would be relocated to adjacent areas that can provide the necessary grade and access for ramps. To maintain current recreation capacity, 10.7 acres of expanded, or new, boat ramp and/or marina land use would be needed. The following potential areas could be used to meet this need:

- Antlers Boat Ramp and Adjacent Marina Area
- Packers Bay Marina
- Silverthorn Marina Area
- Holiday Harbor

Resort Modifications Raising Shasta Dam would affect approximately six resorts around the reservoir to some degree. Inundated structures and structures within 3 feet of the new full pool would be demolished. Septic systems would also be demolished, and remaining structures would either connect to new

localized wastewater treatment facilities or relocated to other septic systems. Fourteen acres of land would be needed to maintain the current resort capacity.

Campground/Day Use Area Modifications Many undeveloped areas have been identified as potential campgrounds to replace capacity lost because of inundation. While some inundated campgrounds would be relocated on fill at their existing location, others would be moved around the reservoir to new locations identified as potential campground sites. Thirty acres of expanded, or new, campgrounds would be needed to maintain the current recreation capacity. The following areas could be used to meet this need:

- Antlers Campground
- Oak Grove Campground
- Hirz Bay Campground
- McCloud Bridge Area

Six acres of expanded, or new, boat-in campgrounds would be needed to maintain the current recreation capacity. The following areas could be used to meet this need:

- Lakeview Marina Area
- Monday Flat Boat-In Camp

Six acres of expanded, or new, day-use campgrounds would be needed to maintain the current recreation capacity. The following areas could be used to meet this need:

- Ellery Creek Campground
- Gregory Creek Campground
- McCloud Bridge Area
- Upper Salt Creek

USFS Facilities Modifications Recreation within the NRA is managed by USFS, which has several facilities located throughout the reservoir area. USFS facilities consist of various storage and maintenance buildings and equipment, fire protection equipment, customer service facilities, office space, and employee living facilities. Two USFS facilities would be inundated, and require relocation or replacement. The station located in the Lakeshore area would be inundated by a Shasta Dam raise, and would be relocated to an area above the new full pool. The new facility would contain all of the features that exist at the current facility. The inundated facility would be demolished, and hauled to waste. Turntable Bay, another USFS facility, would be inundated by a Shasta Dam raise. Additional space at Turntable Bay would allow the facility to be relocated on fill in its current location.

Utilities and Miscellaneous Minor Infrastructure Gas/petroleum facilities, potable water facilities, power and telecommunications infrastructure, and wastewater facilities would be relocated. New facilities would be designed and constructed in accordance with applicable Federal, State, and local codes and requirements. Relocated facilities would be of the same types, sizes, and materials as existing facilities. Demolished facilities would not be reused to construct relocated facilities. Demolished and relocated utilities are summarized as part of the detailed description of each action alternative. An expanded discussion of the approach and methodology for demolition, design, and relocation criteria for each category of utilities is included in the Engineering Summary Appendix.

Construction Staging

Reclamation would establish staging areas for equipment storage and maintenance, construction materials, fuels, lubricants, solvents, and other possible contaminants in coordination with the resource agencies. Staging areas would likely be located within disturbed areas or at existing facilities that are expected to be inundated, such as campgrounds, recreation parking facilities, the top of Shasta Dam, and the parking area along the left wing dam, where feasible.

Staging areas would have a stabilized entrance and exit and would be located at least 100 feet from bodies of water, if possible. If an off-road site is chosen, qualified biological and cultural resources personnel would survey the selected site to verify that no sensitive resources would be disturbed by staging activities. If sensitive resources were found, an appropriate spatial and temporal buffer zone would be staked and flagged to avoid impacts. Where possible, no equipment refueling or fuel storage would take place within 100 feet of a body of water.

Construction Schedule, Equipment, and Workforce

Total construction duration is estimated at 3 to 4 years. An overlap is expected in the timing of construction of some of the construction components. Construction would be phased, when feasible, to avoid negative environmental impacts.

Construction would typically occur during daylight hours, Monday through Friday. However, construction contractors may extend these hours and schedule construction work on weekends, if necessary, to complete aspects of the work within a given time frame. Construction would require typical heavy construction equipment including excavators, backhoes, bulldozers, scrapers, graders, water trucks, front-end loaders, dump trucks, drill rigs, pump trucks, truck-mounted cranes, pickup trucks, barges, helicopters, and miscellaneous equipment.

About 58 highway truck trips would be needed per day to bring construction material to the site. In addition, about 23 highway truckloads per day could be

needed to carry construction debris and waste material to a suitable landfill. The construction labor force is estimated to average about 350 people over the total construction period.

Borrow Sources

Multiple borrow sources are available to meet project needs for concrete, sand and gravel, core and homogenous fill, shell fill, riprap, and filter and drain materials for reservoir area embankments. Potential borrow sources were examined at a preliminary level and would need further sampling and testing to determine suitability and refine quantity estimates. Potential borrow sources include areas of the dike construction sites, areas located below the reservoir's inundation zone, and commercial sources. Commercial sources are located within approximately 2 to 30 miles of the Bridge Bay site, and within approximately 15 to 43 miles of the Lakeshore sites. Potential borrow sources are identified in Figure 2-5. Available fill material from potential borrow sources are described in the Engineering Summary Appendix.

2.4.3 Environmental Commitments Common to All Action Alternatives

As part of project planning and environmental assessment, Reclamation and/or its contractors would incorporate certain environmental commitments and best management practices (BMP) into the SLWRI action alternatives to avoid or minimize potential impacts. Reclamation will also coordinate planning, engineering, design and construction, operation, and maintenance phases of the project with applicable resource agencies.

The following environmental commitments would be incorporated into any action alternative for any project-related construction activities.

Develop and Implement Construction Management Plan

Reclamation would develop and implement a construction management plan to avoid or minimize potential impacts to public health and safety during project construction, to the extent feasible. The construction management plan would inform contractors and subcontractors of work hours, modes and locations of transportation and parking for construction workers; location of overhead and underground utilities; worker health and safety requirements; truck routes; stockpiling and staging procedures; public access routes; terms and conditions of all project permits and approvals; and emergency response services contact information.

The plan would also include construction notification procedures for the police, public works, and fire department in the cities and counties where construction occurs. Notices would also be distributed to neighboring property owners.

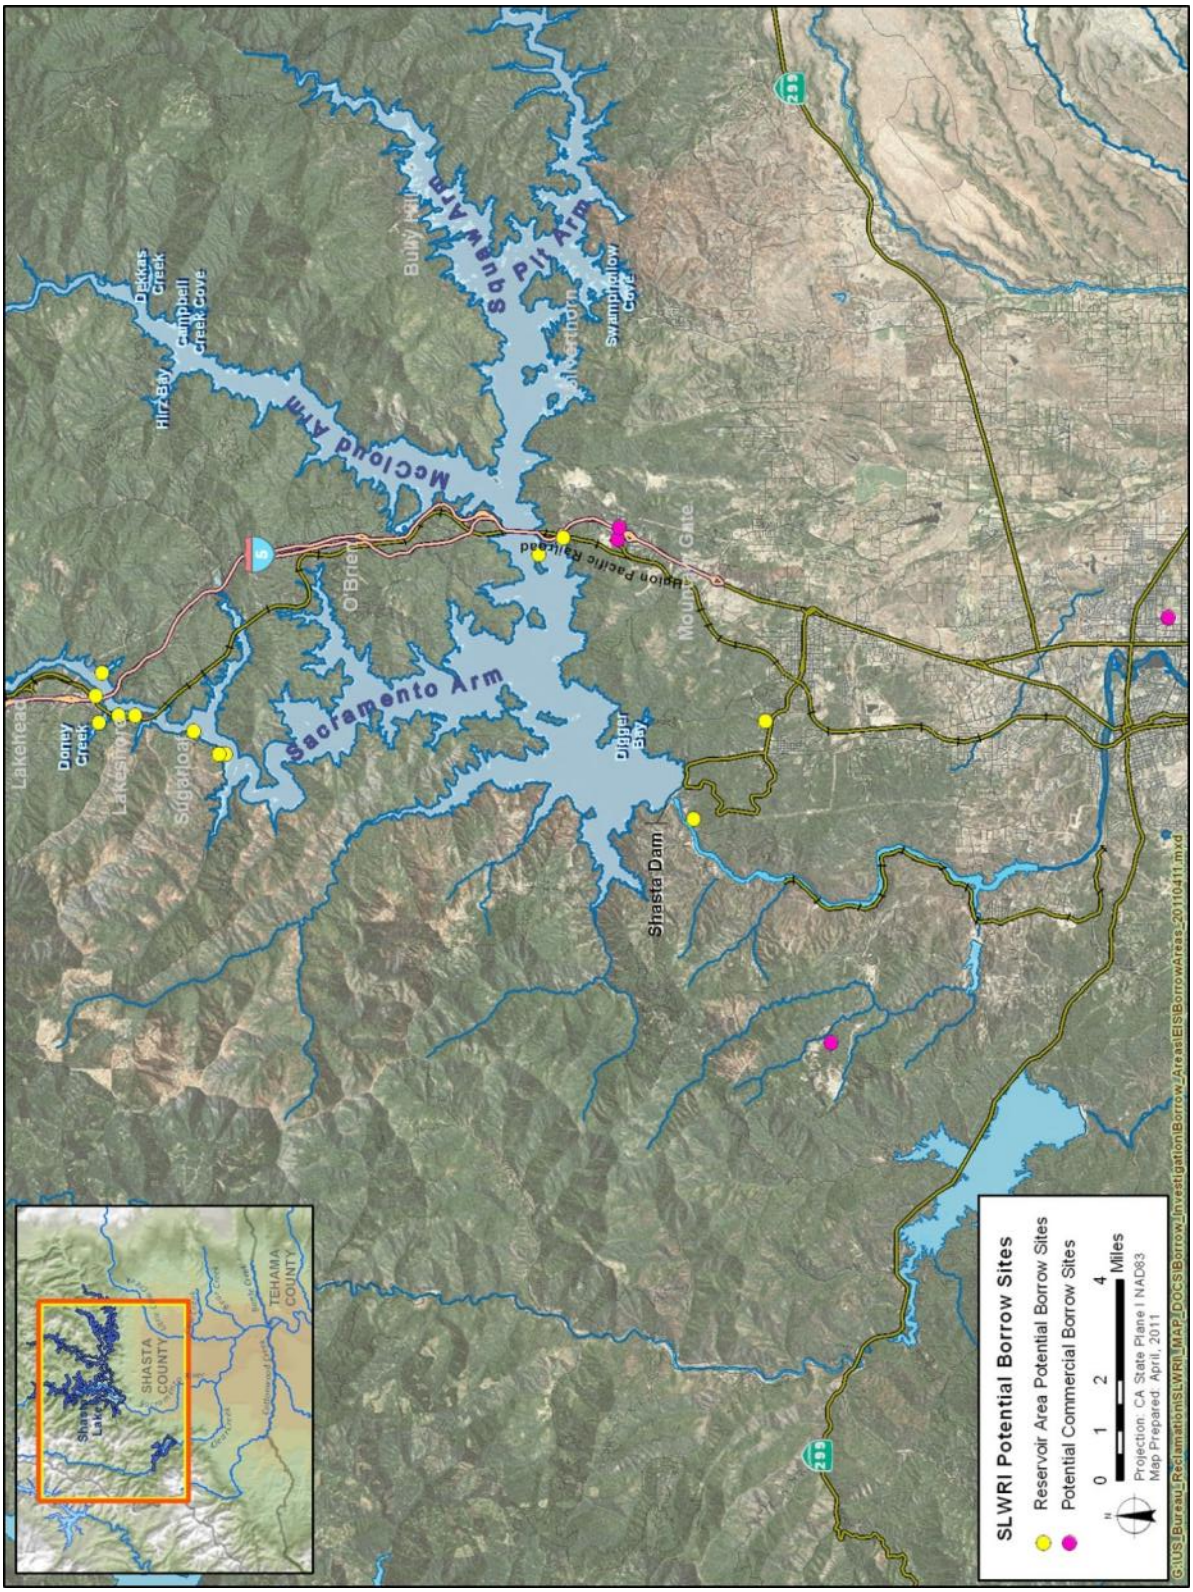

Figure 2-5. Potential Borrow Sources

2.4.4 Environmental Commitments Common to All Action Alternatives

As part of project planning and environmental assessment, Reclamation and/or its contractors would incorporate certain environmental commitments and best management practices (BMP) into the SLWRI action alternatives to avoid or minimize potential impacts. Reclamation will also coordinate planning, engineering, design and construction, operation, and maintenance phases of the project with applicable resource agencies.

The following environmental commitments would be incorporated into any action alternative for any project-related construction activities.

Develop and Implement Construction Management Plan

Reclamation would develop and implement a construction management plan to avoid or minimize potential impacts to public health and safety during project construction, to the extent feasible. The construction management plan would inform contractors and subcontractors of work hours, modes and locations of transportation and parking for construction workers; location of overhead and underground utilities; worker health and safety requirements; truck routes; stockpiling and staging procedures; public access routes; terms and conditions of all project permits and approvals; and emergency response services contact information.

The plan would also include construction notification procedures for the police, public works, and fire department in the cities and counties where construction occurs. Notices would also be distributed to neighboring property owners.

Comply with Permit Terms and Conditions

Reclamation would require its contractors and suppliers, its general contractor, and all of the general contractor's subcontractors and suppliers to comply with all of the terms and conditions of all project permits, approvals, and conditions attached thereto. Compliance with applicable laws, policies, and plans for this project is discussed in Section 26.6 of this PDEIS.

Develop and Implement Erosion and Sediment Control Plan

Reclamation would prepare and implement an erosion and sediment control plan to control short-term and long-term erosion and sedimentation effects, and to stabilize soils and vegetation in areas affected by construction activities. The plan would include all of the necessary local jurisdiction requirements regarding erosion control, and would implement BMPs for erosion and sediment control, as required. Types of BMPs may include, but would not be limited to, earth dikes and drainage swales, stream bank stabilization, and use of silt fencing, sediment basins, fiber rolls, and sandbag barriers.

Develop and Implement Stormwater Pollution Prevention Plan

This project is subject to construction-related stormwater permit requirements of the Federal Clean Water Act (CWA) National Pollutant Discharge

Elimination System program. Reclamation would obtain any required permits through the Central Valley Regional Water Quality Control Board before any ground-disturbing construction activity. According to the requirements of Section 402 of the CWA, Reclamation and/or its contractors would prepare and implement a SWPPP before construction that identifies BMPs to prevent or minimize the discharge of sediments and other contaminants with the potential to affect beneficial uses or lead to violations of water quality objectives of surface waters. The SWPPP would include development of site-specific structural and operational BMPs to prevent and control impacts on runoff quality, and measures to be implemented before each storm event. The SWPPP would contain a site map that shows the construction site perimeter, existing and proposed buildings, lots, roadways, stormwater collection and discharge points, general topography both before and after construction, and drainage patterns across the project. Additionally, the SWPPP must contain a visual monitoring program, a chemical monitoring program for "non-visible" pollutants to be implemented if a BMP fails, and a sediment monitoring plan if the site discharges directly to a water body listed on the CWA 303(d) list for sediment. BMPs for the project could include, but would not be limited to, silt fencing, straw bale barriers, fiber rolls, storm drain inlet protection, hydraulic mulch, and stabilized construction entrances.

Develop and Implement Feasible Spill Prevention and Hazardous Materials Management As part of the SWPPP, Reclamation and/or its contractors would develop and implement a spill prevention and control plan to minimize effects from spills of hazardous, toxic, or petroleum substances for project-related construction activities occurring in or near waterways. The accidental release of chemicals, fuels, lubricants, and nonstorm drainage water into water bodies would be prevented to the extent feasible. Spill prevention kits would always be in close proximity when hazardous materials would be used (e.g., crew trucks and other logical locations). Feasible measures would be implemented so that hazardous materials would be properly handled and the quality of aquatic resources would be protected by all reasonable means during work in or near any waterway. No fueling would be done within the ordinary high-water mark, immediate floodplain, or full pool inundation area, unless equipment stationed in these locations could not be readily relocated. Any equipment that could be readily moved out of the water body would not be fueled in the water body or immediate floodplain. As for stationary equipment, for all fueling done at the construction site, containments would be installed so that any spill would not enter the water, contaminate sediments that may come in contact with the water, or damage wetland or riparian vegetation. Any equipment that could be readily moved out of the water body would not be serviced within the ordinary high-water mark or immediate floodplain.

Additional BMPs designed to avoid spills from construction equipment and subsequent contamination of waterways would also be implemented. These may include, but would not be limited to, the following:

- Storage of hazardous materials in double-containment and, if possible, under a roof or other enclosure.

- Disposal of all hazardous and nonhazardous products in a proper manner.

- Monitoring of on-site vehicles for fluid leaks and regular maintenance to reduce the chance of leakage.

- Containment (using a prefabricated temporary containment mat, a temporary earthen berm, or other measure can provide containment) of bulk storage tanks.

Fisheries Conservation

The measures discussed below would be implemented to minimize potential adverse effects to fish species.

Implement In-Water Construction Work Windows Reclamation would identify and implement feasible in-water construction work windows in consultation with NMFS, USFWS, and California Department of Fish and Game (DFG). In-water work windows would be timed to occur when sensitive fish species were not present or would be least susceptible to disturbance (e.g., July through September).

Monitor Construction Activities A qualified biologist would monitor potential impacts to important fishery resources throughout all phases of project construction. Monitoring may not be necessary during the entire duration of the project if, based on the monitor's professional judgment (and with concurrence from Reclamation), a designated on-site contractor would suffice to monitor such activities and would agree to notify a biologist if aquatic organisms are in danger of harm. However, the qualified biologist must be available by phone and Internet and be able to respond promptly to any problems that arise.

Perform Fish Rescue/Salvage If spawning activities for sensitive fish species were encountered during construction activities, the biologist would be authorized to stop construction activities until appropriate corrective measures were completed or it was determined that the fish would not be harmed.

A qualified biologist would identify any fish species that may be impacted by the project. The biologist would facilitate rescue and salvage of fish and other aquatic organisms that become entrapped within construction structures and cofferdam enclosures in the construction area. Any rescue, salvage, and handling of listed species would be conducted under appropriate authorization (i.e., incidental take statement/permit for the project, Federal Endangered Species Act section 4(d) scientific collection take permit, or a Memorandum of Understanding). If fish are identified as threatened with entrapment in construction structures, construction would be stopped and efforts made to

allow fish to leave the project area before resuming work. If fish are unable to leave the project area of their own volition, then fish would be collected and released outside the work area. Fish entrapped in cofferdam enclosures would be rescued and salvaged before the cofferdam area was completely dewatered. Appropriately sized fish screens would be installed on the suction side of any pumps used to dewater in-water enclosures.

Reporting A qualified biologist would prepare a letter report detailing the methodologies used and the findings of fish monitoring and rescue efforts. Monitoring logs would be maintained and provided, with monitoring reports. The reports would contain, but not be limited to, the following: summary of activities; methodology for fish capture and release; table with dates, numbers, and species captured and released; photographs of the enclosure structure and project site conditions affecting fish; and recommendations for limiting impacts during subsequent construction phases, if appropriate.

Water Quality Protection

The measures discussed below would be implemented to minimize potential adverse effects to water quality.

Implement In-Water Construction Work Windows All construction activities along the Sacramento River would be conducted during months when instream flows are managed outside the flood season (e.g., June 15 to September 15).

Comply with All Permits and Regulations Project activities would be conducted to comply with all additional requirements specified in permits relating to water quality protection. Relevant permits anticipated to be obtained for the proposed action include a California Fish and Game Code 1602 Lake and Streambed Alteration Agreement, Regional Water Quality Control Board Section 401 certification or waiver, and CWA Section 404 compliance through the U.S. Army Corps of Engineers (USACE).

Implement Water Quality Best Management Practices BMPs that would be implemented to avoid and/or minimize potential impacts associated with dam construction and the 10-year-long spawning gravel augmentation program are described below.

Handle Spawning Gravel to Minimize Potential Water Quality Impacts Gravel would be sorted and transported in a manner that minimizes potential water quality impacts (e.g., management of fine sediments, etc.). Gravel would be washed at least once and have a cleanliness value of 85 or higher based on CalTrans Test No. 227. Gravel would also be completely free of oils, clay, debris, and organic material.

Minimize Potential Impacts Associated with Equipment Contaminants For in-river work, all equipment would be steam-cleaned every day to remove hazardous materials before the equipment entered the water.

Minimize Potential Impacts Associated with Access and Staging Existing access roads would be used to the extent possible. Equipment staging areas would be located outside of the Sacramento River ordinary high water mark or the Shasta Dam full pool inundation area, and away from sensitive resources.

Remove Temporary Fills as Appropriate Temporary fill for access, side channel diversions, and/or side channel cofferdams, would be completely removed after completion of construction.

Remove Equipment from River Overnight and During High Flows Construction contractors would remove all equipment from the river on a daily basis at the end of the workday. Construction contractors would also monitor Reclamation's Central Valley Operations Office Web site daily for forecasted flows posted there to determine and anticipate any potential changes in releases. If flows are anticipated to inundate a work area that would normally be dry, the contractor would immediately remove all equipment from the work area.

Revegetation Plan

Reclamation, in conjunction with cooperating agencies and private landowners, would prepare a comprehensive revegetation plan to be implemented in conjunction with other management plans (e.g., erosion and sediment control plan). This plan would apply to any area included as part of an action alternative, such as inundation, relocation, or mitigation activities. Overall objectives of the plan would be to reestablish native vegetation to control erosion; provide effective ground cover; minimize opportunities for nonnative plant species to establish or expand; and provide habitat diversity over time. Reclamation would work closely with cooperating agencies, private landowners, and revegetation specialists to develop the site-specific planting patterns and species assemblages necessary for a revegetation effort of this magnitude.

Invasive Species Management

Reclamation would develop and implement a control plan to prevent the introduction of zebra/quagga mussels and other invasive species to project areas. The control plan would cover all workers, vehicles, watercraft, and equipment (both land and aquatic) that would come into contact with Shasta Lake, the shoreline of Shasta Lake, the Sacramento River, and any riverbanks, floodplains, or riparian areas. Plan activities may include, but would not be limited to, the following:

- Preinspection and cleaning of all construction vehicles, watercraft, and equipment before being shipped to project areas, and postinspections.

- Reinspection of all construction vehicles, watercraft, and equipment on arrival at project areas

- Inspection and cleaning of all personnel before work in project areas

All inspections would be conducted by trained personnel and would include both visual and hands-on inspection methods of all vehicle and equipment surfaces, up to and including internal surfaces that have contacted raw water.

Approved cleaning methods would include a combination of the following:

- Precleaning: draining, brushing, vacuuming, high-pressure water treatment, thermal treatment

- Cleaning: freezing, desiccation, thermal treatment, high-pressure water treatment, chemical treatment

On-site cleanings would require capture, treatment, and/or disposal of any and all water needed to conduct cleaning activities.

Construction Material Disposal

Reclamation's contractors would take measures to recycle or reuse demolished materials, such as steel or copper wire, where practical.

Asphalt Removal

Per California Fish and Game Code 5650 Section (a), all asphaltic roadways and parking lots inundated by the proposed action would be demolished and removed according to Shasta County standards. Asphalt would be disposed of at an approved and permitted waste facility. Dirt roads inundated by the proposed action would remain in place.

2.4.5 Comprehensive Plan 1 (CP1) – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 consists of enlarging Shasta Dam by raising the crest 6.5 feet and enlarging the reservoir by 256,000 acre-feet.

Major Components of CP1

CP1 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 6.5 feet.

- Implementing the set of eight common management measures described above.

By raising Shasta Dam 6.5 feet from a crest at elevation 1,077.5 to elevation 1,084.0, CP1 would increase the height of the reservoir full pool by 8.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications, including replacing the three

drum gates with six sloping, fixed-wheel gates. This increase in full pool height would add approximately 256,000 acre-feet of additional storage to the overall reservoir capacity. Accordingly, the overall full pool storage would increase from 4.55 MAF to 4.81 MAF. Table 2-8 summarizes major physical features associated with CP1.

Under CP1, operations for water supply, hydropower, and environmental requirements would be similar to existing operations, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. As mentioned, this alternative (and all comprehensive plans) includes extending the existing TCD for efficient use of the expanded cold-water pool.

CP1 would also include the potential to revise the operational rules for flood control for Shasta Dam and Reservoir, which could reduce the potential for flood damage, and benefit recreation. Reservoir reoperation would likely include increasing the bottom of the flood control pool elevation based on increased dam height and reservoir capacity. Because of reservoir geometry, this would decrease the depth of the flood control pool, allowing higher winter and spring water levels. Increased reservoir capacity could have further flood damage reduction benefits in years when water levels are below the new flood control pool elevation.

There is also limited potential for changes in flood control rules to allow more operational flexibility in reservoir drawdown requirements in response to storms, resulting in a net increase in the rate of spring reservoir filling during some years. Higher spring water levels and associated increases in reservoir surface area would benefit recreation.

Potential Benefits of CP1

Major potential benefits of CP1, related to contributions to the SLWRI objectives and broad public services, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors in achieving recovery goals for anadromous fish in the Sacramento River. CP1 would increase the ability of Shasta Dam to make cold-water releases and regulate water temperatures for fish in the upper Sacramento River, primarily in dry and critically dry water years. This would be accomplished by raising Shasta Dam 6.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBDD. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBDD. It is estimated that under CP1, improved water temperature conditions could result in an average annual increase in the salmon population of about 366,000 out-migrating juvenile Chinook salmon.

Increase Water Supply Reliability CP1 would increase water supply reliability by increasing firm water supplies for irrigation and M&I deliveries primarily during drought periods. This action would contribute to replacement of supplies redirected to other purposes in the Central Valley Project Improvement Act (CVPIA), which would help reduce estimated future water shortages by increasing firm yield for agricultural and M&I deliveries by at least 76,400 acre-feet per year and average annual yield by about 46,400 acre-feet per year. For this PDEIS, firm yield is considered equivalent to the estimated increase in the reliability of supplies during dry and critically dry periods. The majority of increased firm yield (66,800 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continue to grow and available supplies continue to remain relatively static, more effectively using these supplies could reduce potential critical impacts to agricultural and urban areas resulting from water shortages. Under CP1, approximately $2.3 million would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in an increase in power generation of about 42 gigawatt-hours (GWh) per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities.

Maintain and Increase Recreation Opportunities CP1 includes features to at least maintain the existing recreation capacity at Shasta Lake. Although CP1 does not include specific features to further benefit recreation resources, a small benefit would likely occur to the water-oriented recreation experience at Shasta Lake due to the increase in lake surface area and modernization of recreation facilities. The maximum surface area of the lake would increase by about 1,110 acres (4 percent), from 29,600 acres to about 30,700 acres. There is also limited potential for reservoir reoperation to provide additional benefits to recreation by raising the bottom of the flood control pool elevation and allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other SLWRI Objectives CP1 could also provide benefits related to flood damage reduction, ecosystem restoration, and water quality. Enlarging Shasta Dam would provide for incidental increased reservoir capacity to capture flood flows, which could reduce flood damage along the upper Sacramento River. Improved fisheries conditions as a result of CP1, as described above, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. Furthermore, CP1 could potentially benefit ecosystem restoration through improved Delta water quality conditions by increasing Delta outflow during drought years and reducing salinity during critical periods. CP1 may also contribute to improving Delta water quality through increased Delta emergency response capabilities. When Delta emergencies occur, additional water in Shasta Reservoir could improve operational flexibility for increasing releases to supplement existing water sources to reestablish Delta water quality. In addition to Delta emergency response, increased storage in Shasta Reservoir could increase emergency response capability for CVP/SWP water supply deliveries.

Construction for CP1

Construction activities for CP1 are described in Section 2.4.2, “Construction Activities Common to All Action Alternatives.” Information specific to CP1 construction activities is summarized in Tables 2-9 through 2-15.

Operations and Maintenance for CP1

Shasta Dam is operated in conjunction with other CVP facilities to manage floodwater, storage of surplus winter runoff for irrigation in the Sacramento and San Joaquin valleys, M&I use, maintenance of navigation flows, protection and conservation of fish in the Sacramento River and Delta, and generation of hydroelectric energy. Storage in Shasta Reservoir fluctuates greatly throughout the year; storage is typically highest at the end of winter, in April and May, as the need for flood control reservation space in the reservoir decreases. Storage is typically at its lowest in September and October, after the irrigation season and before winter refill begins. Shasta Reservoir capacity is currently 4,552 TAF, with a maximum objective release capacity of 79,000 cfs. The end-of-September storage target for Shasta Reservoir is 1,900 TAF, except in the driest 10 percent of water years, to conserve sufficient cold water for meeting temperature criteria for the winter-run Chinook incubation period (summer to early fall). Storage levels are lowest by October to provide sufficient flood risk reduction and capture capacity during the following wet months. The storage target gradually increases from October to full pool in May; storage is then withdrawn for high water demand (agricultural, M&I, fishery, and water quality uses, etc.) during summer.

A series of rules and regulations in the form of flow requirements, water quality requirements, water supply commitments, and flood control requirements governs operations at Shasta Reservoir. Federal and State laws, regulations, standards, and plans regulating Shasta Dam operations are described in detail in Chapter 6, "Hydrology, Hydraulics, and Water Management," and include the following:

- NMFS 2004 Operations Criteria and Plan Biological Opinion (NMFS 2004)
- CVPIA (Reclamation 1999)
- CVP long-term water service contracts (see *Hydrology, Hydraulics, and Water Management Technical Report*, Table 1-25)
- Trinity River ROD (Reclamation 2000)
- Flow objective for navigation at Wilkins Slough (Reclamation 2004)
- Flood management requirements in accordance with the Water Control Manual (USACE 1997)
- SWRCB Orders 90-05 and 91-01
- 1960 DFG Reclamation Memorandum of Agreement (DFG 1960)

- Water Quality Control Plan for the San Francisco Bay/San Joaquin Delta Estuary (SWRCB 1995)

- SWRCB Water Right Revised Decision 1641 (SWRCB 2000)

- Coordinated Operations Agreement (Reclamation and DWR 1986)

Under CP1, Shasta Dam operational guidelines would continue unchanged, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. For CP1, existing water quality and temperature requirements would typically be met in most years; therefore, additional water in storage would be released for water supply purposes. Accordingly, minimal increases in flow would be expected in months when Delta exports were constrained, or when flow was not required for water supply purposes.

At a base level, CP1 would store some additional flows behind Shasta Dam during periods when downstream needs would have already been met, but flows would have been released because of storage limitations. The resulting increase in storage would be released downstream when there were opportunities for beneficial use of the water, either to meet water supply reliability demands or to improve Reclamation's abilities to meet its environmental objectives. The additional water in storage would also expand the cold-water pool, thus benefiting fisheries. Conversely, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Releases from Shasta Dam under CP1 would typically increase in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage space could be used to capture additional runoff rather than releasing water to the downstream river, as would occur under Shasta Reservoir's current operations.

Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

2.4.6 Comprehensive Plan 2 (CP2) – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP2 consists primarily of enlarging Shasta Dam by raising the crest 12.5 feet and enlarging the reservoir by 443,000 acre-feet.

Major Components of CP2

CP2 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 12.5 feet.

- Implementing the set of eight common management measures previously described.

A dam raise of 12.5 feet was chosen because it represents a midpoint between the likely smallest dam raise considered and the largest practical dam raise that would not require relocating the Pit River Bridge. By raising Shasta Dam from a crest at elevation 1,077.5 to elevation 1,090.0, CP2 would increase the height of the reservoir's full pool by 14.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications similar to CP1. This increase in full pool height would add approximately 443,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would increase from 4.55 MAF to 5.0 MAF. Table 2-8 summarizes physical features that would be associated with the CP2 dam raise.

Under CP2, operations for water supply, hydropower, and environmental requirements would be similar to existing operations, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. The existing TCD would be extended for efficient use of the expanded cold-water pool.

As described for CP1, this alternative would also include the potential to revise flood control operational rules, which could reduce the potential for flood damage and benefit recreation.

Potential Benefits of CP2

Major potential benefits of CP2, related to contributions to the SLWRI objectives, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors in achieving recovery goals for anadromous fish in the Sacramento River. CP2 would increase the ability of Shasta Dam to make cold-water releases and regulate water temperatures for fish in the upper Sacramento River, primarily in dry and critically dry water years. This would be accomplished by raising Shasta Dam 12.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBDD. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBDD. It is estimated that improved water temperature conditions under CP2 could result in an average annual increase in the salmon population of about 234,000 out-migrating juvenile Chinook salmon.

Increase Water Supply Reliability CP2 would increase water supply reliability by increasing firm water supplies for irrigation and M&I deliveries

primarily during drought periods. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA, which would help reduce estimated future water shortages by increasing the reliability of firm water supplies for agricultural and M&I deliveries by at least 105,100 acre-feet per year and average annual yield by about 62,800 acre-feet per year. For this PDEIS, firm yield is considered equivalent to the estimated increase in the reliability of supplies during dry and critically dry periods. The majority of increased firm yield (85,300 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continue to grow and available supplies continue to remain relatively static, more effectively using these supplies could reduce potential critical impacts to agricultural and urban areas resulting from water shortages. Under CP2, approximately $3.1 million would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in a net increase in power generation of about 68 GWh per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities.

Maintain and Improve Recreation Opportunities CP2 includes features to, at minimum, maintain the existing recreation capacity at Shasta Lake. Although CP2 does not have specific features to further benefit recreation resources, a small benefit would likely occur to the water-oriented recreation experience at Shasta Lake due to the increase in lake surface area and modernization of recreation facilities. The maximum surface area of the lake would increase by about 1,750 acres (6 percent), from 29,600 acres to about 31,300 acres. There is also limited potential for reservoir reoperation to provide additional benefits to recreation by raising the bottom of the flood control pool elevation and allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other SLWRI Objectives CP2 could also provide benefits related to flood damage reduction, ecosystem restoration, and water quality, as described for CP1, but to a greater extent because of increased capacity and associated overall system flexibility.

Construction for CP2

Construction activities for CP2 are described in Section 2.4.2, “Construction Activities Common to All Action Alternatives.” Information specific to CP2 construction activities is summarized in Tables 2-16 through 2-22.

Operations and Maintenance for CP2

Operations under CP2 are governed by the same regulatory constraints as described for CP1. Similar to CP1, under CP2, Shasta Dam operational guidelines would continue unchanged, with the additional storage retained for water supply reliability and to create an expanded cold-water pool for fisheries. For CP2, existing water quality and temperature requirements would typically be met in most years; therefore, additional water in storage would be released for water supply purposes. Accordingly, minimal increases in flow would be expected in months when Delta exports were constrained, or when flow was not usable for water supply purposes.

At a base level, CP2 would store some additional flows behind Shasta Dam during periods when downstream needs would have already been met, but flows would have been released because of storage limitations. The resulting increase in storage would be released downstream when there were opportunities for beneficial use of the water, either to meet water supply reliability demands or to improve Reclamation's abilities to meet its environmental objectives. The additional water in storage would also expand the cold-water pool, thus benefiting fisheries. Conversely, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Releases from Shasta Dam under CP2 would typically increase in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage space could be used to capture additional runoff rather than releasing water to the downstream river, as would occur with Shasta Reservoir's current operations.

Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

2.4.7 Comprehensive Plan (CP3) – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP3 consists primarily of enlarging Shasta Dam by raising the dam crest 18.5 feet and enlarging the reservoir by 634,000 acre-feet.

Major Components of CP3

CP3 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 18.5 feet.
- Implementing the set of eight common management measures previously described.

By raising Shasta Dam 18.5 feet, from a crest at elevation 1,077.5 to elevation 1,096.0, CP3 would increase the height of the reservoir full pool by 20.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise

height would result from spillway modifications similar to CP1. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would increase from 4.55 MAF to 5.19 MAF. Although higher dam raises are technically and physically feasible, 18.5 feet is the largest dam raise that would not require extensive and costly reservoir area relocations, such as relocating the Pit River Bridge, I-5, and the Union Pacific Railroad tracks. Table 2-8 summarizes major components that would be associated with the CP3 dam raise.

Under CP3, operations for water supply, hydropower, and environmental requirements would be similar to existing operations, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. The existing TCD would be extended for efficient use of the expanded cold-water pool.

As described for the above alternatives, this alternative would also include the potential to revise flood control operational rules, which could reduce the potential for flood damage and benefit recreation.

Potential Benefits of CP3

Major potential benefits of CP3, related to contributions to the SLWRI objectives, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors in achieving recovery goals for anadromous fish in the Sacramento River. CP3 would increase the ability of Shasta Dam to make cold-water releases and regulate water temperatures for fish in the upper Sacramento River, primarily in dry and critically water dry years. This would be accomplished by raising Shasta Dam 18.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBDD. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBDD. It is estimated that improved water temperature conditions under CP3 could result in an average annual increase in the Chinook salmon population of about 607,000 out-migrating juvenile fish.

Increase Water Supply Reliability CP3 would increase water supply reliability by increasing firm water supplies for irrigation and M&I deliveries primarily during drought periods. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA, which would help reduce estimated future water shortages by increasing the reliability of firm water supplies for agricultural and M&I deliveries by at least 133,400 acre-feet per year and average annual yield by about 75,800 acre-feet per year. For this PDEIS, firm yield is considered equivalent to the estimated increase in the

reliability of supplies during dry and critically dry periods. The majority of increased firm yield (103,800 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continue to grow and available supplies continue to remain relatively static, more effectively using these supplies could reduce potential critical impacts to agricultural and urban areas resulting from water shortages. Under CP3, approximately $3.8 million would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in a net increase in power generation of about 96 GWh per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities.

Maintain and Increase Recreation Opportunities CP3 includes features to, at a minimum, maintain the existing recreation capacity at Shasta Lake. Although CP3 does not include specific features to further benefit recreation resources, a small benefit would likely occur to the water-oriented recreation experience at Shasta Lake due to the increase in lake surface area and modernization of recreation facilities. The maximum surface area of the lake would increase by about 2,500 acres (8 percent), from 29,600 acres to about 32,100 acres. There is also limited potential for reservoir reoperation to provide additional benefits to recreation by raising the bottom of the flood control pool elevation and allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other SLWRI Planning Objectives CP3 could also provide benefits related to flood damage reduction, ecosystem restoration, and water quality, as described for CP1, but to a greater extent because of increased capacity and associated overall system flexibility.

Construction for CP3

Construction activities for CP3 are described in Section 2.4.2, “Construction Activities Common to All Action Alternatives.” Information specific to CP3 construction activities is summarized in Tables 2-23 through 2-29.

Operations and Maintenance for CP3

Operations under CP3 are governed by the same regulatory constraints as described for CP1. Similar to CP1, under CP3, Shasta Dam operational guidelines would continue unchanged, with the additional storage retained for water supply reliability and to create an expanded cold-water pool for fisheries. For CP3, existing water quality and temperature requirements would be met in most years; therefore, additional water in storage would be released for water supply purposes. Accordingly, minimal increases in flow would be expected in months when Delta exports were constrained, or when flow was not usable for water supply purposes.

At a base level, CP3 would store some additional flows behind Shasta Dam during periods when downstream needs would have already been met, but flows would have been released because of storage limitations. The resulting increase in storage would be released downstream when there were opportunities for beneficial use of the water, either to meet water supply reliability demands or to improve Reclamation's abilities to meet its environmental objectives. The additional water in storage would also expand the cold-water pool, thus benefiting fisheries. Conversely, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Releases from Shasta Dam under CP3 would typically increase in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage space could be used to capture additional runoff rather than releasing water to the downstream river, as would occur with Shasta Reservoir's current operations.

Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

2.4.8 Comprehensive Plan 4 (CP4) – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 focuses on increasing anadromous fish survival by raising Shasta Dam 18.5 feet while also increasing water supply reliability.

Major Components of CP4

CP4 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 18.5 feet.
- Reserving 378,000 acre-feet of the increased storage in Shasta Lake for maintaining cold-water volume or augmenting flows as part of an adaptive management plan for anadromous fish survival.
- Augmenting spawning gravel in the upper Sacramento River.

- Restoring riparian, floodplain, and side channel habitat.

- Implementing the set of eight common management measures previously described.

By raising Shasta Dam 18.5 feet, from a crest at elevation 1,077.5 to elevation 1,096.0, CP4 would increase the height of the reservoir full pool by 20.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications similar to CP1. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would be increased from 4.55 MAF to 5.19 MAF.

The additional storage created by the 18.5-foot dam raise would be used to both improve the ability to meet temperature objectives for winter-run Chinook salmon and to meet habitat requirements for other anadromous fish during drought years and increase water supply reliability. Of the increased reservoir storage space, about 378,000 acre-feet would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Table 2-8 summarizes major components that would be associated with the CP4 dam raise.

Operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as in CP1. The existing TCD would be extended to achieve efficient use of the expanded cold-water pool.

As described for the above alternatives, this alternative also would include the potential to revise the operational rules for flood control for Shasta Dam and Reservoir, which could reduce the potential for flood damage and benefit recreation.

CP4 also includes an adaptive management plan for the cold-water pool, and augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat in the upper Sacramento River.

Adaptive Management of Cold-Water Pool The adaptive management plan may include operational changes to the timing and magnitude of releases from Shasta Dam to benefit anadromous fish, as long as there are no conflicts with current operational guidelines or adverse impacts to water supply reliability. Further discussion regarding adaptive management of the cold-water pool for anadromous fish is included below under "Operations and Maintenance."

Augment Spawning Gravel in Upper Sacramento River Gravel suitable for spawning has been identified as a significant influencing factor in the recovery of anadromous fish populations in the Sacramento River (USFWS 2001, NMFS 2009). Under CP4, spawning-sized gravel would be placed at multiple locations along the Sacramento River between Keswick Dam and the RBDD.

Gravel augmentation would occur at one to three locations every year, for a period of 10 years, unless unusual conditions or agency requests precluded placement during a single year. This program, in combination with the ongoing CVPIA gravel augmentation program, would help address the gravel debt in the upper Sacramento River, but this reach may continue to be gravel-starved into the future. Therefore, the gravel augmentation program proposed herein would be reevaluated after the 10-year period to assess the need for continued spawning gravel augmentation, and to identify opportunities for future actions or programs to do so.

On average, 5,000 to 10,000 tons of gravel would be placed each year, although the specific quantity of gravel placed in a given year may vary from that range. Gravel would be obtained as uncrushed, rounded river rock, free of debris and organic material, from local, commercial sources. To maximize the benefit to anadromous fish, gravel would be washed and sorted to meet specific size criteria. To minimize impacts to salmonid spawning activity, gravel applied to active river channels would be placed between August and September each year, consistent with the time frame for the ongoing CVPIA gravel augmentation program.

Fifteen preliminary locations for spawning gravel augmentation were identified in the Sacramento River between Keswick Dam and Shea Island. Each site would be eligible for gravel placement one or more times during the 10-year program. Selection of these locations was based on potential benefits to anadromous fish and site accessibility. Gravel placement would provide either immediate spawning habitat or long-term recruitment.

Although preliminary sites have been identified, specific gravel augmentation site(s) and volume(s) would be selected each year in the spring or early summer through discussions among Reclamation, USFWS, DFG, and NMFS. The discussions would include topics such as avoiding redundancy with planned CVPIA gravel augmentation activities in a given year; identifying hydrology or morphology issues that could impact the potential benefit of placing gravel at any particular site; identifying changes in spawning trends due to previous years' gravel augmentation activities; evaluating potential new sites; and appropriately distributing selected gravel sites along the river reach(es).

Restore Riparian, Floodplain, and Side Channel Habitat Under CP4, riparian, floodplain, and side channel habitat restoration would be constructed at a suitable location along the Sacramento River. The exact size, scope, and location of a suitable restoration site is still under development and will be provided future versions of this EIS (Draft EIS and/or FEIS). A description potential of riparian, floodplain, and side channel habitat restoration at Reading Island is provided below as an example restoration project. Restoration activities anticipated under CP4 are expected to be similar in size and scope to those described below.

Reading Island lies along the Sacramento River just north of Cottonwood Creek in Shasta County at River Mile 274. Reading Island is approximately 269 acres in area, with 46 acres on the south end of the island owned by U.S. Bureau of Land Management and managed as a day-use park (Figure 2-6). The remaining 223 acres are privately owned. The island is accessible by Adobe Road and a bridge crossing over the Anderson Creek Slough into the U.S. Bureau of Land Management day-use park. Historically, the channel that now forms the slough supported important habitat for anadromous salmonids, including rearing habitat for winter-run Chinook and spawning habitat for Central Valley steelhead.

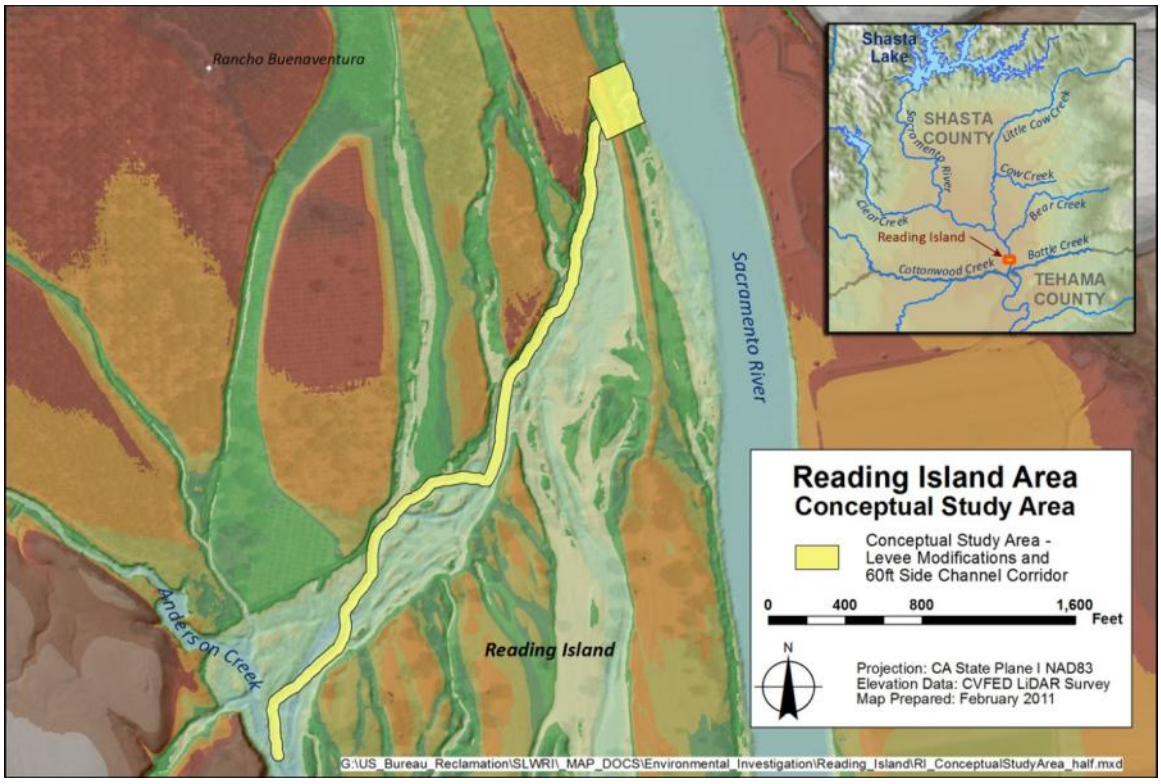

Figure 2-6. Reading Island Conceptual Study Area

At the Reading Island site, an approximately 0.8-mile-long historic Sacramento River channel/floodplain scour channel/side channel (hereafter referred to as "side channel") drains into the present-day Anderson Creek, a remnant Sacramento River side channel. Anderson Creek flows approximately 1.5 miles and then enters the Sacramento River about 0.3 miles upstream from Cottonwood Creek. Average channel width of the side channel is approximately 30 feet.

The Anderson Creek Slough, into which Anderson Creek empties, was blocked at the upstream end in the early 1970s by construction of a levee on the adjoining private property. A few years after construction of the levee, the slough became choked with various species of water plants, primarily primrose

creeper (*Ludwigia peploides).* Before levee construction, the Anderson Creek Slough captured a portion of the Sacramento River flow and functioned as side channel habitat.

After levee construction, water velocity in the side channel slowed substantially and water temperatures increased. Primrose creeper and warm-water nonnative fish species established within the channel. Currently, most of the water entering the slough comes from Anderson Creek and drainage wastewater from irrigation canals. An earthen embankment with two 36-inch-diameter culverts now restricts the flow of water into the side channel. The water surface elevation of the Sacramento River, with a flow rate of 8,500 cfs, is at the approximate elevation of the invert of the culverts, but even when discharge in the Sacramento River increases to approximately 12,000 cfs, there is minimal flow through the culverts into the side channel. Above the slough, Anderson Creek is known to provide rearing habitat for winter-run Chinook, and is managed for steelhead spawning habitat.

Floodplain, riparian, and side channel habitat restoration would involve acquiring property on Reading Island and revegetating floodplain terraces and adjacent riparian areas with native plants. In addition, the Reading Island side channel could be activated over a wider range of flows to provide juvenile salmonid rearing habitat in the side channel, and in Anderson Creek at the downstream end of the side channel. This would be accomplished by breaching the levee at the upstream end of the side channel to restore connectivity with the Sacramento River at flows greater than 4,000 to 6,000 cfs. Preliminary analysis indicates that in addition to breaching the levee, side channel clearing and excavation may be necessary to restore flows capable of supporting suitable spawning habitat. This would include vegetation and debris removal and deepening of the existing channel. At a maximum, side channel clearing and excavation would be performed along the entire 0.8-mile channel, requiring the removal of about 15,560 cubic yards of material.

Planting mix, composition, and density would be determined by a more detailed site analysis, but could include native cottonwood, willow, box elder, valley oak, western sycamore, elderberry, and a variety of understory brush species. Temporary irrigation would be provided on an as-needed basis with a temporary well powered from an existing nearby power supply. The revegetated areas are expected to develop into self-sustaining riparian habitats within 1 to 4 years of initial planting, based on results of previous riparian restoration projects along the Sacramento River. Regraded floodplain areas are expected to change over time depending on hydrologic conditions, but it is anticipated that no elements of this measure would need to be replaced or reapplied during the 50-year project life. The site would be fenced to reduce the potential for access by livestock.

Potential Benefits of CP4

Major potential benefits of CP4, related to the SLWRI objectives, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors in achieving recovery goals for anadromous fish in the Sacramento River. CP4 would significantly increase the ability of Shasta Dam to make cold-water releases and regulate water temperature in the upper Sacramento River, primarily in dry and critically dry water years. This would be accomplished by raising Shasta Dam 18.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBDD. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBDD. It is estimated that improved water temperature conditions under CP4 could result in an average annual increase in Chinook salmon population of nearly 1,199,000 out-migrating juvenile fish.

Under CP4, an increase in the cold-water pool would allow Reclamation to operate Shasta Reservoir to provide not only a more reliable source of water during dry and critical water years, but also to provide more cool water for release into the Sacramento River to improve conditions for anadromous fish. Of the increased storage space, about 378,000 acre-feet (60 percent) would be dedicated to increasing the cold-water supply for anadromous fish survival purposes.

In addition, CP4 includes a gravel augmentation program. Gravel augmentation would occur on average at one or more locations in the Sacramento River between Keswick Dam and the RBDD for a period of 10 years and, on average, 5,000 to 10,000 tons of gravel would be placed each year, although the specific quantity of gravel placed in a given year may vary from that range. Spawning gravel augmentation is expected to positively influence anadromous fish populations in the Sacramento River.

Increase Water Supply Reliability CP4 would increase water supply reliability by increasing firm water supplies for irrigation and M&I deliveries primarily during drought periods. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA, which would help reduce estimated future water shortages by increasing the reliability of firm water supplies for agricultural and M&I deliveries by at least 76,400 acre-feet per year and average annual yield by about 46,400 acre-feet per year. For this PDEIS, firm yield is considered equivalent to the estimated increase in the reliability of supplies during dry and critically dry periods. The majority of increased firm yield (66,800 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, water use efficiency could help reduce current and future

water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continue to grow and available supplies continue to remain relatively static, more effectively using these supplies could reduce potential critical impacts to agricultural and urban areas resulting from water shortages. Under CP4 approximately $2.3 million would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in a net increase in power generation of about 138 GWh per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities.

Conserve, Restore, and Enhance Ecosystem Resources In the upper Sacramento River, the addition of spawning gravel and the restoration of riparian, floodplain, and side channel habitat are expected to improve the complexity of aquatic habitat and its suitability for spawning and rearing. Riparian areas provide habitat for a diverse array of plant and animal communities along the Sacramento River, including numerous threatened or endangered species. Riparian areas also provide shade and woody debris that increase the complexity of aquatic habitat and its suitability for spawning and rearing. Lower floodplain areas, river terraces, and gravel bars play an important role in the health and succession of riparian habitat. Restoration would support the goals of the Sacramento River Conservation Area Forum and other programs associated with riparian restoration along the Sacramento River. In addition, improved fisheries conditions as a result of cold-water carryover storage in CP4, as described above, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. Side channels can support important habitat for anadromous salmonids, including rearing and spawning habitat. Side channel habitats also provide refuge from predators and productive foraging habitat for juvenile anadromous salmonids.

Maintain and Increase Recreation Opportunities CP4 includes features to, at a minimum, maintain the existing recreation capacity at Shasta Lake. Potential recreation benefits would be as stated for CP3. The maximum surface area of the lake would increase by about 2,500 acres (8 percent), from 29,600 acres to about 32,100 acres. There is also limited potential for reservoir reoperation to provide additional benefits to recreation by raising the bottom of the flood control pool elevation and allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other SLWRI Objectives CP4 could also provide benefits related to flood damage reduction and water quality, similar to CP1.

Construction for CP4

Construction activities related to enlarging the reservoir under CP4 are identical to those described for CP3, and are summarized in Tables 2-23 through 2-29. Additional construction effort would be required for the proposed spawning gravel augmentation, as described below.

Gravel augmentation would occur at one to three locations every year for a period of 10 years, unless unusual conditions or agency requests precluded placement during a single year. Construction activities would vary significantly by location, but generally would include clearing, grubbing, and some grading of new access routes to allow construction vehicles to access the river. At several sites, clearing and grubbing of the riverbank would be required to allow gravel to be placed on the bank for recruitment. Gravel would be delivered to the sites by dump trucks. In most cases, gravel would be stockpiled in a staging area and moved with bulldozers, loaders, and/or excavators. Dust control trucks would be present at all times when gravel is on site.

Several sites would require in-water construction work. Generally, this involves gravel being built out into the river channel "step-wise," meaning gravel is dumped and leveled, and the leveled area serves as a working platform for the next step of construction. This practice is common for spawning gravel placement, and minimizes the extent to which construction vehicles drive directly through an active river channel. One or two sites, however, would require construction activity in the active river channel, where construction vehicles would deposit gravel and grade a submerged riffle.

Riparian, Floodplain, and Side Channel Habitat Restoration Riparian, floodplain, and side channel habitat restoration at Reading Island would involve acquiring and revegetating floodplain terraces and adjacent riparian areas with native plants, and breaching the levee at the upstream end of the side channel. Planting mix, composition, and density would be determined by a more detailed site analysis, but could include native cottonwood, willow, box elder, valley oak, western sycamore, elderberry, and a variety of understory brush species.

Breaching the levee would include the use of an excavator, loader, and compaction equipment. For a 3:1 cut through the levee down to the invert elevations of the culvert, with a 60-foot-wide base, approximately 7,901 cubic yards of earthen material would be excavated. If side channel clearing and excavation are necessary, clearing would be performed along the 0.8-mile channel over a maximum average width of 30 feet plus an additional 10 feet for construction equipment access, covering a maximum area of 3.9 acres. Excavation would involve a maximum average width and depth of 20 and 5 feet, respectively, along the length of the channel for a maximum of 15,560 cubic yards of material removal. The transport of excavated material would likely be accomplished with loader and dump trucks. Excavated materials would be taken off site to commercially available, approved locations for safe storage, use, and/or disposal. A mechanical harvester would be used to remove

invasive aquatic vegetation from the side channel and Anderson Slough. In-water construction is expected to take place during periods of low flow in the Sacramento River (October to November) to minimize water quality impacts. Further construction methods, staging areas, and borrow sites would be identified by Reclamation and included in future versions of this document (Draft EIS or FEIS).

Operations and Maintenance for CP4

Operations under CP4 are governed by the same regulatory constraints as described for CP1. Similar to CP1, Shasta Dam operational guidelines would continue unchanged under CP4, with the additional storage retained for water supply reliability and to create an expanded cold-water pool for fisheries. Of the 634,000 acre-feet of additional storage, 378,000 acre-feet of water (60 percent) would be dedicated to increasing the cold-water supply for anadromous fish survival purposes. This would be in addition to any storage targets set by regulations described in Chapter 6, "Hydrology, Hydraulics, and Water Management."

As modeled, the 378,000 acre-feet of additional water would be the first increment of the reservoir filled after the reservoir was enlarged, and would be available as additional water for the cold-water pool each year regardless of water year type, unless Reclamation elected to use the additional water to augment flows protecting anadromous fish in the Sacramento River, as part of a proposed adaptive management plan, as explained below. An additional 256,000 acre-feet of the increased storage space would primarily be used to improve water supply reliability; operations of Shasta Dam related to the 256,000 acre-feet of storage would be identical to CP1.

As stated above, of the total 634,000 acre-feet of additional storage, 378,000 acre-feet of water would be used to increase the cold-water pool for fisheries. The additional 378,000 acre-feet of cold-water pool would be managed by Reclamation in coordination with the Sacramento River Temperature Task Group (SRTTG). Reclamation is currently working with NMFS, USFWS, and DFG through the SRTTG, which is a multiagency group established to adaptively manage flows and water temperatures in the Sacramento River to improve and stabilize Chinook salmon populations in the upper Sacramento River.

Current analysis indicates that the most beneficial use of the additional 378,000 acre-feet of storage for fisheries protection is as an expanded cold-water pool; however, Reclamation has agreed to adaptively manage the 378,000 acre-feet of water, as appropriate, to increase benefits to anadromous fish as part of CP4. Adaptive management is an approach allowing decision makers to take advantage of a variety of strategies and techniques that are adjusted, refined, and/or modified based on an improved understanding of system dynamics. Adaptive management, if applied appropriately, allows for flexible operations based on best available science and new information as it becomes available.

The adaptive management plan may include operational changes to the timing and magnitude of releases primarily to improve the quality and quantity of aquatic habitat. These changes may include increasing minimum flows, timing releases from Shasta Dam to mimic more natural seasonal flows, meeting flow targets for side channels, or retaining the additional 378,000 acre-feet of water in storage to meet temperature requirements. Reclamation would work cooperatively with the SRTTG to determine the best use of the cold-water pool each year under an adaptive management plan. Reclamation would manage the cold-water pool and operate Shasta Dam each year based on recommendations from the SRTTG. Because adaptive management is predicated on using best available science and new information to make decisions, a monitoring program would be implemented as part of the adaptive management plan. SRTTG would conduct monitoring, develop monitoring protocols, and set performance standards to determine the success of adaptive management actions.

Currently, the 378,000 acre-feet of additional storage would be the first increment of water in the reservoir to fill after dam enlargement, and would be available each year independent of water year type if used exclusively to enlarge the cold-water pool. If the 378,000 acre-feet of stored water is used to augment flows based on recommendations from the SRTTG, this water would not be guaranteed to be available for use the following year because of uncertainty in hydrologic conditions, although the potential to store the water, if available, would remain. Once water was released to augment flows as part of the adaptive management plan, the 378,000 acre-feet of additional storage space would be refilled after the 256,000 acre-feet of additional storage space was filled for the primary purpose of increasing water supply reliability. Each year that the 378,000 acre-feet of additional water was held in storage as part of an increase in the cold-water pool, the allocated amount would be available as long as the cold-water pool continued to provide benefits to fisheries.

Since SALMOD modeling and related analysis indicate that in most cases, providing an increased cold-water pool benefits Chinook salmon populations more than increasing flows, impacts and benefits of increasing flows under CP4 are not presented in this PDEIS. Per recommendations in Title 43 of the Code of Federal Regulations Part 46 Section 46.145, substantive increases in flows associated with the adaptive management plan would be evaluated in subsequent NEPA analysis.

Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

2.4.9 Comprehensive Plan 5 (CP5) – 18.5-Foot Dam Raise, Combination Plan

CP5 primarily focuses on increased water supply reliability, anadromous fish survival, Shasta Lake area environmental resources, and increased recreation opportunities.

Major Components of CP5

CP5 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 18.5 feet.
- Constructing additional resident fish habitat in Shasta Lake and along the lower reaches of its tributaries (Sacramento River, McCloud River, and Squaw Creek).
- Constructing shoreline fish habitat around Shasta Lake.
- Augmenting spawning gravel in the upper Sacramento River.
- Restoring riparian, floodplain, and side channel habitat.
- Increasing recreation opportunities at Shasta Lake.
- Implementing the set of eight common management measures previously described.

By raising Shasta Dam 18.5 feet, from a crest at elevation 1,077.5 to elevation 1,096.0, CP5 would increase the height of the reservoir full pool by 20.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications similar to CP1. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would be increased from 4.55 MAF to 5.19 MAF. Table 2-8 summarizes major components that would be associated with the CP5 dam raise.

Under CP5, operations for water supply, hydropower, and environmental requirements would be similar to existing operations, with the additional storage retained for water supply reliability and as an expanded cold-water pool for fisheries benefits. The existing TCD would be extended to achieve efficient use of the expanded cold-water pool.

As described for the above alternatives, this alternative also would include the potential to revise the flood control operational rules for Shasta Dam and Reservoir, which could reduce the potential for flood damage and benefit recreation.

CP5 also includes (1) restoring resident fish habitat in Shasta Lake, (2) restoring fisheries and riparian habitat at several locations along the lower reaches of the tributaries to Shasta Lake, (3) augmenting spawning gravel in the upper

Sacramento River, (4) restoring riparian, floodplain, and side channel habitat in the upper Sacramento River, and (5) increasing recreation opportunities at Shasta Lake.

Construct Shoreline Enhancement The ecosystem enhancement goal for the shoreline environment of Shasta Lake is to improve warm-water fish habitat associated with the transition between the reservoir's aquatic and terrestrial habitats. Shoreline enhancement entails a range of enhancement opportunities along the Shasta Lake shoreline below the full pool elevation (1,090 feet) that would occur with an 18.5-foot dam raise. This area is typically between 0.1 and 1.5 miles upslope from the current full pool elevation of 1,070 feet. The shoreline is defined as the area encompassing nearshore aquatic habitat within the reservoir itself and vegetation and other habitat components adjacent to the reservoir.

Two categories of potential nearshore warm-water fish habitat enhancement activities are (1) structural enhancements, which entail placing artificial structures in the Shasta Lake littoral zone, and (2) vegetative enhancements, which entail planting and seeding to provide submerged and partly submerged vegetative cover when the reservoir is at full pool capacity during the winter/spring months.

Construction activities common to all action alternatives include stockpiling manzanita for fish habitat (see Section 2.4.2). CP5 would include clearing additional manzanita from above the new full pool inundation zone to create further structural enhancements for fish habitat in the Shasta Lake littoral zone.

Vegetative enhancements associated with CP5 would include planting willows (*Salix*) to enhance nearshore fish habitat, and single treatment aerial and hand seeding of annual cereal grains to treat shoreline areas at Shasta Lake. Treatment with cereal grains provides only short-term cover, but is cost-effective across large areas and can be implemented quickly and efficiently. The annual cereal grain grasses provide cover for young fish and also nutrients for plankton as the grasses decompose. The plankton in turn are a valuable food source for juvenile fish.

Construct Tributary Aquatic Habitat Enhancement The primary goal for the enhancement of aquatic habitat in the watershed is to improve the connectivity for native fish species and other aquatic organisms between Shasta Lake and its tributaries. Two categories of potential aquatic habitat enhancement in tributaries are (1) fish passage enhancements, which entail identifying and correcting barriers to fish passage, particularly at culverts and other human-made barriers, and (2) aquatic habitat enhancements, which entail identifying and implementing feasible habitat improvements intended to conserve or restore degraded aquatic and riparian habitat in tributaries to Shasta Lake.

Fish passage enhancements associated with CP5 include opportunities to restore and/or enhance five perennial stream crossings. Barriers to fish passage in the watersheds above Shasta Lake are primarily associated with culverts or other types of stream crossings.

Aquatic habitat enhancements associated with CP5 include enhancing aquatic connectivity and reducing sediment related to roads constructed across intermittent streams. The preliminary site survey identified opportunities to enhance 14 intermittent stream crossings. Based on the information obtained in the survey, these crossings provide opportunities for meeting the objectives of enhancing aquatic connectivity and/or reducing the potential for road-related sediment. Two sites have been identified in the Salt Creek watershed, two sites have been identified in the Sugarloaf Creek watershed, and ten sites have been identified in the McCloud Arm watershed.

Augment Spawning Gravel in Upper Sacramento River As described in CP4, spawning gravel will be added to the upper Sacramento River. This measure is identical to that proposed under CP4.

Restore Riparian, Floodplain, and Side Channel Habitat As described in CP4, riparian, floodplain, and side channel habitat restoration would be constructed at a suitable location along the Sacramento River. This measure is identical to that proposed under CP4.

Recreation Enhancements A total of 18 miles of new hiking trails and 6 trailheads would be constructed to enhance recreation under CP5. Descriptions have been developed for the trails and associated features, and are included in the Engineering Summary Appendix.

Potential Benefits of CP5

Major potential benefits of CP5, related to the SLWRI objectives, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors in achieving recovery goals for anadromous fish in the Sacramento River. CP5 would increase the ability of Shasta Dam to make cold-water releases and regulate water temperature in the upper Sacramento River, primarily in dry and critically dry water years. This would be accomplished by raising Shasta Dam 18.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBDD. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBDD. It is estimated that improved water temperature conditions under CP5 could result in an annual average increase in the Chinook salmon population of about 607,000 out-migrating juvenile fish.

Increase Water Supply Reliability CP5 would increase water supply reliability by increasing firm water supplies for irrigation and M&I deliveries primarily during drought periods. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA, which would help reduce estimated future water shortages by increasing the reliability of firm water supplies for agricultural and M&I deliveries by at least 133,400 acre-feet per year, and average annual yield by about 75,800 acre-feet per year. For this PDEIS, firm yield is considered equivalent to the estimated increase in the reliability of supplies during dry and critically dry periods. The majority of increased firm yield (103,800 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, increased water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continue to grow and available supplies continue to remain relatively static, more effective use of these supplies may reduce potential critical impacts to agricultural and urban areas resulting from water shortages. Under CP5, approximately $3.8 million would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in a net increase in power generation of about 96 GWh per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities.

Conserve, Restore, and Enhance Ecosystem Resources This component includes improving shallow, warm-water fish habitat by using manzanita cleared from above the inundation zone to create structural enhancements, and planting cereal grains to treat shoreline areas. These improvements would help provide favorable spawning conditions, and juvenile fish leaving the tributaries would benefit from improved adjacent shoreline habitat. Placing manzanita brush structures near the Shasta Lake shoreline would enhance the diversity of structural habitat available for the warm-water fish species that occupy Shasta Lake. Establishing vegetation also could benefit terrestrial species that inhabit the shoreline of Shasta Lake.

The lower reaches of perennial tributaries to Shasta Lake would be targeted for aquatic restoration because they provide year-round fish habitat. Native fish species require connectivity to the full range of habitats offered by Shasta Lake and its tributaries. Improved fish passage addresses the requirement to provide access and/or modify barriers to improve ecological conditions that support these native fish assemblages. Aquatic habitat improvements include enhancing aquatic connectivity and reducing sediment related to roads constructed across intermittent streams.

In the upper Sacramento River, the addition of spawning gravel and the restoration of riparian, floodplain, and side channel habitat are expected to

improve the complexity of aquatic habitat and its suitability for spawning and rearing. Riparian areas provide habitat for a diverse array of plant and animal communities along the Sacramento River, including numerous threatened or endangered species. Riparian areas also provide shade and woody debris that increase the complexity of aquatic habitat and its suitability for spawning and rearing. Lower floodplain areas, river terraces, and gravel bars play an important role in the health and succession of riparian habitat. Restoration would support the goals of the Sacramento River Conservation Area Forum and other programs associated with riparian restoration along the Sacramento River. Side channels can support important habitat for anadromous salmonids, including rearing and spawning habitat. Side channel habitats also provide refuge from predators and productive foraging habitat for juvenile anadromous salmonids.

Maintain and Increase Recreation Opportunities CP5 includes features to, at a minimum, maintain the existing recreation capacity at Shasta Lake. In addition, this alternative includes construction of 18 miles of new trails and 6 trailheads to enhance recreation opportunities at Shasta Lake. As with the other alternatives, a small benefit would likely occur to the water-oriented recreation experience at Shasta Lake due to the increase in lake surface area and modernization of recreation facilities. The maximum surface area of the lake would increase by about 2,500 acres (8 percent), from 29,600 acres to about 32,100 acres. There is also limited potential for reservoir reoperation to provide additional benefits to recreation by raising the bottom of the flood control pool elevation and allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other SLWRI Objectives CP5 could also provide benefits related to flood damage reduction and water quality, similar to CP3.

Construction for CP5

Construction activities related to enlarging the reservoir under CP5 are identical to those described for CP3, and are summarized in Tables 2-23 through 2-29. Additional construction efforts would be required for the proposed spawning gravel augmentation and riparian, floodplain, and side channel habitat restoration, which are described under CP4. Construction activities associated with Shasta Lake tributary and shoreline enhancement are described below.

Shasta Lake Tributary and Shoreline Enhancement Structural enhancements associated with CP5 include placing brush structures constructed from whiteleaf manzanita (*Arctostaphylos manzanita*) in the Shasta Lake littoral zone. Because of manzanita's density, installation does not require using anchor or cabling techniques that could result in ancillary negative impacts (e.g., maintenance, hazards to boaters). The brush structures would be assembled in the drawdown zone of the reservoir in an area that would be inundated as the reservoir surface elevation rises in fall. The brush structures are expected to be about 1,800 cubic feet in size. The establishment period

would be the first year after construction; life span of the brush structures is projected to be 10 years.

Table 2-30 identifies the general area, number, and size of proposed structural enhancement locations for the main body of Shasta Lake, and the Pit, Sacramento, McCloud, Big Backbone, and Squaw arms. Selection of specific locations has been deferred so that enhancement locations are consistent with other objectives of the SLWRI. The level of proposed treatment is based on the proportion of available manzanita surrounding Shasta Lake. In general terms, these locations would incorporate available material at locations with preferred topographic features; preferred locations are coves that offer steep drawdown areas during the primary use period (spring, early summer).

Table 2-30. Proposed Structural Enhancement by Arm of Lake and by Arm

Area	Area Treated (acres)	Number of Locations
Main Body	17	595
Pit	12	420
Sacramento	43	1,505
McCloud	8	280
Big Backbone	3	105
Squaw	17	595
Total	**100**	**3,500**

Vegetative enhancements associated with CP5 include planting willows (*Salix*) to enhance nearshore fish habitat, and aerial and hand seeding of annual cereal grains to treat shoreline areas at Shasta Lake.

More than 30 acres could be available to enhance the willow recruitment adjacent to Shasta Lake. Rooted willows would be planted in draws and other moist sites, such as springs, to provide long-term live cover. The establishment period for willows would be the first year after construction; life span is projected to be 5 to 50 years. The establishment period for cereal grains would also be the first year of construction, with the life span projected to be 1 to 3 years. This approach would require native seed and nursery stock; several years of advanced preparation would be needed before planting could take place.

Table 2-31 summarizes proposed enhanced treatment with willows and native grasses by arm.

Table 2-31. Proposed Vegetative Enhancement Treatment of Lake and by Arm

Arm	Willow Planting (acres)	Native Grass Seeding (acres)
Main Body	1	2
Pit	1	4
Sacramento	7	4
McCloud	1	2
Big Backbone	3	2
Squaw	1	2
Total	**14**	**16**

Operations and Maintenance for CP5

Operations and maintenance of Shasta Dam and Reservoir under CP5 would be similar to the operations and maintenance discussed for CP3.

2.5 Comparison of Alternatives

Each of the alternatives has been evaluated against the specified objectives and four criteria of completeness, effectiveness, efficiency, and acceptability, as identified in the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies (WRC 1983). Evaluation of environmental impacts and mitigation measures is an important subfactor of the completeness criterion. Table 2-32 summarizes the overall potential benefits of all alternatives. The quantified benefits were based on modeling efforts that are described in several parts of the PDEIS, including Chapter 6, "Hydrology, Hydraulics, and Water Management;" Chapter 11, "Fisheries and Aquatic Resources;" Chapter 23, "Power and Energy;" the Modeling Appendix; and the Economic Valuation Appendix.

As can be seen in Table 2-32, the alternatives differ in overall benefits.

2.5.1 Completeness

Completeness is a determination of whether a plan includes all elements necessary to realize planned effects, and the degree that intended benefits of the plan depend on the actions of others. Several subfactors that are important in measuring this criterion include (1) authorization, (2) spectrum of objectives being addressed, (3) reliability, (4) physical implementability, and (5) environmental effects and mitigation.

Table 2-32. Summary of Potential Features and Major Benefits of SLWRI Alternatives

Item	CP1	CP2	CP3	CP4	CP5
Raise Shasta Dam (feet)	**6.5**	**12.5**	**18.5**	**18.5**	**18.5**

Notes:

[1] Average annual increase in juvenile Chinook salmon surviving to migrate downstream from the Red Bluff Diversion Dam. Numbers were derived from SALMOD.

[2] Average amount per year for 10-year period.

[3] Total drought period reliability to CVP and SWP. Does not reflect benefits related to water use efficiency actions included in all comprehensive plans.

[4] Tributary aquatic enhancement provides for the connectivity of native fish species and other aquatic organisms between Shasta Lake and its tributaries. Estimates of benefits reflect only connectivity with perennial streams and do not reflect additional miles of connectivity with intermittent streams.

[5] These values do not account for increased visitation due to modernization of recreation facilities associated with all comprehensive plans.

Key:
- = not applicable
CP = comprehensive plan
CVP = Central Valley Project
Delta = Sacramento-San Joaquin Delta
GWh/year = gigawatt-hours per year
NOD = north of Delta
SOD = south of Delta
SLWRI = Shasta Lake Water Resources Investigation
SWP = State Water Project
TAF = thousand acre feet

The No-Action Alternative rates very low for completeness, and each of the action alternatives rates from high to very high. Two distinguishing subfactors are (1) spectrum of objectives being addressed and (2) reliability. CP1, CP2, and CP3 primarily address anadromous fish survival and water supply reliability; however, each of these alternatives indirectly contributes to each of the other objectives, with the exception of ecosystem restoration. Further, the likely reliability and certainty of each of these three alternatives to meet its intended objectives is very high. These alternatives do not significantly rely on any other actions. However, CP4 specifically focuses on anadromous fish through increasing the minimum carryover storage space in Shasta Reservoir each year, and CP5 focuses on additional ecosystem restoration and recreation. With both CP4 and CP5, O&M requirements would increase. Accordingly, overall reliability would be reduced for each alternative.

Another significant subfactor is environmental effects and mitigation. Anticipated impacts are generally comparable between alternatives; some impacts are exacerbated by larger dam raises and the associated scale of those impacts, such as a prolonged construction period and increased area of inundation around Shasta Lake. Generally, the impacts would be mitigable with the measures identified in subsequent chapters. Some impacts, including short-term generation of construction-related emissions in excess of Shasta County Air Quality Management District thresholds, and the temporary exceedence of Shasta County noise level standards, could remain significant and unavoidable despite mitigation measures. Altered flow regimes, changes to the areas inundated by the Sacramento River and Shasta Lake, and disturbances associated with construction activities have the potential to impact environmental resources. These impacts would be largely mitigable. A detailed description and assessment of the impacts to environmental resources, and appropriate mitigation measures, are described by resource area in Chapters 4 through 25.

2.5.2 Effectiveness

Effectiveness is the extent to which an alternative alleviates problems and achieves objectives. For the primary objective of anadromous fish survival, two major relative ranking factors were considered: (1) increasing salmon survival (decreasing salmon mortality) and (2) increasing habitat for spawning. For the primary objective of increasing water supply reliability, ranking was based on the relative amount of new drought period (firm) yield that could be derived from each comprehensive plan. For the secondary objectives, four ranking factors were considered: (1) whether a comprehensive plan included ecosystem restoration, (2) potential to affect flood peaks downstream from Keswick Dam, (3) potential to increase net power generation, and (4) amount of increased recreation opportunities at Shasta Lake.

Comprehensive plans with the greatest effectiveness in meeting objectives appear, at this time, to be CP3, CP 4, and CP5. This is primarily because CP3 and CP5 would provide the largest contribution toward water supply reliability

and CP4 would provide the largest contribution toward anadromous fish survival. All three plans provide benefits to ecosystem restoration (via improved fisheries conditions), flood damage reduction, hydropower generation, recreation, and water quality.

2.5.3 Efficiency

Efficiency is the measure of how efficiently an alternative alleviates identified problems while realizing specified objectives consistent with protecting the Nation's environment. The relative rankings for efficiency are based primarily on likely net benefits obtained under each plan. Assuming the cost of water supplies increases at the same rate as inflation, CP1, CP3, CP4, and CP5 would be economically feasible, and assuming the cost of water supplies increases at 2 percent above inflation, all plans would be economically feasible. At this stage of analysis under either condition, it appears that CP4 has potential to provide the greatest net economic benefits. This is primarily because of the higher potential increase in anadromous fish survival.

2.5.4 Acceptability

Acceptability is the workability and viability of a plan with respect to its potential acceptance by other Federal agencies, State and local government agencies, and public interest groups and individuals. This evaluation criterion will be very important following completion of the Final Feasibility Report and endorsement by a non-Federal sponsor of the comprehensive plan recommended for implementation. It appears that all of the comprehensive plans would be similarly ranked for this criterion. Each of the plans needs to be coordinated with other agencies and public interests.

2.6 Preferred Alternative and Rationale for Selection

This section provides a summary of the comparison of alternatives, identifies the likely preferred alternative, and provides the rationale for selection.

2.6.1 Summary of Comparison

Each of the comprehensive plans is estimated to be complete, each appears to be effective in achieving its intended objectives, and each is cost-efficient. The three comprehensive plans involving a dam raise of 18.5 feet (CP3, CP4, and CP5) best address the planning objectives. This is primarily because of (1) high certainty (completeness) that the plans could achieve their intended benefits, and (2) relatively high effectiveness and economic efficiency.

2.6.2 Rationale for Plan Selection

A plan recommending Federal action should be the plan that best addresses the targeted water resources problems considering public benefits relative to costs. The basis for selecting the recommended plan is to be fully reported and documented, including the criteria and considerations used in selecting a recommended course of action by the Federal Government. It is recognized that

most of the activities pursued by the Federal Government will require assessing trade-offs by decision makers and that in many cases, the final decision will require judgment regarding the appropriate extent of monetized and nonmonetized effects.

The needed rationale to support Federal investment in water resources projects is described in the 2009 *Draft Proposed National Objectives, Principles, and Standards for Water and Related Resources Implementation Studies* (CEQ):

> *The presentations shall summarize and explain the decision rationale leading from the identification of need through the recommendation of a specific alternative. This shall include the steps, basic assumptions, analysis methods and results, criteria and results of various screenings and selections of alternatives, peer review proceedings and results, and the supporting reasons for other decisions necessary to execute the planning process. The information shall enable the public to understand the decision rationale, confirm the supporting analyses and findings, and develop their own fully-informed opinions and/or decisions regarding the validity of the study and its recommendations.*
>
> *Opportunities shall be provided for public reaction and input prior to key study decisions, particularly the tentative and final selection of recommended plans. The above information shall be presented in a decision document or documents, and made available to the public in draft and final forms. The document(s) shall demonstrate compliance with the National Environmental Policy Act (NEPA) and other pertinent Federal statutes and authorities.*

At this stage of the NEPA and Federal planning processes, the potential effects of the alternative plans have been evaluated and compared based on established criteria. As a result, alternatives involving an 18.5-foot raise of Shasta Dam appear to have the greatest environmental benefits, although no environmentally preferable alternative has been selected. It is recognized that further refinement and changes may occur to the comprehensive plans with changes in CVP/SWP operational conditions, and after updates to modeling studies and input from agencies, stakeholders, and the public. The results of these updated studies will be incorporated into the Draft EIS and other future SLWRI documents.

Ultimately, the alternative that best meets the stated objectives and maximizes net public benefits will be identified in the Final Feasibility Report and FEIS with supporting rationale and documentation. If determined to be feasible, it is expected that the plan recommended for implementation will meet all pertinent Federal, State, and local laws, policies, regulations, and other requirements so that it may be ideally recognized as the "Environmentally Preferred Plan"

consistent with NEPA, the "NED Plan" consistent with the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies, the "Least Environmentally Damaging Practicable Alternative" consistent with the CWA, and the "Environmentally Superior Alternative" consistent with CEQA. Then, responsible Federal, State, and local decision makers will decide whether to approve, authorize, and/or appropriate funding for implementation of the preferred alternative.

Chapter 3
Considerations for Describing Affected Environment and Environmental Consequences

3.1 Introduction

Chapters 4 through 25 of this PDEIS are organized by environmental resource area. Each chapter discusses the affected environment and environmental consequences (short- and long-term impacts, direct and indirect impacts, and mitigation measures, and cumulative effects) of implementing the proposed comprehensive plans. Additional details about the affected environment are available for some resource areas in the technical reports; see the appendices to this PDEIS.

3.2 Chapter Contents and Definition of Terms

Chapters 4 through 25 are organized into the following resource and issue areas:

- **Chapter 4** – Geology, Geomorphology, Minerals, and Soils
- **Chapter 5** – Air Quality and Climate
- **Chapter 6** – Hydrology, Hydraulics, and Water Management
- **Chapter 7** – Water Quality
- **Chapter 8** – Noise and Vibration
- **Chapter 9** – Hazards and Hazardous Materials and Waste
- **Chapter 10** – Agriculture and Important Farmlands
- **Chapter 11** – Fisheries and Aquatic Ecosystems
- **Chapter 12** – Botanical Resources and Wetlands
- **Chapter 13** – Wildlife Resources
- **Chapter 14** – Cultural Resources
- **Chapter 15** – Indian Trust Assets
- **Chapter 16** – Socioeconomics, Population, and Housing

- **Chapter 17** – Land Use and Planning
- **Chapter 18** – Recreation and Public Access
- **Chapter 19** – Aesthetics and Visual Resources
- **Chapter 20** – Transportation and Traffic
- **Chapter 21** – Utilities and Service Systems
- **Chapter 22** – Public Services
- **Chapter 23** – Power and Energy
- **Chapter 24** – Environmental Justice
- **Chapter 25** – Wild and Scenic River Considerations for McCloud River

For some of these resource and issue areas, a technical report of the same name is presented in the appendices to this PDEIS. The technical reports describe the affected environment in more detail than the summarized information presented in the main body of this PDEIS.

3.2.1 NEPA Requirements

Council on Environmental Quality (CEQ) regulations for implementing NEPA include the following requirements for an Environmental Impact Statement (EIS) (Title 40, Section 1502.15 of the Code of Federal Regulations (40 CFR 1502.15)):

> *[An] EIS shall succinctly describe the environment of the area(s) to be affected or created by the alternatives under consideration. The descriptions shall be no longer than is necessary to understand the effects of the alternatives. Data and analyses in a statement shall be commensurate with the importance of the impact, with less important material summarized, consolidated, or simply referenced.*

Because of uneven treatment of climate change under NEPA, the International Center for Technology Assessment, Natural Resources Defense Council, and Sierra Club filed a petition with CEQ in March 2008. The petition requested that climate change analyses be included in all Federal environmental review documents. In October 2009, President Barack Obama signed Executive Order 13514, "Federal Leadership in Environmental, Energy, and Economic Performance." The goal of this executive order is "to establish an integrated strategy towards sustainability in the Federal Government and to make reduction of greenhouse gas (GHG) emissions a priority for Federal agencies" (FedCenter.gov 2011).

In response to the 2008 petition and subsequent Executive Order 13514, CEQ issued guidance on including GHG emissions and climate change impacts in environmental review documents under NEPA. CEQ guidance (issued February 18, 2010) suggests that Federal agencies consider opportunities to reduce GHG emissions caused by proposed Federal actions, adapt their actions to climate change impacts throughout the NEPA process, and address these issues in the agencies' NEPA procedures. Following are the two main factors to consider when addressing climate change in environmental documentation:

- Effects of a proposed action and alternative actions on GHG emissions
- Impacts of climate change on a proposed action or alternatives

CEQ notes that "significant" national policy decisions with "substantial" GHG impacts require analysis of their GHG effects. That is, the GHG effects of a Federal agency's proposed action must be analyzed if the action would cause "substantial" annual direct emissions; would implicate energy conservation or reduced energy use or GHG emissions; or would promote cleaner, more efficient renewable-energy technologies. Qualitative or quantitative information on GHG emissions that is useful and relevant to the decision should be used when deciding among alternatives.

CEQ suggests that if a proposed action would cause direct annual emissions of more than 25,000 metric tons of carbon dioxide equivalent, a quantitative and qualitative assessment may be meaningful to decision makers and the public. If annual direct emissions would be less than 25,000 metric tons of carbon dioxide equivalent, Federal agencies are encouraged to consider whether the action's long-term emissions should receive similar analysis.

3.2.2 Approach to Affected Environment

Chapters 4–25 provide an overview of the existing physical environment and socioeconomic conditions that the comprehensive plans could affect. This information was obtained from technical studies prepared by Reclamation for some resource and issue areas; those studies are attached to this PDEIS. Additional information was obtained from published environmental and planning documents, books, Web sites, journal articles, field surveys, and communications with technical experts. Descriptions of the affected environment are organized by geographic region. Conditions in the primary study area – Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff) – are described first. These discussions are followed by descriptions of conditions in the extended study area, which consists of the lower Sacramento River and Delta and CVP/SWP facilities and water service areas.

In certain resource areas, the geographic regions are organized slightly differently than how they are defined in Chapter 1. For example, when effects

are solely due to operational changes, the Trinity, American, and Feather rivers may all be discussed with the geography for CVP/SWP facilities and service areas, since the impacts would be similar in nature.

3.2.3 Methods and Assumptions

Chapters 4 through 25 analyze the direct and indirect effects of the No-Action Alternative and comprehensive plans (i.e., action alternatives) for each environmental resource area. Direct effects are those that would be caused by the action and would occur at the same time and place. Indirect effects are reasonably foreseeable consequences that may occur at a later time or at a distance from the project area. Examples of indirect effects are growth inducement or other effects related to changes in land use patterns, population density, or growth rate, and related effects on the physical environment.

The effects of the No-Action Alternative and action alternatives were determined by comparing estimates of resulting conditions with baseline conditions. These baseline conditions differ between NEPA and CEQA. Under NEPA, the No-Action Alternative (i.e., expected future conditions without the project) is the baseline to which the action alternatives are compared; the No-Action Alternative is also compared to existing conditions. Under CEQA, existing conditions are the baseline to which alternatives are compared.

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is a determining factor in whether an environmental impact statement must be prepared. An environmental document prepared to comply with CEQA must identify the significance of the environmental effects of a proposed project. As stated in State CEQA Guidelines, Section 15382, a "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project."

Rationale for Use of 2004 Biological Assessment for Water Operation Models

In June 2004, Reclamation prepared the 2004 Operations Criteria and Plan (OCAP) to provide a baseline description of facilities and the operating environment of the CVP and SWP. Using operational information in the 2004 OCAP, Reclamation and DWR developed the 2004 OCAP Biological Assessment (BA), prepared as part of the consultation process required by Section 7 of the Endangered Species Act (ESA).

Planning assumptions and information on water operations used to develop alternatives for the SLWRI were developed in 2006, and reflect the coordinated CVP and SWP operational conditions and criteria described in the 2004 OCAP. In addition, the model package used to evaluate potential effects of the alternatives included in this PDEIS was based on operations described in the

2004 OCAP BA and the Coordinated Operations Agreement between Reclamation and DWR for the CVP and SWP, as ratified by Congress.

As Reclamation has proceeded with the SLWRI, essential environmental, hydrologic, and regulatory conditions in the Sacramento River basin and Delta have changed significantly, including substantial declines in key fish populations that use the Sacramento River basin waterways and Delta, such as the delta smelt and Chinook salmon.

Reclamation consulted with the NMFS and USFWS on the 2004 OCAP, and the two agencies issued the 2004 NMFS Biological Opinion (BO) (NMFS 2004) and 2005 USFWS BO (USFWS 2005), respectively. In 2007, the District Court for the Eastern District of California (District Court), in *Natural Resources Defense Council v. Kempthorne*, found the 2005 USFWS BO to be unlawful and inadequate. In May 2008, in *Pacific Coast Federation of Fishermen's Associations v. Gutierrez*, the District Court found the 2004 NMFS BO to be unlawful and inadequate. The District Court remanded both BOs to the fishery agencies.

In August 2008, Reclamation reinitiated consultation with the fishery agencies based on the 2008 *Biological Assessment on the Continued Long-Term Operations of the CVP and SWP* (2008 OCAP BA). USFWS issued the 2008 USFWS BO, finding that the long-term operations of the CVP and SWP, as described in the 2004 OCAP BA, would jeopardize the continued existence of the delta smelt (USFWS 2008). In June 2009, NMFS issued the 2009 NMFS BO (NMFS 2009) finding that the same operations would jeopardize populations of listed salmonids, steelhead, green sturgeon, and orcas. Because both agencies made jeopardy determinations, both agencies included a Reasonable and Prudent Alternative (RPA) in their BOs.

Several lawsuits were filed challenging the validity of the 2008 USFWS BO and 2009 NMFS BO and Reclamation's acceptance of the RPA included with each BO (*Consolidated Salmonid Cases, Delta Smelt Consolidated Cases*). On November 13, 2009, and March 5, 2010, the District Court concluded that Reclamation had violated NEPA by failing to perform any NEPA analysis before provisionally adopting the 2008 USFWS RPA and 2009 NMFS RPA. On December 14, 2010, the District Court found the 2008 USFWS BO to be unlawful and remanded the BO to USFWS. The District Court issued a similar ruling for the 2009 NMFS BO on September 20, 2011. On May 4, 2011, in the *Delta Smelt Consolidated Cases*, the District Court ordered USFWS to prepare a draft BO by October 1, 2011, which was subsequently extended to an unspecified date to be agreed upon by involved parties. Reclamation and USFWS must prepare a final BO and final NEPA document by November 1, 2013, and December 1, 2013, respectively.

The ongoing OCAP reconsultation process is not the only uncertainty facing future water operations in California. In addition to changes in regulatory conditions, California experienced a severe drought from 2007 through 2009. Although the 2010–2011 water year brought water supplies to normal levels, California's complex water supply issues remain. Increased water needs for environmental purposes, regulatory cutbacks on water supplies, and population growth have created more serious water problems than the State faced in the early 1990s drought. In the future, impacts of climate change will further complicate California's water supply difficulties. In response to these issues, plans have been proposed to update California's water system by increasing storage, improving conveyance, protecting the Delta's ecosystem and promoting greater water conservation, and planning assumptions originally used to predict hydrologic conditions in the Sacramento River and Delta have changed.

Reclamation and DWR use CalSim-II to study operations, benefits, and effects of new facilities and operational parameters for the CVP and SWP. A set of operational assumptions was developed in 2006 based on operations described in the 2004 OCAP BA and the Coordinated Operations Agreement between Reclamation and DWR for the CVP and SWP. These assumptions were used to guide development, modeling, and evaluation of potential effects of the No-Action Alternative and action alternatives included in this PDEIS. These existing evaluations were used as the basis of analysis in the PDEIS.

The legal challenges and changing environmental conditions result in uncertainty with regard to both current and future operations. These operational uncertainties are likely to continue, and current and future water operation conditions may be different because operational constraints governing water operations are likely to change with release of revised USFWS and NMFS BOs. The existing SLWRI modeling analysis is being used for comparison purposes, and reflects expected variation among the alternatives, including the type and relative magnitude of anticipated impacts and benefits. Because of the lingering uncertainty about future water operations, the PDEIS is based on existing studies.

Modeling studies will be updated to reflect changes in water operations resulting from ongoing OCAP reconsultation and other relevant water resources projects and programs, including, potentially, Bay-Delta Conservation Plan (BDCP)/Delta Habitat Conservation and Conveyance Plan (DHCCP) efforts. The results of these updated studies will be incorporated into the Draft EIS and other future SLWRI documents.

3.2.4 Significance Criteria

Significance criteria for each resource area are provided in each resource chapter of this PDEIS. These criteria are based on the checklist presented in Appendix G of the State CEQA Guidelines; factual or scientific information and data; and regulatory standards of Federal, State, and local agencies. These

criteria also encompass the factors taken into account under NEPA to determine the significance of an action in terms of the context and the intensity of its effects.

3.2.5 Impact Comparisons and Definitions

Mechanisms that could cause impacts are discussed for each issue area. General categories of impact mechanisms are construction and activities related to future operation and maintenance, as described in Chapter 2, "Alternatives." Project-related impacts are categorized as follows, to describe the intensity or duration of the impact:

- A **temporary** impact would last less than 3 to 4 years and typically would occur only during construction.
- A **short-term** impact could occur during construction and could last from the time construction ceases to within 3 to 5 years after construction.
- A **long-term** impact would last longer than 5 years after the completion of construction. In some cases, a long-term impact could be a permanent impact.
- A **direct** impact is an impact that would be caused by an action and would occur at the same time and place as the action.
- An **indirect** impact is an impact that would be caused by an action but would occur later in time or at another location, yet is reasonably foreseeable in the future.
- A **cumulative** impact is a project's impacts combined with impacts from other past, present, and reasonably foreseeable future projects. A project's incremental impacts are not "cumulatively considerable" solely because other projects would have a significant cumulative impact; rather, the project would also need to contribute considerably to a significant cumulative impact (State CEQA Guidelines, Section 15064(h)(1)).

3.2.6 Impact Levels

The terminology listed below is used to denote the significance of environmental impacts of the No-Action Alternative and action alternatives. These levels of significance are listed for purposes of CEQA only.

- **No impact** would occur if the construction, operation, and maintenance of the alternative under consideration would not have any direct or indirect effects on the environment. "No impact" means no change from existing conditions. This impact level does not need mitigation.

- An impact that would not result in a substantial and adverse change in the environment would be **less than significant**. This impact level does not require mitigation under CEQA, even if applicable measures are available.

- A **significant** impact is defined by Section 21068 of the California Public Resources Code as "a substantial, or potentially substantial, adverse change in the environment." Levels of significance can vary by project, based on the change in the existing physical condition. This PDEIS uses the CEQA definition of "significant impact."

- A **potentially significant** impact is one that, if it were to occur, would be considered a significant impact as described above; however, the occurrence of the impact cannot be immediately determined with certainty. For CEQA purposes, a potentially significant impact is treated as if it were a significant impact. Therefore, under CEQA, feasible mitigation measures or alternatives to the proposed action must be identified, where applicable, to reduce the magnitude of potentially significant impacts.

- A **significant and unavoidable** impact is a substantial or potentially substantial adverse effect on the environment that cannot be reduced to a less-than-significant level even with any feasible mitigation. Under CEQA, a project with significant and unavoidable impacts could proceed, but the lead agency would be required to do the following:

    - Conclude in findings that there are no feasible means of substantially lessening or avoiding the significant impact in accordance with Section 15091(a)(3) of the State CEQA Guidelines (i.e., Title 14, Section 15091(a)(3) of the California Code of Regulations (CCR)).

    - Prepare a statement of overriding considerations, in accordance with Section 15093 of the State CEQA Guidelines, explaining why the lead agency would proceed with a project in spite of the potential for significant impacts.

- A **significant cumulative** impact occurs when the project would make a "cumulatively considerable incremental contribution" to an overall significant cumulative impact. If an overall cumulative impact would not be significant, even when the project would make a cumulatively considerable incremental contribution to the cumulative impact, then it is determined that the project would not cause a significant cumulative impact.

- A **beneficial** impact is a positive change or improvement in the environment and for which no mitigation measures are required.

- An impact may have a level of significance that is too uncertain to be reasonably determined. Such an impact would be designated **too speculative for meaningful evaluation**, in accordance with Section 15145 of the State CEQA Guidelines. Where some degree of evidence points to the reasonable potential for a significant effect, the EIS may explain that a determination of significance is uncertain, but is still assumed to be "potentially significant," as described above. In other circumstances, after thorough investigation, the determination of significance may still be too speculative to be meaningful. This is an effect for which the degree of significance cannot be determined for specific reasons. For example, aspects of the impact itself may be unpredictable or the severity of consequences cannot be known at this time.

3.2.7 Mitigation Development Process and Objectives

Mitigation measures are presented where feasible to avoid, minimize, rectify, reduce, or compensate for significant and potentially significant impacts of the proposed action and alternatives, in accordance with Section 15126.4 of the State CEQA Guidelines and NEPA regulations (40 CFR 1508.20). Each mitigation measure is identified numerically to correspond with the number of the impact being mitigated by the measure. No mitigation measures are needed when an impact is determined to be "less than significant" or "beneficial," or where no impact would occur. Where sufficient feasible mitigation is not available to reduce an impact to a less-than-significant level, the impact is identified as "significant and unavoidable."

3.2.8 Significance after Mitigation

For every impact that would be significant or potentially significant, feasible mitigation is applied to avoid or reduce the impact to a less-than-significant level and one of two conclusions is reached:

1. The mitigation would reduce the impact to a less-than-significant level.

2. No feasible mitigation exists to reduce the impact to a less-than-significant level, and thus the impact would be significant and unavoidable.

Impact significance is reevaluated after application of mitigation in this PDEIS.

3.2.9 Cumulative Effects

This section provides an analysis of overall cumulative effects of the project alternatives and the No-Action Alternative, determined by combining project impacts with other past, present, and reasonably foreseeable probable future

projects producing related impacts (as defined above). This analysis follows applicable guidance provided by CEQ in *Considering Cumulative Effects under the National Environmental Policy Act* (CEQ 1997) and *Guidance on the Consideration of Past Actions in Cumulative Effects Analysis* (CEQ 2005).

Definitions of Cumulative Effects

The CEQ regulations that implement NEPA provisions define cumulative effects as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or nonfederal) or person undertakes such other actions" (40 CFR 1508.7). Cumulative effects can result from individually minor, but collectively significant, actions over time and differ from indirect impacts (40 CFR 1508.8). They are caused by the incremental increase in total environmental effects when the evaluated project is added to other past, present, and reasonably foreseeable future actions. Cumulative effects can thus arise from causes that are totally unrelated to the project being evaluated, and the analysis of cumulative effects looks at the life cycle of the effects, not the project at issue. These effects can be either adverse or beneficial.

Cumulative impacts are defined in the State CEQA Guidelines (14 CCR Section 15355) as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts." A cumulative impact occurs from "the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time" (14 CCR Section 15355(b)).

Consistent with the State CEQA Guidelines (14 CCR Section 15130(a)), the discussion of cumulative impacts in this chapter focuses on significant and potentially significant cumulative impacts. The State CEQA Guidelines (14 CCR Section 15130(b)) state that:

> *The discussion of cumulative impacts shall reflect the severity of the impacts and their likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion should be guided by the standards of practicality and reasonableness, and should focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact.*

Effects of Project Implementation with Climate Change

Each resource area evaluates the effects of SLWRI actions combined with predicted effects of climate change. The ways SLWRI could affect GHG production are included in Chapter 5, "Air Quality and Climate." The Climate Change Projection Appendix provides a summary of global climate forecasts and a discussion of climate change implications for California water resources, particularly those of Shasta Lake, including predictions about changes in monthly and annual natural runoff, reservoir storage and temperature, flood management, power generation, fish conservation, and water supply and quality. The discussion of climate change implications provided in the Climate Change Projection Appendix provides context for consideration of cumulative conditions.

Relationship to CALFED Programmatic Cumulative Effects Analysis

This analysis of cumulative effects in this PDEIS considers but does not tier from the cumulative impacts assessment in the CALFED Programmatic Environmental Impact Statement/Environmental Impact Report (EIR) (CALFED 2000a). The "Shasta Lake Enlargement" project was included in the cumulative impacts analysis of the CALFED Programmatic EIS/EIR as a project in CALFED's Storage Program (CALFED 2000a). This project-specific analysis considers, but stands alone from and refines, the analysis of cumulative effects in the CALFED Programmatic EIS/EIR (CALFED 2000a). This analysis focuses on issues resulting from the effects of this project combined with other reasonably foreseeable projects. This PDEIS considers CALFED projects that have been implemented, are being implemented, or are reasonably foreseeable future projects. The projects that have been implemented are considered as part of existing conditions; reasonably foreseeable future projects are considered as part of future conditions.

Methods and Assumptions

Following CEQ guidance, Reclamation has identified associated actions (past, present, or future) that, when viewed with the proposed or alternative actions, may have significant cumulative impacts. Table 3-1 lists the plans, projects, and programs that were considered for each resource area. Cumulative impacts should not be speculative; rather, they should be based on known long-range plans, regulations, or operating agreements.

Table 3-1. Present and Reasonably Foreseeable Future Actions Included in the Qualitative Analysis of Cumulative Impacts, by Resource Area

Actions	Geology, Geomorphology, Minerals, and Soils	Air Quality and Climate	Hydrology, Hydraulics, and Water Management	Water Quality	Noise and Vibration	Hazards and Hazardous Materials and Waste	Agriculture and Important Farmlands	Fisheries and Aquatic Ecosystems	Botanical Resources and Wetlands	Wildlife Resources	Cultural Resources	Indian Trust Assets	Socioeconomics, Population, and Housing	Land Use and Planning	Recreation and Public Access	Aesthetics and Visual Resources	Transportation and Traffic	Utilities and Service Systems	Public Services	Power and Energy	Environmental Justice	Wild and Scenic River Considerations for McCloud River	Notes
Forecasted 2030 Water Supply Demand			×					×	×	×					×					×			Considered in quantitative assessment of actions related to water resources
Delta-Mendota Canal Intertie			×					×	×	×	×	×			×					×			Considered in quantitative assessment of actions related to water resources
Sacramento Valley Water Management—Phase 8 Short-Term Agreement			×					×	×	×					×					×			Considered in quantitative assessment of actions related to water resources
San Joaquin River Salinity Management Plan			×	×				×	×	×					×					×			Considered in quantitative assessment of actions related to water resources
South Bay Aqueduct Enlargement Project			×					×	×	×	×	×			×					×			Considered in quantitative assessment of actions related to water resources

Key:
CALFED = CALFED Bay-Delta Program
CVP = Central Valley Project
SWP = State Water Project

The State CEQA Guidelines identify two basic methods for establishing the cumulative environment in which the project is to be considered: using a list of past, present, and probable future projects (the "list approach") or using adopted projections from a general plan, other regional planning document, or certified EIR for such a planning document (the "plan approach"). For this analysis of cumulative effects, the list approach and the plan approach have been combined in quantitative and qualitative assessments to generate the most comprehensive future projections possible. The methodology for each of these assessments is described below.

Quantitative Assessments Quantitative assessments were completed for each of the resource areas in this PDEIS, where feasible. The effects of actions related to water resources and effects of development projects were assessed quantitatively. The methodologies for these quantitative assessments are described below.

Quantitative Assessment of Actions Related to Water Resources In this PDEIS, the quantitative assessment of actions related to water resources relied primarily on CalSim-II modeling of hydrologic conditions that could affect vegetation and habitat types or special-status plant species. The model was run using two different baselines: modeling runs of "existing conditions," based on 2005 facilities and demands (a 2005 baseline); and modeling runs of "future conditions," based on forecasted 2030 demands and reasonably foreseeable projects and facilities (a 2030 baseline). The 2030 baseline does not account for potential changes in water demands resulting from the effects of climate change. Potential changes in water demand are described qualitatively in the "Qualitative Assessment of Other Actions" section. In this modeling of the 2030 baseline, reasonably foreseeable projects and facilities were as follows:

- Forecasted 2030 level of demands for water supplies
- Delta-Mendota Canal Intertie Project
- Sacramento Valley Water Management – Phase 8 Short-Term Agreement regarding water transfer supplies
- San Joaquin River Salinity Management Plan
- South Bay Aqueduct Enlargement Project
- Integration of CVP and SWP Operations

Forecasted 2030 Level of Demands for Water Supplies A detailed description of the CalSim-II model, the modeling methodology used in evaluations, and key assumptions (including a description of forecasted 2030 facilities and demands) are provided in the Modeling Appendix. The analysis and modeling results are summarized in the Hydrology, Hydraulics, and Water Management Technical Report. Moreover, Reclamation and DWR have developed "common assumptions" – reasonable assumptions built into the

CalSim-II model that are the standard for evaluating systemwide hydrologic and water supply conditions under existing and future conditions.

Cumulative effects on hydrologic conditions were quantified by comparing modeling runs with No-Action Alternative (2030) conditions to modeling runs with the 2005 baseline. For example, the No-Action Alternative (2030) was compared to existing conditions (the 2005 baseline) to identify the cumulative effects of reasonably foreseeable projects and facilities on hydrologic conditions. Similarly, project alternatives were compared to existing conditions (thus satisfying CEQA requirements) and to the No-Action Alternative (2030) (satisfying NEPA requirements) to identify the combined cumulative effect of project alternatives and other foreseeable projects and facilities. Forecasted year-2030 demands for water were used in the CalSim-II model runs for this PDEIS and are considered to be reasonably foreseeable for determining cumulative impacts, as are all projects included as "common assumptions."

Delta-Mendota Canal Intertie The Delta-Mendota Canal Intertie Project involves constructing and operating a pumping plant and a pipeline connecting the Delta-Mendota Canal with the California Aqueduct in the Delta (extended study area), in accordance with the OCAP. The intertie would be used to meet current water supply demands, allow for maintenance and repair of the CVP Delta export and conveyance facilities, and provide operational flexibility for responding to CVP- or SWP-related emergencies. The intertie would include a 450-cubic-foot-per-second (cfs) pumping plant at the Delta-Mendota Canal that would allow water to be pumped from the canal to the California Aqueduct via an underground pipeline. Reclamation and DWR have completed NEPA and CEQA documentation for this project. The notice of intent/notice of preparation (NOI/NOP) was released in 2006, public scoping meetings were held in August 2006, and the DEIS/EIR was released for public comment in July 2009. The FEIS/EIR and ROD were filed in December 2009 and construction began in October 2010.

Sacramento Valley Water Management—Phase 8 Short-Term Agreement The Phase 8 Short-Term Agreement is a commitment by Reclamation and DWR to meet the flow-related standards of State Water Resources Control Board (SWRCB) Water Right Decision 1641 (DWR 2002). The agreement provides for collaboration among interested parties to develop projects to meet water supply, water quality, and environmental needs in the Sacramento Valley and Bay-Delta areas, and throughout California. The parties to the Phase 8 Short-Term Agreement are more than 40 water suppliers in the Sacramento Valley, DWR, Reclamation, and downstream water users. These parties developed a cooperative water management partnership to better manage water and provide a mechanism for satisfying Bay-Delta water quality and flow objectives. The actions in the agreement consist of locally proposed groundwater projects, reservoir reoperation, system improvements, and surface water and groundwater planning studies. These short-term projects and actions

would be implemented for 10 years in Shasta, Butte, Sutter, Glenn, Tehama, Colusa, Sacramento, Placer, and Yolo counties.

The Phase 8 Short-Term Agreement was signed in December 2002 and the NOI/NOP was published in August 2003.

San Joaquin River Salinity Management Plan This plan outlines actions used for water quality management to improve salt and boron conditions on the lower San Joaquin River. Developed in conjunction with the management agency agreement between Reclamation and the Central Valley Regional Water Quality Control Board, the plan describes current actions and proposed mitigation. The plan focuses on three major groups of actions taken by Reclamation:

- Providing flows to the system
- Reducing salt load to the river
- Facilitating mitigation

Actions to reduce salt loads include the Grassland Bypass Project, which is designed to improve water quality in the channels used to deliver water to wetland areas and the San Joaquin River. Before the Grassland Bypass Project was implemented, drainage water from farms in the 97,000-acre Grassland Drainage Area was discharged into the San Joaquin River through Salt Slough and other channels used to deliver water to wetland areas. This drainage water contains high concentrations of selenium, salts, boron, and other constituents that are harmful to wildlife.

South Bay Aqueduct Enlargement Project The South Bay Aqueduct conveys water from the Delta through more than 40 miles of pipelines and canals to the Zone 7, Alameda County, and Santa Clara Valley water districts. Those water districts, in turn, serve the cities of Livermore, Dublin, Pleasanton, San Ramon, Fremont, Newark, Union City, Milpitas, Santa Clara, and San Jose. The first conveyance facility constructed for the SWP, the South Bay Aqueduct was designed for a capacity of 300 cfs. Recent flow tests and studies have shown that the actual capacity is 270 cfs.

The purpose of the South Bay Aqueduct Enlargement Project is to increase the aqueduct's capacity to 430 cfs to meet Zone 7 Water Agency's future needs and provide operational flexibility to reduce the SWP's peak power consumption.

The following are the principal features of this project:

- Add four 45-cfs pumps to the South Bay Pumping Plant, and expand the existing plant structure and add a new service bay and switchyard

- Construct a third (Stage 3) Brushy Creek pipeline and surge tank parallel to the existing two barrels

- Construct a 500-acre-foot reservoir (425 acre-feet of active storage) to be served by the Stage 3 Brushy Creek Pipeline

- Raise the height of the canal embankments, canal lining, and canal overcrossing structures and bridges along the Dyer, Livermore, and Alameda canals and at the Patterson Reservoir

- Modify check structures and siphons along the Dyer, Livermore, and Alameda canals

- Construct new drainage overcrossing structures to eliminate drainage into the canals

Construction is proceeding on enlargement of the South Bay Pumping Plant to make room for the four new pump units being fabricated (DWR 2011a). Project completion is expected in 2012.

Integration of CVP and SWP Operations For many years, Reclamation and DWR have attempted to increase coordination and integration of CVP and SWP operations. Such coordination allows one project to use the other's resources to improve water supply reliability and reduce costs. Reclamation and DWR plan to integrate the strengths of the CVP and SWP (storage and conveyance, respectively) to maximize water supplies for the benefit of both CVP and SWP contractors that rely on water delivered from the Bay-Delta. The agencies will ensure that such integration will not impair in-Delta uses and will be consistent with fishery, water quality, and other flow and operational requirements of the Clean Water Act (CWA) and the Federal and California endangered species acts. The project agencies have agreed to pursue the following actions:

- *Convey water for Reclamation at the SWP* Upon implementation of the increase to 8,500 cfs at the Harvey O. Banks Pumping Plant (Banks), DWR will divert and pump 100 thousand acre-feet (TAF) of Reclamation's Level 2 refuge water before September 1. This commitment will allow Reclamation to commit up to 100 TAF of conveyance capacity at the C.W. "Bill" Jones (formerly Tracy) Pumping Plant, previously reserved for wheeling refuge supplies, for CVP supplies.

- *Adjust in-basin obligations* Upon implementation of the increase to 8,500 cfs at Banks, Reclamation will supply up to 75 TAF from its upstream reservoirs to alleviate a portion of the SWP's in-basin obligation.

- *Provide extra conveyance and storage* Before the increase to 8,500 cfs at Banks, DWR will provide up to 50 TAF for pumping and conveyance of Reclamation's Level 2 refuge water. Likewise, Reclamation will supply up to 37,500 acre-feet from its upstream storage to alleviate a portion of the SWP's obligation to meet in-basin uses. The biological effects analyzed in this PDEIS are for the full 100 TAF of conveyance and up to 75 TAF of storage, as may occur when the 8,500 cfs at Banks is operational. The biological effects of the 50 TAF of conveyance and up to 37,500 acre-feet of storage that may occur at the existing permitted Banks capacity are not analyzed separately; it is assumed that those effects are encompassed by the analysis of the larger amounts and capacities that may occur when the 8,500 cfs at Banks is operational.

- *Coordinate operation of upstream reservoirs* Under certain limited hydrologic and storage conditions, when water supply is relatively high in Shasta Lake yet relatively low in Lake Oroville, the SWP may rely on Shasta storage to support February allocations based on 90-percent-exceedence projections. When the CVP's and SWP's February 90-percent-exceedence forecasts project that CVP storage in Shasta Lake will be greater than approximately 2.4 million acre-feet and SWP storage in Lake Oroville on September 30 will be less than 1.5 million acre-feet, the SWP may rely on Shasta Lake water to provide allocations. The following conditions apply:

    - Should the actual hydrology be drier than the February 90-percent-exceedence forecast, the SWP may borrow Shasta Lake water equal to the amount needed to maintain the allocation made under the 80-percent-exceedence forecast, not to exceed 200 TAF.

    - Borrowing of stored water will be requested by April 1. Reclamation and DWR will develop a plan within 15 days of the date of the request to determine the potential amount of water to be borrowed. The plan will identify the amounts, timing, and any limitation or risk to implementation and will comply with conditions on Shasta Lake and Sacramento River operations imposed by applicable BOs. Water borrowed by the SWP will be provided by making adjustments to the accounting of responsibilities in Article 6 of the Coordinated Operations Agreement.

- *Maximize use of San Luis Reservoir storage* DWR, in coordination with Reclamation and their respective contractors, will develop an annual contingency plan to ensure that storage in San Luis Reservoir remains adequate to avoid water quality problems for CVP contractors diverting directly from the reservoir. The plan will identify actions and triggers to provide up to 200 TAF of source shifting, allowing

Reclamation to use the CVP share of San Luis Reservoir more effectively to increase CVP allocations.

Additionally, a solution to the San Luis Reservoir low-point problem is in the long-term operation of the CVP and SWP and is part of this consultation. The CALFED ROD (August 28, 2000) identified solving the low-point problem in San Luis Reservoir as a complementary action that would avoid water quality problems associated with the low point and increase the effective storage capacity in San Luis Reservoir up to 200 TAF. This action, though not implemented at present, is part of the future proposed action on which Reclamation is consulting. All site-specific and localized actions related to implementing a solution to the San Luis Reservoir low-point problem, such as constructing physical facilities in or around San Luis Reservoir and any other site-specific effects, will be addressed in a separate consultation.

Quantitative Assessment of Effects on Air Quality For this cumulative effects analysis, regional impacts on air quality have been addressed through a quantitative analysis using the plan approach. As described in Chapter 5, "Air Quality and Climate," significance thresholds for the Shasta County Air Quality Management District (SCAQMD) are defined in the Shasta County General Plan. Analysis of local cumulative impacts is based on both the plan approach, which defines impact thresholds, and the list approach, which identifies projects that may emit pollutants in the same area as the proposed action. SCAQMD standards for criteria pollutants have been established to limit the emissions of individual projects when considering the cumulative effect of all projects on regional pollutant concentrations. Therefore, a significant direct project impact would also be a significant cumulative impact.

The URBEMIS2007 emissions model was used to estimate emissions of pollutants from construction activities. Among the inputs to the model for construction analysis were the types and quantities of construction equipment to be used, along with the hours of use; areas of land to be graded; number of truck trips and trip distances for export of spoils and import of materials; volumes of buildings to be demolished; areas of buildings to be built; and areas of land to be paved. For postconstruction activities, principal inputs were the number of vehicle trips and average trip distances. The methods and results of this analysis are described in greater detail in Chapter 5, "Air Quality and Climate."

Qualitative Assessment of Other Actions Past, present, and reasonably foreseeable future actions were also assessed qualitatively. Information on current and historical conditions was used to evaluate combined effects of past actions on botanical resources. For present and reasonably foreseeable future actions, a list of related actions was compiled. The combined effects of past, present, and reasonably foreseeable future actions were then evaluated with effects of the project. The combined effects of past actions and the list of related present and reasonably foreseeable future projects are described further below.

Past Actions A large number of past actions have occurred in the study area. These past actions have strongly influenced existing conditions, and some past actions created "legacies" that are still affecting resources. Among the legacies are the sediment released by hydraulic mining and the metal contamination that is still being generated by abandoned mines. The following are the most important of these past actions:

- Population growth and associated development of socioeconomic resources and infrastructure
- Conversion of natural vegetation to agricultural and developed land uses
- Introduction of nonnative plant and animal species
- Resource extraction (e.g., mining, grazing, and timber harvests)
- Water development actions, particularly the construction and operation of Shasta Dam, the rest of the CVP, and the SWP

Present and Reasonably Foreseeable Future Actions Present projects and reasonably foreseeable (probable) future projects are those projects that are currently under construction, approved for construction, or in final stages of formal planning.

The present or reasonably foreseeable (probable) future actions considered in this cumulative effects analysis are those actions located within the primary or extended study area that have been identified as potentially affecting resources that also may be affected by the SLWRI. These actions were identified by compiling and then reviewing a preliminary list of actions. A preliminary list of actions was compiled by reviewing available information regarding planned projects (including agency Web sites). Actions were then reviewed for inclusion in the cumulative effects analysis based on three criteria:

- The action has an identified sponsor actively pursuing project development; the sponsor has completed or issued NEPA and/or CEQA compliance documents such as a DEIS or DEIR; and the action appears to be "reasonably foreseeable," given other considerations such as public and stakeholder controversy.
- Available information defines the action in sufficient detail to allow meaningful analysis.
- The action could affect resources potentially affected by the SLWRI.

Any action that could affect resources potentially affected by the SLWRI and was under construction was considered "reasonably foreseeable."

Based on this review, the effects of the following actions were qualitatively considered in the assessment of cumulative effects of the SLWRI. This list is organized into four categories of actions: water resources, resource management and restoration, levee, and development actions. Some unknown subset of the following projects, while not strictly meeting the criteria above, would likely be implemented: the *Bay Delta Conservation Plan* (and associated alternative Delta conveyance facilities), the North-of-Delta Offstream Storage Facility (Sites Reservoir), the Upper San Joaquin River Basin Storage Investigation (Temperance Flat Reservoir), and the South Delta Improvements Program. It would be speculative to consider these projects at any more than a conceptual basis because these projects and their effects are not defined in sufficient detail to allow meaningful analysis.

Water Resources Actions In addition to the water resources actions described above in the section "Quantitative Assessment of Actions Related to Water Resources," the water resources–related actions described below were identified as reasonably foreseeable.

Red Bluff Diversion Dam Pumping Plant In 2002 and again in 2006, Reclamation circulated a DEIS/EIR that analyzed various options for improving fish passage at Red Bluff Diversion Dam (RBDD) and requested public comments. Shortly after the 2006 release of the DEIS/EIR, Reclamation stated that Alternative 2B, featuring construction of a new pumping plant and operation of the RBDD gates in the out position for approximately 10 months of the year, was its Preferred Alternative (72 *Federal Register* 4292, January 30, 2007). Reclamation subsequently prepared an FEIS/EIR and ROD calling for a pumping plant to be constructed upstream from the dam to improve the ability to divert water into the Tehama-Colusa Canal when gravity diversion is not possible because the RBDD gates are out. Reclamation completed consultations with the USFWS and NMFS under Section 7 of the Federal ESA regarding construction of the new plant. The new pumping plant would be capable of operating throughout the year, providing water diversions for Tehama-Colusa Canal Authority customers.

Green sturgeon spawn upstream from RBDD; most upstream and downstream migration by adults occurs before July and after August. Once the new pumping plant has been constructed and is operational, RBDD would cease operations with the gates permanently open to improve passage by adult green sturgeon and other spawning fish.

The pumping plant project will occur in three phases. The first, completion of the NEPA/CEQA process, has already been accomplished. The design and permitting phase is commencing, subject to the availability of funding, and is anticipated to take about 18 months. As funding permits, property acquisition will also occur during this phase, and further funding commitments will be secured during this time. The final phase, facilities construction, is anticipated

to take approximately 18 months, but this timeline will be updated during final design and permitting.

North-of-Delta Offstream Storage Investigation The North-of-Delta Offstream Storage Investigation is a feasibility study being performed by Reclamation and DWR, in partnership with local interests and pursuant to the ROD for the CALFED Programmatic EIS/EIR (DWR 2011b). This study is evaluating potential projects for offstream storage of surface water at Sites Reservoir in the upper Sacramento River Basin. Such storage could increase water supply reliability for all beneficial uses (agricultural, urban, and environmental).

The Sites Reservoir Project could contribute to cumulative effects on water supplies and associated resources. The project could increase water supplies available for export in years when export supplies otherwise would be limited. This project also could modify the timing and magnitude of upstream reservoir releases in wet years.

An NOI/NOP for this project was issued in November 2001 and public scoping for the environmental document occurred in January 2002. The complete plan formulation report was published in September 2008 and the EIS/EIR is scheduled to be completed by December 2011.

Folsom Dam Raise Project USACE, sponsored by the Sacramento Area Flood Control Agency (SAFCA) and the Central Valley Flood Protection Board, is responsible for the Folsom Dam Raise Project in the CVP service area on the American River. This project will raise Folsom Dam 7 feet to reduce the Sacramento area's flood risks. The Folsom Dam Raise Project involves raising Folsom Dam and the related dikes/auxiliary dam, modifying L. L. Anderson Dam, constructing a bridge downstream from Folsom Dam, completing temperature shutter modifications, and restoring the area's ecosystem (USACE et al. 2009). Construction on the dam raise began in December 2007 and is expected to be completed in 2015.

Bay Delta Conservation Plan (and Alternative Delta Conveyance Facilities) Four broad concepts have been studied to address urban water quality, water supply reliability, and environmental concerns in the Delta: physical barriers, hydraulic barriers, through-Delta facilities, and isolated facilities. During the last 50 years, a variety of proposals modifying or combining all these concepts have been suggested to improve Delta conditions and allow for beneficial use of Delta water supplies. The *Bay Delta Conservation Plan* is currently being developed. Several alternative Delta conveyance facilities are being evaluated as part of the plan. Among these alternatives is an isolated facility that would convey water around the Delta for local supply and export through a hydraulically isolated channel.

An isolated facility similar to that currently proposed in the *Bay Delta Conservation Plan* was proposed previously, formulated in a plan proposed by the Interagency Delta Committee in 1965 as the Peripheral Canal. A statute that would have authorized this and many other additions to the SWP was rejected by California voters in 1982. That proposal consisted of constructing an isolated canal from near Hood on the Sacramento River to Clifton Court Forebay (with a fish screen near Hood), siphons, and the capability to release water to Delta channels to improve water circulation in Delta channels.

An isolated facility that would convey water around the Delta could improve water quality for urban and agricultural water users; the facility would also eliminate reverse flow in the Delta and improve Delta water quality and flow by releasing water to south Delta channels. Because the intake gate for this facility would be upstream from much of the Delta along the Sacramento River, it would substantially reduce impacts of bromide and agricultural drainage on water delivered to urban water purveyors.

Possible collateral measures to improve water quality at the intake gate would be to divert major agricultural drainage from the Sacramento Valley and effluent from the Sacramento Regional Water Treatment Plant to the Yolo Bypass. This option would also reduce the effects of CVP and SWP export facilities on fish by eliminating predation in Clifton Court Forebay, closing the Delta Cross Channel gates to improve fish migration, and eliminating reverse flow. Implementing this project would result in substantial changes to CVP and SWP system operations and cause a potentially significant impact on hydropower generation and facilities.

Franks Tract Project Reclamation and DWR propose to implement the Franks Tract Project to improve water quality and fisheries conditions in the Delta. Reclamation and DWR are evaluating installing operable gates to control the flow of water at key locations (Threemile Slough and/or West False River) to limit the entry of fish species of concern and higher salinity water into Franks Tract. In addition to improving water quality, the gates would limit migration of delta smelt into the central and south Delta, where their survival rates are reduced. By protecting fish resources, this project also would improve the operational reliability of the CVP and SWP because curtailments (pumping restrictions) in project operations would likely be less frequent.

The project gates would be operated seasonally (January through September) and during certain hours of the day, depending on fisheries and tidal conditions. Boat passage facilities would be included to allow watercraft to pass through when the gates are in operation. The Franks Tract Project is consistent with ongoing planning efforts for the Delta to help balance competing uses and create a more sustainable system for the future. Public scoping meetings were held in October 2008 and preparation of a joint EIS/EIR for the project is under way. The EIS/EIR is expected to be published in fall 2011, with a ROD to be issued and CEQA certification to occur in spring 2012.

Reclamation and DWR have conducted studies to evaluate the feasibility of modifying hydrodynamic conditions near Franks Tract to improve Delta water quality and enhance the aquatic ecosystem. The results of these studies indicate that modifying hydrodynamic conditions near Franks Tract may substantially reduce the Delta's salinity and protect its fishery resources, including the sharply declining populations of delta smelt, a Federally listed and State-listed species that is endemic to the Delta.

The goals of the Franks Tract Project are as follows:

- Modify hydrodynamic conditions to protect fish species of concern, particularly delta and longfin smelt.

- Improve operational flexibility of the CVP and SWP by protecting Delta fish resources; reduce intrusion of higher salinity water resulting from normal tidal influences, sea level rise, or catastrophic levee failures; and protect water quality during extended closures of the Delta Cross Channel.

- Develop water quality and fish protection measures consistent with long-term planning efforts.

In-Delta Storage Program (Delta Wetlands Project) DWR, in coordination with the California Bay-Delta Authority and with technical assistance from Reclamation, completed the State feasibility study for the In-Delta Storage Program in the south Delta, within the extended study area. The In-Delta Storage Project would provide capacity to store approximately 217 TAF of water in the south Delta for a wide array of water supply, water quality, and ecosystem benefits. The project would consist of two storage islands (Webb Tract and Bacon Island) and two habitat islands (Holland Tract and Bouldin Island), an embankment design, consolidated inlet and outlet structures, project operations, and habitat management plans. The objectives of the project are to enhance water supply reliability and the operational flexibility of the CVP/SWP system, contribute to ecosystem restoration, and provide water for the Environmental Water Account (EWA) (DWR 2011c). (See the discussion of the EWA below.)

Detailed planning work on the In-Delta Storage Project has been suspended since July 2006 when State funding was cut (DWR 2011c).

Los Vaqueros Reservoir Expansion Project Reclamation, DWR, and Contra Costa Water District are implementing the Los Vaqueros Reservoir Expansion Project in the Delta, within the extended study area. The project's goal is to improve water quality and water supply reliability for Bay Area water users while enhancing the Delta's environment. The existing Los Vaqueros Reservoir storage will be expanded from the existing 100 TAF to 160 TAF to improve water quality and water supply reliability. The Contra Costa Water

District's board of directors certified the EIR and approved the Los Vaqueros Reservoir Expansion Project on March 31, 2010. Construction began in March 2011 (Reclamation and CCWD 2011).

South Delta Improvements Program DWR and Reclamation are seeking permits for the installation and operation of permanent operable gates to implement improvements in the south Delta for protection of local water levels, water quality, and Chinook salmon (DWR 2010). Construction of operable gates at four locations in the south Delta under the South Delta Improvements Program (SDIP) incorporates dredging and extension of agricultural intakes. These proposed actions are intended to maximize diversion capability into Clifton Court Forebay while providing an adequate water supply for South Delta Water Agency and reducing adverse effects of SWP exports on aquatic resources. The SDIP includes physical/structural improvements and operational changes (Reclamation and DWR 2005).

The SDIP was included in the OCAP, which covers SWP and CVP operations. Both USFWS and NMFS rendered jeopardy BOs on the OCAP. The NMFS opinion, issued in June 2009, specifically directs DWR to halt implementation of the SDIP. NMFS indicates that consultation for the SDIP cannot be reinitiated until after 3 years of fish predation studies at the South Delta temporary barriers are completed. After all permits have been acquired, DWR can proceed with construction. No schedule has been established for project completion.

Central Valley Flood Protection Plan Legislation passed in 2007 directs DWR to develop three documents that will guide improvement of integrated flood management:

- *State Plan of Flood Control Descriptive Document* to inventory and describe the flood management facilities, land, programs, conditions, and mode of operations and maintenance for the State/Federal flood protection system in the Central Valley.

- *Flood Control System Status Report* to assess the status of the facilities included in the State Plan of Flood Control Descriptive Document, identify deficiencies, and make recommendations.

- *Central Valley Flood Protection Plan* (CVFPP) to describe a sustainable, integrated flood management plan that reflects a systemwide approach for protecting areas of the Central Valley that currently receive protection from flooding by existing facilities of the State Plan of Flood Control. The plan will incorporate the State Plan of Flood Control and Flood Control System Status Update. The CVFPP must be prepared by January 1, 2012, and is scheduled for adoption by the Central Valley Flood Control Board by July 1, 2012.

The CVFPP will be a sustainable, integrated flood management plan that describes the existing flood risk in the Central Valley and recommends actions to reduce the probability and consequences of flooding. Produced in partnership with Federal, tribal, local, and regional partners and other interested parties, the CVFPP will also identify the mutual goals, objectives, and constraints important in the planning process; distinguish plan elements that address mutual flood risks; and, finally, recommend improvements to the State/Federal flood protection system.

Resource Management and Restoration Actions The actions related to resource management and restoration that are described below were identified as reasonably foreseeable.

Trinity River Mainstem Fishery Restoration Program The Trinity River Restoration Program staff, funded by Federal, State, and local agencies, is responsible for implementing the Trinity River Mainstem Fishery Restoration Program in the CVP service area at Lewiston Dam on the Trinity River. The program plans to implement recovery actions for the Trinity River and its fish and wildlife populations. This plan includes direct in-channel actions, continued watershed restoration activities, replacement of bridges and structures within the floodplain, and a program to monitor and improve restoration activities. Some of the actions and activities have been implemented and are operational. The plan has two restoration goals: reestablish the natural physical processes that create and maintain high-quality aquatic habitat; and create spawning and rearing conditions downstream from the dams, including adequate water temperatures, that best compensate for lost habitat upstream.

The ROD for the Trinity River Restoration Program was signed in December 2000 and, after various legislative delays, was put into action after November 2004. Full implementation of the releases specified in the ROD and construction of the channel rehabilitation sites depend on identifying and implementing an appropriate realty strategy for private landowners along the river (TRRP 2011).

Central Valley Project Improvement Act The Central Valley Project Improvement Act (Title 34, Sections 3401–3408(h) of Public Law 102-575) is concerned with restoring anadromous fish populations, providing water supplies for Federal and State refuges, mitigating effects of the CVP on other fish and wildlife, and retiring drainage-impaired farmlands. To fulfill these provisions, the Central Valley Project Improvement Act established an ongoing program creating a fund for restoration actions. The program is financed by the CVP's water and power users and administered by Reclamation. Funds are contributed to multiple restoration actions annually to finance restoration of aquatic, riparian, and other habitats and modify CVP operations.

CALFED Ecosystem Restoration Program DFG, USFWS, and NMFS implement the CALFED Ecosystem Restoration Program (CALFED 2000b), which works to improve the ecological health of the Bay-Delta

watershed by restoring and protecting habitats, ecosystem functions, and native species. The program includes all projects authorized, funded, and permitted (even if not constructed) to date, particularly in the Delta, that aim to do any of the following:

- Recover at-risk native species dependent on the Delta, Suisun Bay, and San Francisco Bay
- Minimize the downward population trends of native species that are not listed
- Protect and restore functional habitat types in the Bay-Delta estuary and its watershed for ecological and public values
- Prevent the establishment of additional nonnative invasive species and reduce the negative ecological and economic impacts of established nonnative species in the Bay-Delta estuary
- Improve and/or maintain water and sediment quality conditions that fully support healthy and diverse aquatic ecosystems in the Bay-Delta estuary and watershed

Since its inception, Ecosystem Restoration Program agencies have consolidated their vision into a single "blueprint" for ecosystem restoration. They further identified more than 600 programmatic actions and the 119 milestones throughout the Bay-Delta watershed. The blueprint has been implemented through a large number of competitive and directed grants.

Environmental Water Account The EWA Operating Principles Agreement has provided the basis for the operation of the EWA Program since the CALFED ROD was signed in August 2000. The EWA is described below, followed by a discussion of the limited EWA that resulted from the OCAP biological assessment.

EWA Overview The five EWA agencies (DWR, DFG, NMFS, USFWS, and Reclamation) all signed the EWA Operating Principles Agreement, giving the program its operational guidance through September 2004. The five agencies signed a memorandum of understanding (MOU) extending the EWA through December 31, 2007. The principle underlying the EWA was that Reclamation and DWR would operate the CVP and SWP in response to requests by DFG, NMFS, and USFWS to provide protections to fish beyond those required in existing regulatory standards. Specifically, additional water would be provided to the projects later in the season at no extra cost to the Federal and State water contractors.

In 2006, the EWA agencies were cooperating on development of an EIS/EIR for a long-term extension of the EWA Program. However, because Reclamation

decided to pursue reconsultation on the OCAP for the CVP and SWP Delta facilities, the agencies suspended work on the long-term EWA EIS/EIR and instead developed a supplement to the EIS/EIR covering EWA operations through 2011. That supplement was completed in early summer 2008 and was certified by DWR.

The supplemental EWA EIS/EIR was originally intended to facilitate another MOU among the five EWA agencies extending the EWA on a short-term basis through 2011. However, the decision of the U.S. District Court in *NRDC v. Kempthorne* (2007 WL 4462395 (E.D. Cal., December 14, 2007)) placed constraints on the CVP's and SWP's Delta export pumps, in the form of prescribed pumping limits that essentially replace most of the voluntary adaptive decisions on pumping curtailments made under the EWA Program.

In *NRDC v. Kempthorne*, the court directed USFWS to complete and issue a new BO addressing the OCAP, with emphasis on protection of delta smelt. The uncertainty of the resulting requirements on Delta export operations of the CVP and SWP is a major unknown factor in assessing the role of a continued EWA Program.

In 2007, the EWA agencies used new scientific information to reduce pumping based on criteria different from those used in previous EWA operational years; this action was similar to those prescribed by the decision in *NRDC v. Kempthorne*. Pumping from the CVP and SWP pumps was curtailed by 501,500 acre-feet during the 2007 water year, the largest curtailment made during the 7-year history of the EWA Program.

DWR and DFG are also discussing measures to protect longfin smelt. Additional constraints to protect salmon and longfin smelt could further constrain Delta exports and increase the EWA-type water cost to provide such protection.

The intent for the EWA Program was to use public funding during the program's initial years to provide the replacement water required to meet the program goal of no uncompensated water cost to CVP and SWP water users. Substantial public funding was provided in several bond issues; however, most of that funding has been used, and the remaining public funding for the continuation of the EWA is very limited.

There is no plan at this time to provide additional public funding to continue the EWA Program. Since 2008, public funding has been insufficient to provide replacement water to compensate for reductions in Delta pumping to protect Delta fish species, as was done in prior years. In addition, some of the pumping reductions that were previously voluntary may became mandatory. Thus, the nature of the future EWA Program, if any, is subject to further discussion among the five EWA agencies.

DWR has executed an agreement with Yuba County Water Agency to implement a portion of the Yuba Accord, providing about 60 TAF of water per year to DWR for EWA purposes through 2015. DWR also retained enough funds to provide a one-time purchase of up to about 150 TAF for EWA purposes in 2009. Reclamation had some funding from congressional authorization of the EWA Program through 2010, and expected to receive additional appropriations through that period, optimistically enough to purchase about 25 TAF for the next few years.

DWR envisions that Federal resources will be used to address additional fisheries issues in the Delta while funding is available, and that State resources will be used for the Vernalis Adaptive Management Program and its shoulders.

While developing the OCAP project description as the basis for the USFWS and NMFS reconsultation, Reclamation and DWR defined a "limited EWA" as being part of that project description. It is described below.

Limited Environmental Water Account per OCAP Biological Assessment The original EWA was established in 2000 by the CALFED ROD, and operating criteria are described in detail in the EWA Operating Principles Agreement attachment to the ROD. In 2004, the EWA was extended to operate through the end of 2007. Reclamation, USFWS, and NMFS received congressional authorization to participate in the EWA at least through September 30, 2010, per the CALFED Bay-Delta Authorization Act (Public Law 108-361). However, for these Federal agencies to continue participation in the EWA beyond 2010, additional authorization will be required, and continued program activities and funding are highly uncertain.

The EWA agencies acquire assets and determine how the assets should be used to benefit the at-risk native fish species of the Bay-Delta estuary. Operation of the EWA Program is guided by the EWA Team, which comprises technical and policy representatives from each of the five EWA agencies. The EWA Team coordinates its activities with the Water Operations Management Team.

The original purpose of the EWA was to enable diversion of water by the CVP and SWP from the Delta, with diversions to be reduced when at-risk fish species may be harmed, but without uncompensated loss of water to CVP and SWP contractors. Typically, when pumping was curtailed, the EWA replaced the lost water by purchasing surface water or groundwater supplies from willing sellers and by taking advantage of regulatory flexibility and certain operational assets. From 2001 through 2007, when pumping at Banks was curtailed to protect Delta fish, the EWA often owed a debt of water to the SWP, usually reflected in San Luis Reservoir.

The EWA agencies are undertaking environmental review to determine the future of the EWA. No decision has yet been made about the EWA; therefore, for the purposes of this PDEIS, the EWA has been analyzed with limited assets,

focusing on providing assets to support the Vernalis Adaptive Management Program and, in some years, the "post-Vernalis Adaptive Management Program shoulder." The following are the EWA's assets:

- Releases of water described in Component 1 of the Yuba Accord – that is, annual release of an average of 60 TAF of water from the Yuba River to the Delta. Such releases are an EWA asset through 2015, with a possible extension through 2025. In most years the 60 TAF is expected to be reduced by carriage-water costs estimated at 20 percent, leaving an EWA asset of 48 TAF per year. The SWP will provide the 48 TAF per year from project supplies beyond 2015 if releases of Yuba Accord Component 1 water are not extended.

- Purchases of assets, to the extent that funds are available.

- Operational assets granted to the EWA in the CALFED ROD, as follows:

  - A 50 percent share of SWP export pumping of Central Valley Project Improvement Act Section 3406(b)(2) water and Environmental Restoration Program water from upstream releases

  - A share of the use of SWP pumping capacity in excess of the SWP's needs to meet contractor requirements with the CVP on an equal basis, as needed. (Such use may be under the Joint Point of Diversion.)

  - Any water acquired through flexibility in the export/inflow ratio.

  - Use of a 500-cfs increase in authorized Banks capacity from July through September (from 6,680 to 7,180 cfs).

  - Storage in project reservoirs upstream from the Delta and in San Luis Reservoir, with a lower priority than project water. Such stored water will share storage priority with water acquired for Level 4 refuge needs.

- Operational assets averaged 82 TAF from 2001 through 2006, and ranged from 0 to 150 TAF.

San Luis Reservoir Low Point Improvement Project As part of this project, Reclamation is investigating three alternatives to address the water quality problems within the CVP's San Felipe Division (Santa Clara and San Benito counties) that arise when San Luis Reservoir levels drop below 300 TAF during late summer in dry water years, resulting in large algal blooms. The alternatives being considered are to (1) expand the 6-TAF Pacheco Reservoir to 80 TAF or 130 TAF, (2) lower the San Felipe Intake at San Luis Reservoir, or (3) implement a combination comprehensive plan. The combination

comprehensive plan would involve increasing groundwater recharge and recovery capacity, implementing desalination measures, reoperating Santa Clara Valley Water District's raw- and treated-water systems, and implementing institutional measures. If Pacheco Reservoir were to be enlarged, the reservoir would be filled with Delta water; thus, additional impacts on Delta aquatic species (e.g., juvenile salmonids and delta smelt) could result from an increase in Delta exports. The environmental scoping report for the San Luis Reservoir Low Point Improvement Project was released in January 2009 and the plan formulation report was published in January 2011.

B. F. Sisk Dam Corrective Action Project B.F. Sisk Dam (also known as San Luis Dam) is a 300-foot-high, compacted earthfill embankment located on the west side of California's Central Valley approximately 12 miles west of Los Banos. Owned by Reclamation and operated by DWR, the dam is more than 3½ miles long. B.F. Sisk Dam impounds San Luis Reservoir, which has a total capacity of more than 2 million acre-feet. The dam was built between 1963 and 1967 to provide supplemental storage of irrigation water for the CVP and municipal and industrial water for the SWP. The Gianelli Pumping-Generating Plant lifts water from both the California Aqueduct and the Delta-Mendota Canal (via O'Neill Forebay) into San Luis Reservoir for storage.

The dam and reservoir are located in an area of high potential for severe earthquakes on active faults, primarily the Ortigalita Fault, which crosses the reservoir. In the early 1980s, Reclamation conducted an extensive investigation of the seismic safety of B. F. Sisk Dam. The general conclusion was that some of the less dense soils could undergo liquefaction in a major earthquake. However, the investigation determined that liquefaction would not be sufficiently widespread to cause the dam's slopes to become unstable. Using the methods available at the time, Reclamation predicted that the amount of deformation that would occur under severe shaking would be small, and concluded that the dam had no safety deficiencies.

By 2005, the state of the art in seismic analysis of dams had changed substantially, and additional investigations of dam safety were performed. With the updated methodology and earthquake loadings, the dam crest was predicted to settle during the most severe earthquakes, causing the height of the dam's crest to be at the reservoir's maximum water level. It is possible (although not likely) that the embankment deformation would exceed the available freeboard, which would cause the reservoir to overtop the embankment and erode a breach of the dam. Even without overtopping, it is possible that water flowing through cracks in the dam embankment could erode a breach as well.

Reclamation and DWR are conducting engineering and economic studies to determine alternatives for corrective actions that would address potential safety concerns related to structural stability under extreme seismic loading conditions. The agencies will prepare a joint EIS/EIR to evaluate the effects of implementing the B. F. Sisk Dam Corrective Action Project.

Shasta-Trinity National Forest Land and Resource Management Plan USFS has prepared the Shasta-Trinity National Forest (STNF) Land and Resource Management Plan (LRMP) to guide the management of the Shasta and Trinity national forests in the vicinity of Shasta Lake, in the primary study area. The primary goals of the STNF LRMP are to integrate a mix of management activities that allow use and protection of forest resources; meet the needs of guiding legislation; and address national, regional, and local issues. The plan also includes goals to do all of the following:

- Protect unique landscapes and their wild and scenic characteristics for the indefinite future
- Maintain a rich diversity of plants, fish, and wildlife
- Provide high-quality recreational experiences
- Provide a long-term sustained yield of timber, forage, and other resource products and services consumed by society

The plan also includes specific goals relating to wildlife, habitat, water quality, fires and fuel management, visual quality, recreation, minerals, law enforcement, and cultural resources (USFS 1995a). The STNF proposes projects to implement the LRMP, and publishes a list of those projects in the quarterly Schedule of Proposed Actions (USFS 2011). Proposed actions within the analysis area are included in the cumulative effects analysis.

Iron Mountain Mine Restoration Plan The Iron Mountain Mine Trustee Council developed the *Iron Mountain Mine Restoration Plan*. This plan identifies restoration actions to address injuries to or lost use of natural resources from acid mine drainage from the Iron Mountain Mine complex, located west of the upper Sacramento River in the primary study area. The plan involves restoring salmonid populations, riparian habitat, and instream ecological functions. The plan also involves implementing restoration projects to compensate for the lost use of public areas and public services. The aquatic and riparian habitats affected by releases of hazardous substances at or from the Iron Mountain Mine site include the site creeks (Boulder, Slickrock, Flat, and Spring) and the mainstem and tributaries of the Sacramento River from Keswick Reservoir to RBDD. As additional compensation for damage to natural resources, this project includes an option for the Federal government to acquire approximately 1,250 acres for transferring into public ownership and to be administered by the U.S. Bureau of Land Management (BLM) (IMMTC 2002, NOAA 2009). The Iron Mountain Mine Trustee Council has allocated funds to several projects designed to meet the goals of the *Iron Mountain Mine Restoration Plan*.

Mendocino National Forest Land and Resource Management Plan USFS developed the *Mendocino National Forest Land and Resource Management*

Plan (Mendocino National Forest LRMP) to direct the management program for use and protection of the Mendocino National Forest in the primary and extended study areas. The plan fulfills legislative requirements while addressing national, regional, and local issues. The Mendocino National Forest LRMP also includes goals for fish and wildlife, wild and scenic rivers, minerals and energy, law enforcement, heritage resources, fire and fuels, facilities, air quality and diversity (USFS 1995b). The Mendocino National Forest LRMP is currently being implemented.

Sacramento River Conservation Area Forum Program The Sacramento River Conservation Area Forum is a nonprofit organization that works to protect, restore, and enhance the fisheries and riparian habitat along the Sacramento River in the primary and extended study areas, from Keswick Dam downriver to Verona. This is a cooperative effort that works to ensure that habitat restoration and management addresses not only the dynamics of riparian ecosystems, but also the realities of local agricultural and recreational issues associated with land use changes occurring along the river. The program (Resources Agency 2003) has goals to protect, restore, and enhance fisheries and riparian habitat along the Sacramento River and its tributaries and develops and implements site-specific and subreach plans for areas within the conservation area.

U.S. Bureau of Land Management Redding Resource Management Plan BLM prepared this plan (BLM 1992) to identify the direction for the proposed management of public lands and Federal mineral estate it administers within the primary study area and the extended study area along the middle Sacramento River. The primary goal of BLM's Redding Resource Management Plan is to manage public lands to prevent deterioration of habitat for special-status species, thereby precluding the need for Federal or State listing of those species. In 1993, BLM issued a ROD announcing its intent to implement the plan.

Sacramento River National Wildlife Refuge Draft Comprehensive Conservation Plan This plan, put forth by USFWS, provides a 15-year strategy for achieving the goals of the Sacramento River National Wildlife Refuge, located between Red Bluff and Colusa along the middle Sacramento River in the extended study area. One of the plan's goals is to contribute to the recovery of endangered and threatened species and provide natural diversity and abundance of migratory birds and anadromous fish by restoring and managing viable riparian habitats along the Sacramento River, using the principles of landscape ecology. The plan also seeks to provide high-quality opportunities for hunting, fishing, wildlife viewing, and photographic visits; provide visitor safety; and ensure compliance with regulations through law enforcement (USFWS 2005b).

The *Draft Comprehensive Conservation Plan and Environmental Assessment for the Sacramento National Wildlife Refuge* (USFWS 2005b) became available for review and comment in July 2008, with the review period scheduled to end

in September 2008. The final conservation plan will be developed through modifications made during the internal and public review processes.

Comprehensive Management Plan for the Sacramento River Wildlife Area DFG has prepared a this plan for the 3,770-acre Sacramento River Wildlife Area between Red Bluff and Colusa along the middle Sacramento River in the extended study area. This plan provides an ecosystem approach to managing the Great Valley riparian habitat communities in the wildlife area for their ecological values and the enjoyment of the public (DFG 2004).

North Delta Flood Control and Ecosystem Restoration Project Reclamation and DWR propose the North Delta Flood Control and Ecosystem Restoration Project in the north Delta, within the extended study area (DWR 2011d). The goal of this project is to implement flood control improvements in a manner that benefits aquatic and terrestrial habitats, species, and ecological processes. Components being considered for flood control include setback levees, detention basins, dredging, and levee degradation for floodplain expansion, which may also be configured to create quality habitat for species of concern in the north Delta area. These goals would be accomplished by using McCormick-Williamson Tract and Staten Island in the Delta.

The DEIR was released in January 2008, followed by the FEIR in 2010. The design will be completed by fall 2011, with construction expected to be complete in summer 2013.

Levee Actions The actions related to levees that are described below were identified as reasonably foreseeable.

California Department of Water Resources Levee Repair DWR and USACE are responsible for repairing critical erosion sites on California's Federal/State levee system throughout the primary and extended study areas, including the CVP and SWP service areas. Repairs are necessary to keep the levee systems functioning. Some of these systems have deteriorated over time or do not meet current design standards, or both. In general, repairs to Federal and State project levees are being made under three main programs: the Critical Erosion Repairs Program, the Sacramento River Bank Protection Project, and the Public Law 84-99 Rehabilitation Program. A fourth program to repair critically damaged levees in the San Joaquin Flood Control System is under development by DWR. DWR is also working with local agencies to survey and document damage from erosion at additional sites that are under local control (not part of the Federal/State flood control system). The aim is also to assist local jurisdictions in determining the best approach for needed repairs (DWR 2011e).

Nearly 300 levee repair sites have been identified to date. More than 100 of the most critical sites have been repaired. Repairs to others are either in progress or

scheduled to be completed in the near future, and still more repair sites are in the process of being identified, planned, and prioritized (DWR 2011e).

CALFED Levee System Integrity Program DWR, DFG, and USACE implement the CALFED Levee System Integrity Program, which maintains and improves the integrity of the Bay-Delta estuary's levee system. The goal of the Levee System Integrity Program is to reduce risk to land use and associated economic activities, water supply, agriculture and residential use, infrastructure, and the ecosystem from the effects of catastrophic breaching of Delta levees. Resources protected by the program include water quality, ecosystem health, infrastructure such as utilities and transportation corridors, agriculture, and recreational industries.

Since 2000, protection for and maintenance of nearly 700 miles of Delta levees has been increased, with ongoing maintenance undertaken along more than 600 miles of eligible project and nonproject levees. Further, stability was improved for more than 45 additional miles of levees. Large levee rehabilitation projects have been undertaken on numerous islands, along with projects to grow native vegetation, reuse more than 2 million cubic yards of dredge material for levee stability and habitat development, and develop approximately 50 acres of riparian and wetland habitat and 3,000 linear feet of shaded riverine aquatic habitat (CALFED 2011).

Natomas Levee Improvement Program Landside Improvement Project SAFCA is implementing the multiple-phase Natomas Levee Improvement Program Landside Improvements Project along the lower Sacramento River in the extended study area, in conjunction with USACE. The project involves implementing improvements to the perimeter levee system of the Natomas Basin in Sutter and Sacramento counties and modifying associated landscaping and irrigation/drainage infrastructure. The project objectives are to provide at least a 100-year level of flood protection to the Natomas Basin as quickly as possible, provide "200-year" protection to the basin over time, and avoid any substantial increase in expected annual damages as new development occurs in the basin (SAFCA 2007).

Multiple CEQA and NEPA documents have been issued by SAFCA and USACE for various phases of this project since 2008. The FEIS for Phase 4a of the project was issued by USACE in February 2010. Construction of some phases of the project is in progress. All construction is expected to be completed by 2014 (SAFCA 2010).

West Sacramento Levee Improvement Program The West Sacramento Levee Improvement Program involves constructing improvements to the levees that protect West Sacramento to meet local and Federal flood protection criteria. The program area includes the entire boundaries of the West Sacramento Area Flood Control Agency, which encompass portions of the Sacramento River, the Yolo Bypass, the Sacramento Bypass, and the

Sacramento Deep Water Ship Channel. The levee system associated with these waterways includes more than 50 miles of levees in Reclamation Districts 900, 537, and 811; DWR's Maintenance Area 4; and the Sacramento Deep Water Ship Channel. These levees completely surround West Sacramento. For the purposes of this program, the levees have been generally divided into nine reaches: Sacramento River Levee North, Sacramento River Levee South, Port North Levee, Port South Levee, South Cross Levee, Deep Water Ship Channel Levee East, Deep Water Ship Channel Levee West, Yolo Bypass Levee, and Sacramento Bypass Levee. Construction began in 2008 and will continue through 2012 (City of West Sacramento 2010).

Land Use Planning Actions Land use plans and policies are described in Chapter 17, "Land Use and Planning"; applicable plans are listed in this section with brief summaries. Inconsistency with land use plans and policies does not necessarily indicate that adverse affects on the environment would occur; however, land use plans and policies guide development and land management activities that would affect the physical environment, and SLWRI actions could have additive or combined effects.

Federal Land Use Planning Federal lands are not subject to county or city general plans. Land use planning direction for the Whiskeytown-Shasta-Trinity National Recreation Area (NRA) is guided by national legislation, regional forest directives, and forest-specific management directives found in the STNF LRMP.

County and City Land Use Planning Land use planning is the province of local governments in California. All cities and counties in California are required by the State to adopt a general plan that establishes goals and policies for long-term development, protection from environmental hazards, and conservation of identified natural resources (California Government Code, Section 65300). General plans lay out the pattern of future residential, commercial, industrial, agricultural, open-space, and recreational land uses within a community. To facilitate implementation of planned growth patterns, general plans identify goals and/or policies to establish land use patterns.

The *Shasta County General Plan* (2004) provides planning guidance for privately owned land in Shasta County. Land use directives are provided in the form of goals, policies, objectives, standards, and guidelines. The *Shasta County General Plan* designates the following land uses along the Sacramento River from Shasta Dam south to the Tehama County line:

- Rural residential
- Greenway
- Habitat resource
- Natural habitat

- Agricultural – cropland
- Agricultural – small-scale crops, grazing
- Mineral resources

The *Tehama County General Plan* (2009) designates the following land uses along the Sacramento River from the Shasta County line in the north to Red Bluff:

- Habitat resource, resource lands, and public/wilderness
- Cropland and grazing
- General commercial
- Scenic easement and open space
- Commercial recreation
- Urban and city
- Rural small lot, rural large lot, and suburban

The *City of Shasta Lake General Plan* (1999)designates the following land uses along Shasta Dam Boulevard, the primary roadway leading up to Shasta Dam:

- Community Park
- 100-Year Floodplain
- Public Facilities
- Commercial
- Mixed Use
- Rural Residential (1 unit/2 acres; 1 unit/5 acres)
- Suburban Residential (3 units/acre)
- Urban Residential (10 units/acre)
- Urban Residential – High (20 units/acre)

The City of Redding adopted an updated general plan in 2000 (City of Redding 2000). This general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Greenway
- Park, Park-Golf
- Public Facility; Public Facility–School
- Recreational

- General Office
- General Commercial
- Neighborhood Commercial
- Residential (2 to 3.5, 3.5 to 6, 6–10 units/acre)
- Critical Mineral Resource Overlay
- Mixed Use Neighborhood Overlay

The City of Anderson released its updated general plan in May 2007 (City of Anderson 2007). This general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Commercial
- Industrial
- Public/Quasi-Public
- Medium-Density Residential
- Rural Residential/Rural Estate

The City of Red Bluff most recently amended the Land Use Element of its general plan in 1993. The general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Primary Floodplain
- Exclusive Agriculture
- General Commercial
- Central Business Districts
- Single-Family Residential
- General and Neighborhood Apartment Districts
- General Industrial
- Public Agency District
- Park

The lower Sacramento River and Delta portions of the extended study area are within the planning jurisdiction of Butte, Colusa, Contra Costa, Glenn, Sacramento, Solano, Sutter, Yolo, and Yuba counties. The largest cities in this region are Antioch, Chico, Davis, Fairfield, Martinez, Marysville, Pittsburg, Sacramento, Vacaville, Vallejo, West Sacramento, and Woodland. Each of these entities currently has an adopted general plan and zoning ordinance. Land

use planning documents are adopted by Federal agencies for Federally managed lands in the lower Sacramento River and Delta areas.

The CVP extends from the Cascade Range near Redding in the north to the Tehachapi Mountains near Bakersfield in the south. The CVP serves farms, homes, and industry in California's Central Valley as well as major urban centers in the San Francisco Bay Area. SWP contractors are located in the southern San Joaquin Valley, along the central coast, and in Southern California. The CVP and SWP service areas include portions of both the primary and extended study areas. CVP water irrigates more than 3 million acres of farmland and provides drinking water to nearly 2 million consumers. SWP deliveries are 70 percent urban and 30 percent agriculture, serving 20 million Californians and more than 600,000 irrigated acres, respectively. Each of the counties and incorporated cities in the CVP and SWP service areas has its own adopted general plan and zoning ordinance. Federally managed lands in the service areas are managed in accordance with land use and planning documents similar to the STNF LRMP and BLM's resource management plan, and military installations located in the service areas have their own planning processes.

Development The development actions that are described below were identified as reasonably foreseeable.

Antlers Bridge Replacement The California Department of Transportation (Caltrans), in cooperation with the Federal Transit Administration, is replacing Antlers Bridge over Shasta Lake, which is located on Interstate 5 near the community of Lakehead in Shasta County, in the primary study area. This project involves constructing a 1,942-foot, five-lane segmental bridge with deep-pile foundations that are 12 feet in diameter. The project also includes realignment of a 0.4-mile-long segment of Interstate 5, requiring hillside excavation, construction of a five-lane freeway section, and demolition of the existing 1,500 feet of steel deck truss bridge. The new bridge is being constructed next to the existing bridge, which will remain open to traffic until the new bridge is completed. This project will affect visual resources, fish and wildlife, and water quality standards. However, incorporation of mitigation will reduce these impacts to a less-than-significant level. The project is not expected to have any other significant impacts (Caltrans and FHWA 2007). Construction began in 2009 and will be completed in 2014.

Stillwater Business Park The City of Redding is constructing the Stillwater Business Park (City of Redding 2011), a 700-acre master-planned business park with corporate, manufacturing, and office uses within the Redding city limits in the primary study area. Phase 1 of the project entails developing up to 3,245,300 square feet of primarily light industrial, general industrial, and high-tech cluster uses throughout the entire site. Phase 2 will involve developing up to 1,165,100 square feet of the same uses on the remaining parcels that have not been developed under Phase 1. Developable land includes 16 parcels ranging in size from 5 acres to 100 acres. Two parcels totaling 186

acres will be designated for open space. Currently, 16 lots are available for development.

Shasta Metro Enterprise Zone Program The Economic Development Corporation of Shasta County is responsible for the Shasta Metro Enterprise Zone Program, implemented around Shasta Lake and the upper Sacramento River, in the primary study area. Enterprise zones are designated by the State as economic development areas created to encourage and stimulate economically depressed areas. This is generally achieved via tax, hiring, and financial incentives from the State, in combination with local assistance. On November 6, 1991, the State designated the Shasta Metro Enterprise Zone, which expired on November 5, 2006. Shasta County applied for a new zone and received final designation effective November 6, 2006, to November 5, 2021 (EDC 2011). The Shasta Metro Enterprise Zone is intended to stimulate development and redevelopment projects within the project area.

The Shasta Metro Enterprise Zone covers more than 11,000 parcels, or more than 50 percent of all business entities in Shasta County. An EIR for the Shasta Metro Enterprise Zone was certified and approved by the Shasta County Board of Supervisors on January 15, 2008 (Shasta County 2008).

Significance Criteria For purposes of this PDEIS, cumulative impacts of an alternative under the SLWRI would be significant if implementing the alternative would make a considerable incremental contribution to a significant cumulative effect. The alternative's contribution is evaluated in combination with the effects of other past, present, and reasonably foreseeable future projects to determine whether (1) the overall cumulative effect would be significant and (2) the alternative's contribution would be considerable. Cumulatively significant impacts would do any of the following:

- Cause a significant adverse effect on a resource (using the criteria for significance described in the "Environmental Consequences and Mitigation Measures" sections of Chapters 4 through 25 of this PDEIS)
- Adversely affect a resource that already has a degraded or declining condition because of substantial adverse effects that have already occurred
- Cause effects that were initially not significant, but that would be part of an irreversible degrading or declining trend

3.3 Resources Eliminated from Further Consideration

CEQA and the State CEQA Guidelines provide for identification and elimination from detailed study of the issues that are not significant or that have been covered by prior environmental review (Public Resources Code, Section

21002.1; State CEQA Guidelines, Section 15143). The NEPA regulations provide similar provisions (40 CFR 1501.7(a)(3)).

During initial scoping with the public and governmental agencies, and based on information obtained through literature review, agency correspondence, consultations, and field data collection, it was determined that no resource areas were able to be eliminated from detailed study. Therefore, all resource areas covered by NEPA and CEQA are addressed in this PDEIS.

3.4 Regulatory Framework

3.4.1 Federal

National Environmental Policy Act

NEPA is the nation's broadest environmental law, applying to all Federal agencies and most of the activities they manage, regulate, or fund that affect the environment. This law requires Federal agencies to disclose and consider the environmental implications of their proposed actions. NEPA establishes environmental policies for the nation, provides an interdisciplinary framework for Federal agencies to avoid or minimize environmental impacts, and contains action-forcing procedures to ensure that Federal agency decision-makers take environmental factors into account.

Clean Water Act

Section 404 Section 404 of the CWA requires that a permit be obtained from USACE for the discharge of dredged or fill material into "waters of the United States, including wetlands." Waters of the United States include wetlands and lakes, rivers, streams, and their tributaries. Waters of the United States are defined for regulatory purposes, at 33 CFR 328.3, as follows:

> *(1) All waters which are currently used, or were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of tide; (2) All interstate waters, including interstate wetlands; (3) All other waters such as intrastate lakes, rivers, streams, mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, the use, degradation or destruction of which could affect interstate or foreign commerce; (4) All impoundments of waters otherwise defined as waters of the United States under the definition; (5) Tributaries of waters identified in paragraphs 1–4 in this section; (6) The territorial seas; and (7) Wetlands adjacent to waters identified in paragraphs 1–6 in this section.*

CWA Section 404(b) requires that USACE process permits in compliance with guidelines developed by the U.S. Environmental Protection Agency (EPA).

These guidelines (the CWA Section 404(b)(1) Guidelines) require the analysis of alternatives available to meet the project's purpose and need, including those alternatives that avoid and minimize discharges of dredged or fill materials in waters. Once alternatives deemed to be practicable have been identified, the only action that USACE can permit must be the least environmentally damaging practical alternative.

Actions typically subject to Section 404 requirements are those that would take place in wetlands or stream channels, including intermittent streams, even if they have been realigned. Within stream channels, a permit under Section 404 would be needed for any discharge activity below the ordinary high-water mark. (The ordinary high-water mark is the line on the shore established by the fluctuations of water. It is indicated by physical characteristics such as a clear, natural line impressed on the bank; shelving; changes in the character of soil; destruction of terrestrial vegetation; or the presence of litter or debris.)

The ROD for the CALFED final programmatic EIS/EIR includes a CWA Section 404 MOU signed by Reclamation, EPA, USACE, and DWR. Under the terms of the MOU, when a project proponent applies for a Section 404 individual permit for CALFED projects, the proponent is not required to reexamine program alternatives already analyzed in the programmatic EIS/EIR. USACE and EPA will focus on project-level alternatives that are consistent with the programmatic EIS/EIR when they select the least environmentally damaging practicable alternative at the time of a Section 404 permit decision.

Section 401 Under CWA Section 401, applicants for a Federal license or permit to conduct activities that may discharge a pollutant into waters of the United States must obtain certification from the state in which the discharge would originate. If appropriate, the certification must be obtained from the interstate water pollution control agency with jurisdiction over affected waters at the point where the discharge would originate. Therefore, all projects that have a Federal component and may affect state water quality (including projects that require a Federal agency approval such as issuance of a Section 404 permit) must also comply with CWA Section 401.

In California, the authority to grant water quality certification has been delegated to the SWRCB. Applications for water quality certification under CWA Section 401 are typically processed by the regional water quality control board with local jurisdiction—in this case the Central Valley Regional Water Quality Control Board. For a project to receive water quality certification, the project's potential impacts must be evaluated in light of water quality standards and CWA Section 404 criteria that govern discharges of dredged and fill materials into waters of the United States.

Federal Endangered Species Act

USFWS and NMFS share responsibility for implementing the ESA. Generally, USFWS manages terrestrial and freshwater species, while NMFS manages

marine and "anadromous" species (species that migrate from salt water to spawn in freshwater), such as Chinook salmon. Both agencies ensure that ESA requirements are followed and evaluate projects that may affect the continued existence of a Federally listed (threatened or endangered) species.

Section 9 of the ESA prohibits the take of Federally listed species. "Take" is defined under the ESA, in part, as killing, harming, or harassing. Under Federal regulations, take is further defined to include habitat modification or degradation where it actually results in death or injury to wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering.

Section 7 of the ESA outlines procedures for Federal interagency cooperation to conserve Federally listed species and designated critical habitat. Section 7(a)(2) requires Federal agencies to consult with USFWS to ensure that they are not undertaking, funding, permitting, or authorizing actions likely to jeopardize the continued existence of listed species. NMFS also ensures that projects will not adversely affect essential fish habitat, as defined in the 1996 Sustainable Fisheries Act (Public Law 104-297). The goal is to stop or reverse the continued loss of fish habitats by protecting, conserving, and enhancing habitat.

Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson-Stevens Fishery Conservation and Management Act (commonly known as Magnuson-Stevens Act) establishes a management system for national marine and estuarine fishery resources. This legislation requires Federal agencies to consult with NMFS regarding actions or proposed actions permitted, funded, or undertaken that may adversely affect "essential fish habitat." Essential fish habitat is defined as "waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity."

The Magnuson-Stevens Act states that migratory routes to and from the spawning grounds of anadromous fish are considered essential fish habitat. The phrase "adversely affect" refers to the creation of any impact that reduces the quality or quantity of essential fish habitat. The concept of essential fish habitat is similar to that of "critical habitat" under the ESA; however, measures recommended to protect essential fish habitat by NMFS are advisory, not prescriptive. Federal activities that occur outside of essential fish habitat but that may nonetheless affect waters and substrate that constitute essential fish habitat must also be considered in the consultation process.

Under the Magnuson-Stevens Act, effects on habitat managed under the *Pacific Salmon Fishery Management Plan* must also be considered. The Magnuson-Stevens Act states that consultation regarding essential fish habitat should be consolidated, where appropriate, with the interagency consultation, coordination, and environmental review procedures required by other Federal statutes, such as NEPA, the Federal Wildlife Coordination Act, the CWA, and the ESA.

Fish and Wildlife Coordination Act

Coordination under the Fish and Wildlife Coordination Act is intended to promote conservation of fish and wildlife resources by preventing their loss or damage. It also provides for development and improvement of fish and wildlife resources in connection with water projects. Federal agencies that undertake water projects must fully consider recommendations made by USFWS, NMFS, and the appropriate fish and wildlife agency – in this case, DFG – in their project reports and include measures to reduce impacts on fish and wildlife in project plans.

Federal Clean Air Act

The Federal Clean Air Act (CAA) was enacted to protect and enhance the nation's air quality to promote public health and welfare and the productive capacity of the nation's population. The CAA requires that Federal actions be evaluated to determine their potential impacts on air quality in the project region. California has a corresponding law, which also must be considered during the EIS/EIR process.

For specific projects, Federal agencies must coordinate with the appropriate air quality management district and EPA. This coordination determines whether the project conforms with the CAA and the state implementation plan.

Section 176 of the CAA prohibits Federal agencies from engaging in or supporting an action or activity that does not conform with an applicable state implementation plan. Actions and activities must conform to the plan's purposes of eliminating or reducing violations of national ambient air quality standards, reducing the severity of violations, and attaining those standards expeditiously.

Federal Water Project Recreation Act

The Federal Water Project Recreation Act requires Federal agencies with authority to approve water projects to include recreation development as a condition of approving permits. Recreation development must be considered along with any navigation, flood control, reclamation, hydroelectric, or multipurpose water resource project. The act states that "consideration shall be given to the opportunities, if any, which the project affords for outdoor recreation and for fish and wildlife enhancement…wherever any such project can reasonably serve either or both of these purposes consistently" (Title 16, Section 460l-12 of the U.S. Code (16 USC 460l-12)).

Safe Drinking Water Act

The Safe Drinking Water Act mandates that EPA establish regulations to protect human health from contaminants in drinking water. This law authorizes EPA to develop national standards for drinking water and to create a joint Federal/state-tribal system to ensure compliance with these standards. The law also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its Safe Drinking Water Act authority. EPA and authorized states/tribes enforce the primary drinking water standards, which are contaminant-specific concentration limits that apply to certain public supplies of drinking water. The primary standards consist of two elements: goals for maximum contaminant levels, which are nonenforceable health-based goals; and maximum contaminant levels, which are enforceable limits set as close to the maximum contaminant level goals as possible, considering cost and feasibility of attainment.

National Historic Preservation Act

Section 106 of the National Historic Preservation Act of 1966 and its implementing regulations (36 CFR Part 800, as amended in 2004) requires Federal agencies to consider the effects of their actions, or those they fund or permit, on properties that are listed or eligible for listing in the National Register of Historic Places (commonly known as the National Register). The National Register is a register of districts, sites, buildings, structures, and objects of significance in American history, architecture, archaeology, engineering, and culture. The regulations provided in 36 CFR Part 60.4 describe the criteria to evaluate cultural resources for inclusion in the National Register. Cultural resources can be significant on the national, state, or local level. Properties may be listed in the National Register if they possess integrity of location, design, setting, materials, workmanship, feeling, and association, and meet any one of the following criteria:

(A) Are associated with events that have made a significant contribution to the broad patterns of our history

(B) Are associated with the lives of persons significant in our past

(C) Embody the distinctive characteristics of a type, period, or method of construction, or represent the work of a master, or possess high artistic values, or represent a significant and distinguishable entity whose components may lack individual distinction

(D) Have yielded, or may be likely to yield, information important in prehistory or history

Generally, properties are not considered eligible for the National Register if they have achieved significance within the past 50 years. Certain exceptions are made in the regulation, such as a religious property deriving primary significance from architectural distinction, or a grave of a historical figure of outstanding importance if there is no appropriate site directly associated with his productive life.

Farmland Protection Policy Act

The Farmland Protection Policy Act requires that a Federal agency examine the potential impacts of a proposed action on prime and unique farmland, as defined

by the U.S. Natural Resources Conservation Service. If the action would adversely affect farmland preservation, the Federal agency must consider alternatives to lessen the adverse effects.

Rivers and Harbors Appropriation Act of 1899

The River and Harbors Appropriation Act of 1899 (commonly known as the Rivers and Harbors Act) addresses activities that involve constructing dams, bridges, dikes, or other obstructions across any navigable water. To place any obstruction to navigation outside established Federal lines, or to excavate from or deposit material in such waters, a permit must be obtained from USACE. Navigable waters are defined in 33 CFR 329.4 as follows:

> *Those waters that are subject to the ebb and flow of the tide and/or are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce. A determination of navigability, once made, applies laterally over the entire surface of the waterbody, and is not extinguished by later actions or events which impede or destroy navigable capacity.*

Sections of the River and Harbors Act applicable to the proposed action are described below.

Section 9 Section 9 (33 USC 401) prohibits the construction of any dam or dike across any navigable water of the United States without consent from Congress and approval of the plans by the Chief of Engineers and the Secretary of the Army. Where the navigable portions of the water body lie wholly within the limits of a single state, the structure may be built under authority of the legislature of that state if the location and plans or any modification thereof are approved by the Chief of Engineers and by the Secretary of the Army.

Section 10 Section 10 (33 USC 403) prohibits the unauthorized obstruction or alteration of any navigable water of the United States. Construction of any structure in or over any navigable water of the United States, or the accomplishment of other work affecting the course, location, condition, or physical capacity of such waters, is unlawful unless the work has been authorized by the Chief of Engineers.

Section 13 Section 13 (33 USC 407) states that the Secretary of the Army may permit the discharge of refuse into navigable waters if the Chief of Engineers has determined that the discharge will not injure anchorage and navigation. Discharges of refuse are prohibited unless a permit has been obtained. Although the prohibition in this section – known as the Refuse Act – is still in effect, the Secretary of the Army's permit authority has been superseded by the permit authority given to the EPA Administrator and the states under Sections 402 and 405 of the CWA, respectively.

Migratory Bird Treaty Act

The Migratory Bird Treaty Act, first enacted in 1918, implements domestically a series of treaties between the United States and Great Britain (on behalf of Canada), Mexico, Japan, and the former Soviet Union that provide international protection of migratory birds. The act authorizes the Secretary of the Interior to regulate the taking of migratory birds; it is unlawful, except as permitted by regulations, "to pursue, take, or kill any migratory bird, or any part, nest or egg of any such bird…" (16 USC 703). This prohibition includes both direct and indirect acts, although harassment and habitat modification are not included unless they result in direct loss of birds, nests, or eggs. The current list of species protected by the Migratory Bird Treaty Act includes several hundred species and essentially includes all native birds. The act offers no statutory or regulatory mechanism for obtaining an incidental take permit for the loss of nongame migratory birds.

Bald and Golden Eagle Protection Act

The Bald and Golden Eagle Protection Act, enacted in 1940 and amended multiple times since, prohibits the taking of bald and golden eagles without a permit from the Secretary of the Interior. Similar to the ESA, the Bald and Golden Eagle Protection Act defines "take" to include "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest or disturb" (16 USC 668-668c). Any disturbance that would injure an eagle, decrease productivity, or cause nest abandonment—including habitat alterations that could have these results—is considered take and can result in civil or criminal penalties.

National Forest Management Act

The National Forest Management Act requires USFS to "provide for a diversity of plant and animal communities" (16 USC 1604(g)(3)(B)) as part of its multiple-use mandate. USFS must maintain "viable populations of existing native and desired non-native species in the planning area" (36 CFR 219.19). The Sensitive Species program is designed to meet this mandate and to demonstrate USFS's commitment to maintaining biodiversity on National Forest System lands.

A key requirement of National Forest Management Act is preparation of land and resource management plans that establish the goals, objectives, and standards and guidelines for managing the lands and resources of National Forest System lands managed by the various National Forests.

Federal Land Policy and Management Act

Sections 201 and 202 of the Federal Land Policy and Management Act of 1976 (FLPMA) (43 USC 1711–1712) and the regulations in 43 CFR 1600 provide guidance and direction for implementing BLM's land use planning requirements established by resource management plans. Resource management plans and subsequent planning decisions are the basis for every on-the-ground action undertaken by BLM.

Resource management plans ensure that public lands are managed in accordance with the intent of Congress as stated in the FLPMA, under the principles of multiple use and sustained yield. As required by the FLPMA and BLM policy, public lands must be managed in a manner that will do all of the following:

- Protect the quality of ecological and scientific values
- Preserve and protect certain public lands in their natural condition, where appropriate
- Provide food and habitat for fish and wildlife and domestic animals
- Provide for outdoor recreation and human occupancy and use
- Recognize the nation's need for domestic sources of minerals, food, timber, and fiber from the public lands by encouraging collaboration and public participation throughout the planning process

Resource management plans are among the primary mechanisms for guiding BLM activities to achieve compliance with the FLPMA.

National Wild and Scenic Rivers Act

The National Wild and Scenic Rivers Act of 1968, as amended (Public Law 90-542; 16 USC 1271–1287), established the National Wild and Scenic Rivers System. This system identifies distinguished rivers of the nation that possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values. The National Wild and Scenic Rivers Act preserves the free-flowing condition of designated rivers and protects their local environments. Section 5(d)(1) of the act requires Federal agencies to consider potential national wild, scenic, and recreational river areas when planning for the use and development of water and related land resources. Wild, scenic, and recreational river areas are defined as follows:

- *"Wild" river areas* are rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.
- *"Scenic" river areas* are rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible by roads in places.
- *"Recreational" river areas* are rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Designation as a National Wild and Scenic River explicitly prohibits the Federal government from licensing or permitting new hydroelectric dams or major diversions on these rivers. Federal agencies are also prohibited from assisting any water resource projects that may directly affect the resources for which the river was designated. Public lands within a corridor averaging one-quarter mile on both sides of the rivers are managed to protect resources designated as outstandingly remarkable for their scenic, recreational, historical/cultural, fish, wildlife, ecological, geological, or hydrologic value.

Indian Trust Assets

All Federal agencies have a responsibility to protect Indian trust assets. Indian trust assets are legal interests in assets held in trust by the Federal government for Native American tribes or individuals. Assets may be owned property, physical assets, intangible property rights, a lease, or the right to use something. Typically they include lands, minerals, water rights, hunting and fishing rights, natural resources, money, and claims.

Executive Order 11988 (Flood Hazard Policy)

Executive Order 11988 is a flood hazard policy for all Federal agencies that manage Federal lands, sponsor Federal projects, or provide Federal funds to state or local projects. The order requires that all Federal agencies take necessary action to reduce the risk of flood loss; restore and preserve the natural and beneficial values served by floodplains; and minimize the impacts of floods on human safety, health, and welfare.

Executive Order 11990 (Protection of Wetlands)

Executive Order 11990 is an overall wetlands policy for all agencies that manage Federal lands, sponsor Federal projects, or provide Federal funds to state or local projects. The order requires Federal agencies to follow avoidance, mitigation, and preservation procedures with public input before they propose new construction in wetlands. Executive Order 11990 can restrict the sale of Federal land containing wetlands; however, it does not apply to Federal discretionary authority for non-Federal projects (other than funding) on non-Federal land.

Executive Order 12898 (Environmental Justice Policy)

Executive Order 12898 requires Federal agencies to identify and address disproportionately high and adverse human health and environmental effects of Federal programs, policies, and activities on minority and low-income populations. The requirements of Executive Order 12898 apply to all Federal actions that are located on Federal lands, sponsored by a Federal agency, or funded with Federal monies and may affect minority or low-income populations.

Executive Order 13007 (Indian Sacred Sites) and April 29, 1994, Executive Memorandum

Executive Order 13007 (May 24, 1996) requires Federal agencies with land management responsibilities to accommodate access to and ceremonial use of Indian sacred sites by Indian religious practitioners and avoid adversely affecting the physical integrity of such sacred sites. Where appropriate, agencies are to maintain the confidentiality of sacred sites. Among other things, Federal agencies must provide reasonable notice of proposed actions or land management policies that may restrict future access to or ceremonial use of, or adversely affect the physical integrity of, sacred sites. The agencies must comply with the April 29, 1994, executive memorandum, "Government-to-Government Relations with Native American Tribal Governments."

Executive Order 13112 (National Invasive Species Management Plan)

Executive Order 11312 directs all Federal agencies to prevent and control introductions of invasive nonnative species in a cost-effective and environmentally sound manner to minimize their economic, ecological, and human health impacts. Executive Order 11312 established the national Invasive Species Council, made up of Federal agencies and departments, and the supporting Invasive Species Advisory Committee, composed of state, local, and private entities. The Invasive Species Council and Advisory Committee oversee and facilitate implementation of the executive order, including preparation of a national invasive-species management plan.

Federal Transit Administration

To address the human response to groundborne vibration, the Federal Transit Administration has set forth guidelines for maximum acceptable vibration criteria for different types of land uses. These include 65 vibration decibels for land uses where low ambient vibration is essential for interior operations (e.g., hospitals, high-tech manufacturing, and laboratory facilities), 80 vibration decibels for residential uses and buildings where people normally sleep, and 83 vibration decibels for institutional land uses with primarily daytime operations (e.g., schools, churches, clinics, and offices) (FTA 2006).

Standards have also been established to address the potential for groundborne vibration to cause structural damage to buildings. These standards were developed by the Committee of Hearing, Bio Acoustics, and Bio Mechanics at the request of EPA (FTA 2006). For fragile structures, this committee recommends a maximum limit of 0.25 inch per second peak particle velocity (FTA 2006). (Peak particle velocity is a measure of the intensity of ground vibration, specifically the time rate of change of the amplitude of ground vibration.)

Federal Land Use Policies

Federal land use policies apply only to actions on or affecting the uses of Federal lands. The Federal lands in the vicinity of the study area include the following:

- National Forest System lands administered by the Shasta-Trinity National Forest
- Reclamation-owned lands along the Sacramento River just south of Shasta Dam
- BLM-owned lands along the Sacramento River, just north of Red Bluff

Encroachment within these Federal properties would require approval from these entities.

Shasta-Trinity National Forest Management Plan

The *Shasta-Trinity National Forest Management Plan* was most recently revised in 1995. This document is revised every 10 to 15 years; it supersedes any previous forest plans, timber management plans, or NRA plans. It contains the goals and objectives for Shasta-Trinity National Forest, its standards and guidelines, management prescriptions to be applied to land areas, and management area direction. It also sets forth requirements for monitoring and implementation of the plan. The allocations associated with this plan not only reflect the capability and suitability of the land for various uses, but also respond to the public issues (such as recommendations for Wild and Scenic River designations) and development opportunities identified during the planning process.

Whiskeytown-Shasta-Trinity National Recreation Area Management Plan

The Whiskeytown-Shasta-Trinity NRA consists of the Shasta and Trinity units (managed by USFS) and the Whiskeytown Unit (managed by the National Park Service). Shasta-Trinity National Forest has initiated the scheduled revision of the management plan for the Shasta and Trinity units of the Whiskeytown-Shasta-Trinity NRA. Congress established the NRA on November 8, 1965, in Public Law 89-336. USFS and the National Park Service are required under the act to carry out administration under management plans, which must be revised periodically. The management plan was most recently revised in 1996. Through a series of amendments, USFS is now proceeding to update the *Shasta-Trinity National Recreation Area Management Guide*, with completion anticipated within the next 2 years. This plan is typically revised every 10 to 15 years.

The Shasta-Trinity National Recreation Area Management Guide guides the management of the NRA by interpreting the goals, objectives, standards, guidelines, and management prescriptions from the enabling legislation, Federal regulations, and the Forest Land and Resource Management Plan. It will address the management of resources, changes in technology, and recreation trends in Shasta-Trinity National Forest and the vicinity. Plan amendments may occur whenever monitoring requirements indicate a need for change. The Forest Supervisor can approve amendments to the plan if they are determined not to be significant; significant amendments require approval of the Regional Forester. Public notification and adherence to NEPA is required in any case.

Redding Resource Management Plan

BLM owns and manages lands along the Sacramento River just north of Red Bluff. This land is managed by BLM in accordance with the *Redding Resource Management Plan*. This plan covers more than 250,000 acres in north central California within Butte, Shasta, Siskiyou, Tehama, and Trinity counties. Many Areas of Critical Environmental Concern and National Wild and Scenic River corridors are included within these easily accessed and heavily used public lands. Completed in 1993, the *Redding Resource Management Plan* primarily addresses recreation, land tenure, access, and forest management.

Federal Energy Regulatory Commission

Changes to hydroelectric facilities on the Pit River – Instream flow releases or modifications to downstream structures – may necessitate an amendment to a Federal Energy Regulatory Commission (FERC) license. Typical modifications that require an amendment to a license or exemption include capacity changes, design changes, operational changes, land status changes, and time extensions. Before issuing a license amendment, FERC ensures that proposed changes to hydropower facilities comply with NEPA. For noncapacity-related amendments, the nature of the proposed change, the project type (based on proposed capacity), and the project's construction status determine which items outlined in the FERC Division of Hydropower Administration and Compliance's *Compliance Handbook* to include in the amendment application. Any item in the original license that would be modified as a result of the project would require that a revised version be filed along with the amendment application.

Once the need for an amendment is determined, the appropriate resource agencies are consulted. The extent of agency consultation depends on whether the amendment is capacity-related or noncapacity-related. After prefiling consultation is completed, the licensee files the amendment application. The FERC Division of Hydropower Administration and Compliance then determines whether a public notice is warranted and whether NEPA review is required. NEPA review entails preparing an environmental assessment and/or an EIS. The license amendment process is detailed in the *Compliance Handbook*.

U.S. Coast Guard

The U.S. Coast Guard is responsible for approving the locations of and plans for bridges and causeways constructed across navigable waters of United States. The Coast Guard also approves the locations of and plans for international bridges and the alteration of bridges found to be unreasonable obstructions to navigation.

3.4.2 State

California Environmental Quality Act

Prompted by the passage of NEPA in 1969, CEQA was signed into law in 1970 as California's counterpart to NEPA. CEQA requires State and local agencies to identify the significant environmental impacts of their actions and to avoid or mitigate those impacts, if feasible. The objectives of CEQA are to do all of the following:

- Disclose to decision makers and the public the significant environmental effects of proposed activities
- Identify ways to avoid or reduce environmental damage
- Prevent environmental damage by requiring implementation of feasible alternatives or mitigation measures
- Disclose to the public the reasons for agency approval of projects with significant environmental effects
- Foster interagency coordination in the review of projects
- Enhance public participation in the planning process

California Endangered Species Act

Pursuant to the California Endangered Species Act (CESA), a permit from DFG is required for projects that could result in the take of a plant or animal species that is State-listed as threatened or endangered. Under the CESA, "take" is defined as an activity that would directly or indirectly kill an individual of a species, but the CESA definition of take does not include "harming" or "harassing," as the Federal ESA definition does. As a result, the threshold for take is higher under the CESA than under the ESA (i.e., habitat modification is not necessarily considered take under the CESA).

Sections 3503 and 3503.5 of the California Fish and Game Code state that it is unlawful to take, possess, or needlessly destroy the nest or eggs of any bird, or to take, possess, or destroy any raptors (i.e., species in the orders Falconiformes and Strigiformes), including their nests or eggs. Destruction of active nests caused by removal of vegetation in which the nests are located is a typical violation of these codes. Violation of Section 3503.5 could also include failure of active raptor nests that results from disturbance of nesting pairs by nearby project construction. This statute does not provide for the issuance of any type of incidental take permit.

California Fish and Game Code—Fully Protected Species

Protection of fully protected species is described in Sections 3511, 4700, 5050, and 5515 of the California Fish and Game Code. These statutes prohibit take or

possession of fully protected species. DFG is unable to authorize incidental take of fully protected species when activities are proposed in areas inhabited by those species. DFG has informed non-Federal agencies and private parties that they must avoid take of any fully protected species in carrying out projects.

California Fish and Game Code Section 1602—Streambed Alteration

All diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by DFG under Section 1602 of the California Fish and Game Code. Under Section 1602, it is unlawful for any person, governmental agency, or public utility to do the following without first notifying DFG:

> …*substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake.*

A stream is defined as a body of water that flows at least periodically or intermittently through a bed or channel that has banks and supports fish or other aquatic life. This definition includes watercourses with a surface or subsurface flow that supports or has supported riparian vegetation. DFG's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife.

California Fish and Game Code Sections 5900–5904, 5930–5948, 7261, and 7370—Fish Passage

The California Fish and Game Code include the following provisions intended to protect fish passage:

- *Sections 5900–5904* prohibit constructing or maintaining any device or contrivance in any stream that prevents, impedes, or tends to prevent or impede the passing of fish upstream and downstream.

- *Sections 5930–5948* require DFG to inspect California's dams to ensure that dam owners are maintaining fish passage. DFG may require dam owners to install a suitable fishway if passage is impeded.

- *Section 7261* authorizes the California Fish and Game Commission to designate as "Heritage Trout Waters" any waters that provide anglers with an opportunity to catch native trout, consistent with the conservation of the California native trout. The McCloud River redband trout occurs in the McCloud River upstream from McCloud Dam.

- *Section 7370* prohibits taking or possessing for commercial purposes, buying or selling, or offering to buy or sell all or part of any sturgeon, including its eggs, unless the sturgeon was cultured, taken from another state, or taken pursuant to a sport fishing license. Green sturgeon occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.

Central Valley Flood Protection Board Encroachment Permit

Under Title 23 of the California Code of Regulations, the Central Valley Flood Protection Board (formerly called the State of California Reclamation Board) issues encroachment permits to maintain the integrity and safety of flood control project levees and floodways that were constructed according to the flood control plans adopted by the board or the California Legislature.

California Water Rights

A water right is a legally granted and protected right to take possession of water and put it to beneficial use. As authorized by the California Water Code, the SWRCB allocates surface water rights and permits the diversion and use of water throughout the state. Through its Division of Water Rights, the SWRCB issues permits to divert water for new appropriations, change existing water rights, or store water for a certain length of time. The SWRCB attaches conditions to these permits to ensure that the water user prevents waste, conserves water, does not infringe on the rights of others, and puts the State's water resources to the most beneficial use in the best interest of the public.

California Public Resources Code

The California Public Resources Code, Section 5093.542, established through enactment of the California Wild and Scenic Rivers Act, as amended (Sections 5093.50 – 5093.70), aims to preserve designated rivers that possess extraordinary scenic, recreation, fishery, or wildlife values. With the act's passage, the California system protected segments of the Smith and Klamath river and their tributaries, and the Scott, Salmon, Trinity, Eel, Van Duzen, and American rivers. Segments of the McCloud River, Deer Creek, and Mill Creek were subsequently protected under the act in 1989 and 1995, respectively, although these segments were not formally designated as components of the State's Wild and Scenic Rivers System.

No dam, reservoir, diversion, or other water impoundment facility may be constructed on any river segment included in the State system. No water diversion facility may be constructed on any river segment included in the State system unless the Resources Secretary determines that the facility is needed to supply domestic water to local residents and that the facility will not adversely affect the river's free-flowing condition and natural character. In reference to the McCloud River, Section 5093.542(c) of the Public Resources Code states the following:

> *Except for participation by the [California] Department of Water Resources in studies involving the technical and economic feasibility of enlargement of Shasta Dam, no department or agency of the state shall assist or cooperate with, whether by loan, grant, license, or otherwise, any agency of the federal, state, or local government in the planning or construction of any dam, reservoir, diversion, or other water impoundment facility that could have an adverse effect on the free-flowing condition of the McCloud River, or on its wild trout fishery.*

Designation as a Wild and Scenic River does not affect existing water rights and facilities. Proposed changes in existing rights and facilities or applications for new water rights and facilities on designated segments are subject to the domestic-use restriction and the nondegradation standard. Designated segments are considered fully appropriated streams by the SWRCB.

The California Public Resources Code, Section 5093.542, shares similar criteria and definitions in regard to the purpose of protecting rivers with the National Wild and Scenic Rivers Act: identifying free-flowing rivers with extraordinary values suitable for protection, establishing a study process to include rivers in the system, and classifying river segments as either wild, scenic, or recreational based largely on the degree of development along each river segment included in the system. The primary purpose of both the Federal Wild and Scenic Rivers Act and State Public Resources Code is to prohibit new water impoundments on designated rivers.

The California Public Resources Code also contains several other sections relevant to the project. Some examples include Section 5096.225 (California Park and Recreational Facilities Act of 1984), Section 5094 (Federal Water Project Recreation Act), and the CWA.

California Harbors and Navigation Code

The California Harbors and Navigation Code details the jurisdiction of the California Department of Boating and Waterways, which is focused on the development of public access to waterways, the safety of vessels and boating facilities, and on-the-water safety.

Porter-Cologne Water Quality Control Act

Under the Porter-Cologne Water Quality Control Act, “waters of the State” fall under the jurisdiction of the appropriate regional water quality control board (in this case, the Central Valley Regional Water Quality Control Board). Under the act, the regional water quality control board must prepare and periodically update water quality control basin plans. Each basin plan sets forth water quality standards for surface water and groundwater, and actions to control nonpoint and point sources of pollution to achieve and maintain these standards. Projects that affect wetlands or waters must meet the regional water quality

control board's waste discharge requirements, which may be issued in addition to a water quality certification under Section 401 of the CWA.

California Land Conservation Act of 1965 (Williamson Act)

The California Land Conservation Act of 1965, commonly known as the Williamson Act, is the principal method for encouraging preservation of agricultural lands in California. The Williamson Act enables local governments to enter into contracts with private landowners that restrict specific parcels of land to agricultural or related open space use for 10 years. In return, landowners receive property tax assessments that are based on farming and open space uses rather than full market value. Local governments receive an annual subvention (subsidy) of forgone property tax revenues from the State via the Open Space Subvention Act of 1971.

The Williamson Act empowers local governments to establish "agricultural preserves" consisting of lands devoted to agricultural uses and other compatible uses. When establishing such preserves, the locality may offer to owners of included agricultural land the opportunity to enter into annually renewable contracts that restrict the land for at least 10 years. In return, the landowner is guaranteed a relatively stable tax base, founded on the value of the land for agricultural/open space use only and unaffected by its development potential.

Cancelling a Williamson Act contract requires the landowner to undergo an extensive review and approval process and pay fees of up to 12.5 percent of the property value. The local jurisdiction approving the cancellation must find that the cancellation is consistent with the purpose of the California Land Conservation Act or is in the public interest. Several subfindings must be made to support either finding, as defined in Section 51282 of the California Government Code.

California Clean Air Act

The California Clean Air Act of 1988 requires nonattainment areas to achieve and maintain the State ambient air quality standards by the earliest practicable date and local air districts to develop plans for attaining the State ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide standards.

California Native Plant Protection Act

In addition to the CESA, the California Native Plant Protection Act provides protection to endangered and "rare" plant species, subspecies, and varieties of wild native plants in California. The definitions of "endangered" and "rare" in the California Native Plant Protection Act closely parallel the CESA definitions of "endangered" and "threatened" plant species.

California Surface Mining and Reclamation Act

The California Surface Mining and Reclamation Act of 1975 (SMARA) (Public Resources Code, Section 2710 et seq.) addresses surface mining. Activities subject to SMARA include but are not limited to mining of minerals, gravel,

and borrow material. SMARA requires mitigation to reduce adverse impacts on public health, property, and the environment. Because the SLWRI may obtain borrow material for project construction from sites not previously permitted, Reclamation must comply with SMARA. SMARA applies to an individual or entity that would disturb more than 1 acre or remove more than 1,000 cubic yards of material through surface mining activities, including the excavation of borrow pits for soil material. SMARA is implemented through ordinances for permitting developed by local government "lead agencies" that provide the regulatory framework under which local mining and reclamation activities are conducted. The State Mining and Geology Board reviews the local ordinances to ensure that they meet the procedures established by SMARA.

California Native Plant Society Species Designations

The California Native Plant Society is a statewide nonprofit organization that seeks to increase understanding of California's native flora and to preserve this rich resource for future generations. California Native Plant Society has developed and maintains lists of vascular plants of special concern in California. California Native Plant Society-listed species have no formal legal protection, but the values and importance of these lists are widely recognized.

California Scenic Highway Program

The Scenic Highways Element is an optional element of the *California Highway Designs Manual* authorized by Section 65303 of the Government Code. The stated intent (Streets and Highways Code, Section 260) of the California Scenic Highway Program is to protect and enhance California's natural scenic beauty and to protect the social and economic values provided by the state's scenic resources. Official designation requires a local jurisdiction to enact a scenic corridor protection program that protects and enhances scenic resources. A properly enforced program can do all of the following:

- Protect against encroachment of inappropriate land uses
- Mitigate uses that detract from scenic values by proper siting, landscaping, or screening
- Make development more compatible with the environment by requiring building siting, height, colors, and materials that are harmonious with the surroundings
- Regulate grading to cause minimal alteration of existing contours and to preserve important vegetative features along the highway

State Lands Commission Land Use Lease

The California State Lands Commission was given authority and responsibility to manage and protect the important natural and cultural resources on certain public lands within the state and the public's rights to access these lands. Two distinct types of public lands are under the commission's jurisdiction: sovereign

lands and school lands. Sovereign lands encompass approximately 4 million acres. These lands include the beds of California's naturally navigable rivers, lakes, and streams, and the state's tidal and submerged lands along the coastline, extending from the shoreline out to 3 miles offshore.

State of California General Plan Guidelines

The State of California has developed land-use compatibility guidelines for community-noise environments. The *State of California General Plan Guidelines*, published by the Governor's Office of Planning and Research (OPR 2003), provides guidance for the acceptability of projects within specific community-noise-equivalent-level/day-night noise level (L_{dn}) contours. With regard to this project, water recreational uses are considered to be acceptable in areas where exterior noise levels do not exceed 75 A-weighted decibels community-noise-equivalent-level/L_{dn}. Water recreational uses are normally unacceptable in areas exceeding 70 A-weighted decibel L_{dn} and clearly unacceptable in excess of 80 A-weighted decibel L_{dn}. The guidelines also present adjustment factors that may be used to arrive at noise-acceptability standards that reflect the noise-control goals of the community, the particular community's sensitivity to noise, and the community's assessment of the relative importance of noise issues.

California Department of Transportation

Caltrans recommends a threshold of 0.2 inch per second peak particle velocity for normal residential buildings and 0.08 inch per second peak particle velocity for old or historically significant structures (Caltrans 2002). These standards are more stringent than the Federal standard established by the Committee of Hearing, Bio Acoustics, and Bio Mechanics, presented above under "Federal Transit Administration."

Caltrans is responsible for planning, designing, construction, operating, and maintaining all State-owned roadways in California. The *Caltrans Highway Designs Manual* establishes uniform policies and procedures to carry out Caltrans's highway design functions. The highway design criteria and policies in the manual provide a guide for applying standards in the design of projects and, rather than implementing enforceable regulations, present information and guidance.

3.4.3 Regional and Local

Shasta County Air Quality Management District's Authority to Construct and Permit to Operate

Facilities with equipment that may emit air pollution or would be used for controlling air pollution are subject to SCAQMD permit requirements. SCAQMD grants two types of permits: Authority to Construct, and Permit to Operate. An Authority to Construct permit must be obtained before building or installing a new emissions unit or modifying an existing emissions unit that

requires a permit. A Permit to Operate is issued after all construction is completed and the emission unit is ready for operation.

Other Local Permits and Requirements

Several other local permits and requirements may apply to the proposed action. Shasta and Tehama counties and their public works departments will require compliance with local plans and ordinances, such as the county general plan, zoning ordinances, grading plan, and various use permits. Utility easements and various encroachments also may be required.

This page left blank intentionally.

Chapter 4
Geology, Geomorphology, Minerals, and Soils

The evaluation in this chapter is based on a review of existing literature and data, along with information obtained from the shoreline erosion surveys, wetland delineation, and geotechnical investigations and surveys. The information included in the technical analysis is also derived from the following sources:

- CALFED Bay-Delta Program (CALFED). 2000a. CALFED Bay Delta Program Final Programmatic Environmental Impact Statement/Environmental Impact Report. Available at: http://calwater.ca.gov/CALFEDDocuments/Final_EIS_EIR.shtml. Accessed August 29, 2007.

- California Department of Water Resources. 2006. North-of-the-Delta Offstream Storage Investigation Initial Alternatives Information Report. Available at: http://www.usbr.gov/mp/nodos/docs/index.html. Accessed August 29, 2007.

- Contra Costa Water District. 2006. Contra Costa Water District Alternative Intake Project Draft Environmental Impact Report/Environmental Impact Statement.

4.1 Affected Environment

This section describes the affected environment related to geology, seismicity, soils/erosion, mineral resources, and geomorphology for the dam and reservoir modifications proposed under the SLWRI. The following evaluation is based on a review of existing literature and data, along with information obtained from shoreline erosion surveys, wetland delineation, and geotechnical investigations and surveys. For a more in-depth description, see the *Geology, Geomorphology, Minerals, and Soils Technical Report.*

The environmental setting for the geology, seismicity, soils/erosion, mineral resources, and geomorphology assessment of the Shasta Lake and vicinity portion of the primary study area comprises the watersheds draining to Shasta Lake, and the land area forming the shoreline of Shasta Lake. Five major drainages flow into Shasta Lake and form “arms” of the lake: Big Backbone Creek, the Sacramento River, the McCloud River, Squaw Creek, and the Pit River. This section also refers to the East and West “arms” of the main body of the lake as Main Body East Arm and Main Body West Arm.

4.1.1 Geology

The geology of the study area is described below for both the primary and extended study areas. The bedrock geology of the project study area is described in the following paragraphs. Boundaries of geomorphic provinces referenced in Section 4.1.1 are shown in Figure 4-1.

Shasta Lake and Vicinity

The Shasta Lake and vicinity portion of the primary study area is illustrated in Figure 4-2. The drainages contributing to Shasta Lake cover a broad expanse of land with a widely diverse and complicated geology. Shasta Lake is situated geographically at the interface between the Central Valley, Klamath Mountains, and Modoc Plateau and Cascades geomorphic provinces.

The bedrock geology for the Shasta Lake and vicinity area is shown in Figure 4-3. The mapping legend that accompanies Figure 4-3 is presented in Table 4-1. Shasta Lake itself and adjacent lands (i.e., Shasta Lake and Vicinity) are underlain by rocks of the Klamath Mountains and, to a much more limited extent, the Modoc Plateau and Cascades geomorphic provinces. The regional topography is highly dissected, consisting predominantly of ridges and canyons with vertical relief ranging from the surface of Shasta Lake at 1,070 feet above mean sea level (msl) to ridges and promontories more than 6,000 feet above msl. This diversity in topography is primarily a result of the structural and erosional characteristics of rock units in the Shasta Lake and vicinity area.

Klamath Mountains Geomorphic Province The Klamath Mountains Geomorphic Province is located in northwestern California between the Coast Range on the west and the Cascade Range on the east. The Klamath Mountains consist of Paleozoic metasedimentary and metavolcanic rocks and Mesozoic igneous rocks that make up individual mountain ranges extending to the north. The Klamath Mountain Geomorphic Province consists of four mountain belts: the eastern Klamath Mountain belt, central metamorphic belt, western Paleozoic and Triassic belt, and western Jurassic belt. Low-angle thrust faults occur between the belts and allow the eastern blocks to be pushed westward and upward. The central metamorphic belt consists of Paleozoic hornblende, mica schists, and ultramafic rocks. The western Paleozoic and Triassic belt, and the western Jurassic belt consist of slightly metamorphosed sedimentary and volcanic rocks.

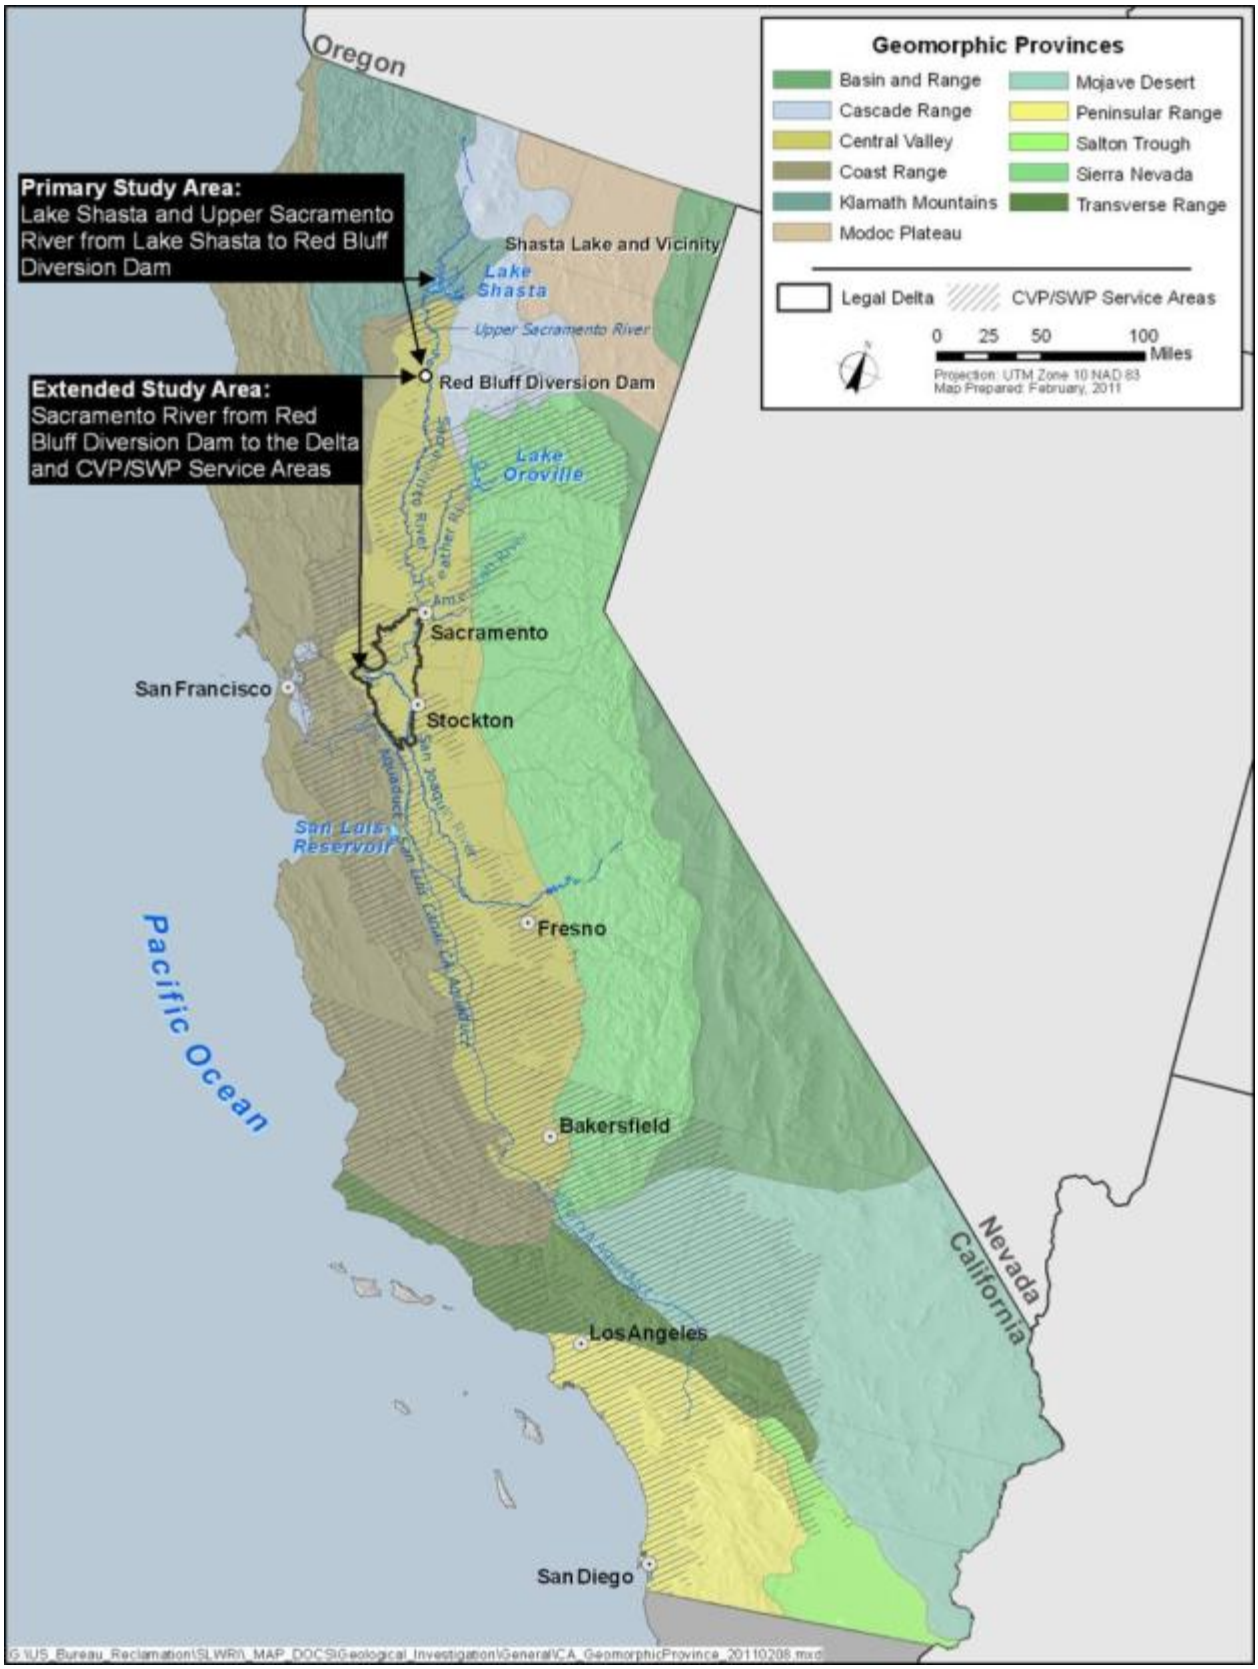

Figure 4-1. Geomorphic Provinces of California

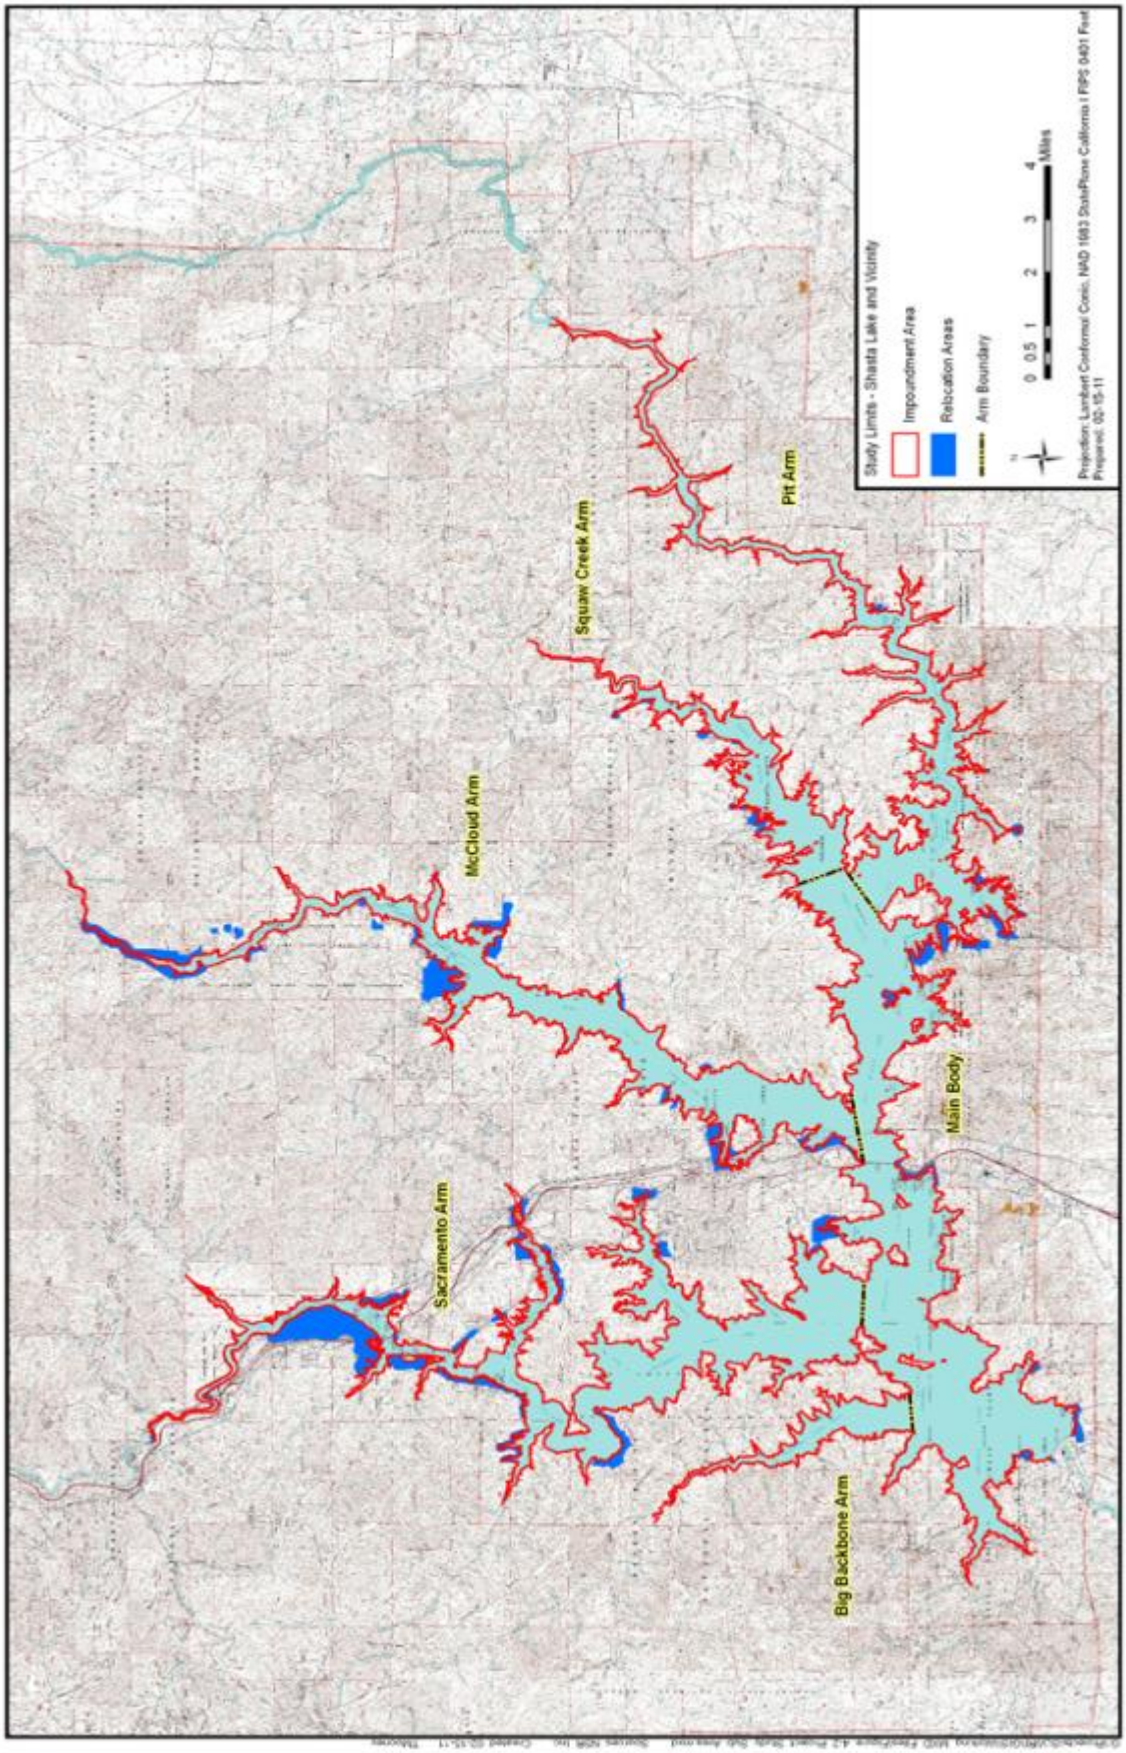

Figure 4-2. Shasta Lake and Vicinity Portion of the Primary Study Area

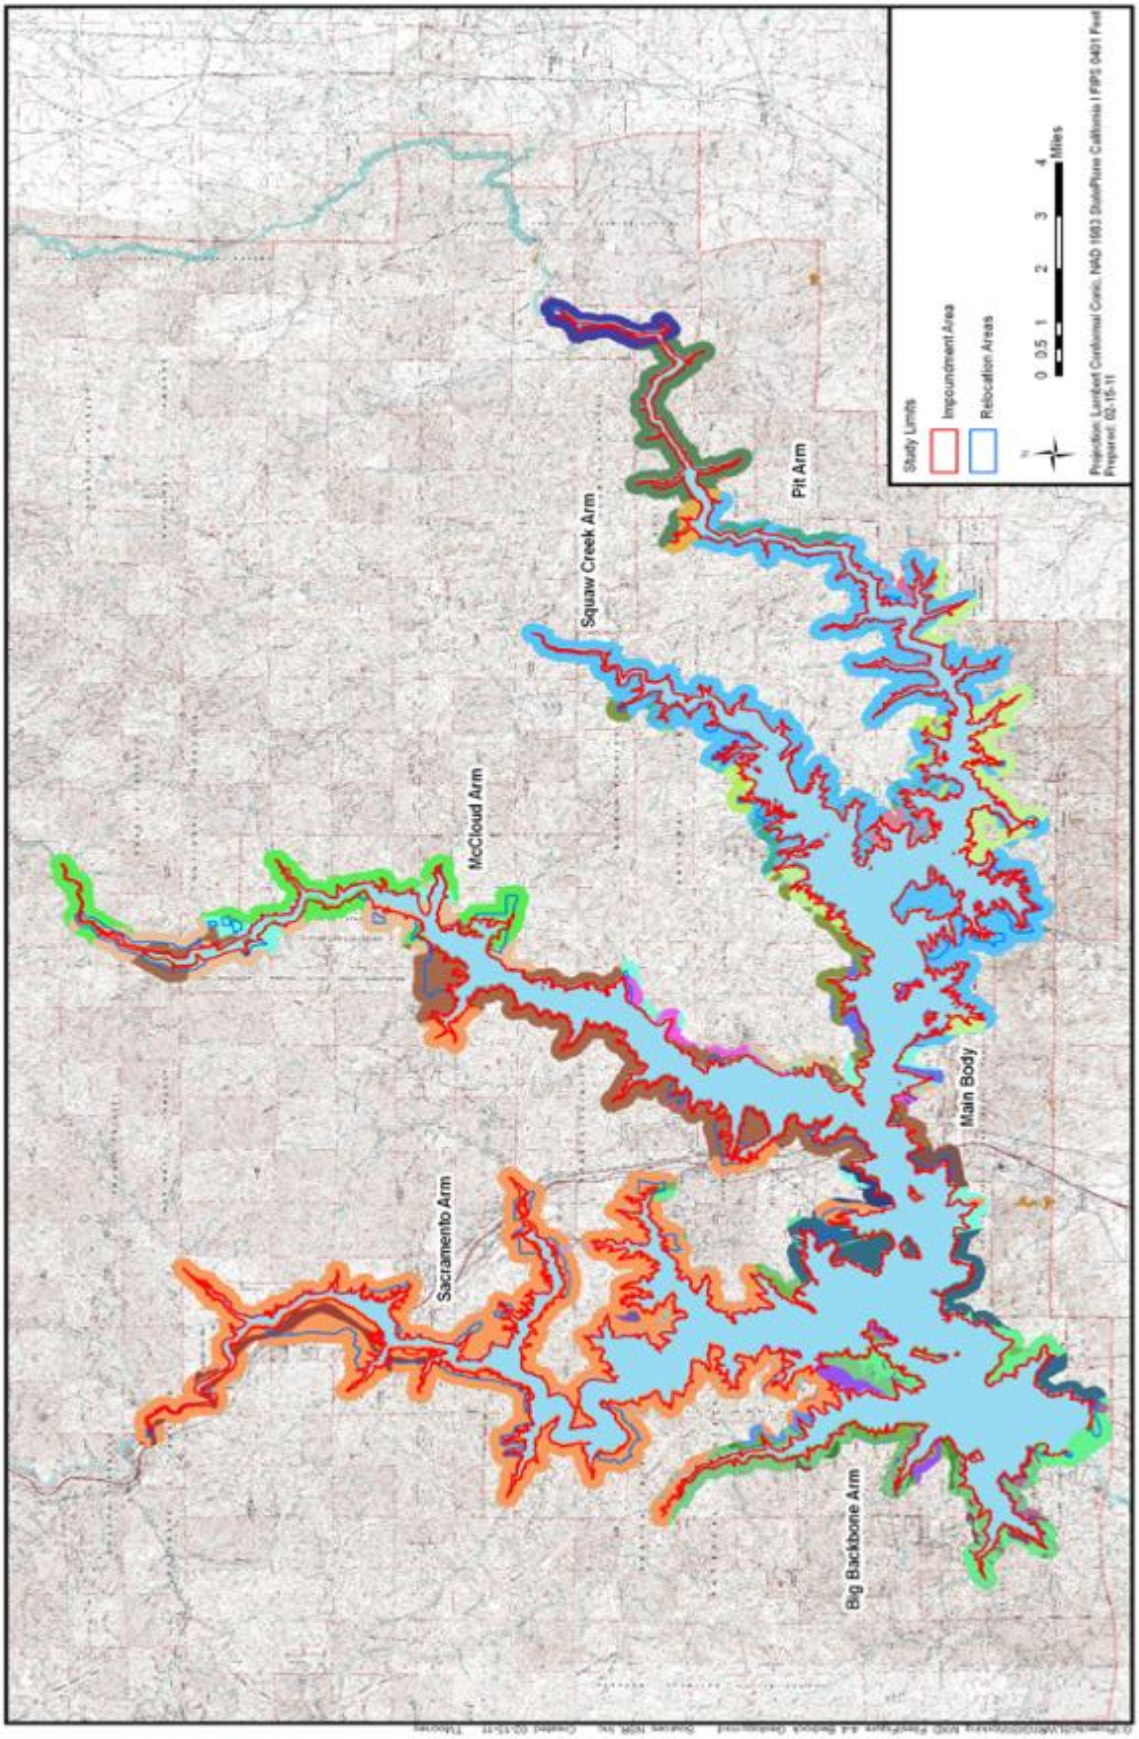

Figure 4-3. Bedrock Geology – Shasta Lake and Vicinity

Table 4-1. Key to Bedrock Geology Map Units – Shasta Lake and Vicinity

A large portion of the Shasta Lake and vicinity area is underlain by rocks of the eastern Klamath Mountain belt. The strata of the eastern belt constitute a column 40,000 to 50,000 feet thick, and represent the time from Ordovician (about 490 years before present) to Jurassic (about 145 million years before present). The stratigraphic column of formations that comprise the eastern Klamath Mountain belt, including a scale of geologic time, is shown in Table 4-2 (Hackel 1966). Important eastern belt rocks that underlay Shasta Lake and vicinity include metavolcanics of Devonian age (i.e., Copley Greenstone and Balaklala Rhyolite formations), metasedimentary rocks of Mississippian age (i.e., Bragdon Formation), thin-bedded to massive sedimentary rocks of Permian age (i.e., McCloud Limestone Formation), and metasedimentary and metavolcanic rocks of Triassic age (i.e., Pit, Modin, and Bully Hill Rhyolite formations) (Reclamation 2009). Intrusive igneous rocks (e.g., localized granitic bodies) make up less than 5 percent of the rocks in the sub-area, but are well represented on the Shasta Lake shoreline, particularly in the south-central area of the lake. Mesozoic intrusive dikes are scattered in the western portion of the map area.

The McCloud Limestone is prominently exposed within the McCloud, Pit, Main Body, and Big Backbone arms of Shasta Lake. Within the lake footprint, the McCloud River Arm has the largest exposure of this limestone, followed by the Pit, Main Body, and Big Backbone arms. Along the McCloud River Arm, this limestone crops out on the eastern shore from the mouth at the main body of the lake to Hirz Bay. Above Hirz Bay, it is intermittently exposed on both sides of the McCloud Arm. Along the Pit Arm near the mouth of Brock Creek, the McCloud Limestone is exposed along the north and southern banks. The McCloud Limestone is exposed near the southern shore of Allie Cove in the eastern portion of the Main Body Arm. Along the Big Backbone Arm, the McCloud Limestone is exposed near the eastern shore between the outlets of Shoemaker and Limerock creeks. Outside the Shasta Lake footprint, an outcrop of the McCloud Limestone is exposed along the McCloud River approximately 10 miles upstream from the mouth into the McCloud River Arm. The McCloud Limestone is also exposed on the north side of Bohemotash Mountain, which is approximately 2 miles from the mouth of Big Backbone Creek at the Big Backbone Arm.

“Skarn” is a geologic term that refers to metamorphic rocks formed in the contact zone of magmatic intrusions (e.g., granite) with carbonate-rich rocks (e.g., limestone) Skarn deposits are rich in lime-silicate minerals, and locally contain magnetite. Permian-aged skarn deposits are present within the McCloud River Arm. The deposits are located near the mouths of Marble and Potter creeks and on the peninsula at the eastern margin of the inlet of the McCloud River Arm. The skarn deposits occur adjacent to the McCloud Limestone at the mouths of Marble and Potter creeks, but the McCloud Limestone is absent near skarn deposits on the peninsula.

Table 4-2. Stratigraphic Column of Formations of the Eastern Klamath Mountain Belt

Period/Age Before Present (million years)	Formation	Thickness (feet)	General Features
Jurassic (145-200)	Potem Formation	1,000	Argillite and tuffaceous sandstones, with minor beds of conglomerate, pyroclastics, and limestone.
	Bagley Andesite	700	Andesitic flows and pyroclastics.
	Arvison Formation of Sanborn (1953)	5,090	Interbedded volcanic breccia, conglomerate, tuff, and minor andesitic lava flows.
Triassic (200-250)	Modin Formation	5,500	Basal member of volcanic conglomerate, breccia, tuff, and porphyry, with limestone fragments from the Hosselkus formation.
	Brock Shale	400	Dark massive argillite interlayered with tuff or tuffaceous sandstone.
	Hosselkus Limestone	0-250	Thin-bedded to massive light-gray limestone.
	Pit Formation	2,000-4,400	Predominantly dark shale and siltstone, with abundant lenses of metadacite and quartz-keratophyre tuffs.
	Bully Hill Rhyolite	100-2,500	Lava flows and pyroclastic rocks, with subordinate hypabyssal intrusive bodies.
Permian (250-300)	Dekkas Andesite	1,000-3,500	Chiefly fragmental lava and pyroclastic rocks, but includes mudstone and tuffaceous sandstone.
	Nosoni Formation	0-2,000	Mudstone and fine-grained tuff, with minor coarse mafic pyroclastic rocks and lava.
	McCloud Limestone	0-2,500	Thin-bedded to massive light-gray limestone, with local beds and nodules of chert.
Carboniferous (300-360)	Baird Formation	3,000-5,000	Pyroclastic rocks, mudstone, and keratophyre flows in lower part; siliceous mudstone, with minor limestone, chert, and tuff in middle part; and greenstone, quartz, keratophyre, and mafic pyroclastic rocks and flow breccia in upper part.
	Bragdon Formation	6,000±	Interbedded shale and sandstone, with grit and chert-pebble conglomerate abundant in upper part.
Devonian (360-420)	Kennett Formation	0-400	Dark, thin-bedded, siliceous mudstone and tuff.
	Balaklala Rhyolite	0-3,500	Light-colored quartz-keratophyre flows and pyroclastics.
	Copley Greenstone	3,700+	Keratophyric and spilitic pillow lavas and pyroclastic rocks.
Silurian (420-450 my	Gazelle Formation	2,400+	Siliceous graywackes, mudstone, chert-pebble conglomerate, tuff, and limestone.
Ordovician (450-490)	Duzel Formation	1,250+	Thinly layered phyllitic greywacke, locally with radiolarian chert and limestone.

A small area of the fossiliferous Cretaceous Chico Formation, consisting of Great Valley marine sedimentary rocks, occurs near Jones Valley Creek, a tributary to the Pit River Arm. Although this rock unit occurs in the immediate vicinity, it is not exposed along the shoreline of the lake and falls outside the Shasta Lake and vicinity area. Some outcrops of McCloud Limestone, especially in the vicinity of McCloud River Bridge, are also fossiliferous.

Modoc Plateau and Cascades Geomorphic Provinces The Cascade Range and Modoc Plateau together cover approximately 13,000 square miles in the northeast corner of California. The Cascade Range and Modoc Plateau (collectively the Modoc Plateau and Cascades Geomorphic Province) are very similar geologically and consist of young volcanic rocks that are Miocene to Pleistocene age. Included in this province are two composite volcanoes, Mt. Shasta and Mt. Lassen, and the Medicine Lake Highlands, a broad shield volcano.

The Cascade volcanics have been divided into the Western Cascade series and the High Cascade series. The Western Cascade series rocks consists of Miocene-aged basalts, andesites, and dacite flows interlayered with rocks of explosive origin, including rhyolite tuff, volcanic breccia, and agglomerate. This series is exposed at the surface in a belt 15 miles wide and 50 miles long from the Oregon border to the town of Mt. Shasta. After a short period of uplift and erosion that extended into the Pliocene, volcanism resumed creating the High Cascade volcanic series. The High Cascade series forms a belt 40 miles wide and 150 miles long just east of the Western Cascade series rocks. Early High Cascade rocks formed from very fluid basalt and andesite that extruded from fissures to form low shield volcanoes. Later eruptions during the Pleistocene contained more silica, causing more violent eruptions. Large composite cones like Mt. Shasta and Mt. Lassen had their origins during the Pleistocene (Norris and Webb 1990).

The Modoc Plateau consists of a high plain of irregular volcanic rocks of basaltic origin. The numerous shield volcanoes and extensive faulting on the plateau give the area more relief than otherwise may be expected for a plateau. The Modoc Plateau averages 4,500 feet in elevation and is considered a small part of the Columbia Plateau, which covers extensive areas of Oregon, Washington, and Idaho.

Volcanic rocks of the Modoc Plateau and Cascades Geomorphic Province are present adjacent to the eastern and northeastern boundaries of the Shasta Lake and vicinity area. In the vicinity of Shasta Lake they occur near the Pit River Arm and along the upper Sacramento River Arm. These rocks are generally younger than 4 million years old. Volcaniclastic rocks, mudflows, and tuffs of the Tuscan Formation occur in the Pit River area, and localized volcanic deposits occur in isolated locations.

The areal extent of bedrock types within the Shasta Lake and vicinity area is presented in Table 4-3 for the portion of the subarea between 1,070 feet and 1,090 feet above msl (i.e., Impoundment Area); and in Table 4-4 for the portion of the subarea potentially disturbed by construction activities (i.e., Relocation Areas).

Table 4-3. Areal Extent of Bedrock Types – Shasta Lake and Vicinity (Impoundment Area)

Map Unit	Formation	Bedrock Types	Study Area (acres)	Study Area (% Total Impoundment Area)

Upper Sacramento River (Shasta Dam to Red Bluff)

The portion of the study area along the Sacramento River downstream to the Red Bluff Diversion Dam encompasses portions of the Cascade Range, Klamath Mountains, and Central Valley Geomorphic Provinces.

Central Valley Geomorphic Province The Central Valley Geomorphic Province is a large, asymmetrical, northwest-trending, structural trough formed between the uplands of the California Coast Ranges to the west and the Sierra Nevada to the east, and is approximately 400 miles long and 50 miles wide (Page 1985). The Coast Ranges to the west are made up of pre-Tertiary and Tertiary semiconsolidated to consolidated marine sedimentary rocks. The Coast Range sediments are folded and faulted and extend eastward beneath most of the Central Valley. The Sierra Nevada to the east side of the valley is composed of pre-Tertiary igneous and metamorphic rocks.

Along the western side of the Sacramento Valley, rocks of the Central Valley Geomorphic Province include Upper Jurassic to Cretaceous marine sedimentary rocks of the Great Valley Sequence; fluvial deposits of the Tertiary Tehama Formation; Quaternary Red Bluff, Riverbank, and Modesto Formations; and Recent alluvium.

The Great Valley Sequence was formed from sediments deposited within a submarine fan along the continental edge. The sediment sources were the Klamath Mountains and Sierra Nevada to the north and east, and include mudstones, sandstones, and conglomerates.

Tertiary and Quaternary fluvial sedimentary deposits unconformably overlie the Great Valley Sequence. The Pliocene Tehama Formation is the oldest, derived from erosion of the Coast Ranges and Klamath Mountains, and consists of pale green to tan semiconsolidated silt, clay, sand, and gravel. Along the western margin of the valley, the Tehama Formation is generally thin, discontinuous, and deeply weathered.

The Red Bluff Formation is a broad erosional surface, or pediment, of low relief formed on the Tehama Formation between 0.45 and 1.0 million years ago. Thickness varies to about 30 feet.

Recent alluvium consists of loose sedimentary deposits of clay, silt, sand, gravel, and boulders. The deposits may originate from landslides, colluvium, stream channel deposits, and floodplain deposits. Landslides occur along the project area but are generally small, shallow debris slides or debris flows.

Stream channel deposits generally consist of unconsolidated sand and gravel, with minor amounts of silt and clay. Floodplain deposits are finer grained and consist almost entirely of silt and clay (DWR 2003).

Lower Sacramento River and Delta

The study area along the lower Sacramento River and the Delta encompasses the Central Valley Geomorphic Province, as described above for the upper Sacramento River portion of the primary study area.

The Delta is a broad depression in the Franciscan bedrock that resulted from an east-west expansion of the San Andreas and Hayward fault systems, filled by sediments deposited over many millions of years via the Sacramento and San Joaquin Rivers and other tributary rivers and streams.

CVP/SWP Service Areas

The CVP/SWP service areas encompass portions of the Central Valley, Sierra Nevada, Coast Ranges, Cascade Range, Peninsular Ranges, Transverse Ranges, Mojave Desert, Modoc Plateau, and Klamath Mountains Geomorphic Provinces.

The south-of-Delta CVP/SWP service areas include two distinct, noncontiguous areas: in the north are the San Felipe Division's CVP service area and the South Bay SWP service area; to the south are the SWP service areas. The northern section of this region encompasses the Coast Ranges Geomorphic Province and the southern portion of this section includes portions of the Peninsular Ranges, Tranverse Ranges, and Mojave Desert Geomorphic Provinces. Additional information on the geomorphic provinces is available in the *Geology, Geomorphology, Minerals, and Soils Technical Report*.

4.1.2 Geologic Hazards

Geologic hazards are described below for both the primary and extended study areas.

Shasta Lake and Vicinity

Six types of geologic hazards have potential to occur within and near the Shasta Lake and vicinity project area: seismic hazards, volcanic eruptions and associated hazards, mudflows, snow avalanches, slope instability, and seiches.

Seismic Hazards Seismic hazards consist of the effects of ground shaking and surface rupture along and around the trace of an active fault. Ground shaking is the most hazardous effect of earthquakes because it is the most widespread and accompanies all earthquakes. Ground shaking can range from high to low intensity and is often responsible for structure failure leading to the largest loss of life and property damage during an earthquake. The Modified Mercalli intensity ratings reflect the relationship between earthquake magnitudes and shaking intensity. Higher magnitude earthquakes typically produce higher shaking intensities over wider areas, which may result in greater damage.

Surface rupture occurs when an earthquake results in ground rupture, causing horizontal and/or vertical displacement. Surface rupture typically is narrow in rock and wider in saturated soils, and also typically tends to occur along previous fault lines.

An active fault is defined by the Alquist-Priolo Earthquake Fault Zoning Act as a fault that has caused surface rupture within the last 11,000 years. The nearest active fault to the southern portion of the Shasta Lake and vicinity project area is the Battle Creek Fault Zone located approximately 27 miles south of the dam (CDC 2006a). The maximum credible earthquake for the southern portion of the Shasta Lake and vicinity area has a moment magnitude of 7.3. A maximum peak ground acceleration of 0.101 g[1] was calculated for the southern portion of the Shasta Lake and vicinity area based on an earthquake moment magnitude of 6.5 from the Battle Creek Fault Zone. The Northeastern California Fault system, located approximately 28 miles south of Shasta Dam, may be capable of causing the highest ground shaking at the site. A maximum peak ground acceleration of 0.126 g was calculated for the Shasta Dam location.

[1] Peak ground acceleration is expressed in units of "g", the acceleration due to Earth's gravity. Thus, 1g = 9.81m/s^2

According to the California Geological Survey Alquist-Priolo Act Active Fault Maps, the nearest active fault north of the Shasta Lake and vicinity area is the Hat Creek-Mayfield-McArthur Fault Zone, located about 50 miles to the northeast of Shasta Dam (Jennings 1975). This fault zone is composed of numerous parallel north-northwest trending normal faults. According to the Alquist-Priolo Act maps, the Hat Creek-Mayfield-McArthur Fault is capable of generating magnitude 7.0 earthquakes with a relatively long return period of 750 years (Petersen et al. 1996).

Other earthquake fault zones within or near the Shasta Lake and vicinity area include the following:

- Pittville Fault located in portions of the Day Bench
- Rocky Ledge Fault located north of Burney in Long Valley and east of Johnson Park

Northeast of the Shasta Lake and vicinity area, portions of Shasta and Siskiyou counties include the area between Lassen Peak and Medicine Lake Highlands. This area is cut by a series of active normal faults that are part of the Sierra Nevada-Great Basin dextral shear zone (Shasta County 2004). These faults are capable of affecting the upper watersheds northeast of the Sacramento Valley. These faults include the previously mentioned Hat Creek-Mayfield-McArthur Fault Zone, the Gillem-Big Crack faults near the California-Oregon border southeast of Lower Klamath Lake, and the Cedar Mountain Fault southwest of Lower Klamath Lake. The faults in this zone are capable of earthquakes up to magnitude 7.0. Farther northeast, the Likely Fault is judged capable of a magnitude 6.9 earthquake. In the northeast corner of the state, the Surprise Fault is capable of a magnitude 7.0 earthquake.

Seismic activity has been reported in the area of Shasta Dam and Shasta Lake, and has typically been in the 5.0 magnitude or lower range. The nearest seismic activity to Shasta Dam and Shasta Lake was a magnitude 5.2 earthquake that occurred 3 miles northwest of Redding, near Keswick Dam, in 1998 (Petersen 1999).

Volcanic Eruptions and Associated Hazards Volcanic hazards include potential eruptions, and their products and associated hazards. In the Shasta Lake and vicinity subarea these include lava flows, pyroclastic flows, domes, tephra, and mudflows and floods triggered by eruptions. Three active centers of volcanic activity, all associated with the Modoc Plateau and Cascades Geomorphic Province, occur near enough to this Shasta Lake and vicinity area to merit discussion: the Medicine Lake Highlands, Lassen Peak, and Mount Shasta.

Medicine Lake Highlands is located approximately 65 air miles northeast of Shasta Lake and includes a broad shield volcano that has a large caldera at its

summit and more than 100 smaller lava cones and cinder cones on its flanks. The volcano developed over a period of 1,000,000 years, mainly through lava flows. The most recent activity was approximately 500 years ago, when a large tephra eruption was followed by an extrusion of obsidian. Volcanic activity is likely to persist in the future (USFS 1994), specifically local lava flows and tephra eruptions.

Lassen Peak lies 50 miles southeast of Shasta Lake. Lassen Peak is a cluster of dacitic domes and vents that have formed over the past 250,000 years. The most recent eruption occurred in 1914. That eruption began as a tephra eruption with steam blasts, and climaxed with a lateral blast, hot avalanches, and mudflows. Most ash from the 1914 eruption was carried to the east of the volcano.

The most prominent, active volcanic feature in the vicinity of Shasta Lake is Mount Shasta, which is located approximately 45 miles north of Shasta Lake. Mount Shasta has erupted at least once per 800 years during the last 10,000 years, and about once per 600 years during the last 4,500 years. Mount Shasta last erupted in 1786. Eruptions during the last 10,000 years produced lava flows and domes on and around the flanks of Mount Shasta. Pyroclastic flows extended up to 12 miles from the summit. Most of these eruptions also produced mudflows, many of which reached tens of miles from Mount Shasta.

Eruptions of Mount Shasta could endanger the communities of Weed, Mount Shasta, McCloud, and Dunsmuir. Such eruptions will most likely produce deposits of lithic ash, lava flows, domes, and pyroclastic flows that may affect low- and flat-lying ground almost anywhere within 12 miles of the summit. However, on the basis of its past behavior, Mount Shasta is not likely to erupt large volumes of pumiceous ash (tephra) in the future. Areas subject to the greatest risk from air-fall tephra are located mainly east and within about 30 miles of the summit (Miller 1980).

Floods commonly are produced by melting of snow and ice during eruptions of ice-clad volcanoes like Mount Shasta, or by heavy rains that may accompany eruptions. By incorporating river water as they move down valleys, mudflows may grade into slurry floods carrying unusually large amounts of rock debris. Eruption-caused floods can occur suddenly and can be of large volume. If floods caused by an eruption occur when rivers are already high, floods far larger than normal can result. Streams and valley floors around Mount Shasta could be affected by such floods as far downstream as Shasta Lake. The danger from floods caused by eruptions is similar to that from floods having other origins, but floods caused by eruptions may be more damaging because of a higher content of sediment that would increase the bulk specific gravity of the fluid (Miller 1980).

Mudflows Small mudflows, not caused by eruptions, are common at Mount Shasta. Relatively small but frequent mudflows have been produced historically (1924, 1926, 1931, and 1977) by melting of glaciers on Mount Shasta during

warm summer months. Mudflows that occurred during the summer of 1924 entered the McCloud River and subsequently flowed into the Sacramento River (Miller 1980).

Snow Avalanches Avalanche hazards near the Shasta Lake and vicinity subarea typically occur in steep, high-elevation terrane. These areas are generally above the treeline or in sparsely vegetated areas. Significant avalanche areas are limited to locations on the upper slopes outside of the Shasta Lake and vicinity area.

Slope Instability (Mass Wasting) Slope instability hazards occur in areas of active and relict mass wasting features (e.g., active and relict landslides, debris flows, inner gorge landscape positions, and complexes of these features). Slope instability hazards occur throughout the Shasta Lake and vicinity area, and are most common in areas of steep topography. Locations in the Shasta Lake and vicinity area of mapped slope instability hazards are shown in Figure 4-4.

The terrane underlying the subarea and surrounding region has been influenced by a combination of tectonic uplift, mass wasting, and fluvial and surface erosion processes. The influence of these processes is ongoing, with evidence of ancient and more recent mass wasting features over the entire area, consisting of debris slides, torrents, and flows, with lesser amounts of rotational/translational landslides. The extent or distribution of mass wasting features across the region is believed not to have changed appreciably as a result of land use activities following Anglo-American settlement (USFS 1998).

Much of the topography in the general vicinity of Shasta Lake is steep, with concave swales; therefore, landslides are relatively common, ranging from small mudflows and slumps to large debris slides, debris flows, and inner gorge landslides. Small shallow debris slides associated with localized alluvial/colluvial rock units occur along the shoreline of Shasta Lake. Rock slides caused by mining activities have also occurred on the slopes surrounding Shasta Lake.

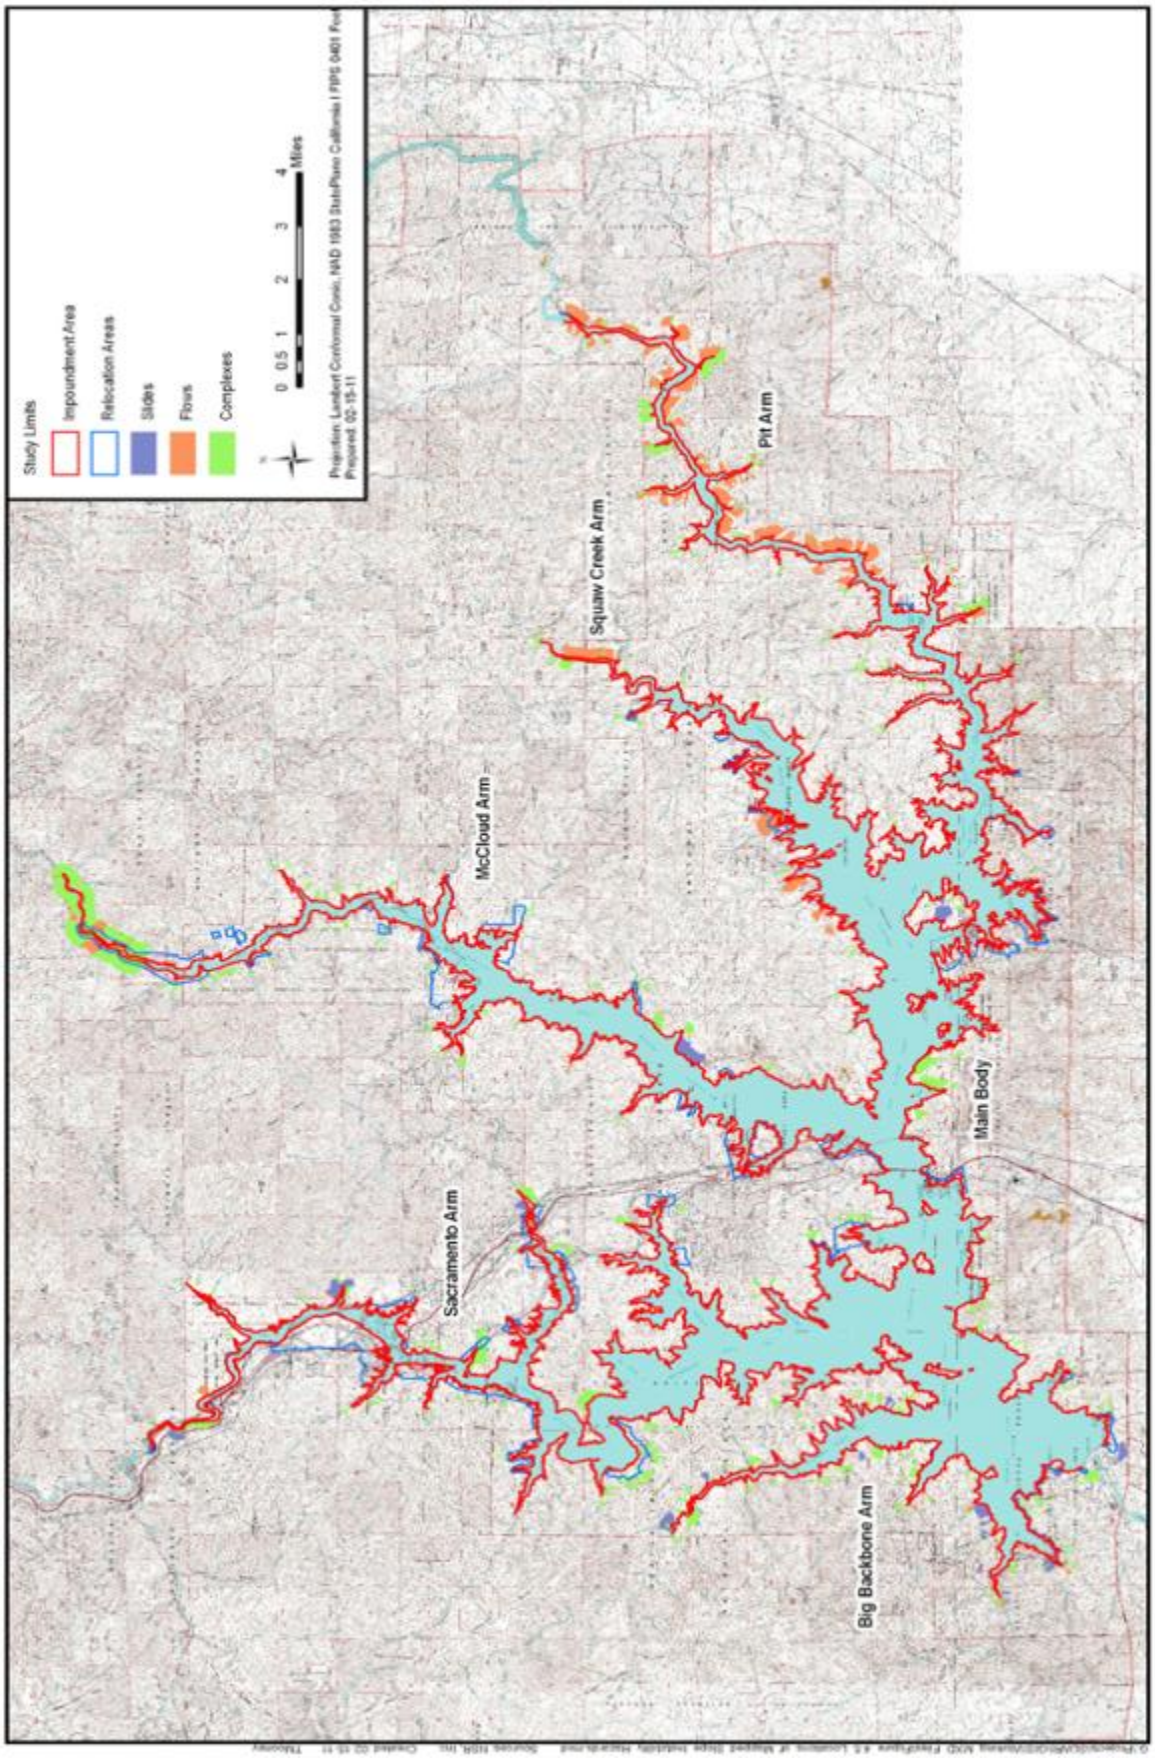

Figure 4-4. Locations of Mapped Slope Instability Hazards – Shasta Lake and Vicinity

The areal extent of mapped slope instability hazards within the Shasta Lake and vicinity area is presented in Table 4-5 for the portion of the subarea between 1,070 feet and 1,090 feet above msl (Impoundment Area); and in Table 4-6 for the portion of the subarea potentially disturbed by construction activities under the action alternatives (Relocation Areas). About 173 acres (7 percent) of the Impoundment Area is occupied by features that are potentially unstable. Potentially unstable features occupy about 232 acres (7 percent) of the Relocation Area. Most of the mapped slope instability hazards are debris flows.

Table 4-5. Areal Extent of Mapped Slope Instability Hazards – Shasta Lake and Vicinity (Impoundment Area)

Map Unit	Formation	Study Area (acres)	Study Area (% Total Sub-Area)
1050	Slides	9.5375	0.38%
1100	Flows	66.6091	2.67%
1200	Complexes	97.1695	3.89%

Table 4-6. Areal Extent of Mapped Slope Instability Hazards – Shasta Lake and Vicinity (Relocation Areas)

Map Unit	Formation	Study Area (acres)	Study Area (% Total Sub-Area)
1050	Slides	2.9947	0.09%
1100	Flows	52.9767	1.59%
1200	Complexes	175.8020	5.26%

Seiches A seiche is an oscillation of a body of water in an enclosed or semi enclosed basin that varies in period, depending on the physical dimensions of the basin, from a few minutes to several hours, and in height from a few millimeters to a few meters. Seiches arise chiefly as a result of sudden local changes in atmospheric pressure, aided by wind and occasionally tidal currents. Seiches can also be triggered by strong earthquake ground motion or large landslides entering a body of water.

If Mount Shasta were to erupt again, volcanic ash could fall in the study area, though as previously described, Mount Shasta is not likely to erupt large volumes of pumiceous ash (tephra) in the future. Minor seiches in Shasta Lake also could be generated by debris flows in the arms of the lake where its tributaries enter (City of Redding 2000). A large megathrust on the Cascadia subduction zone off the Pacific coast could generate enough ground shaking to generate a seiche in Shasta Lake.

Regardless of its cause, the effects of a seiche would depend on the local conditions at the time. If the reservoir were filled to capacity, there may be some overspill by way of the dam spillways. Substantial overtopping of the dam itself is extremely unlikely, as such an event would require a seiche more than 6 meters high, even if the reservoir were filled to capacity. Excess flows into the Sacramento River triggered by a seiche in Shasta Lake would be attenuated by Keswick Reservoir (City of Redding 2000).

Upper Sacramento River (Shasta Dam to Red Bluff)

The upper Sacramento River portion of the primary study area could potentially be affected by geologic hazards in the region attributed to seismic hazards and volcanic eruptions and associated hazards. Mudflows, snow avalanches, slope instability, and seiches are not considered to be geologic hazards in this portion of the primary study area.

Seismic Hazards The northeastern area of Shasta County is part of an area between Lassen Peak and the Medicine Lake Volcano (in Siskiyou County), which is cut by a series of active normal faults that are part of the Sierra Nevada-Great Basin dextral shear zone (Shasta County 2004). These faults are likely to affect the upper watersheds northeast of the Sacramento Valley. These faults include the Mayfield-MacArthur-Hat Creek faults, 25 to 85 miles north of Lake Almanor; the Gillem-Big Crack Faults near the California-Oregon border southeast of Lower Klamath Lake; and the Cedar Mountain Fault southwest of Lower Klamath Lake. The faults in this zone are capable of earthquakes up to magnitude 7.0.

Shasta County, is a seismically active region, but has not experienced significant property damage or loss of life from earthquakes in the past 120 years. The City of Redding (2005) reported that maximum recorded intensities have reached Modified Mercalli VII. The majority of intense seismic activity in Shasta County has occurred in the eastern half of the county, around Lassen Peak (City of Redding 2005).

The Shasta County General Plan states that the maximum intensity event expected to occur in eastern Shasta County is Modified Mercalli VIII (Shasta County 2004). In the western half of Shasta County, the maximum intensity event is expected to be Modified Mercalli VII (City of Redding 2005). Shasta County is entirely within Seismic Zone 3 of the Uniform Building Code. Redding is an area of “moderate seismicity” and the Hat Creek and McArthur areas are of “moderate-to-high seismicity” (Shasta County 2004).

South of Shasta County along the upper Sacramento River, potential surface faulting could be associated with the Great Valley thrust fault system, which is capable of earthquakes up to magnitude 6.8 along the west side of the Sacramento Valley. This fault system forms the boundary between the Coast Ranges and the Sacramento and San Joaquin Valleys.

The San Andreas Fault system is located west of the Sacramento and San Joaquin Valleys and is made up of a series of faults that lie along a 150-mile-long northwest trending zone of seismicity. This zone is 10 to 45 miles west of the Sacramento Valley and extends from Suisan Bay past Lake Berryessa and Lake Pillsbury to near the latitude of Red Bluff. The Green Valley, Hunting Creek, Bartlett Springs, Round Valley, and Lake Mountain Faults are the mapped active faults of the San Andreas Fault system most likely to affect the

upper watersheds west of the Sacramento Valley. The faults within this system are capable of earthquakes up to 7.1 in magnitude.

The Indian Valley Fault southeast of Lake Almanor and the Honey Lake Fault zone east of Lake Almanor are likely to affect the upper watersheds east of the Sacramento Valley, and are capable of a magnitude 6.9 earthquake. Surface rupture occurred in 1975 along the Cleveland Hill Fault south of Lake Oroville. The Foothills Fault system, which borders the east side of the Sacramento and San Joaquin Valleys, is judged to be capable of a magnitude 6.5 earthquake.

Volcanic Eruptions and Associated Hazards Shasta County is at the southern end of the Cascade Range (as described above for geology of the upper Sacramento River). The most recent volcanic activity in Shasta County occurred between 1914 and 1917, when Lassen Peak erupted, producing lava flows, numerous ash falls, and a large mudflow. The mudflow, a result of melting snow and ash, flowed down Lost Creek and Hat Creek (Shasta County 2004).

It is unlikely that a large mudflow from Mt. Shasta would endanger Shasta County (Shasta County 2004).

Lower Sacramento River and Delta

The lower Sacramento River and Delta portion of the extended study area could potentially be affected by geologic hazards in the region attributed to seismic hazards. Volcanic eruptions and associated hazards, mudflows, snow avalanches, slope instability, and seiches are not considered to be geologic hazards in this portion of the extended study area.

The nearest active fault to the lower Sacramento River below Red Bluff is the Dunnigan Hills Fault, which has experienced fault displacement within the last 10,000 years (Jennings 1994). The Dunnigan Hills Fault runs along the Sacramento River and is located between 6 and 10 miles west of the river near the Town of Dunnigan. The Cleveland Fault is located approximately 30 miles east of the Sacramento River near the Town of Oroville. In addition, the Great Valley thrust fault system and San Andreas fault system extend along the Sacramento River to the west, as described above for the upper Sacramento River portion of the primary study area.

Failure of Delta levees is the primary threat to the region as a result of seismic activity. The Delta levees are located in a region of relatively low seismic activity compared to the San Francisco Bay Area (Bay Area). The major strike-slip faults in the Bay Area (San Andreas, Hayward, and Calaveras faults) are located over 16 miles from the Delta region. The less active Green Valley and Marsh Creek–Clayton faults are over 9 miles from the Delta region. Small but significant local faults are situated in the Delta region, and there is a possibility that blind thrust faults occur along the west Delta.

CVP/SWP Service Areas

The CVP/SWP service areas portion of the extended study area could potentially be affected by geologic hazards in the region attributed to seismic hazards. Volcanic eruptions and associated hazards, mudflows, snow avalanches, slope instability, and seiches are not considered to be geologic hazards in this portion of the extended study area. A number of active faults exist along the Sacramento and San Joaquin rivers in the CVP/SWP service areas.

Major earthquake activity has centered along the San Andreas Fault zone, including the great San Francisco earthquake of 1906 in the Bay Area. Since that earthquake, four events of magnitude 5.0 on the Richter scale or greater have occurred in the Bay Area. The San Andreas and Hayward Faults remain active, with evidence of recent slippage along both faults.

In the San Joaquin River region, the Great Valley thrust fault system forms the boundary between the Coast Ranges and the west boundary of the San Joaquin Valley. This fault system is capable of earthquakes up to magnitude 6.7 along the west side of the San Joaquin Valley.

Active faults likely to affect the upper watersheds at the end of the San Joaquin Valley include the White Wolf Fault, which ruptured in 1952 with a magnitude 7.2 earthquake; the Garlock Fault, capable of a magnitude 7.3 earthquake; and several smaller faults l0 to 30 miles north of the White Wolf Fault.

A list of all of the reported faults, fault zones, and systems, according to the California Geological Survey, that are located south-of-Delta within the CVP/SWP service areas is presented in the California Public Resources Code, Division 2 Geology, Mines and Mining, Chapter 7.5 Earthquake Fault Zoning (CDC 2006a).

4.1.3 Geomorphology

Geomorphology in the study area is described below for both the primary and extended study areas.

Shasta Lake and Vicinity

As previously described, most of Shasta Lake and vicinity area is within the Klamath Geomorphic Province. The topography of the study area ranges from moderate to steep, and elevation ranges from approximately 1,070 to more than 6,000 feet above msl. The orientation and slopes of the ridges are controlled by the bedrock geology and structure. Generally speaking, the eastern slopes of the ridges are steeper than the western slopes. Hillslope gradient ranges from 0 percent to more than 100 percent within the Shasta Lake and vicinity area.

The regional stream network and boundaries of watersheds adjacent to Shasta Lake are shown in Figure 4-5. The boundaries of watersheds adjacent to Shasta Lake (shown in Figure 4-5) are the same as the boundaries of 6th Field

Hydrologic Unit Code watersheds defined in the subarea by the USFS. Regional-scale characteristics of the streams that are tributary to Shasta Lake are presented in Figure 4-6, where they are organized by arm. The total area of watersheds draining to the lake on a regional scale is 6,665 square miles. Of this total, watersheds that are immediately adjacent and contribute directly to Shasta Lake (i.e., 6th Field Hydrologic Unit Code watersheds) comprise about 512 square miles (see Table 4-7). These immediately adjacent watersheds include small portions of the five major tributaries to the lake (i.e., Big Backbone Creek, Sacramento River, McCloud River, Squaw Creek, and Pit River), and small watersheds that are adjacent and directly contributory to the Main Body Arm of the lake.

In general, the stream networks adjacent and directly tributary to Shasta Lake are irregular and dendritic. The drainages are steep, and the drainage density ranges from 3.0 to 6.4 miles of stream per square mile of drainage area (Table 4-7). The drainage density is the lowest in the Main Body Arm because this area has several small catchments. The density is the highest in the more well-defined arms, a function of their larger catchment areas of the tributary watersheds.

The lengths of streams within watersheds that are adjacent to Shasta Lake are also reported in Figure 4-6, where they again are aggregated by arm and further subdivided by flow regime (i.e., intermittent or perennial) and stream gradient. There are about 2,903 miles of ephemeral, intermittent, and perennial stream channels within these adjacent watersheds. Most (64 percent) of the stream channels are intermittent and have a stream slope greater than 10 percent. About 14 percent of the stream channels are perennial, with slopes less than 7 percent. Generally speaking, channels with gradients of less than 7 percent are known to support fish and other aquatic organisms. About 79 percent of these potential fish-bearing tributaries occur within the Sacramento River, Squaw Creek, and Pit River arms.

Again, the values reported in Table 4-7 do not include large parts of the Sacramento River, Squaw Creek, Pit, McCloud, and Big Backbone watersheds; only the “face drainages” within the arms themselves are included in the reported values.

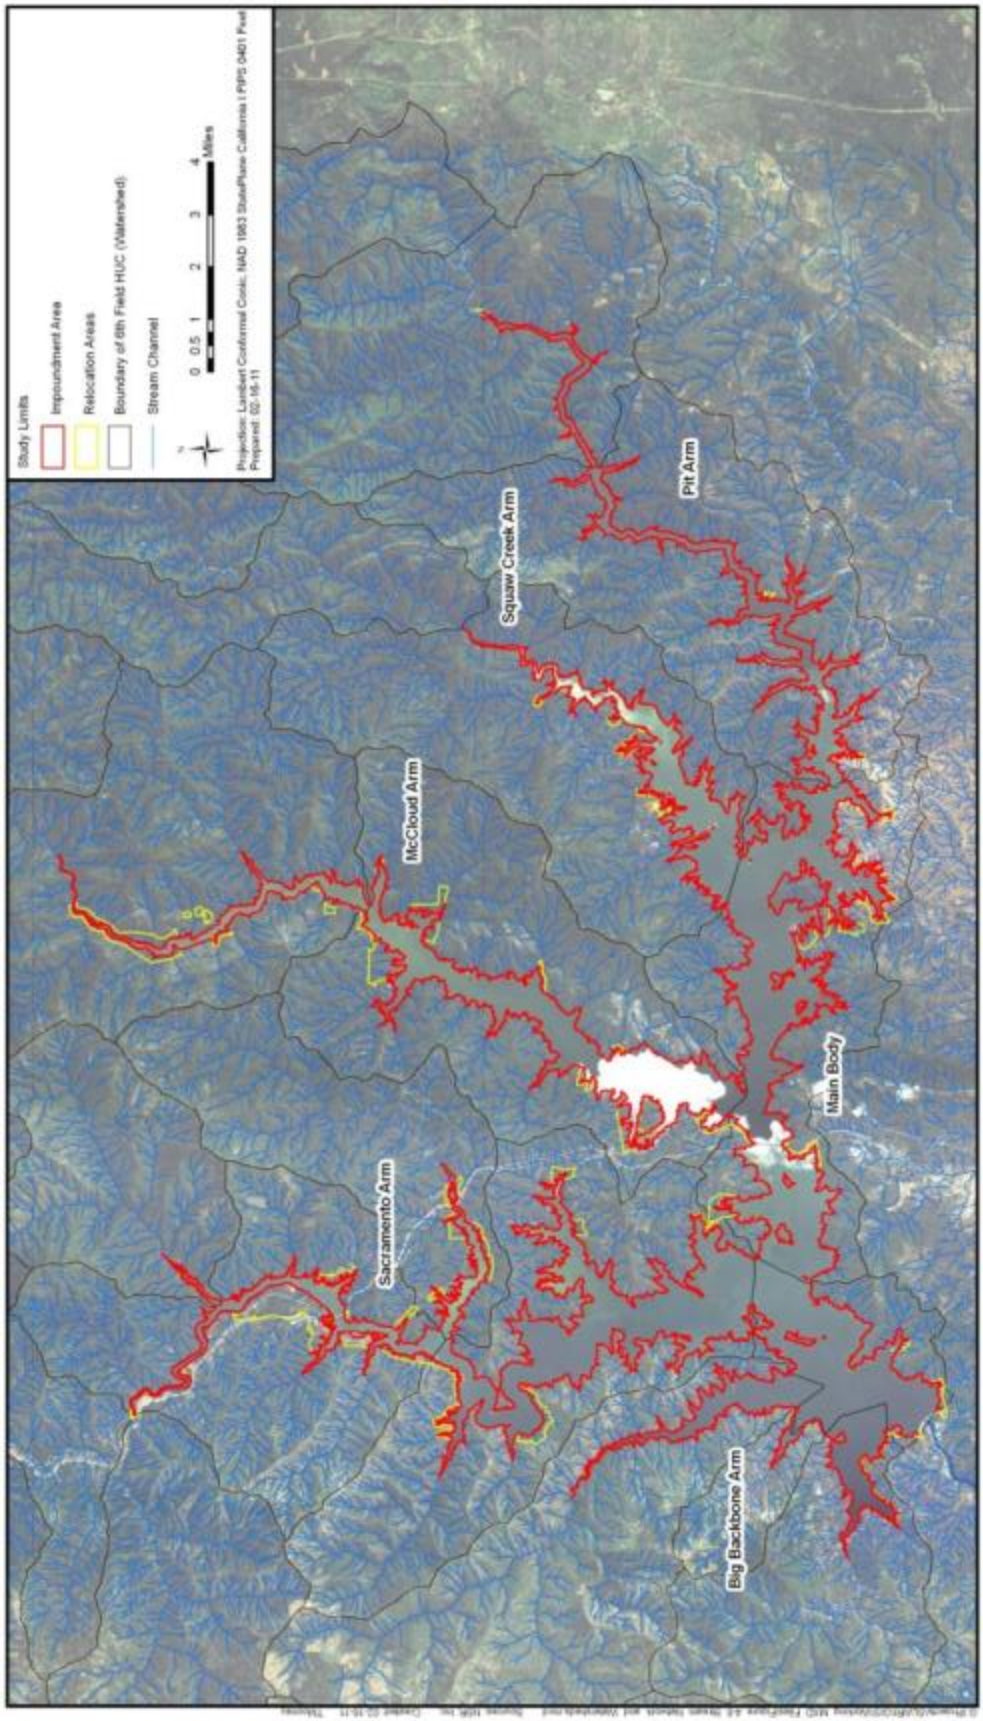

Figure 4-5. Regional Stream Network and Boundaries of Watersheds Adjacent to Shasta Lake and Vicinity

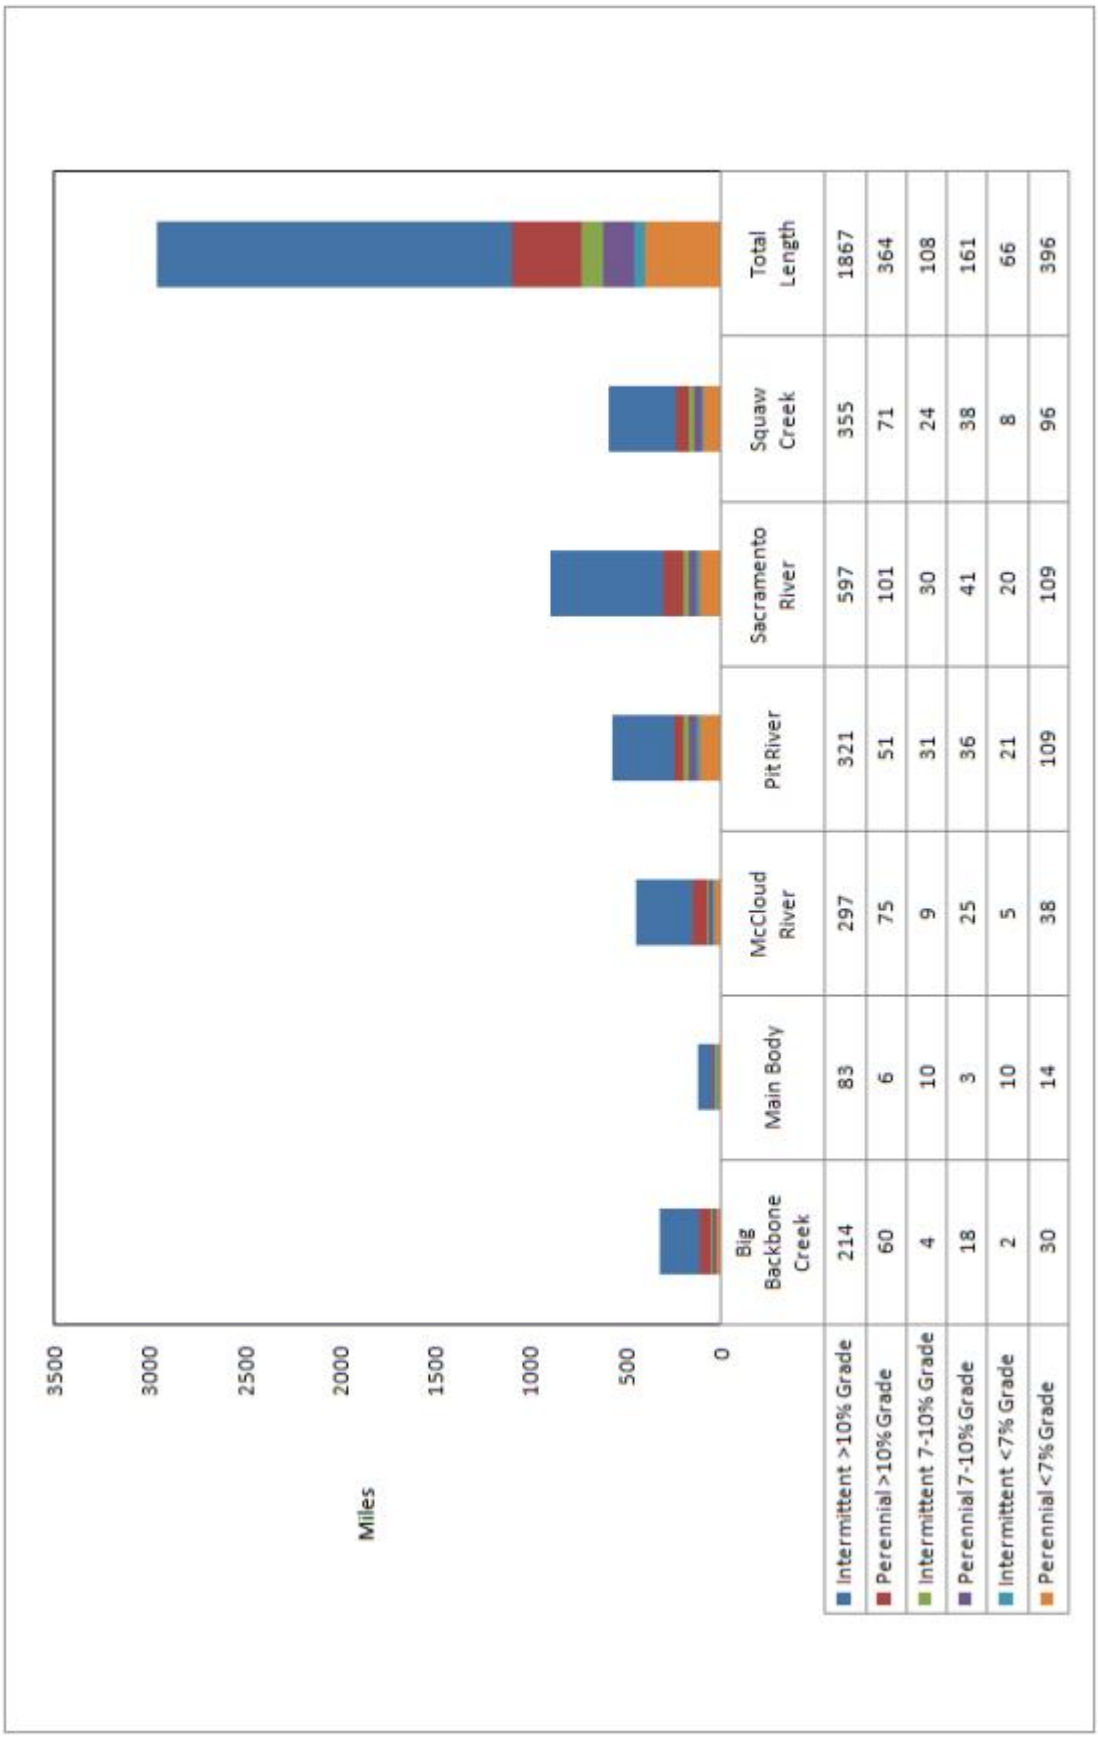

Figure 4-6. Regional-Scale Characteristics of Streams Tributary to Shasta Lake

Table 4-7. Characteristics of Watersheds Adjacent and Directly Tributary to Shasta Lake

Lake Arm	Drainage Area (square miles)	Stream Length (miles)	Drainage Density (miles/square miles)	Average Elevation (feet)	Max Elevation (feet)	Mean Annual Precipitation (inches)
Big Backbone Creek	60	325	5.4	2,185	4,633	74
Main Body	37	112	3.0	1,260	2,723	67
McCloud River	77	444	5.7	1,911	4,669	79
Pit River	100	551	5.5	1,700	3,246	73
Sacramento River	137	880	6.4	1,825	4,589	76
Squaw Creek	100	583	5.8	2,100	5,046	83
Total	512	2,903	5.7	1,885	5,046	77

Using existing data and information (NSR 2003), the following observations were made concerning the relative stability of the riverine reaches. Of the five main tributaries influencing Shasta Lake, all except Big Backbone Creek and the Sacramento River are underlain by shallow bedrock that limits channel incision. For this reason, Squaw Creek, and the Pit and McCloud rivers are relatively stable streams that are unlikely to be changed significantly in response to average floods. Although they occur infrequently, debris flows have the potential to substantially affect particularly shallow bedrock reaches of these tributaries, as is evident in Dekkas Creek. The Sacramento River and Big Backbone Creek are relatively dynamic because the channel bed has the potential to undergo physical changes in response to a moderate flood. Although Big Backbone Creek and Squaw Creek have similar watershed areas, Squaw Creek has more bedrock reaches than Big Backbone Creek and is therefore inherently more stable.

Upper Sacramento River (Shasta Dam to Red Bluff)

The geomorphology of the Sacramento River is a product of several factors: the geology of the Sacramento Valley, hydrology, climate, vegetation, and human activity. Large flood events drive lateral channel migration and remove large flow impediments. Riparian vegetation stabilizes riverbanks and reduces water velocities, inducing deposition of eroded sediment. In the past, a balance existed between erosion and deposition along the Sacramento River. However, construction of dams, levees, and water projects has altered streamflow and other hydraulic characteristics of the Sacramento River. In some areas, human-induced changes have stabilized and contained the river, while in other reaches, the loss of riparian vegetation has reduced sediment deposition and led to increased erosion.

Lower Sacramento River and Delta

Downstream from Red Bluff, the lower Sacramento River is relatively active and sinuous, meandering across alluvial deposits within a wide meander belt. The active channel consists of point bars composed of sand on the inside of meander bends, and is flanked by active floodplain and older terraces. While

most of these features consist of easily eroded, unconsolidated alluvium, there are also outcrops of resistant, cemented alluvial units such as the Modesto and Riverbank Formations. Geologic outcroppings and man-made structures, such as bridges and levees, act as local hydraulic controls and confine movement of much of the lower Sacramento River. Natural geomorphic processes in the Delta have been highly modified by changes to upstream hydrology (reservoirs and streamflow regulation) and construction of levees, channels, and other physical features.

Since construction of Shasta Dam in the early 1940s, flood volumes on the river have been reduced, which has reduced the energy available for sediment transport. Straightening and a reduced rate of meander migration of the river may be associated with flow regulation because of Shasta Dam. The reduction in active channel dynamics is compounded by the physical effects of riprap bank protection structures, which typically eliminate shaded bank habitat and associated deep pools, and halt the natural processes of channel migration.

CVP/SWP Service Areas

Geomorphology in the CVP/SWP service areas is a product of the same factors mentioned above, which include geology, hydrology and climate, vegetation, and human activity. Geomorphology in the CVP service areas is summarized in the descriptions of the primary study area and the lower Sacramento River and Delta portions of the extended study area.

Geomorphology in the SWP service areas extends into the southern geomorphic provinces of California and along part of the coast. The southern geomorphic provinces and coastal province include the Transverse Ranges, Peninsular Ranges, Mojave Desert, and Coast Ranges. The Transverse Ranges, composed of overlapping mountain blocks, consist of parallel and subparallel ranges and valleys. The Peninsular Ranges Geomorphic Province is composed of northwest to southeast trending fault blocks, extending from the Transverse Ranges into Mexico. The Peninsular Ranges are similar to the Sierra Nevada in that they have a gentle westerly slope and generally consist of steep eastern faces. Mojave Desert Geomorphic Province topography is controlled by two faults: the San Andreas Fault, trending northwest to southeast, and the Garlock Fault, trending east to west (Jennings 1938). Before development of the Garlock Fault, sometime during the Miocene, the Mojave Desert was part of the Basin and Range Geomorphic Province. The Mojave Desert is now dominated by alluvial basins, which are aggrading surfaces from adjacent upland continental deposits (Norris and Webb 1990). The Coast Ranges have been greatly affected by plate tectonics. The Coast Ranges Geomorphic Province consists of elongate ranges and narrow valleys that run subparallel to the coast. Some of the mountain ranges along the Coast Range terminate abruptly at the sea (Norris and Webb 1990).

4.1.4 Mineral Resources

This section describes the known mineral resources of commercial or otherwise documented economic value in both the primary and extended study areas. The mineral resources of concern include metals and industrial minerals (e.g., aggregate, sand, and gravel, oil and gas, and geothermal resources that would be of value to the region).

Shasta Lake and Vicinity

The following section describes mineral resources in the Shasta Lake and vicinity portion of the primary study area.

Metals The lands within the Shasta Lake and Vicinity area are highly mineralized, with a history of significant mineral production. The Shasta Lake and vicinity area encompasses portions of two historic base metal mining districts, the west Shasta and east Shasta copper-zinc districts. The two districts focused on development of massive sulfide (Kuroko-Type) deposits of submarine volcanogenic origin that formed contemporaneously with, and by the same process as, the host volcanic rocks. Similar to other areas in the Klamath Mountains, copper was by far the predominant commodity produced. Zinc, sulfur, iron, limestone, gold, and silver were produced as byproducts of copper production.

The Golinsky mine complex is located in the west Shasta district, approximately 7 miles west of Shasta Dam in the headwaters of Dry Creek and Little Backbone Creek. This inactive, abandoned mine complex is the only large historic producing mine within the Shasta Unit of the National Recreation Area (NRA). Other mines within the Shasta NRA occur in the east Shasta district, concentrated between the McCloud and Squaw arms of Shasta Lake. The east Shasta district includes the Bully Hill, Copper City, and Rising Star mines, all of which are located in the Bully Hill area. These mines ceased operation before Shasta Dam was built.

These types of mineral deposits, in conjunction with the historic lode mining methods, have resulted in the discharge of toxic mine waste and acidic waters to Shasta Lake and some tributaries on a recurring basis (USFS 2000). The Golinsky mine complex has been subject to extensive remediation to reduce the discharge of toxic mine waste and acidic waters to Shasta Lake.

Industrial Minerals Industrial minerals occurring in the vicinity of the Shasta Lake include alluvial sand and gravel, crushed stone, volcanic cinders, limestone and diatomite. In 2002, Shasta County produced 462,000 tons of sand and gravel, 852,000 tons of crushed stone (including limestone), and 51,000 tons of volcanic cinders. Limestone used to produce portland cement and diatomite are not included in these figures.

The supply of portland cement concrete (PCC) grade alluvial sand and gravel within the region is more limited than non-PCC grade material. The primary

sources for alluvial sand and gravel near the Shasta Lake and vicinity area are the Sacramento River (downstream from Keswick Dam), Clear Creek, Cottonwood Creek, and Hat Creek. Crushed stone has been produced at a limestone quarry in Mountain Gate, a granite quarry in Keswick, an andesite quarry in Mountain Gate, a shale quarry in Oak Run, and at two basalt quarries in the Lake Britton area near Burney. Volcanic cinders are produced at sites east of the Shasta Lake and vicinity area.

Limestone is used in a variety of industrial applications, but the bulk of limestone is used for the production of portland cement concrete. Most of the limestone resources within and near the Shasta Lake and vicinity area are located in fairly remote mountainous areas where extraction is uneconomical. However, significant mining of limestone for PCC production occurs immediately south of Shasta Lake, in Mountain Gate. Diatomite is produced from sources near Lake Britton, east of the Shasta Lake and vicinity area.

Geothermal Resources Significant geothermal resources occur in the Medicine Lake Highlands, approximately 65 air miles northeast of Shasta Lake. The potential capacity at Medicine Lake overall has been estimated at 480 megawatts (PacifiCorp 2010). Development of the Medicine Lake geothermal resources has been the subject of extensive litigation of environmental issues and Native American concerns.

Upper Sacramento River (Shasta Dam to Red Bluff)

Economically viable minerals found within the upper Sacramento River portion of the primary study area consist of alluvial sand and gravel, crushed stone, volcanic cinders, limestone, and diatomite. Additional mineral resources are found in the surrounding regions within Shasta and Tehama Counties. These mineral resources include asbestos, barium, calcium, chromium, copper, gold, iron, lead, manganese, molybdenum, silver, and zinc (USGS 2005).

Lower Sacramento River and Delta

Economically viable minerals found within the lower Sacramento River and Delta portion of the extended study area consist of alluvial sand and gravel, crushed stone, calcium, and clay. Additional mineral resources are found in the surrounding regions, including chromium, gold, granite, lithium, manganese, mercury, pumice, and silver (USGS 2005).

CVP/SWP Service Areas

The U.S. Geologic Survey mineral resources database indicates that numerous minerals resources are currently mined or have been mined within the CVP/SWP service areas. These minerals include antimony, asbestos, barium, bismuth, boron, calcium, chromium, clay, copper, diatomite, feldspar, fluorite, gold, gypsum-anhydrite, halite, iron, lead, limestone, magnetite, manganese, marble, mercury, molybdenum, pumice, quartz, sand and gravel, silica, silver, slate, stone (crushed/broken), talc, tin, titanium, tungsten, uranium, and vanadium (USGS 2005).

4.1.5 Soils

Soils and erosion area are described below for both the primary and extended study areas. Soils in the project study area are described in the following sections in terms of their biomass productivity, susceptibilities to erosion, subsidence, liquefaction and expansion, and suitability for onsite application of waste material.

Soil biomass productivity is a measure of the capability of a site to produce biomass. The purpose of this management interpretation is to measure site productive capability when vegetative indicators (e.g., crop yields, site trees, and other vegetative biomass data) are not directly available (Miles 1999). Factors that influence soil biomass productivity include soil depth, parent material, available water-holding capacity, precipitation, soil temperature regime, aspect, and reaction (i.e., pH). Soil biomass productivity is characterized using four relative rankings: high, moderate, low, and nonproductive.

Susceptibility to erosion is characterized in terms of erosion hazard rating. The ratings indicate the hazards of topsoil loss in an unvegetated condition as might occur following disturbance by construction. Ratings are based on soil erosion factor K (a measure of the susceptibility of soil particles to detachment and transport by rainfall and runoff, based primarily on soil texture but also considering structure, organic matter, and permeability), slope, and content of rock fragments. Three ratings are recognized: slight, moderate, and severe. A rating of slight indicates that no post-disturbance acceleration of naturally occurring erosion is likely; moderate indicates that some acceleration of erosion is likely, and that simple erosion-control measures are needed; and severe indicates that significant erosion is expected, and that extensive erosion-control measures are needed.

Land subsidence is broadly defined to mean the sudden sinking or gradual downward settling of the land surface with little or no horizontal motion. Land subsidence can arise from a number of causes, including the weathering characteristics of the underlying bedrock (e.g., as occurs for certain limestone formations), decomposition of the organic matter fraction of soils that are derived from peaty or mucky parent materials, aquifer-system compaction, underground mining, and natural compaction. Three processes account for most instances of water-related subsidence: compaction of aquifer systems, drainage and subsequent oxidation of organic soils, and dissolution and collapse of susceptible rocks.

Soil liquefaction is a phenomenon in which the strength and stiffness of a soil is reduced by earthquake shaking or other rapid loading. Liquefaction occurs in saturated soils when the pore spaces between individual soil particles are completely filled with water. This water exerts a pressure on the soil particles that influences how tightly the particles themselves are pressed together. Before an earthquake, the water pressure is relatively low. However, earthquake

shaking can cause the water pressure to increase to the point where the soil particles can readily move with respect to each other. When liquefaction occurs, the strength of soils decrease, and the ability of soils to support foundations for buildings and bridges are reduced.

Expansive soils are soils that contain water absorbing minerals, mainly "active" clays (e.g., montmorillonite). Such soils may expand by 10 percent or more when wetted. The cycle of shrinking and expanding exerts continual pressure on structures, and over time can reduce structural integrity. Soil susceptibility to expansion (i.e., shrinking and swelling) is tested using Uniform Building Code Test Standard 18-1.

Soil suitability for onsite application of waste material focuses on the suitability of the soil to support the use of septic tanks or alternative wastewater disposal systems. Suitability interpretations are based on consideration of soil depth, permeability, rock content, depth to groundwater (including seasonally perched water), and slope.

Shasta Lake and Vicinity

Soils in the Shasta Lake and vicinity area derive from materials weathered from metavolcanic and metasedimentary rocks and from intrusions of granitic rocks, serpentine, and basalt. Soils derived from the metavolcanic sources, such as greenstone, include the Goulding and Neuns families. Soils derived from metasedimentary materials include the Marpa family. Holland family soils are derived from metasedimentary and granitic rocks.

In general, metamorphosed rocks do not weather rapidly, and shallow soils are common in the subarea, especially on steep landscape positions. Soils from metamorphosed rocks generally contain large percentages of coarse fragments (e.g., gravels, cobbles, stones), which reduce their available water holding capacity and topsoil productivity. Granitic rocks may weather deeply, but soils derived from them may be droughty due to high amounts of coarse quartz grains and low content of "active" clay. Soils derived from granitic rocks commonly are highly susceptible to erosion.

Soil map units in the Shasta Lake and vicinity area are shown in Figure 4-7. The mapping legend that accompanies Figure 4-7 is presented in Table 4-8. The areal extent of soil map units within the Shasta Lake and vicinity area is presented in Table 4-9 for the portion of the subarea between 1,070 feet and 1,090 feet above msl (Impoundment Area); and in Table 4-10 for the portion of the subarea potentially disturbed by construction activities (Relocation Areas). Sixty soil map units, comprised of soil families and miscellaneous land types (e.g., rock outcrop, limestone) are recognized to occur in the subarea. Common soil families are Marpa, Neuns, Goulding, and Holland. These are well-drained soils with fine loamy or loamy-skeletal (i.e., gravelly or cobbly) profiles.

W	Water	28.6	0.86%

Soil Biomass Productivity Soil biomass productivity in the Shasta-Trinity National Forest (STNF) ranges from nonproductive to high (USFS 1994). Using Forest Service Site Class (FSSC) as a surrogate metric for soil biomass productivity, approximately 36 percent of the study area is occupied by soils of low biomass productivity, about 39 percent of the area is occupied by soils of moderate productivity, and about 13 percent is occupied by "nonproductive" soils and miscellaneous land types (e.g., rock outcrop). Soils of high biomass productivity are unlikely to occur in the Shasta Lake and vicinity area.

Soil Susceptibility to Erosion (Uplands) Interpretations of soil susceptibility to erosion are presented in Table 4-11 for the portion of the subarea between 1,070 feet and 1,090 feet above msl (Impoundment Area); and in Table 4-12 for the portion of the subarea potentially disturbed by construction activities. Of the approximately 5,837 acres in the Shasta Lake and vicinity area, 5,377 acres (92 percent of total area) are assigned a hazard rating of severe.

Table 4-11. Summary of Soil Erosion Hazard – Shasta Lake and Vicinity (Impoundment Area)

Soil Erosion Hazard	Study Area (acres)	Study Area (% Total Sub-Area)
Moderate	38.55	1.54%
Severe	2248.81	90.03%
Not Rated	210.00	8.41%

Table 4-12. Summary of Soil Erosion Hazard – Shasta Lake and Vicinity (Relocation Areas)

Soil Erosion Hazard	Study Area (acres)	Study Area (% Total Sub-Area)
Moderate	119.97	3.59%
Severe	3127.62	93.65%
Not Rated	92.01	2.76%

Soil Susceptibility to Erosion (Shoreline) There are more than 420 miles of shoreline around Shasta Lake. As described below under Methods and Assumptions, a conceptual model was developed to quantify current erosion rates and predict future erosion rates (see Attachment 1, Shoreline Erosion Technical Memorandum).

Based on the model output, about 50 percent of the shoreline has a low erosion severity. The remaining shoreline has moderate (35 percent) to high (15 percent) erosion severity. Most of the shoreline that is exposed during routine drawdown periods (i.e., drawdown zone) has been subject to substantial erosion, and very little soil remains after more than 60 years of reservoir operations.

Soil Susceptibility to Subsidence Published interpretations of soil susceptibility to subsidence are generally not available for the Shasta Lake and vicinity area. The likelihood that subsidence would occur due to decomposition of soil organic matter is low due to the absence of soils derived from peaty or mucky parent materials. Similarly, the likelihood of subsidence due to aquifer-system compaction is low due to the absence of significant, widespread groundwater withdrawal in the Shasta Lake and vicinity area. Land subsidence has potential to occur in areas underlain by highly-weatherable, carbonate-rich rocks (e.g., certain limestones), and in areas affected by underground construction.

Soil Susceptibility to Liquefaction Published interpretations of soil susceptibility to liquefaction are generally not available for the Shasta Lake and vicinity area. The likelihood that soil liquefaction would occur is low because of the absence of the necessary high groundwater conditions in the Shasta Lake and vicinity area.

Soil Susceptibility to Expansion Published interpretations of soil susceptibility to expansion (i.e., shrinking and swelling) are generally not available for most of the Shasta Lake and vicinity area. The likelihood that expansive soils occur is low because the weathering products derived from the local bedrock typically contain low concentrations of "active" clays (e.g., montmorillonite).

Soil Suitability for Onsite Application of Waste Material Published interpretations of soil suitability for onsite application of waste material (i.e., capability to support use of septic tanks or alternative wastewater disposal systems) are generally not available for the Shasta Lake and vicinity area. In general, soils in the Shasta Lake and vicinity area are poorly suited to these uses due to shallow soil depth, high rock content, and excessive slope.

Upper Sacramento River (Shasta Dam to Red Bluff)

The following section describes soil susceptibility to erosion (channel shoreline), soil susceptibility to erosion (wind), soil susceptibility to subsidence, soil susceptibility to liquefaction, and soil susceptibility to expansion in the upper Sacramento River portion of the primary study area.

Soils in the Sacramento River Basin are divided into four physiographic groups: upland soils, terrace soils, valley land soils, and valley basin soils. Upland soils are prevalent in the hills and mountains of the region and are composed mainly of sedimentary sandstones, shales, and conglomerates originating from igneous rocks. Terrace and upland soils are predominant between Redding and Red Bluff; however, valley land soils border the Sacramento River through this area. Valley land and valley basin soils occupy most of the Sacramento Valley floor south of Red Bluff. Valley land soils consist of deep alluvial and aeolian soils that make up some of the best agricultural land in the State. The valley floor was once covered by an inland sea, and sediments were formed by deposits of

marine silt followed by mild uplifting earth movements. After the main body of water disappeared, the Sacramento River began eroding and redepositing silt and sand in new alluvial fans.

Soil Susceptibility to Erosion (Channel Shoreline) Shasta and Keswick Dams have a significant influence on sediment transport in the Sacramento River because they block sediment that would normally be transported downstream. The result has been a net loss of coarse sediment, including salmon spawning gravels, in the Sacramento River below Keswick Dam. In alluvial river sections, bank erosion and sediment deposition cause river channel migrations that are vital to maintaining instream and riparian habitats, but which can cause loss of agricultural lands and damage to roads and other structures.

Soil Susceptibility to Erosion (Wind) Soil erodibility, climatic factors, soil surface roughness, width of field, and quantity of vegetative coverage affect the susceptibility of soils to wind erosion. Wind erosion leaves the soils shallower and can remove organic matter and needed plant nutrients. In addition, blowing soil particles can damage plants, particularly young plants. Blowing soils also can cause off-site problems such as reduced visibility and increased allergic reaction to dust.

Soil Susceptibility to Subsidence Land subsidence in the Sacramento Valley is localized and concentrated in areas of overdraft from groundwater pumping. Land subsidence had exceeded 1 foot by 1973 in two main areas in the southwestern part of the valley near Davis and Zamora; however, additional subsidence since then has not been reported.

Soil Susceptibility to Expansion Most of Shasta County is characterized by moderately expansive soils with areas of low expansiveness in the South Central Region and southeastern corner of the county. Small scattered areas of highly expansive soils exist in the mountains of the Western Upland, French Gulch, and North East Shasta County planning areas. The hazard associated with expansive soils is that areas of varying moisture or soil conditions can differentially expand or shrink, causing stresses on structures that lead to cracking or settling. Effects of expansive soils on structures can be mitigated through requiring proper engineering design and standard corrective measures.

Lower Sacramento River and Delta

The following section describes soil susceptibility to erosion (channel shoreline), soil susceptibility to erosion (wind), soil susceptibility to subsidence, soil susceptibility to liquefaction, and soil susceptibility to expansion in the lower Sacramento River and Delta portion of the extended study area.

The soils of the Sacramento River basin are divided into four physiographic groups, as described above for the upper Sacramento River portion of the study area.

The soils of the Delta region vary primarily as a result of differences in geomorphological processes, climate, parent material, biological activity, topography, and time. The soils are divided into the following four general soil types:

- Delta organic soils and highly organic mineral soils
- Sacramento River and San Joaquin River deltaic soils
- Basin and basin rim soils
- Moderately well to well-drained valley, terrace, and upland soils

The Delta region contains soils primarily with the required physical and chemical soil characteristics, growing season, drainage, and moisture supply necessary to qualify as Prime Farmland. This includes 80 to 90 percent of the area of organic and highly organic mineral soils, Sacramento River and San Joaquin River deltaic soils, and basin and basin rim soils. Most of the remaining soils of the Delta region qualify as farmland of statewide importance.

Soil Susceptibility to Erosion (Channel Shoreline) The extended study area downstream from the Red Bluff Diversion Dam along the Sacramento River is a major alluvial river section that is active and sinuous, meandering across alluvial deposits within a wide meander belt. In alluvial river sections, bank erosion and sediment deposition cause migrations of the river channel that are extremely important in maintaining instream and riparian habitats, but also can cause loss of agricultural lands and damage to roads and other structures. Geologic outcroppings and man-made structures, such as bridges and levees, act as local hydraulic controls along the river. Bank protection, consisting primarily of rock riprap, has been placed along various sections of the Sacramento River to reduce erosion and river meandering.

The great quantities of sediment transported by the rivers into the Delta move primarily as suspended load. Of the estimated 5 million tons per year of sediment inflow into the Delta, about 80 percent originates from the Sacramento River and San Joaquin River drainages; the remainder is contributed by local streams. Approximately 15 percent to 30 percent of the sediment is deposited in the Delta; the balance moves into the San Francisco Bay system or out through CVP and SWP facilities.

Soil Susceptibility to Erosion (Wind) The Delta organic soils and highly organic mineral soils have wind erodibility ratings of 2 to 4 on a scale where 1 is most erodible and 8 is least erodible. The high wind erodibility of Delta soils is caused by the organic matter content of the soil. The rate of wind erosion is estimated at 0.1 inches per year.

Soil Susceptibility to Subsidence Subsidence of the Delta's organic soils and highly organic mineral soils is attributable primarily to biochemical oxidation of organic soil material as a result of long-term drainage and flood protection. The highest rates of subsidence occur in the central Delta islands, where organic matter content in the soils is highest.

Development of the islands resulted in subsidence of the island interiors and greater susceptibility of the topsoil to wind erosion. Subsidence, as it relates to Delta islands, refers generally to the falling level of the land surface from primarily the oxidation of peat soil. Levee settlement may be partially caused by peat oxidation if land adjacent to levees is not protected from subsidence.

Soil Susceptibility to Expansion Soils within the lower Sacramento River and Delta portion of the extended study area vary from having low to high shrink-swell potential. In general, soils in the narrow corridor upstream along the Sacramento River have low shrink-swell potential according the United States Department of Agriculture's State Soil Geographic (STATSGO) Database Soil Surveys, with the exception of some soils with moderate shrink-swell potential near the Red Bluff Diversion Dam (USDA 1995). Downstream, the shrink-swell potential of soils near the Delta is generally classified by the STATSGO Soil Surveys as "high." The hazard associated with expansive soils is that areas of varying moisture or soil conditions can differentially expand or shrink, causing stresses on structures that lead to cracking or settling. This hazard is identifiable through standard soil tests. Its effects on structures can be mitigated through the requirements of proper engineering design and standard corrective measures.

CVP/SWP Service Areas

As described above for the upper Sacramento River portion of the primary study area, soils in the CVP/SWP service areas are divided into four physiographic groups: valley land, valley basin, terrace land, and upland soils. According to the U.S. Department of Agriculture's STATSGO Database, soils within the CVP/SWP service areas consist of clay, loam, silt, and sand, some of which is gravelly. The CVP/SWP service areas also consist of unweathered and weathered bedrock that is evident through outcrops at the ground surface (USDA 1995).

4.2 Regulatory Framework

The following section describes the Federal, State, and local regulatory setting for geological resources.

4.2.1 Federal

This section discusses the Federal regulatory setting for water quality, runoff, air quality, earthquakes, paleontological resources, and natural resources.

Clean Water Act

The Clean Water Act (CWA) includes provisions for reducing soil erosion for the protection of water quality. The CWA made it unlawful for any person to discharge pollutants from a point source (including construction sites), into navigable waters, unless a permit was obtained under its provisions. This pertains to construction sites where soil erosion and storm runoff and other pollutant discharges could affect downstream water quality.

National Pollutant Discharge Elimination System

The National Pollutant Discharge Elimination System process, established by the CWA, is intended to meet the goal of preventing or reducing pollutant runoff. Projects involving construction activities (e.g., clearing, grading, or excavation) with land disturbance greater than 1 acre must file a Notice of Intent with the applicable Regional Water Quality Control Board (RWQCB) to indicate the intent to comply with the State General Permit for Storm Water Discharges Associated with Construction Activity (General Permit). This permit establishes conditions to minimize sediment and pollutant loading and requires preparation and implementation of a Storm Water Pollution Prevention Plan before construction.

Clean Air Act

The Clean Air Act also has provisions for reducing soil erosion relevant to air and water quality. On construction sites, exposed soil surfaces are vulnerable to wind erosion, and small soil particulates are carried into the atmosphere. Suspended particulate matter (PM10 and PM2.5) is one of the six criteria air pollutants of the Clean Air Act.

Earthquake Hazards Reduction Act

In October 1977, the U.S. Congress passed the Earthquake Hazards Reduction Act to "reduce the risks to life and property from future earthquakes in the United States through the establishment and maintenance of an effective earthquake hazards and reduction program." To accomplish this, the act established the National Earthquake Hazards Reduction Program. The National Earthquake Hazards Reduction Program Act (NEHRPA) significantly amended this program in November 1990 by refining the description of agency responsibilities, program goals, and objectives. The NEHRPA designates the Federal Emergency Management Agency as the lead agency of the program and assigns it several planning, coordinating, and reporting responsibilities. Other NEHRPA agencies include the National Institute of Standards and Technology, the National Science Foundation, and U.S. Geologic Survey.

Antiquities Act of 1906

Federal protection for significant paleontological resources would apply to the project if any construction or other related project impacts occurred on Federally owned or managed lands. Federal legislative protection for paleontological resources stems from the Antiquities Act of 1906 (Public Law 59-209; 16 United States Code 431 et seq.; 34 Stat. 225), which calls for

protection of historic landmarks, historic and prehistoric structures, and other objects of historic or scientific interest on federal land.

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF Land and Resource Management Plan (LRMP) (USFS 1995) contains forest goals, standards, and guidelines designed to guide the management of the STNF. The following goals, standards, and guidelines related to geologic and seismic hazards and soils issues associated with the study area were excerpted from the STNF LRMP.

- Goals (LRMP, p. 4-5):
  - Maintain or improve soil productivity and prevent excessive surface erosion, mass wasting, and cumulative watershed impacts.
- Standard and Guidelines (LRMP, p. 4-25):
  - Determine the sensitivity of each 2nd or 3rd order watershed using soil, geologic, and streamflow characteristics.
  - Implement Forest Soil Quality Standards and Best Management Practices for areas identified as having highly erodible soils. Specifically, apply the special practices dealing with timber harvest, site preparation, and road construction in highly erodible soils.
  - Forest Soil Quality Standards in relation to ground cover, soil organic matter, and soil porosity will be used to protect soil productivity (as referenced in Appendix O of the LRMP).1/Environmental Consequences/Impacts and Mitigation Measures

Bureau of Land Management Resource Management Plan

The Bureau of Land Management's (BLM) Resource Management Plan, which is its plan for managing federal lands in Shasta County, was amended by the 1994 Record of Decision for the Northwest Forest Plan (Final Supplemental Environmental Impact Statement for Amendments to Forest Service and Bureau of Land Management Planning Documents within the Range of the Northern Spotted Owl). This amendment required preparation of watershed analyses prior to initiating BLM activities. As a party to the Northwest Forest Plan, BLM, like the USFS, is also required to ensure that projects are consistent with the Aquatic Conservation Strategy.

Federal Minerals Management

Mineral development is permitted on all public lands not withdrawn from mineral entry. The U.S. Mining Laws (30 United States Codee 21-54) confer statutory right to enter upon public lands in search of minerals. Regulations found in 36 Code of Federal Regulations 228, Subpart A, set forth rules and

procedures to minimize adverse environmental impacts on national forest resources. Access for mineral exploration and development is generally unrestricted, subject to the mitigation of adverse impacts to surface resources.

Access for mineral exploration on STNF land is restricted in wildernesses, the "wild" portions of Wild and Scenic Rivers, botanical areas, Research Natural Areas, NRAs, and areas that have been withdrawn from mineral entry. Minerals in the NRA are not locatable (minerals that may be acquired under the Mining Law of 1872, as amended) but they are leasable (USFS 1994).

Access for mineral-related activities to wilderness, the NRA, and other lands typically withdrawn from mineral entry is subject to valid existing rights. The type of access authorized must be consistent with the proposed use and of a type that would maintain the special character of the areas to the fullest extent possible.

The Federal lands within the Shasta Unit of the NRA were withdrawn from mineral entry under the 1872 Mining Law by the NRA legislation, subject to valid existing rights. Five claims in the Shasta NRA predate the withdrawal. Currently, there are no approved operating plans for these five mining claims.

4.2.2 State

This section discusses the State regulatory setting for soil erosion, water quality, earthquakes, mining, air quality (related to asbestos) paleontological resources, and building design.

Porter-Cologne Act

State regulations, including the Porter-Cologne Act and Fish and Game Code 1600, have provisions to reduce soil erosion. The Porter-Cologne Act established the State Water Resources Control Board and nine RWQCBs that regulate water quality. The RWQCBs carry out the National Pollutant Discharge Elimination System permitting process for point source discharges and the CWA Section 401 certification program.

Fish and Game Code 1600

Fish and Game Code 1600 requires notification for projects that are planned to occur in, or in close proximity to, a river, stream, or lake, or their tributaries. Applicants are to enter into a "streambed alteration agreement" with DFG when a construction activity would (1) divert, obstruct, or change the natural flow or the bed, channel, or bank of any river, stream, or lake, (2) use material from a streambed, or (3) result in the disposal of debris, waste, or other material containing crumbled, flaked, or ground pavement that could pass into a river, stream, or lake. The Federal Government is not required to submit a Fish and Game code 1600 permit; however, the same impacts will be addressed under CWA Section 401 and 404 permits.

Alquist-Priolo Earthquake Fault Zoning Act

The Alquist-Priolo Earthquake Fault Zoning Act (Public Resources Code Section 2621 et seq.) was passed by the California Legislature to mitigate the hazard of surface faulting to structures. The act's main purpose is to prevent the construction of buildings used for human occupancy on the surface trace of active faults. The act addresses only the hazard of surface fault rupture and is not directed toward other earthquake hazards. Local agencies must regulate most development in fault zones established by the State Geologist. Before a project can be permitted in a designated Alquist-Priolo Earthquake Fault Zone, cities and counties must require a geologic investigation to demonstrate that proposed buildings would not be constructed across active faults.

1990 Seismic Hazards Mapping Act

The 1990 Seismic Hazards Mapping Act (California Public Resources Code Sections 2690-2699.6) addresses strong ground shaking, liquefaction, landslides, or other ground failures as a result of earthquakes. This act requires statewide identification and mapping of seismic hazard zones, which would be used by cities and counties to adequately prepare the safety element of their general plans and protect public health and safety (California Geological Survey 2003). Local agencies are also required to regulate development in any seismic hazard zones, primarily through permitting. Permits for development projects are not issued until geologic investigations have been completed and mitigation measures have been developed to address identified issues.

Surface Mining and Reclamation Act of 1975

The Surface Mining and Reclamation Act of 1975 (California Public Resources Code Sections 2710 et seq.) addresses surface mining and requires mitigation to reduce adverse impacts to public health, property, and the environment. Surface Mining and Reclamation Act applies to anyone (including a government agency) that disturbs more than 1 acre or removes more than 1,000 cubic yards of material through surface mining activities, even if activities occur on Federally managed lands (CDC 2006b). Local city and county "lead agencies" develop ordinances for permitting that provide the regulatory framework for mining and reclamation activities. The permit generally includes a permit to mine, a reclamation plan to return the land to a useable condition, and financial reports to ensure reclamation would be feasible. The State Mining and Geology Board reviews lead agency ordinances to ensure they comply with Surface Mining and Reclamation Act (CDC 2006b).

Asbestos Airborne Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations

The Asbestos Airborne Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations (see Title 17 California Code of Regulations (CCR) Section 93105) (CCR 2001a) contains the requirements for construction operations that would disturb any portion of an area that is located in a geographic ultramafic rock unit or that has naturally occurring asbestos, serpentine, or ultramafic rock. Construction or grading operations on property

where the area to be disturbed is greater than 1 acre require an Asbestos Dust Mitigation Plan to be submitted and approved by the air quality management district before the start of construction. The Asbestos Dust Mitigation Plan must be implemented at the beginning and must be maintained throughout the operation. To receive an exemption from this Asbestos Airborne Toxic Control Measure, a State registered professional geologist must conduct a geologic evaluation of the property and determine that no serpentine or ultramafic rock is likely to be found in the area to be disturbed. This report must be presented to the executive officer or air pollution control officer of the air pollution control or air quality management district, who may then grant or deny the exemption.

Asbestos Airborne Toxic Control Measure for Surfacing Applications

The Asbestos Airborne Toxic Control Measure for Surfacing Applications (17 CCR Section 93106) applies to any person who produces, sells, supplies, offers for sale or supply, uses, applies, or transports any aggregate material extracted from property where any portion of the property is located in a geographic ultramafic rock unit or the material has been determined to be ultramafic rock, or serpentine, or material that has an asbestos content of 0.25 percent or greater. Unless exempt, the use, sale, application, or transport of material for surfacing is restricted, unless it has been tested using an approved asbestos bulk test method and determined to have an asbestos content that is less than 0.25 percent. Any recipient of such materials may need to be provided a receipt with the quantity of materials, the date of the sale, verification that the asbestos content is less than 0.25 percent, and a warning label. Anyone involved in the transportation of the material must keep copies of all receipts with the materials at all times.

California Public Resources Code Chapter 1.7

No State or local agency requires a paleontological collecting permit to allow for the recovery of fossil remains discovered as a result of construction-related earthmoving on State or private land in a project site. California Public Resources Code Chapter 1.7 (Archaeological, Paleontological, and Historical Sites), Section 5097.3, specifies that State agencies may undertake surveys, excavations, or other operations as necessary on State lands to preserve or record paleontological resources.

California Building Standards Code

The State of California provides minimum standards for building design through the California Building Standards Code (CBC) (CCR 2001b). Where no other building codes apply, Chapter 29 regulates excavation, foundations, and retaining walls. The CBC also applies to building design and construction in the State and is based on the Federal Uniform Building Code used widely throughout the country (generally adopted on a state-by-state or district-by-district basis). The CBC has been modified for California conditions with numerous more detailed and/or more stringent regulations.

The State's earthquake protection law (California Health and Safety Code Section 19100 et seq.) requires that structures be designed to resist stresses produced by lateral forces caused by wind and earthquakes. Specific minimum seismic safety and structural design requirements are set forth in Chapter 16 of the CBC. The CBC identifies seismic factors that must be considered in structural design.

Chapter 18 of the CBC regulates the excavation of foundations and retaining walls, and Appendix Chapter A33 regulates grading activities, including drainage and erosion control, and construction on unstable soils such as expansive soils and liquefaction areas.

4.2.3 Regional and Local

The following section describes the regional and local regulatory setting for geological resources.

County General Plans

Section 65302(g) of the California Government Code requires that county general plans include an element that identifies and appraises seismic and geologic hazards.

Seismic hazards that must be addressed in this section include the following:

- Surface faulting
- Ground shaking
- Ground failure

Non-seismic hazards addressed include the following:

- Volcanoes
- Erosion
- Expansive soils

Local Guiding Ordinances

In addition to identifying and appraising seismic and geologic hazards, counties and municipalities in the project study area also commonly set requirements for grading and erosion control, including prevention of sedimentation or damage to off-site property. Usually these requirements are established via a grading ordinance, which is administered through issuance of grading permits. Grading permits typically require a vested map and the following information:

- Detailed grading plan
- Geological studies if located within an area prone to slippage, having highly erodible soils, or of known geologic hazards

- Detailed drainage or flood control information as required by the department of public works
- Final plan for development if the project is located in a zone district that requires a final development plan
- Noise analysis if the project is located in the vicinity of a high noise generating use

4.3 Environmental Consequences and Mitigation Measures

This chapter is organized by the project alternatives described in Chapter 1, Affected Environment, and discusses environmental consequences to geology, geologic hazards, geomorphology, minerals, and soils associated with implementation of the project alternatives. It also describes potential mitigation measures associated with impacts to geology that are significant or potentially significant.

4.3.1 Methods and Assumptions

In general, the analysis presented in this section is qualitative and is based on general information on geology, geologic hazards, geomorphology, minerals, and soils, as reported in Section 4.1. Environmental consequences associated with geologic resources that could result from implementing alternatives were evaluated qualitatively based on expected construction methods; environmental commitments common to all action alternatives; and the locations, materials, and durations of project construction and related activities.

As described in following paragraphs, for the Shasta Lake and vicinity project area more quantitative analyses were undertaken to address geomorphology (i.e., stream characteristics in watersheds that are adjacent and directly tributary to Shasta Lake) (also see Section 4.1.3) and shoreline erosion (also see Section 4.1.5).

Geomorphology

The analysis of fluvial characteristics of watersheds that are adjacent and directly tributary to Shasta Lake evaluated the impact of raising Shasta Dam on stream channel equilibrium, focusing on the balance between sediment transport capacity and channel stability. The average gradient and flow regime of a watercourse are often the variables that control the sediment transport capacity of a given stream channel. The flow regime of a stream is determined by the measure of the average flow of surface water. The analysis assumed that any stream that has a predicted average annual flow above 0.1 cubic feet per second (cfs) functions as a perennial stream, and any stream with a predicted flow of less than 0.1 cfs functions as an intermittent stream.

Typically, over time, streams reach a natural state of equilibrium based on their gradient and sediment transport capacity. Raising the water level of Shasta Lake may affect the equilibrium of watercourses that are controlled by the present reservoir level. Raising the dam may destabilize these streams by altering the length of stream that will be incorporated into the drawdown. Raising the dam will affect the gradient of adjacent watercourses by altering the length of the watercourse and the change in elevation due to seasonal fluctuations in lake water levels. This is the rationale behind analyzing the gradient and flow regime of watercourses that are adjacent and directly tributary to Shasta Lake.

The stream networks in the Shasta Lake and vicinity area were characterized using the Net Trace model generated in a geographic information system (GIS) environment. Net Trace was used because existing California and USFS stream layers lack the level of detail and necessary variables needed to assess the impact of raising the water level of Shasta Lake on stream channel equilibrium. Initially, sub-10-meter digital elevation models covering the Shasta Lake and vicinity were imported into GIS. Using the methods described in Programs for digital elevation model Analysis (Miller 2003), a surface stream network with user-selected attributes was created using Net Trace. The following characteristics were then calculated for each stream segment: drainage area, riparian area, length, flow direction (degrees), stream order, elevation, gradient statistics, mean precipitation, and mean annual stream flow (cfs).

To verify the accuracy of the Net Trace stream model, the measured bed gradient along surveyed transects on Squaw Creek and Big Backbone Creek was compared to the modeled gradient values calculated by Net Trace along the same transect. The combined average difference between the measured and modeled bed gradient was approximately 4.5 percent, meaning that the measured stream bed gradient is steeper than the modeled gradient. A sampling bias is believed to be the cause of the disparity. For example, 22 segments were surveyed along the Squaw Creek transect and used to determine the measured bed gradient; however, only 5 segments were available from the Net Trace model to calculate the gradient. Simply, the surveyed transects were measured at greater level of detail than were calculated in the Net Trace model.

Although the surveyed gradient values are more accurate than the modeled values, it would be impractical to survey every watercourse within a study area as large as that of the SLWRI. Since this study seeks to characterize the stream channel, a more reasonable approach was to compare the surveyed water surface gradient to the modeled values. This approach eliminates the topographic details of the streambed surface and measures the surface gradient of the stream over the entire transect. The combined average difference between the measured surface gradient and modeled bed gradient was about 2 percent, meaning the measured stream bed gradient is 2 percent steeper than the modeled gradient. Although this disparity is noteworthy, the modeled stream network is considered an accurate representation of the hydrologic system of the study area, and the lower gradient values produce a more conservative estimate of

sediment transport within the system. These results suggest that the digital elevation model-generated stream network is accurate enough to be used as a measure of the potential impacts of raising Shasta Dam on stream channel equilibrium.

Using GIS, the Net Trace stream network was intersected with polygons representative of shoreline area affected through the inundation by each alternative. These intersections were completed for each arm of Shasta Lake. The total stream length and riparian area affected by the inundation were calculated for each arm and summarized to calculate the value for the entire shoreline of Shasta Lake. The affected stream length and riparian areas were also calculated in further detail for perennial and intermittent streams by stream-gradient categories of less than or greater than 10 percent.

Soil Erosion (Shoreline)

A conceptual model was developed to predict the rate and volume of shoreline erosion. The methods and assumptions used for the model are described in Attachment 1, Shoreline Erosion Technical Memorandum. The conceptual model represents the spatial and temporal components of shoreline erosion, and was developed as a framework for field investigations, quantifying present erosion rates, and predicting future erosion rates. The process-based model characterizes the primary causes of shoreline erosion and uses external erosion triggers to weight the relative erodibility of the shoreline. The model was developed using results from similar studies; available precipitation, wind, and lake level data; information concerning the engineering properties of the bedrock geology and soils; the shoreline and hillslope topography; measured erosion processes and rates from sequential historical aerial photographs; and field investigations. Because there were very few shoreline erosion studies for reservoirs as large as Shasta Lake to use as background and support for the analysis, readily available references were used to help characterize the process of shoreline erosion, verify the predicted shoreline erosion rates, and design mitigation measures.

The model divided the shoreline into two zones, which helped account for the episodic nature of erosional events. The nearshore zone is classified as the area above the 1,070-foot contour, and represents the “bathtub” ring around the reservoir. The drawdown zone is classified as the area between the 1,070-foot contour and the 1,020-foot contour. The latter contour was used to represent the drawdown level that typically occurs to meet USACE requirements for flood storage capacity. The nearshore zone is eroded by wave action when the reservoir is full. During drawdown periods, this zone erodes as a result of upland surface runoff, subsurface flow, and fluvial incision along stream channels and gullies.

To represent the temporal component of shoreline erosion, the model compartmentalizes shoreline development into three time steps. The first step lasts for about 15 years and is when most of the erosion occurs (Morris and Fan

1997). During this time, the inundated soils are fully saturated; as a result, they lose cohesion and are subject to rapid erosion, transport, and deposition. Shoreline exposed in the drawdown zone is typically eroded to bedrock or to resilient soil layers, leaving an exposed surface that supports little vegetation. Within this zone, stream channels and gullies rapidly incise the underlying soil and rock.

The second time step can last between about 0 and 150 years. During this time, stable shoreline topography is developing through a sequence of slope-forming events. For modeling purposes, the types of slope-forming events were classified by lithotopo unit because several common processes trigger and control erosion. The shoreline erosion survey data suggest that stable hillslopes are typically associated with shallow soils on coherent bedrock, forming steep topography (greater than 65 percent slope gradient). Unstable hillslopes are associated with deep soils on moderately steep areas (between 30 percent and 65 percent). Around Shasta Lake, stable shoreline formed rapidly during the first 15 years of lake management. Conversely, about 60 years later, unstable hillslopes are still responding to erosional forces and, in some locations, continue to erode at a very high rate (greater than 900 cubic yards/acre/year).

The third time step is used to represent a period when the shoreline slope is stable and soil shear strength remains greater than the shear stresses acting on the slope. During this time, the erosion rate continues to decrease and eventually equals the upslope erosion rates. The analysis assumes that most of the shoreline around Shasta Lake will become stable as the reservoir ages, and the data show that about half of the shoreline is presently stable.

4.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental consequences that would be caused by, or result from, the proposed action. Under NEPA, the significance of an environmental consequence is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. At a minimum, impacts of an alternative on geology, geologic hazards, geomorphology, mineral resources,

and soils would be significant under CEQA if project implementation would do the following:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, or injury, or death involving the following:
  - Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault
  - Strong seismic ground shaking
  - Seismic-related ground failure, including liquefaction
  - Landslides
- Result in substantial soil erosion or loss of topsoil
- Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse
- Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (CCR 2001b), creating substantial risks to life or property
- Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for disposal of wastewater
- Result in the loss or availability of known mineral resources that would be of future value to the region

Significance statements are relative to both existing conditions (2005) and future conditions (2030), unless stated otherwise.

4.3.3 Topics Eliminated from Further Discussion

The topics of snow avalanches, expansive soil, and soil liquefaction are eliminated from the discussion of environmental consequences owing to the low likelihood of their occurrence as previously discussed (see Sections 4.1.2 for snow avalanches and 4.15 for other eliminated topics).

Paleontological resources are not included in the discussion of environmental consequences. As described in Section 4.1.1, a small area of the fossiliferous Cretaceous Chico Formation occurs near Jones Valley Creek, a tributary to the

Pit River Arm, but this rock unit is not exposed along the shoreline of the lake, and falls outside the study sub-area. Some outcrops of McCloud Limestone, especially in the vicinity of McCloud River Bridge, also contain fossil corals and other microinvertebrates. Some areas underlain by limestone are likely to be disturbed regardless of the action alternative being considered. However, the fossils that comprise the McCloud Limestone are well documented in the scientific literature, and it is unlikely that paleontological resources of scientific or cultural significance occur in this formation.

Paleontological resources have been eliminated from further discussion in the upper Sacramento River (Shasta Dam to Red Bluff), lower Sacramento River and Delta, and CVP/SWP service areas because no impacts are anticipated to these resources as a result of reoperation of the dam.

4.3.4 Direct and Indirect Effects

The following section describes the potential environmental consequences of the project, and impacts and mitigation measures.

No-Action Alternative

This section describes potential impacts that would occur under the NEPA No-Action Alternative. Under the No-Action Alternative, no additional Federal action would be taken to address water reliability issues or increase anadromous fish survival. Shasta Dam would not be modified, and the CVP would continue operating similar to the existing condition. No new construction would occur under the No-Action Alternative and the full pool elevation of the reservoir would remain at approximately 1,070 feet above msl.

Shasta Lake and Vicinity This section describes impacts to the Shasta Lake and vicinity portion of the primary study area.

Impact Geo-1 (No-Action): Exposure of Structures and People to Geologic Hazards Resulting From Seismic Conditions, Slope Instability, and Volcanic Eruption Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no increase in the risk of geologic hazards to people or structures. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-2 (No-Action): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Under the No-Action Alternative, the full pool level would not be increased. Therefore, there would be no change to streams tributary to Shasta Lake. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-3 (No-Action): Loss or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no loss or diminished availability of

known mineral resources that would be of future value to the region. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-4 (No-Action): Lost or Diminished Soil Biomass Productivity Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no lost or diminished soil biomass productivity. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-5 (No-Action): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under the No-Action Alternative, the full pool level would not be increased. Therefore, there would be no increase in soil erosion or loss of topsoil due to shoreline processes. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-6 (No-Action): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes Under the No-Action Alternative, there would be no disturbance of upland landscape positions. Therefore, there would be no increase in soil erosion or loss of topsoil due to upland processes. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-7 (No-Action): Be Located on a Geologic Unit or Soil That Is Unstable, or That Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no increase in the risk of land subsidence. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-8 (No-Action): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils That Are Unsuited to Land Application of Waste Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no increase in the risk of failure of septic tanks or alternative wastewater disposal systems. There would be no impact. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts to the upper Sacramento River portion of the primary study area.

Impact Geo-9 (No-Action): Substantial Increase in Channel Erosion and Meander Migration No Shasta Dam enlargement activities would be implemented, and no new water releases from the dam would occur as a result of the No-Action Alternative. The water releases from the dam would continue to vary based on time of year, water year-types, and system conditions. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-10 (No-Action): Substantial Soil Erosion or Loss of Topsoil Due to Construction No Shasta Dam enlargement activities would be implemented, and no gravel augmentation activities would occur as a result of the No-Action

Alternative. Therefore, no soil additional soil erosion would be anticipated on the banks along the river channel. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Geo-11 (No-Action): Alteration of Fluvial Geomorphology Under the No-Action Alternative, no activities to breach the levee to Reading Island would occur and therefore, no changes in fluvial geomorphology would be anticipated along Anderson Creek. There would be no impact. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta This section describes impacts to the lower Sacramento River and Delta portions of the extended study area associated with the No-Action Alternative.

Impact Geo-12 (No-Action): Substantial Increase in Channel Erosion and Meander Migration No Shasta Dam enlargement activities would be implemented, and no new water releases from the dam would occur as a result of the No-Action Alternative. The water releases from the dam would continue to vary based on time of year, water year-types, and system conditions. Therefore, there would be no impact.

This impact would be similar to Impact Geo-9 (No-Action) for the primary study area.

For the same reasons described above for Impact Geo-9 (No-Action), there would be no impact. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Area This section describes the impacts associated with the No-Action Alternative to the CVP/SWP service areas within the extended study area.

Impact Geo-13 (No-Action): Substantial Increase in Channel Erosion and Meander Migration No Shasta Dam enlargement activities would be implemented, and no new water releases from the dam would occur as a result of the No-Action Alternative. No changes in operations would occur under the No-Action Alternative. The water releases from the from Shasta Dam, Folsom Dam, and Oroville Dam would continue to vary based on time of year, water year-types, and system conditions, but would not be anticipated to be outside of normal operating conditions. Therefore, there would be no impact.

This impact would be similar to Impact Geo-9 (No-Action) for the primary study area.

For the same reasons described above for Impact Geo-9 (No-Action), there would be no impact. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

This section describes impacts associated with CP1, which focuses on increasing water supply reliability while contributing to increased anadromous fish survival by raising Shasta Dam 6.5 feet. The dam raise would increase the reservoir's full pool by 8.5 feet, and enlarge total storage space in the reservoir by 256,000 acre-feet.

Shasta Lake and Vicinity This section describes impacts to the Shasta Lake and vicinity portion of the primary study area.

Impact Geo-1 (CP1): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption
Implementing CP1 has the potential to increase the exposure of structures and people to geologic hazards.

There are very few seismic hazard areas within the Shasta Lake and vicinity area. No active faults are known to be present within or immediately adjacent to the Shasta Lake and vicinity area, and there is a low risk of fault rupture (CDC 2006a) According to Jennings (1994) and CDC (1997), all known faults around the Shasta Lake and vicinity area are classified as inactive. (Inactive faults show no evidence of movement in the last 10,000 years (i.e., Holocene). Because there are few active faults in close proximity to the Shasta Lake and vicinity area the likelihood of strong seismic ground shaking also is low. Detailed, site-specific geologic and foundation investigations will be completed to develop design criteria to withstand reasonably probable seismic events. This impact would be less than significant.

Under CP1, the pool level increase would inundate 78 acres of mapped slope instability hazards (i.e., active and relict landslides, debris flows, inner gorge landscape positions, and complexes of these features). Relocation of infrastructure is proposed to occur in the vicinity of about 232 acres of mapped slope instability hazards. Inundation of bedrock and soils resulting from the increased pool elevation, and earthwork and vegetation removal associated with new construction, could reduce the stability of hillslopes prone to mass wasting. The existing relict and active mass wasting features may become less stable. The risks associated with increased slope instability due to the rise in pool elevation and relocation of infrastructure have been considered in formulating the description of CP1. Areas of known instability have been addressed via avoidance or through design measures intended to minimize the risk of increased instability. This impact would be less than significant.

Hazards associated with volcanic eruptions have a low probability of occurring within the Shasta Lake and vicinity area. Significant impacts resulting from eruptions in the Medicine Lake Highlands and at Lassen Peak are unlikely due to their distance from Shasta Lake and the lack of drainage connections. Eruptions of Mount Shasta are not likely to deposit lithic ash, lava flows,

domes, or pyroclastic flows within the reservoir, and Mount Shasta is not likely to erupt large volumes of pumiceous ash. The danger from floods caused by eruptions is similar to that from floods having other origins, and would be mitigated via the proposed dam modifications (e.g., increased spillway capacity) and operational procedures. This impact would be less than significant.

Similarly, the dangers from mudflows and seiche hazards are low, and would be mitigated via the proposed dam modifications (e.g., increased spillway capacity) and operational procedures. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP1): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Under CP1, stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Lower gradient channels (less than 7 percent slope) with existing delta deposits would be affected more than higher gradient channels. It is likely that the delta deposits would expand both upstream and downstream as a result of this alternative. When the lake is full and regional flooding occurs, sediment transported from the uplands would be deposited as deltas at the confluence of the streams and lake. When the lake level is low during baseflow periods, stream channels within the inundation zone are likely to be channelized as they downcut into the Delta deposits. In the lower gradient channels, the stream type could shift to an unstable braided channel.

Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,080 feet of elevation. CP1 could also destabilize the stream channels as a result of riparian vegetation loss on the lower and upper banks and a more mobile stream bed.

Based on a GIS-generated stream network, the total stream length inundated as a result of CP1 is estimated to be 18.5 miles (see Figure 4-8), which equates to about 0.7 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 18.5 miles inundated, about 6.2 miles are streams with a gradient of less than 7 percent. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

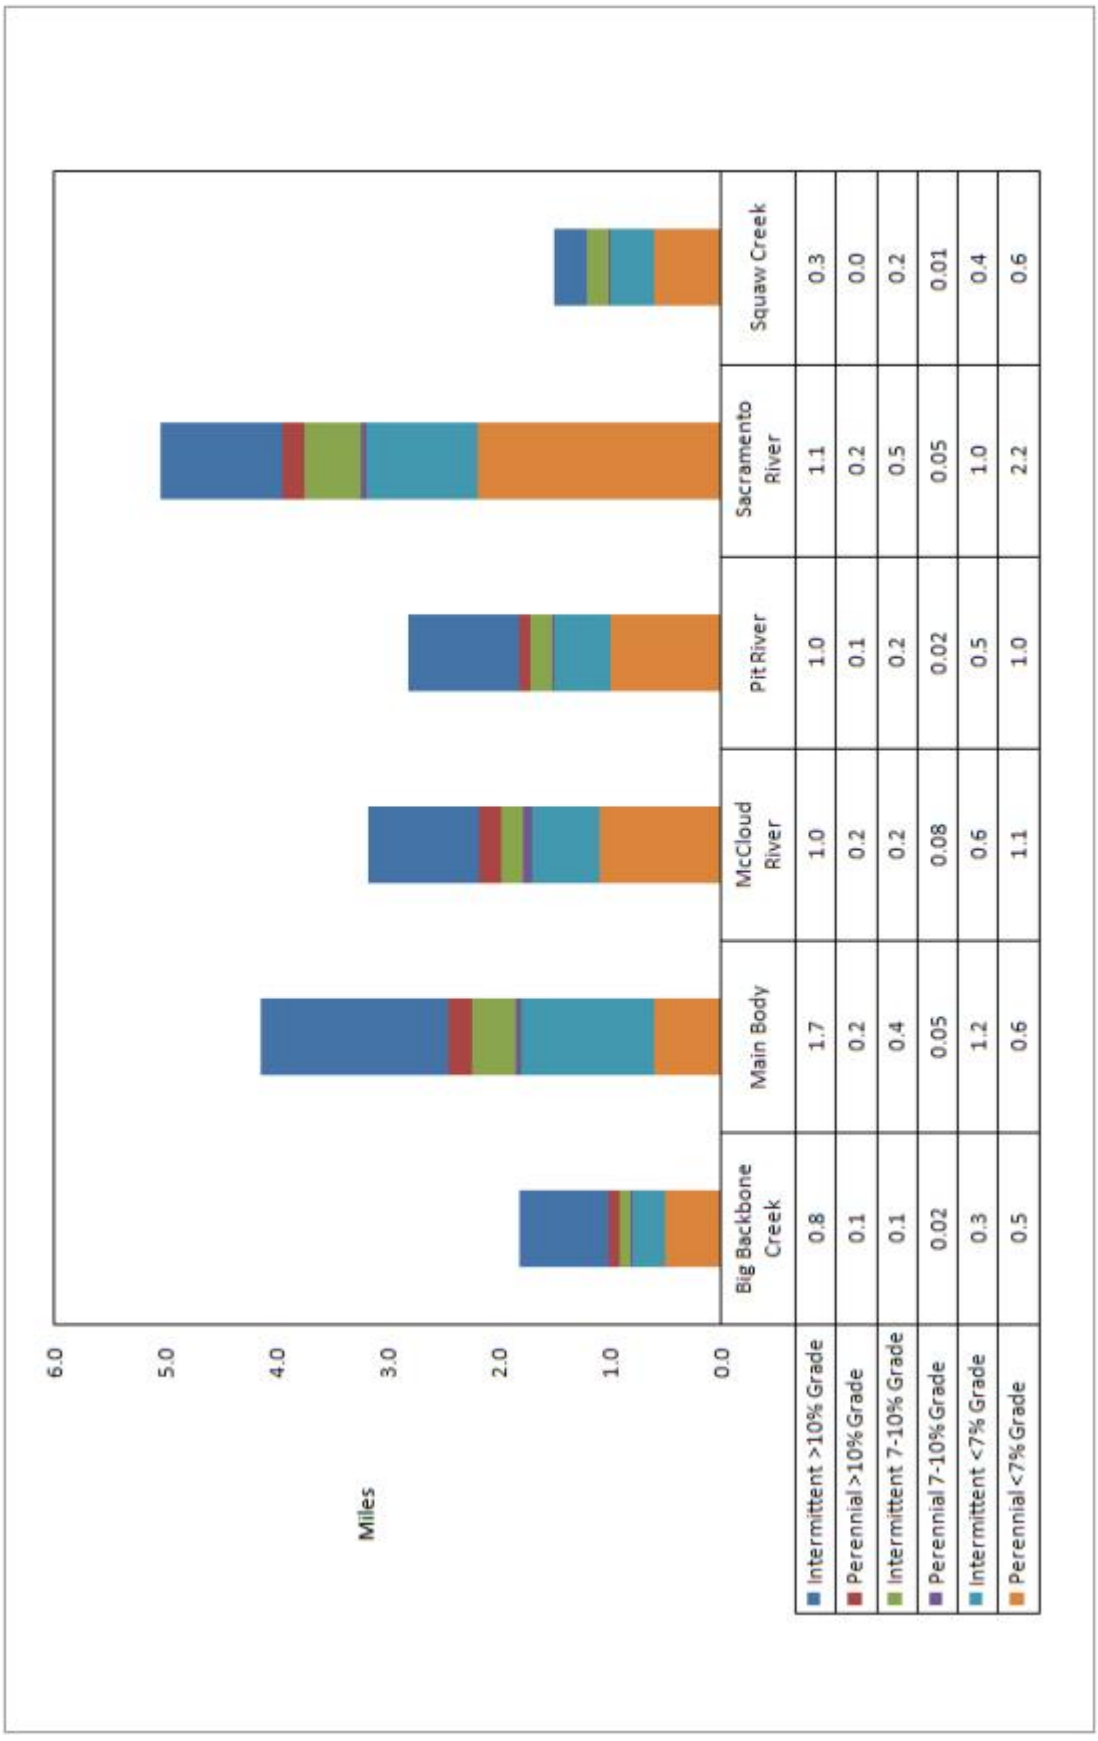

Figure 4-8. Stream Lengths in Watersheds Adjacent to Shasta Lake that Would Be Periodically Inundated Under Alternative CP1

Impact Geo-3 (CP1): Loss or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region Significant quantities of cement, concrete sand and aggregate, and coarse aggregate would be needed under CP1. Cement Types I, II, III, and V are produced locally but supplies are limited. Required quantities of concrete sand and aggregate are available from local commercial suppliers. The tonnage of sand anticipated to be needed is roughly more than 150 percent of the annual Shasta County production of sand and gravel. Embankment material (i.e., coarse aggregate) could be obtained from local sources, including from within Shasta Lake itself. Implementation of CP1 has the potential to diminish the availability of cement, and of concrete sand and aggregate, in the region. This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-4 (CP1): Lost or Diminished Soil Biomass Productivity Under CP1, soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction including relocation of infrastructure. Using Equivalent FSSC as a surrogate metric for soil biomass productivity, implementation of CP1 would result in loss of the following acreages by productivity rank: moderate productivity – 1,954.6 acres; low productivity – 1,604.5 acres; nonproductive - 565 acres.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-5 (CP1): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP1, the area of shoreline that would be periodically inundated would be about 1,229 acres. Substantial soil erosion and loss of topsoil would result.

The inundated area would be subjected to shoreline erosional processes. For the first 15 years after raising the dam, the average rate of shoreline erosion would increase substantially, from 90 cubic yards per acre per year to about 300 cubic yards per acre per year. For the first time step (i.e., 15 years), the total average annual volume of potential shoreline erosion from CP1 would be about 421,000 cubic yards per year. Within 60 years of raising the dam, the average annual volume is predicted to decrease to 107,000 cubic yards per year.

Sediment delivery from shoreline erosion would likely be greatest in the Sacramento River Arm, eastern portion of the Main Body Arm, and McCloud River Arm. These three arms are predicted to deliver more than 66,000 cubic yards per year for the first 15 years after raising the dam. Within 60 years of raising the dam, the average rate for these arms is predicted to decrease to 19,000 cubic yards per year. The western portion of the Main Body Arm and the Backbone Creek Arm are predicted to have the lowest shoreline erosion rates, resulting in a 15-year average annual potential erosion volume of less than 26,000 cubic yards per year. The Pit River Arm is predicted to produce about

50,000 cubic yards per year and the Squaw Creek Arm about 35,000 cubic yards per year.

Assuming the available vegetation removal prescriptions between the 1,070-foot and 1,080-foot contours, for the first time step (i.e., 15 years after raising Shasta Dam), there would be about 421,000 cubic yards per year of shoreline erosion. After about 15 to 20 years, depending on climatic variability, the new shoreline would form and would start to stabilize. Total reservoir erosion is predicted to decrease by 70 percent between 15 and 60 years after raising the dam. The wetter the climate cycle, the more rapidly the shoreline is predicted to form.

The analysis also calculated the 15-year erosion volume using the prescribed vegetation treatments and modeled higher erosion rates for shoreline with partial and complete vegetation removal. The Big Backbone, Squaw Creek, and Pit River arms would have very little vegetation removal, which would not affect the short-term rate of shoreline erosion. The Main Body, Sacramento River, and McCloud River arms would have substantial amounts of vegetation removal, which would result in higher short-term erosion rates. For these arms, areas treated by vegetation removal represent about half of the total predicted erosion.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-6 (CP1): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes Interpretations of soil susceptibility to erosion are presented in Table 4-12 for the portion of the subarea potentially disturbed by construction activities. Up to approximately 3,340 acres in the upland portion of the Shasta Lake and vicinity area could be disturbed, and up to 3,128 acres (94 percent of total area) are assigned a hazard rating of severe. A severe rating indicates that significant erosion is expected, and that extensive erosion-control measures are needed.

Construction-related erosion will be avoided and minimized via implementation of the stormwater pollution prevention plans (i.e., erosion and sediment control plans including site revegetation) that are a part of the environmental commitments common to all action alternatives. These plans will address the necessary local jurisdiction requirements regarding erosion control and site revegetation, and would implement best management practices for erosion and sediment control. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP1): Be Located on a Geologic Unit or Soil That is Unstable, or That Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence Of the approximately 3,340 acres in the upland portion of the Shasta Lake and vicinity area, 175.5 acres (5.3 percent of total area) occupy

landscape positions underlain by limestone. Land subsidence has potential to occur in areas underlain by certain limestones, and in areas affected by underground construction. Detailed, site-specific geologic and foundation investigations will be completed to inform project design as to how to avoid potential subsidence due to these potential causes. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP1): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste In general, soils in the Shasta Lake and vicinity area are poorly suited to use as septic tank leach fields or alternative waste disposal systems due to shallow soil depth, high rock content, and excessive slope. Relocated wastewater facilities will be designed and constructed to satisfy the conditions of the Shasta County Environmental Health Division Sewage Disposal System Permit. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts to the upper Sacramento River portion of the primary study area associated with CP1.

Impact Geo-9 (CP1): Substantial Increase in Channel Erosion and Meander Migration This impact would be similar to Impact Geo-9 for the No-Action Alternative. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing condition, this alternative would change the maximum pool elevation and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows could potentially change downstream stream erosion and change downstream geomorphologic characteristics. However, the frequency and duration of high flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. This impact would be less than significant.

Reductions of stream bedload contribution are greatest during high flow events. Bed and bank conditions in streams and rivers are created, maintained, and destroyed by natural geomorphic processes whose rates and patterns are regulated through complex interactions of flow, sediment transport, and properties of the channel and floodplain (including slope, erodibility, and morphology). Because large fluvial systems, such as the Sacramento River and its floodplain, are affected by the interaction of a wide variety of geomorphic processes, quantifying and understanding how they evolve can be complex. The legacy of land and water use in a region add to the complexity, modulating factors such as flow, sediment supply, and floodplain erodibility, thus affecting the dynamics of riverine and floodplain characteristics.

High flow events can mobilize and scour gravel stored in the channel bed, routing the sediment downstream. In the alluvial reaches of unregulated rivers, the sediment scoured from a local reach is generally replaced by sediment transported from upstream, supplied from tributaries, or recruited from storage in riverbanks. There may be short-term or local changes in the amount of gravel stored in a channel bed due to episodic sediment delivery (e.g., mass wasting events in the watershed) or extreme flow events, but over a broader time span, unregulated rivers generally achieve a balance between sediment supply and routing so that in-channel sediment storage is maintained.

The first significant natural source of sediment to the Sacramento River is nearly 30 miles (48 kilometers) downstream from Keswick Dam at Cottonwood Creek (River Mile 273.5). Tributaries between Keswick Dam and Cottonwood Creek contribute little sediment to the mainstem because they drain small basins of erosion-resistant material or, as is the case for Clear Creek, are themselves regulated by dams and are affected by aggregate mining. Much of the upper Sacramento River (i.e., from River Mile 302 to approximately River Mile 273.5) is bounded by erosion-resistant bedrock and terrace deposits, such that bank erosion is not fast enough, relative to in-channel transport, to provide a significant source of coarse sediment. In other words, the rate of supply from erosion of banks due to meander migration in the upper river is minimal.

Meander migration and bank erosion occur by two processes: progressive channel migration, in which flows erode banks incrementally, and episodic meander-bend cutoff, in which the channel avulses to a completely new course. Cutoffs may be partial or complete, depending on initial meander bend geometry and the resistance of bank and floodplain materials to erosion, among other factors. Complete cutoffs are often referred to as "chute cutoffs." Partial cutoffs are sometimes also referred to as "neck cutoffs" in geomorphology texts and literature. While progressive migration and episodic cutoff can generally be thought of as distinct (i.e., mutually exclusive) processes, they are nevertheless interrelated because they simultaneously regulate and are affected by sinuosity and other channel characteristics.

An Erosion and Sediment Control Plan would be implemented, as described in Chapter 2, *Environmental Commitments Common to All Action Alternatives,* to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-10 (CP1): Substantial Soil Erosion or Loss of Topsoil Due to Construction Under implementation of CP1 no gravel augmentation activities or construction activities to breach the levee to Reading Island would occur and therefore, no soil additional soil erosion would be anticipated on the banks along the river channel. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP1): Alteration of Fluvial Geomorphology Under implementation of CP1, no activities to breach the levee to Reading Island would occur and therefore, no changes in fluvial geomorphology would be anticipated along Anderson Creek. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts to the lower Sacramento River and Delta portions of the extended study area associated with CP1.

Impact Geo-12 (CP1.): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP1 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Under implementation of CP1, there would be a potential reduction in high flow events. Therefore, increases in Sacramento River flow would be limited and affects to reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as flood bypasses in the extended study area. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), but would take place in the lower Sacramento River and Delta and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts to the CVP/SWP service areas within the extended study area associated with CP1.

Impact Geo-13 (CP1): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP1 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This would be a less than significant impact.

This impact would be very similar to Impact Geo-9 (CP1), but would be associated with the CVP/SWP service areas that extend along the Sacramento River and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

This section describes impacts associated with CP2, which focuses on enlarging Shasta Dam and Reservoir by raising Shasta Dam 12.5 feet. The dam raise

would increase the reservoir's full pool by 14.5 feet, and enlarge total storage space in the reservoir by 443,000 acre-feet.

Shasta Lake and Vicinity This section describes impacts to the Shasta Lake portion of the primary study area.

Impact Geo-1 (CP2): Exposure of Structures and People to Geologic Hazards Resulting From Seismic Conditions, Slope Instability, and Volcanic Eruption Implementing CP2 has the potential to increase the exposure of structures and people to geologic hazards similar to CP1. For the same reasons as apply to CP1, impacts resulting from seismic conditions would be less than significant for CP2.

Under CP2, the pool level increase would inundate 110 acres of mapped slope instability hazards. Relocation of infrastructure is proposed to occur in the vicinity of about 232 acres of mapped slope instability hazards. For the same reasons as apply to CP1, impacts resulting from slope instability hazards would be less than significant for CP2.

For the same reasons as apply to CP1, impacts resulting from hazards associated with volcanic eruptions would be less than significant for CP2. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP2): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Like CP1, under CP2 stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,084 feet of elevation.

Based on a GIS-generated stream network, the total stream length inundated as a result of CP2 would be 25.5 miles (see Figure 4-9), which equates to about 0.9 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 25.5 miles inundated, about 8.2 miles are streams with a gradient less than 7 percent. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-3 (CP2): Loss or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region Implementing CP2 has the same potential as CP1 to diminish the availability in the region of cement, and of concrete sand and aggregate. For the same reasons as apply to CP1, this impact would be significant and unavoidable for CP2. Mitigation for this impact is not available.

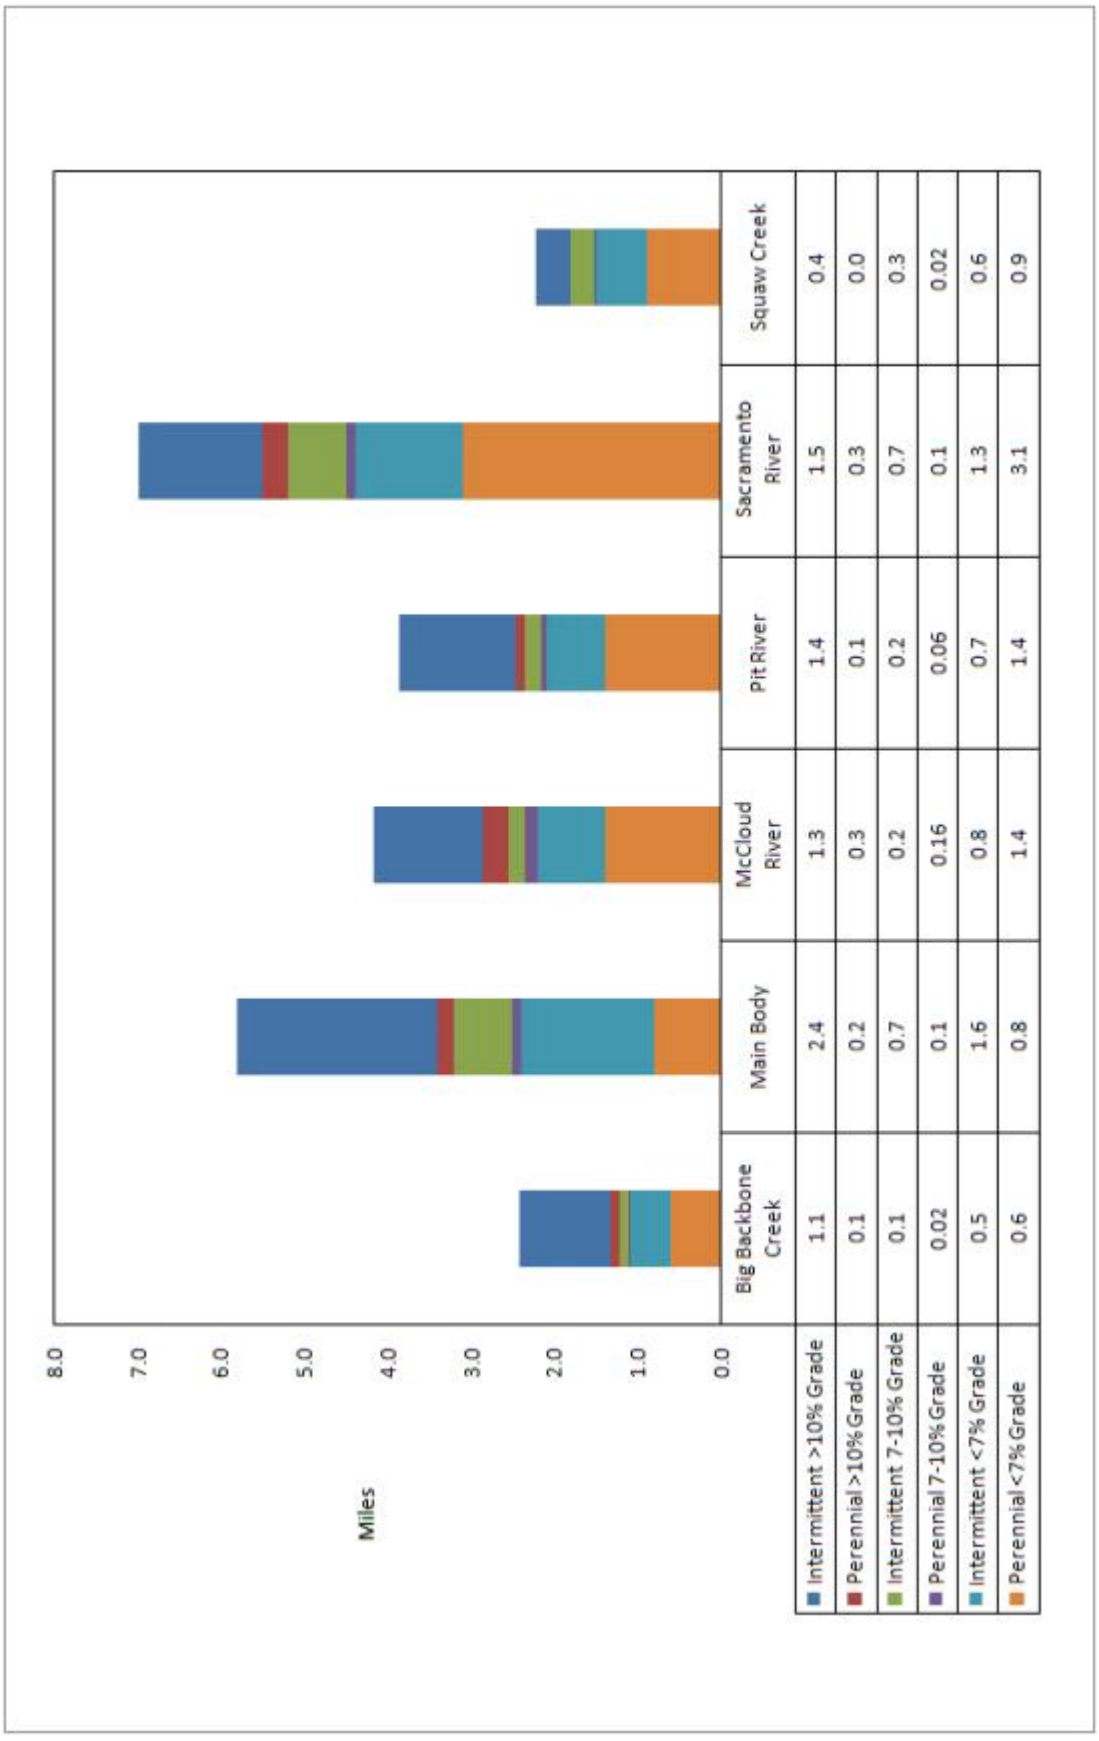

Figure 4-9. Stream Lengths in Watersheds Adjacent to Shasta Lake that Would Be Periodically Inundated Under Alternative CP2

Impact Geo-4 (CP2): Lost or Diminished Soil Biomass Productivity Like CP1, under CP2 soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction including relocation of infrastructure. Using Equivalent FSSC as a surrogate metric for soil biomass productivity, implementation of CP2 would result in loss of the following acreages by productivity rank: moderate productivity, 2,128 acres; low productivity, 1,751 acres; nonproductive, 638 acres.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-5 (CP2): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP2, the area of shoreline that would be inundated would be about 1,734 acres. Substantial soil erosion and loss of topsoil would result.

For the first 15 years after raising the dam, the average rate of shoreline erosion would increase substantially, from 90 cubic yards per acre per year to about 300 cubic yards per acre per year. For the first time step (i.e., 15 years), the total average annual volume of potential shoreline erosion from CP2 would be about 549,000 cubic yards per year. Within 60 years of raising the dam, the average annual volume is predicted to decrease to 150,000 cubic yards per year.

Sediment delivery from shoreline erosion would likely be greatest in the Sacramento River Arm, eastern portion of the Main Body Arm, and McCloud River Arm. These three arms are predicted to deliver more than 90,000 cubic yards per year for the first 15 years after raising the dam. Within 60 years of raising the dam, the average rate for these arms is predicted to decrease to 27,000 cubic yards per year. The western portion of the Main Body Arm and the Backbone Creek Arm are predicted to have the lowest shoreline erosion rates, a 15-year average annual potential erosion volume of less than 43,000 cubic yards per year. The Pit River Arm is predicted to produce about 67,000 cubic yards per year and the Squaw Creek Arm about 63,000 cubic yards per year.

Assuming the available vegetation removal prescriptions between the 1,070-foot and 1,084-foot contours, for the first time step (i.e., 15 years after raising Shasta Dam), there would be about 549,000 cubic yards per year of shoreline erosion. After about 15 to 20 years, depending on climatic variability, the new shoreline would form and would start to stabilize. Total reservoir erosion is predicted to decrease by 70 percent between 15 and 60 years after raising the dam. The wetter the climate cycle, the more rapidly the shoreline is predicted to form.

The analysis also calculated the 15-year erosion volume using the prescribed vegetation treatments and modeled higher erosion rates for shoreline with partial and complete vegetation removal. The Big Backbone, Squaw Creek, and Pit River Arms would have very little vegetation removal, which would not

affect the short-term rate of shoreline erosion. The Main Body, Sacramento River, and McCloud River arms would have substantial amounts of vegetation removal, which would result in higher short-term erosion rates. For these arms, areas treated by vegetation removal represent about half of the total predicted erosion.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-6 (CP2): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes Alternative CP2 is similar to Alternative CP1 with respect to its potential to cause substantial soil erosion or loss of topsoil due to upland processes. The area disturbed by construction activities under CP2 is roughly the same as the area disturbed under CP1, up to approximately 3,340 acres. Of this area, up to approximately 3,128 acres are assigned a hazard rating of severe. For the same reasons as apply to CP1, this impact would be less than significant for CP2. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP2): Be Located on a Geologic Unit or Soil That is Unstable, or That Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence Alternative CP2 is similar to Alternative CP1 with respect to its potential to cause or be effected by subsidence. For the same reasons as apply to CP1, this impact would be less than significant for CP2 Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP2): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste Alternative CP2 is similar to Alternative CP1 with respect to its potential to cause or be effected by failure of septic tanks or alternative wastewater disposal systems due to soils that are unsuited to land application of waste. For the same reasons as apply to CP1, this impact would be less than significant for CP2. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes the impacts to the upper Sacramento River portion of the primary study area associated with CP2.

Impact Geo-9 (CP2): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP2 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing condition, this alternative would change the maximum pool elevation and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows could potentially change downstream stream erosion and change downstream geomorphologic characteristics.

However, the frequency and duration of high flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. An Erosion and Sediment Control Plan would be implemented, as described in Chapter 2, *Environmental Commitments Common to All Action Alternatives,* to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be slightly greater under CP2. This impact would be less than significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-10 (CP2): Substantial Soil Erosion or Loss of Topsoil Due to Construction Under implementation of CP2 no gravel augmentation activities would occur and therefore, no soil additional soil erosion would be anticipated on the banks along the river channel. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP2): Alteration of Fluvial Geomorphology Under implementation of CP2, no activities to breach the levee to Reading Island would occur and therefore, no changes in fluvial geomorphology would be anticipated along Anderson Creek. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts to the lower Sacramento River and Delta portions of the extended study area associated with CP2.

Impact Geo-12 (CP2): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP2 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Under implementation of CP1, there would be a potential reduction in high flow events. Therefore, increases in Sacramento River flow would be limited and affects to reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as by flood bypasses in the extended study area. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be slightly greater under CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts to the CVP/SWP service areas within the extended study area associated with CP2.

Impact Geo-13 (CP2): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP2 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be slightly greater under CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

This section describes impacts associated with CP3, which focuses on the greatest practical enlargement of Shasta Dam and Reservoir consistent with the goals of the 2000 CALFED Bay-Delta Program Record of Decision (CALFED 2000b). CP3 was formulated for the primary purposes of increased water supply reliability and increased anadromous fish survival by raising Shasta Dam 18.5 feet. The dam raise would raise the reservoir's full pool by 20.5 feet, and enlarge total storage space in the reservoir by 5.19 million acre-feet.

Shasta Lake and Vicinity This section describes impacts to the Shasta Lake portion of the primary study area for CP3.

Impact Geo-1 (CP3): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption
Implementing CP3 has the potential to increase the exposure of structures and people to geologic hazards similar to CP1. For the same reasons as apply to CP1, impacts resulting from seismic conditions would be less than significant for CP3.

Under CP3, the pool level increase would inundate 173 acres of mapped slope instability hazards (i.e., active and relict landslides, debris slides, and inner gorge landscape positions). Relocation of infrastructure is proposed to occur in the vicinity of about 232 acres of mapped slope instability hazards. For the same reasons as apply to CP1, impacts resulting from slope instability hazards would be less than significant for CP3

For the same reasons as apply to CP1, impacts resulting from hazards associated with volcanic eruptions would be less than significant for CP3. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP3): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Similar to CP1, under CP3 stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,090 feet of elevation.

Based on a GIS-generated stream network, the total stream length inundated as a result of CP3 would be 36.5 miles (see Figure 4-10), which equates to about 1.3 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 36.5 miles inundated, about 12.1 miles are streams with a gradient less than 7 percent. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-3 (CP3): Loss or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region Implementing CP3 has the same potential as CP1 to diminish the availability in the region of cement, and of concrete sand and aggregate. For the same reasons as apply to CP1, this impact would be significant and unavoidable for CP3. Mitigation for this impact is not available.

Impact Geo-4 (CP3): Loss or Diminished Soil Biomass Productivity Like CP1, under CP3 soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction including relocation of infrastructure. Using Equivalent FSSC as a surrogate metric for soil biomass productivity, implementation of CP3 would result in loss of the following acreages by productivity rank: moderate productivity – 2,301 acres; low productivity – 2,092 acres; nonproductive – 760 acres.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-5 (CP3): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP3, the area of shoreline that would be inundated would be about 2,498 acres. Substantial soil erosion and loss of topsoil would result.

For the first 15 years after raising the dam, the average rate of shoreline erosion would increase substantially, from 90 cubic yards per acre per year to about 300 cubic yards per acre per year. For the first time step (i.e., 15 years), the total average annual volume of potential shoreline erosion from CP3 would be about 767,000 cubic yards per year. Within 60 years of raising the dam, the average annual volume is predicted to decrease to 216,000 cubic yards per year.

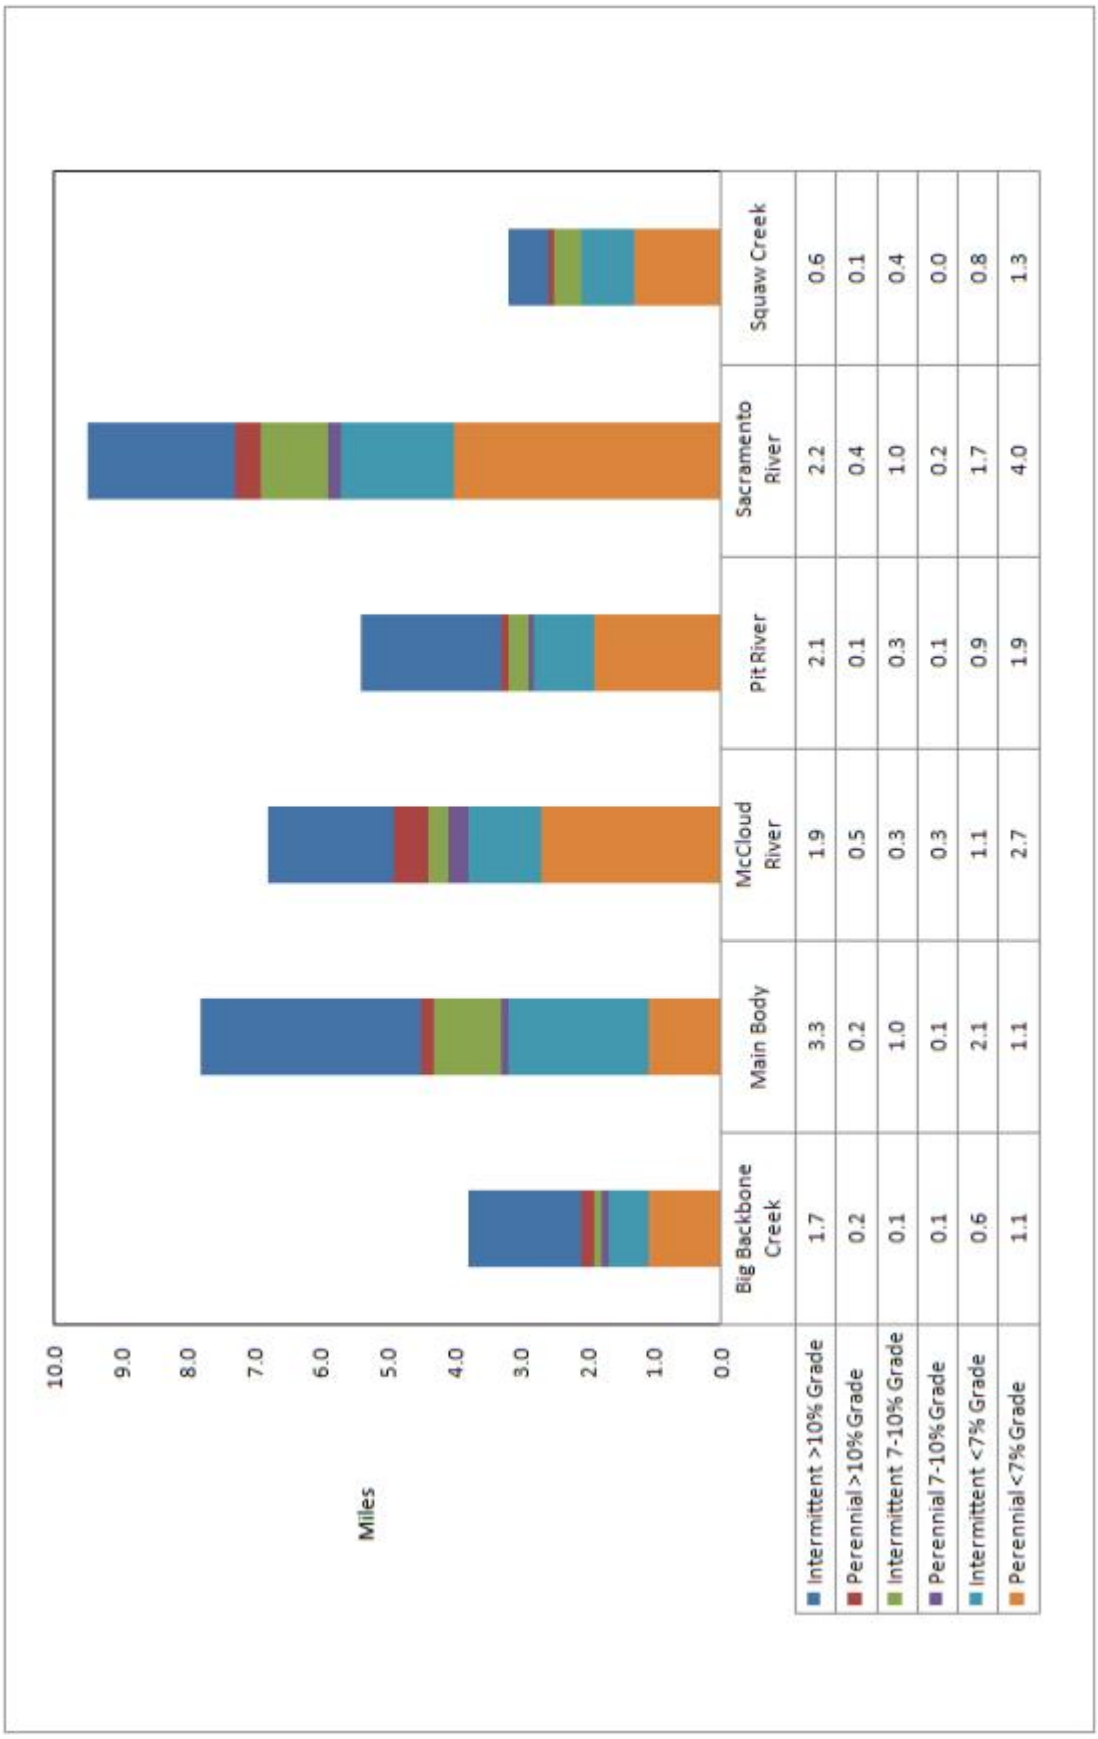

Figure 4-10. Stream Lengths in Watersheds Adjacent to Shasta Lake that Would Be Periodically Inundated Under Alternatives CP3, CP4, and CP5

Sediment delivery from shoreline erosion would likely be greatest in the Sacramento River Arm, eastern portion of the Main Body Arm, and McCloud River Arm. These three arms are predicted to deliver more than 140,000 cubic yards per year for the first 15 years after raising the dam. Within 60 years of raising the dam, the average rate for these arms is predicted to decrease to 39,000 cubic yards per year. The western portion of the Main Body Arm and Backbone Creek Arm are predicted to have the lowest shoreline erosion rates, a 15-year average annual potential erosion volume of less than 57,000 cubic yards per year. The Pit River Arm is predicted to produce about 99,000 cubic yards per year and the Squaw Creek Arm about 68,000 cubic yards per year.

Assuming the available vegetation removal prescriptions between the 1,070-foot and 1,090-foot contours, for the first time step (i.e., 15 years after raising Shasta Dam), there would be about 767,000 cubic yards per year of shoreline erosion. After about 15 to 20 years, depending on climatic variability, the new shoreline would form and would start to stabilize. Total reservoir erosion is predicted to decrease by 70 percent between 15 and 60 years after raising the dam. The wetter the climate cycle, the more rapidly the shoreline is predicted to form.

The analysis also calculated the 15-year erosion volume using the prescribed vegetation treatments and modeled higher erosion rates for shoreline with partial and complete vegetation removal. The Big Backbone, Squaw Creek, and Pit River Arms would have very little vegetation removal, which would not affect the short-term rate of shoreline erosion. The Main Body, Sacramento River, and McCloud River arms would have substantial amounts of vegetation removal, which would result in higher short-term erosion rates. For these arms, areas treated by vegetation removal represent about half of the total predicted erosion.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-6 (CP3): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes Alternative CP3 is similar to Alternative CP1 with respect to its potential to cause substantial soil erosion or loss of topsoil due to upland processes. The area disturbed by construction activities under CP3 is about 3,340 acres. Of this area, approximately 3,128 acres are assigned a hazard rating of severe. For the same reasons as apply to CP1, this impact would be less than significant for CP3. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP3): Be Located on a Geologic Unit or Soil That is Unstable, or That Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence Alternative CP3 is similar to Alternative CP1 with respect to its potential to cause or be effected by subsidence. For the same

reasons as apply to CP1, this would be less than significant for CP3. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP3): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste Alternative CP3 is similar to Alternative CP1 with respect to its potential to cause or be effected by failure of septic tanks or alternative wastewater disposal systems due to soils that are unsuited to land application of waste. For the same reasons as apply to CP1, this would be less than significant for CP3. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts to the upper Sacramento River portion of the primary study area associated with CP3.

Impact Geo-9 (CP3): Potential Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP3 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing condition, this alternative would change the maximum pool elevation and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows could potentially change downstream stream erosion and change downstream geomorphologic characteristics. However, the frequency and duration of high flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. An Erosion and Sediment Control Plan would be implemented, as described in Chapter 2, *Environmental Commitments Common to All Action Alternatives*, to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be greater under CP3. This impact would be less than significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-10 (CP3): Substantial Soil Erosion or Loss of Topsoil Due to Construction Under implementation of CP3 no gravel augmentation activities would occur and therefore, no soil additional soil erosion would be anticipated on the banks along the river channel. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP3): Alteration of Fluvial Geomorphology Under implementation of CP3, no activities to breach the levee to Reading Island would occur and therefore, no changes in fluvial geomorphology would be

anticipated along Anderson Creek. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts to the lower Sacramento River and Delta portions of the extended study area associated with CP3.

Impact Geo-12 (CP3): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP3 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Under implementation of CP1, there would be a potential reduction in high flow events. Therefore, increases in Sacramento River flow would be limited and affects to reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as by flood bypasses in the extended study area. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be greater under CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts to the CVP/SWP service areas within the extended study area associated with CP3.

Impact Geo-13 (CP3): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP3 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be slightly greater under CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

This section describes impacts associated with CP4, which focuses on increasing the volume of cold water available to the Shasta Dam temperature control device through reservoir reoperations, and on raising Shasta Dam by raising Shasta Dam 18.5 feet. The dam raise would increase the reservoir's full

pool by 20.5 feet, and enlarge total storage space by 634,000 acre-feet. This additional storage space would expand the Shasta Lake cold-water supply available to the temperature control device by 378,000 acre-feet, a feature that would help regulate cooler water temperatures in the upper Sacramento River.

Shasta Lake and Vicinity This section describes impacts to the Shasta Lake portion of the primary study area for CP4.

Impact Geo-1 (CP4): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption Implementing CP4 has the potential to increase the exposure of structures and people to geologic hazards similar to CP1. For the same reasons as apply to CP1, impacts resulting from seismic conditions would be less than significant for CP4.

Like CP3, under CP4, the pool level increase would inundate 173 acres of mapped slope instability hazards. Relocation of infrastructure is proposed to occur in the vicinity of about 232 acres of mapped slope instability hazards. For the same reasons as apply to CP1, impacts resulting from slope instability hazards would be less than significant for CP4.

For the same reasons as apply to CP1, impacts resulting from hazards associated with volcanic eruptions would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP4): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Like CP3, under CP4 stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,090 feet of elevation.

Based on a GIS-generated stream network, the total stream length inundated as a result of CP4 would be the same as for CP3, about 36.5 miles (see Figure 4-10). This value equates to about 1.3 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 36.5 miles inundated, about 12.1 miles are streams with a gradient less than 7 percent. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-3 (CP4): Loss or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region Implementing CP4 has the same potential as CP1 to diminish the availability in the region of cement, and of concrete sand and aggregate. For the same reasons as apply to CP1, this impact would be significant and unavoidable for CP4. Mitigation for this impact is not available.

Impact Geo-4 (CP4): Lost or Diminished Soil Biomass Productivity Like CP3, under CP4 soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction including relocation of infrastructure. The acreages of these losses would be the same as those reported for CP3.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-5 (CP4): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP4, the area of shoreline that would be inundated would be the same as the area reported under CP3, about 2,498 acres. Substantial soil erosion and loss of topsoil would result. The previous descriptions of the time steps and associated volumes of soil lost due to shoreline processes under CP3 also apply to CP4.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-6 (CP4): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes Alternative CP4 is similar to Alternative CP3 with respect to its potential to cause substantial soil erosion or loss of topsoil due to upland processes. The area disturbed by construction activities under CP4 is roughly the same as the area disturbed under CP3, about 3, 340 acres. Of this area, approximately 3,128 acres are assigned a hazard rating of severe. For the same reasons as apply to CP1, this impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP4): Be Located on a Geologic Unit or Soil That is Unstable, or That Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence Alternative CP4 is similar to Alternative CP1 with respect to its potential to cause or be effected by subsidence. For the same reasons as apply to CP1, this impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP4): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste Alternative CP4 is similar to Alternative CP1 with respect to its potential to cause or be effected by failure of septic tanks or alternative wastewater disposal systems due to soils that are unsuited to land application of waste. For the same reasons as apply to CP1, this impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts to the upper Sacramento River portion of the primary study area associated with CP4.

Impact Geo-9 (CP4): Potential Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP4 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing condition, this alternative would change the maximum pool elevation and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows could potentially change downstream stream erosion and change downstream geomorphologic characteristics. However, the frequency and duration of high flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. An Erosion and Sediment Control Plan would be implemented, as described in Chapter 2, Environmental Commitments Common to All Action Alternatives, to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant.

This impact would be the same as Impact Geo-9 (CP1) and would be less than significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-10 (CP4): Substantial Soil Erosion or Loss of Topsoil Due to Construction CP4 involves replenishing spawning gravel in the Upper Sacramento River between Keswick Dam and Red Bluff diversion Dam. Implementation of these activities could potentially contribute to soil erosion or loss of topsoil from clearing, grading, and grubbing activities required while constructing roadways to access the new spawning gravel sites. In addition, soil erosion could also potentially occur at sites where clearing and grubbing of the river bank would be required to allow the gravel to be placed on the river bank for recruitment. An Erosion and Sediment Control Plan would be implemented, as described in Chapter 2, Environmental Commitments Common to All Action Alternatives, to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP4): Alteration of Fluvial Geomorphology Under implementation of CP4, measures would be taken to restore riparian, floodplain, and side channel habitat at Reading Island, which lies along the Sacramento River just north of Cottonwood Creek in Shasta County. Implementation of CP4 would involve breaching the levee separating Anderson Creek Slough from the Sacramento River. Breaching of the levee would ideally allow Anderson Creek Slough, which previously captured a portion of the Sacramento River flow and functioned as a side channel habitat to reestablish connectivity at flows greater than 4,000 to 6,000 cfs. The reestablished side channel could potentially experience changes in fluvial geomorphology that could result in channelized or unstable braided streams depending on the gradient of the channel. However, restoration of habitat through planting of native vegetation would stabilize

channel banks. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts to the lower Sacramento River and Delta portions of the extended study area associated with CP4.

Impact Geo-12 (CP4): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP4 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Under implementation of CP1, there would be a potential reduction in high flow events. Therefore, increases in Sacramento River flow would be limited and affects to reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as by flood bypasses in the extended study area. This impact would be less than significant.

This impact would be similar to Impact Geo-9 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts to the CVP/SWP service areas within the extended study area associated with CP4.

Impact Geo-13 (CP4): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP4 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant.

This impact would be the same as Impact Geo-9 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

This section describes impacts associated with CP5, which includes raising Shasta Dam 18.5 feet. This alternative also includes (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing additional and/or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. The dam raise would increase the reservoir's full pool elevation by 20.5 feet to about 1,090 feet above msl, and enlarge total storage space by 634,000 acre-feet.

Shasta Lake and Vicinity This section describes impacts to the Shasta Lake portion of the primary study area for CP5.

Impact Geo-1 (CP5): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption Implementing CP5 has the potential to increase the exposure of structures and people to geologic hazards similar to CP1. For the same reasons as apply to CP1, impacts resulting from seismic conditions would be less than significant for CP5.

Like CP3, under CP5, the pool level increase would inundate 173 acres of mapped slope instability hazards. Relocation of infrastructure is proposed to occur in the vicinity of about 232 acres of mapped slope instability hazards. For the same reasons as apply to CP1, impacts resulting from slope instability hazards would be less than significant for CP5.

For the same reasons as apply to CP1, impacts resulting from hazards associated with volcanic eruptions would be less than significant for CP5. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP5): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Like CP3, under CP5 stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,090 feet of elevation.

Based on a GIS-generated stream network, the total stream length inundated as a result of CP5 would be the same as for CP3, about 36.5 miles (see Figure 4-10). This value equates to about 1.3 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 36.5 miles inundated, about 12.1 miles are streams with a gradient less than 7 percent. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-3 (CP5): Lost or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region Implementing CP5 has the same potential as CP1 to diminish the availability in the region of cement, concrete sand, and aggregate. For the same reasons that apply to CP1, this impact would be significant and unavoidable for CP5. Mitigation for this impact is not available.

Impact Geo-4 (CP5): Lost or Diminished Soil Biomass Productivity Like CP3, under CP5 soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction including relocation of infrastructure. The acreages of these losses would be the same as those reported for CP3.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-5 (CP5): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP5, the area of shoreline that would be inundated would be the same as the area reported under CP3, about 2,498 acres. Substantial soil erosion and loss of topsoil would result. The previous descriptions of the time steps and associated volumes of soil lost due to shoreline processes under CP3 also apply to CP5.

This impact would be significant and unavoidable. Mitigation for this impact is not available.

Impact Geo-6 (CP5): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes Alternative CP5 is similar to Alternative CP3 with respect to its potential to cause substantial soil erosion or loss of topsoil due to upland processes. The area disturbed by construction activities under CP5 is roughly the same as the area disturbed under CP3, about 3,340 acres. Of this area, approximately 3,128 acres are assigned a hazard rating of severe. For the same reasons as apply to CP1, this impact would be less than significant for CP5. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP5): Be Located on a Geologic Unit or Soil That is Unstable, or That Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence Alternative CP5 is similar to Alternative CP1 with respect to its potential to cause or be effected by subsidence. For the same reasons as apply to CP1, this impact would be less than significant for CP5. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP5): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste Alternative CP5 is similar to Alternative CP1 with respect to its potential to cause or be effected by failure of septic tanks or alternative wastewater disposal systems due to soils that are unsuited to land application of waste. For the same reasons as apply to CP1, this impact would be less than significant for CP5. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts to the upper Sacramento River portion of the primary study area associated with CP5.

Impact Geo-9 (CP5): Potential Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP5 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing condition, this alternative would change the maximum pool elevation

and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows could potentially change downstream stream erosion and change downstream geomorphologic characteristics. However, the frequency and duration of high flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. An Erosion and Sediment Control Plan would be implemented, as described in Chapter 2, Environmental Commitments Common to All Action Alternatives, to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant.

Because Shasta Dam and Reservoir operations would be the same for CP3 and CP5, this impact would be the same as Impact Geo-9 (CP3) and would be less than significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-10 (CP5): Substantial Soil Erosion or Loss of Topsoil Due to Construction CP5 involves replenishing spawning gravel in the Upper Sacramento River between Keswick Dam and Red Bluff Diversion Dam. Implementation of these activities could potentially contribute to soil erosion or loss of topsoil from clearing, grading, and grubbing activities required while constructing roadways to access the new spawning gravel sites. In addition, soil erosion could also potentially occur at sites where clearing and grubbing of the river bank would be required to allow the gravel to be placed on the river bank for recruitment. An Erosion and Sediment Control Plan would be implemented, as described in Chapter 2, Environmental Commitments Common to All Action Alternatives, to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP5): Alteration of Fluvial Geomorphology Under implementation of CP5, measures would be taken to restore riparian, floodplain, and side channel habitat at Reading Island, which lies along the Sacramento River just north of Cottonwood Creek in Shasta County. Implementation of CP5 would involve breaching the levee separating Anderson Creek Slough from the Sacramento River. Breaching the levee would ideally allow Anderson Creek Slough, which previously captured a portion of the Sacramento River flow and functioned as a side channel habitat, to reestablish connectivity at flows greater than 4,000 to 6,000 cfs. The reestablished side channel could potentially experience changes in fluvial geomorphology that could result in channelized or unstable braided streams, depending on the gradient of the channel. However, restoration of habitat through planting of native vegetation would stabilize channel banks. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts to the lower Sacramento River and Delta portions of the extended study area associated with CP5.

Impact Geo-12 (CP5): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP5 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Under implementation of CP1, there would be a potential reduction in high flow events. Therefore, increases in Sacramento River flow would be limited and affects to reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as by flood bypasses in the extended study area. This impact would be less than significant.

Because Shasta Dam and Reservoir operations would be the same for CP3 and CP5, this impact would be the same as Impact Geo-9 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts to the CVP/SWP service areas within the extended study area associated with CP5.

Impact Geo-13 (CP5): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP5 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant.

Because Shasta Dam and Reservoir operations would be the same for CP3 and CP5, this impact would be the same as Impact Geo-9 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

4.3.5 Mitigation Measures

This section discusses mitigation measures for each significant impact described in the environmental consequences section, as presented in Table 4-13.

Table 4-13. Summary of Mitigation Measures for Geology, Geomorphology, Minerals, and Soils

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Geo-1: Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruptions	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-2: Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure Geo-2: Replace Lost Ecological Functions of Aquatic Habitats By Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-3: Loss or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region	LOS before Mitigation	NI	SU	SU	SU	SU	SU
	Mitigation Measure	None required.	None available.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact Geo-4: Lost or Diminished Soil Biomass Productivity	LOS before Mitigation	NI	SU	SU	SU	SU	SU
	Mitigation Measure	None required	None available.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact Geo-5: Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes	LOS before Mitigation	NI	SU	SU	SU	PS	SU
	Mitigation Measure	None required	None available				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU

Table 4-13. Summary of Mitigation Measures for Geology, Geomorphology, Minerals, and Soils (contd.)

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Geo-6: Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-7: Be Located on a Geologic Unit or Soil That is Unstable, or That Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.

	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS

Key:
CVP = Central Valley Project
LOS = level of significance
LTS = less than significant
NI = No Impact
PS = potentially significant
S = significant
SU = significant and unavoidable
SWP = State Water Project

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

The following section describes the mitigation measures associated with potential impacts of CP1.

Mitigation Measure Geo-2 (CP1): Replace Lost Ecological Functions of Aquatic Habitats By Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact The loss of 18.5 miles of intermittent and perennial streams (including 6.2 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would render the impact less than significant.

Mitigation Measure Geo-9 (CP1): Implement Channel-Sensitive Water Release Schedules Dam operators will establish water release schedules that would maintain flow levels equal to or similar to current operating conditions. Under a sound water release regime, single event flows would remain at levels similar to the existing condition, although the frequency and duration of these flows could increase. This potential increase in frequency and duration would not be considered significant provided that single event flow levels do not exceed current operating conditions. Implementation of this mitigation measure would reduce the impact to a less than significant level.

Mitigation Measure Geo-9 (CP1) would reduce the impact of potential channel erosion and meander migration to a level of less than significant.

In wet years, CP1 would decrease potential channel erosion and meander migration compared to the existing condition, because of the dam's ability to store more water than is currently possible. Greater storage capacity would provide dam operators more flexibility in timing and amount of water that would be released during wet years, decreasing the need for large releases when the dam is at or near capacity. This impact would be less than significant after implementation of channel-sensitive water release schedules.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

The following section describes the mitigation measures associated with potential impacts of CP2.

Mitigation Measure Geo-2 (CP2): Replace Lost Ecological Functions of Aquatic Habitats By Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact The loss of 25.5 miles of intermittent and perennial streams (including 8.2 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would render the impact less than significant.

Mitigation Measure Geo-9 (CP2): Implement Channel-Sensitive Water Release Schedules This mitigation measure is identical to Mitigation Measure Geo-9 (CP1).

Implementation of Mitigation Measure Geo-9 (CP2) would reduce the stream channel erosion and meander migration impact associated with CP2 to a less than significant level.

In wet years, CP2 would decrease potential channel erosion and meander migration compared to the existing condition, because of the dam's ability to retain more water than is currently possible. Greater storage capacity would provide dam operators more flexibility in the timing and amount of water that would be released during wet years, decreasing the need for large releases when the dam is at or near capacity. This impact would be less than significant after implementation of channel-sensitive water release schedules.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

The following section describes the mitigation measures associated with potential impacts of CP3.

Mitigation Measure Geo-2 (CP3): Replace Lost Ecological Functions of Aquatic Habitats By Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact The loss of 36.5 miles of intermittent and perennial streams (including 12.1 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic

habitats in or near the Shasta Lake and vicinity area. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would render the impact less than significant.

Mitigation Measure Geo-9 (CP3): Implement Channel-Sensitive Water Release Schedules This mitigation measure is identical to Mitigation Measure Geo-9 (CP1).

Implementation of Mitigation Measure Geo-9 (C3) would reduce the stream channel erosion and meander migration impact associated with CP3 to a less than significant level.

In wet years, CP3 would decrease potential channel erosion and meander migration compared to the existing condition, because of the dam's ability to retain more water than is currently possible. More retention capacity would provide dam operators more flexibility in the timing and amount of water that would be released during wet years, decreasing the need for large releases when the dam is at or near capacity. This impact would be less than significant after implementation of channel-sensitive water release schedules.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

The following section describes the mitigation measures associated with potential impacts of CP4.

Mitigation Measure Geo-2 (CP4): Replace Lost Ecological Functions of Aquatic Habitats By Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is identical to Mitigation Measure Geo-2 (CP3). Implementation of this mitigation measure would reduce the impact to a less than significant level.

Mitigation Measure Geo-9 (CP4): Implement Channel-Sensitive Water Release Schedules This mitigation measure is identical to Mitigation Measure Geo-9 (CP1).

Implementation of Mitigation Measure Geo-9 (CP4) would reduce the stream channel erosion and meander migration impact associated with CP4 to a less than significant level. Mitigation Measure Geo-9 (CP4) would also provide mitigation for the less than significant impacts Geo-10 (CP4), and Geo-11 (CP4).

In wet years, CP4 would decrease potential channel erosion and meander migration compared to the existing condition, because of the dam's ability to

retain more water than is currently possible. More retention capacity would provide dam operators more flexibility in the timing and amount of water that would be released during wet years, decreasing the need for large releases when the dam is at or near capacity. This impact would be less than significant after implementation of channel-sensitive water release schedules.

CP5 – 18.5-Foot Dam Raise, Combination Plan

The following section describes the mitigation measures associated with potential impacts of CP5.

Mitigation Measure Geo-2 (CP5): Replace Lost Ecological Functions of Aquatic Habitats By Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is identical to Mitigation Measure Geo-2 (CP3). Implementation of this mitigation measure would reduce the impact to a less than significant level.

Mitigation Measure Geo-9 (CP5): Implement Channel-Sensitive Water Release Schedules This mitigation measure is identical to Mitigation Measure Geo-9 (CP1).

Implementation of Mitigation Measure Geo-9 (CP5) would reduce the stream channel erosion and meander migration impact associated with CP5 to a less than significant level. Mitigation Measure Geo-9 (CP5) would also provide mitigation for the less than significant impacts Geo-10 (CP5), and Geo-11 (CP5).

In wet years, CP5 would decrease potential channel erosion and meander migration compared to the existing condition, because of the dam's ability to retain more water than is currently possible. More retention capacity would provide dam operators more flexibility in the timing and amount of water that would be released during wet years, decreasing the need for large releases when the dam is at or near capacity. This impact would be less than significant after implementation of channel-sensitive water release schedules.

4.3.6 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and environmental Consequences" discusses overall cumulative impacts of the project alternatives, including the relationship to CALFED Programmatic Cumulative Impacts Analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria.

This section provides an analysis of overall cumulative impacts of the project alternatives with other past, present, and reasonably foreseeable future projects producing related impacts. For both the primary and extended study areas, a number of factors could substantially affect geology, soils and erosion, mineral resources, and geomorphology as an outcome of present and future actions. These actions may result in either a beneficial or adverse impact for the study

areas. However, there is a high level of uncertainty regarding potential effects of the reasonably foreseeable future actions. Therefore, geology, soils and erosion, mineral resources, and geomorphology are expected to remain in similar conditions to existing conditions with the exception of potential effects associated with future climate change as described below.

The effects of climate change on operations at Shasta Lake could potentially result in changes to downstream geomorphology. As described in the Climate Change Projection Appendix, climate change could result in higher reservoir releases in the future due to an increase in winter and early spring inflow into the lake from high intensity storm events. The change in reservoir releases could be necessary to manage for flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in downstream channel equilibrium.

The effects of increased monthly inflow into Shasta Lake in winter and early spring could also potentially result in changes to stream channel equilibrium and geomorphology upstream from the lake and at the point where the streams meet the lake.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As discussed in Section 4.3.4 above, CP1 could result in (1) several localized project-level impacts related to exposure of structures and people to geologic hazards (less than significant), (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable), (3) soil erosion from shoreline processes (significant and unavoidable), (4) soil erosion from upland processes (less than significant), (5) location of project features on unstable geologic or soil units (less than significant), and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP1 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonable foreseeable future projects in the region, CP1 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation is not available for either of these impacts; therefore, these cumulative impacts would be considered significant and unavoidable.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to geomorphology. While implementation of CP1 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential

impacts associated with channel meander and erosion under CP1 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River (Shasta Dam to Red Bluff) portion of the primary study area, and in the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As discussed in Section 4.3.4 above, CP2 could result in (1) several localized project-level impacts related to exposure of structures and people to geologic hazards (less than significant), (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable), (3) soil erosion from shoreline processes (significant and unavoidable), (4) soil erosion from upland processes (less than significant), (5) location of project features on unstable geologic or soil units (less than significant), and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP2 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonable foreseeable future projects in the region, therefore, CP2 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation is not available for either of these impacts; therefore, these cumulative impacts would be considered significant and unavoidable.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to geomorphology. While implementation of CP2 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP2 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River (Shasta Dam to Red Bluff) portion of the primary study area, and in the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

As discussed in Section 4.3.4 above, CP3 could result in (1) several localized project-level impacts related to exposure of structures and people to geologic hazards (less than significant), (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable), (3) soil erosion from shoreline processes (significant and unavoidable), (4) soil erosion from upland

processes (less than significant), (5) location of project features on unstable geologic or soil units (less than significant), and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP3 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonable foreseeable future projects in the region, therefore, CP3 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation is not available for either of these impacts; therefore, these cumulative impacts would be considered significant and unavoidable.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to geomorphology. While implementation of CP3 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP3 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River (Shasta Dam to Red Bluff) portion of the primary study area, and in the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

As discussed in Section 4.3.4 above, CP4 could result in (1) several localized project-level impacts related to exposure of structures and people to geologic hazards (less than significant), (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable), (3) soil erosion from shoreline processes (significant and unavoidable), (4) soil erosion from upland processes (less than significant), (5) location of project features on unstable geologic or soil units (less than significant), and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP4 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonable foreseeable future projects in the region, therefore, CP4 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation is not available for either of these impacts; therefore, these cumulative impacts would be considered significant and unavoidable.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to geomorphology. While implementation of CP4 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP4 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River (Shasta Dam to Red Bluff) portion of the primary study area, and in the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP5 – 18.5-Foot Dam Raise, Combination Plan

As discussed in Section 4.3.4 above, CP5 could result in several localized project-level impacts related to exposure of structures and people to geologic hazards (less than significant), alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable), soil erosion from shoreline processes (significant and unavoidable), soil erosion from upland processes (less than significant), location of project features on unstable geologic or soil units (less than significant), and the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP5 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonable foreseeable future projects in the region, therefore, CP5 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation if not available for either of these impacts; therefore these cumulative impacts would be considered significant and unavoidable.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to geomorphology. While implementation of CP5 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP5 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River (Shasta Dam to Red Bluff) portion of the primary study area, and in the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

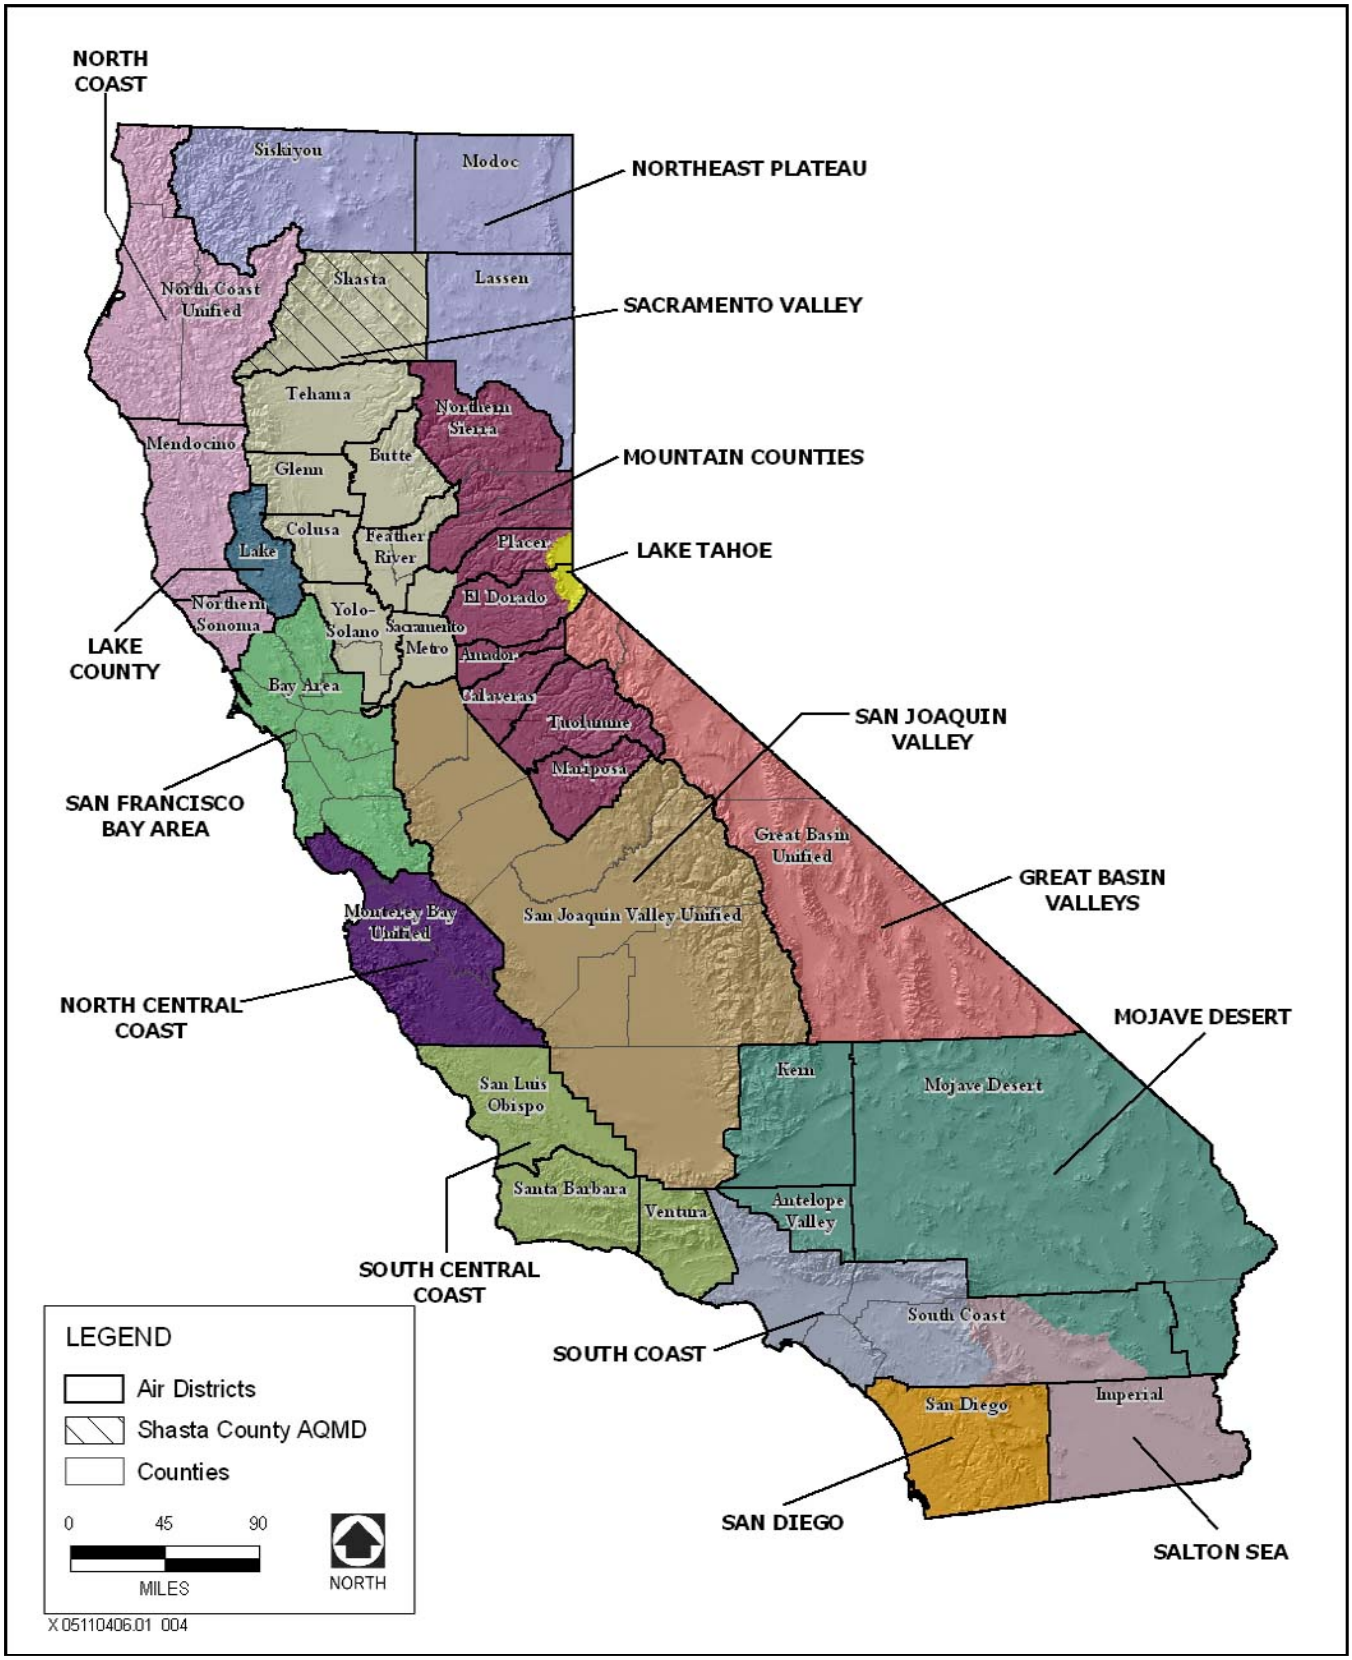
Chapter 5
Air Quality and Climate



5.1 Affected Environment

This section describes existing air quality conditions in the primary study area for the dam and reservoir modifications proposed under the SLWRI. The climate and the emissions of criteria air pollutants and toxic air contaminants (TAC) at Shasta Lake and vicinity and the upper Sacramento River from Shasta Dam to Red Bluff are described. In addition, the attainment status of Shasta County relative to national and State air quality standards is summarized.

The primary study area for air quality analysis has two components—local and regional. The local area is the area immediately surrounding Shasta Dam and Shasta Lake where project construction would occur. Regionally, Shasta and Tehama counties are located in the Northern Sacramento Valley Air Basin (NSVAB), a subarea of the Sacramento Valley Air Basin (SVAB). The SVAB also includes all of Butte, Colusa, Glenn, Sacramento, Sutter, Yolo, and Yuba counties; the western portion of Placer County; and the eastern portion of Solano County. Figure 5-1 depicts the locations of these air basins, highlighting the Shasta County Air Quality Management District (SCAQMD) area. The NSVAB includes the seven counties located in the northern portion of the Sacramento Valley: Butte, Colusa, Glenn, Shasta, Sutter, Tehama, and Yuba.

The SLWRI would not include any construction or operational activities in the extended study area (the lower Sacramento River and Delta and the CVP and SWP service areas) that would affect air quality. Therefore, this section only minimally discusses air quality conditions in the extended study area. Details about conditions in the extended study area are available in the *Air Quality and Climate Technical Report*.

This section also summarizes current climate change effects of greenhouse gas (GHG) emissions on what is referred to in this chapter as the “global study area.”

Source: ARB 2004; data compiled by AECOM in 2011

Figure 5-1. Air Basins in California, Including the SCAQMD Area

5.1.1 Regional Climate in the Primary Study Area

The NSVAB is bounded on the north and west sides by the Coast Ranges and on the east side by the southern portion of the Cascade Range and the northern portion of the Sierra Nevada. These mountain ranges provide a substantial physical barrier to locally created air pollution, as well as pollution transported northward on prevailing winds from the Sacramento metropolitan area (NSVPAD 2010). The valley is often subject to inversion layers that, coupled with geographic barriers and high summer temperatures, create high potential for air pollution problems.

5.1.2 Criteria Air Pollutants

Concentrations of the following air pollutants are used as indicators of ambient air quality conditions: ozone, carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), respirable and fine particulate matter (PM_{10} and $PM_{2.5}$), and lead. Because these are the most prevalent air pollutants known to be deleterious to human health, they are commonly referred to as "criteria air pollutants."

Each criteria air pollutant is described briefly below. A more in-depth discussion is provided in the *Air Quality and Climate Technical Report*.

Ozone

Ozone is a photochemical oxidant and the primary component of smog. Ozone is not directly emitted into the air, but is formed through complex chemical reactions between precursor emissions of reactive organic gases (ROG) and oxides of nitrogen (NO_X) in the presence of sunlight. ROG are volatile organic compounds (VOC). ROG emissions result primarily from incomplete combustion and the evaporation of chemical solvents and fuels. NO_X are a group of gaseous compounds of nitrogen and oxygen that results from the combustion of fuels.

Ozone located in the lower atmosphere is a major health and environmental concern. Meteorology and terrain play a major role in ozone formation. Low wind speeds or stagnant air coupled with warm temperatures and clear skies provide the optimum conditions for ozone formation. Therefore, summer is the peak ozone season. Ozone is a regional pollutant that often affects large areas. Ozone concentrations over or near urban and rural areas reflect an interplay of emissions of ozone precursors, transport, meteorology, and atmospheric chemistry (Godish 2004).

Carbon Monoxide

CO is a colorless, odorless, and poisonous gas produced by incomplete burning of carbon in fuels, primarily from mobile (transportation) sources. Approximately 77 percent of the nation's CO emissions are from mobile sources. The other 23 percent consist of CO emissions from wood-burning stoves, incinerators, and industrial sources. The highest concentrations are generally associated with cold, stagnant weather conditions that occur during

winter. In contrast to ozone, which is a regional pollutant, CO causes problems on a local scale.

Nitrogen Dioxide

NO_2 is a brownish, highly reactive gas that is present in all urban environments. The major human-made sources of NO_2 are combustion devices, such as boilers, gas turbines, and mobile and stationary combustion engines. NO_2 forms quickly from emissions from cars, trucks and buses, power plants, and off-road equipment. In addition to contributing to the formation of ground-level ozone and fine particle pollution, NO_2 is linked with a number of adverse effects on the respiratory system (EPA 2010). The combined emissions of NO and NO_2 are referred to as NO_X, which are reported as equivalent NO_2. Because NO_2 is formed and depleted by reactions associated with ozone, the NO_2 concentration in a particular geographical area may not be representative of the local NO_X emission sources.

Sulfur Dioxide

SO_2 is produced by such stationary sources as coal and oil combustion, steel mills, refineries, and pulp and paper mills. SO_2 is a respiratory irritant. On contact with the moist mucous membranes, SO_2 produces sulfurous acid.

Particulate Matter

Respirable particulate matter with an aerodynamic diameter of 10 micrometers or less is referred to as PM_{10}. PM_{10} consists of particulate matter emitted directly into the air, such as fugitive dust, soot, and smoke from mobile and stationary sources, construction operations, fires, and natural windblown dust, and particulate matter formed in the atmosphere by condensation and/or transformation of SO_2 and ROG. $PM_{2.5}$ includes a subgroup of finer particles that have an aerodynamic diameter of 2.5 micrometers or less (EPA 2011a).

Lead

Lead is a metal found naturally in the environment and in manufactured products. The major sources of lead emissions have historically been mobile and industrial sources. As a result of the phase-out of leaded gasoline, metal processing is currently the primary source of lead emissions. The highest levels of lead in air are generally found near lead smelters. Other stationary sources are waste incinerators, utilities, and lead-acid battery manufacturers.

5.1.3 Monitoring Station Data and Criteria Pollutant Attainment Area Designations

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Concentrations of criteria air pollutants are measured at several monitoring stations in Shasta County. The Redding Health Department and Shasta Lake stations are the closest stations to the project construction area with recent data for ozone and particulate matter. In general, the ambient air quality

measurements from these stations are representative of the study area's air quality. Table 5-1 summarizes the air quality data from the most recent 3 years.

Table 5-1. Summary of Annual Ambient Air Quality Data (2007–2009)

	2007	2008	2009
OZONE			
Redding Health Department Monitoring Station			
Maximum concentration (1-hour/8-hour average, ppm)	0.089/0.073	0.090/0.82	0.084/0.069
Number of days State 1-hour/8-hour standard exceeded	0/5	0/13	0/0
Number of days national 1-hour/8-hour standard exceeded	0/0	0/4	0/0
FINE PARTICULATE MATTER ($PM_{2.5}$)			
Redding Health Department Monitoring Station			
Maximum concentration ($\mu g/m^3$)	18.6	200.2	20.2
Number of days national standard exceeded (measured[a])	0	5	0
RESPIRABLE PARTICULATE MATTER (PM_{10})			
Redding Health Department Monitoring Station			
Maximum concentration ($\mu g/m^3$)	36.0	232.0	32.6
Number of days State standard exceeded (measured/calculated[a])	0/0	5/32.7	0/0
Number of days national standard exceeded (measured/calculated[a])	0/0	1/6.6	0/0
Shasta Lake Monitoring Station			
Maximum concentration ($\mu g/m^3$)	57.0	104.9	32.2
Number of days State standard exceeded (measured/calculated[a])	1/-	3/19.5	0/0
Number of days national standard exceeded (measured/calculated[a])	0/0	0/0	0/0

Source: ARB 2011

Note:

[a] Measured days are those days that an actual measurement was greater than the level of the State daily standard or the national daily standard. Measurements are typically collected every 6 days. Calculated days are the estimated number of days that a measurement would have been greater than the level of the standard had measurements been collected every day. The number of days above the standard is not necessarily the number of violations of the standard for the year.

Key:

* = insufficient data available to determine value.

$\mu g/m^3$ = micrograms per cubic meter

$PM_{2.5}$ = fine particulate matter with an aerodynamic diameter of 2.5 micrometers or less

PM_{10} = respirable particulate matter with an aerodynamic diameter of 10 micrometers or less

ppm = parts per million

The monitoring data are used to designate areas according to their attainment status for criteria air pollutants. The purpose of these designations is to identify those areas with air quality problems and thereby initiate planning efforts for improvement. The three basic designation categories are "nonattainment," "attainment," and "unclassified." "Unclassified" is used in an area that cannot be classified on the basis of available information as meeting or not meeting the standards. In addition, the California designations include a subcategory of the nonattainment designation, "nonattainment-transitional," that is given to nonattainment areas that are progressing and nearing attainment. The most current attainment designations for Shasta County are shown in Table 5-2 for each criteria air pollutant.

Lower Sacramento River and Delta

The lower Sacramento River and Delta areas are within the SVAB and the San Joaquin Valley Air Basin. As described in greater detail in the *Air Quality and Climate Technical Report*, these basins are Federal and State nonattainment areas for ozone, PM_{10}, and $PM_{2.5}$.

CVP/SWP Service Areas

The CVP and SWP service areas extend beyond the Central Valley into the San Francisco Bay Area, North Central Coast, South Central Coast, and Mountain Counties air basins. Federal and State ozone attainment designations for all California counties and air basins are provided in the *Air Quality and Climate Technical Report*. All counties in California south of Shasta County, with the exception of Lake, Sonoma, Tuolumne, and Mariposa counties, are State nonattainment areas for PM_{10} (ARB 2010a).

5.1.4 Toxic Air Contaminants in the Primary Study Area

TACs, or in Federal terms hazardous air pollutants (HAP), are air pollutants that may cause or contribute to an increase in mortality or in serious illness, or that may pose a hazard to human health. TACs are usually present in minute quantities in the ambient air; however, their high toxicity or health risk may pose a threat to public health even at low concentrations. Of the TACs for which data are available in California, diesel particulate matter (diesel PM), naturally occurring asbestos, benzene, 1,3-butadiene, acetaldehyde, carbon tetrachloride, hexavalent chromium, para-dichlorobenzene, formaldehyde, methylene chloride, and perchloroethylene pose the greatest known health risks. Dioxins are also considered to pose substantial health risk and diesel PM poses the greatest health risk. Current facilities permitted by SCAQMD in the project vicinity are Lehigh Southwest Cement Company, Mountain Gate Quarry, Knauf Insulation, and Sierra Pacific Industries.

Table 5-2. Ambient Air Quality Standards and Designations

Pollutant	Averaging Time	California		National Standards [a]		
		Standards [b,c]	Attainment Status (Shasta County) [d]	Primary [c,e]	Secondary [c,f]	Attainment Status (Shasta County) [g]
Ozone	1-hour	0.09 ppm (180 µg/m^3)	N (Moderate)	*Note h*	Same as primary standard	–
	8-hour	0.070 ppm	–	0.075 ppm (147 µg/m^3)		U/A
Carbon monoxide	1-hour	20 ppm (23 mg/m^3)	U	35 ppm (40 mg/m^3)	–	U/A
	8-hour	9 ppm (10 mg/m^3)		9 ppm (10 mg/m^3)		
	8-hour (Lake Tahoe)	6 ppm (7 mg/m^3)	–	–	–	–
Nitrogen dioxide (NO_2)	Annual Arithmetic Mean	0.030 ppm (57 µg/m^3)	–	0.053 ppm (100 µg/m^3) [i]	Same as primary standard	U/A
	1-hour	0.18 ppm (339 µg/m^3)	A	0.100 ppm (188 µg/m^3) [i]		–
Sulfur dioxide (SO_2)	24-hour	0.04 ppm (105 µg/m^3)	A	–	–	U
	3-hour	–	–	–	0.5 ppm (1300 µg/m^3) [j]	
	1-hour	0.25 ppm (655 µg/m^3)	A	0.075 ppm (196 µg/m^3) [j]	–	–
Respirable particulate matter (PM_{10})	Annual Arithmetic Mean	20 µg/m^3	N	–	Same as primary standard	U/A
	24-hour	50 µg/m^3		150 µg/m^3 [f]		
Fine particulate matter ($PM_{2.5}$)	Annual Arithmetic Mean	12 µg/m^3	U	15 µg/m^3	Same as primary standard	U/A
	24-hour	–	–	35 µg/m^3		
Lead [k]	30-day Average	1.5 µg/m^3	A	–	–	–
	Calendar Quarter	–		1.5 µg/m^3	Same as primary standard	A
	Rolling 3 Month Average	–		0.15 µg/m^3		
Sulfates	24-hour	25 µg/m^3	A	No national standards		
Hydrogen sulfide	1-hour	0.03 ppm (42 µg/m^3)	U			
Vinyl chloride [k]	24-hour	0.01 ppm (26 µg/m^3)	U/A			
Visibility-reducing particle matter	8-hour	Extinction coefficient of 0.23 per kilometer—visibility of 10 mi or more	U			

Table 5-2. Ambient Air Quality Standards and Designations (contd.)

Sources: ARB 2010a, 2010b; EPA 2011b; data compiled by AECOM in 2011

Notes:

[a] National standards (other than ozone, particulate matter, and those based on annual averages or annual arithmetic means) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration in a year, averaged over 3 years, is equal to or less than the standard. The PM10 24-hour standard is attained when 99 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. The PM2.5 24-hour standard is attained when 98 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. Contact the U.S. Environmental Protection Agency (EPA) for further clarification and current Federal policies.

[b] California standards for ozone, CO (except Lake Tahoe), SO_2 (1- and 24-hour), NO_2, particulate matter, and visibility-reducing particles are values that are not to be exceeded. All others are not to be equaled or exceeded. California ambient air quality standards are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.

[c] Concentration expressed first in units in which it was promulgated (i.e., parts per million (ppm) or micrograms per cubic meter ($\mu g/m^3$)). Equivalent units given in parentheses are based upon a reference temperature of 25 degrees Celsius (°C) and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.

[d] Unclassified (U): A pollutant is designated unclassified if the data are incomplete and do not support a designation of attainment or nonattainment.

Attainment (A): A pollutant is designated attainment if the State standard for that pollutant was not violated at any site in the area during a 3-year period.

Nonattainment (N): A pollutant is designated nonattainment if there was a least one violation of a State standard for that pollutant in the area.

Nonattainment/Transitional (NT): A subcategory of the nonattainment designation. An area is designated nonattainment/transitional to signify that the area is close to attaining the standard for that pollutant.

[e] National Primary Standards: The levels of air quality necessary, with an adequate margin of safety, to protect the public health.

[f] National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

[g] Nonattainment (N): Any area that does not meet (or that contributes to ambient air quality in a nearby area that does not meet) the national primary or secondary ambient air quality standard for the pollutant.

Attainment (A): Any area that meets the national primary or secondary ambient air quality standard for the pollutant.

Unclassifiable (U): Any area that cannot be classified on the basis of available information as meeting or not meeting the national primary or secondary ambient air quality standard for the pollutant.

[h] The 1-hour ozone national ambient air quality standard was revoked on June 15, 2005, for all areas in California.

[i] To attain this standard, the 3-year average of the 98th percentile of the daily maximum 1-hour average at each monitor within an area must not exceed 0.100 part per million (ppm) (effective January 22, 2010). Note that the EPA standards are in units of parts per billion (ppb). California standards are in units of ppm. To directly compare the national standards to the California standards, the units can be converted from ppb to ppm. In this case, the national standards of 53 ppb and 100 ppb are identical to 0.053 ppm and 0.100 ppm, respectively.

[j] On June 2, 2010, EPA established a new 1-hour SO_2 standard, effective August 23, 2010, which is based on the 3-year average of the annual 99th percentile of 1-hour daily maximum concentrations. EPA also proposed a new automated Federal Reference Method (FRM) using ultraviolet technology, but will retain the older pararosaniline methods until the new FRM have adequately permeated State monitoring networks. EPA also revoked both the existing 24-hour SO_2 standard of 0.14 ppm and the annual primary SO_2 standard of 0.030 ppm, effective August 23, 2010.

The secondary SO_2 standard was not revised at that time; however, the secondary standard is undergoing a separate review by EPA. Note that the new standard is in ppb. California standards are in ppm. To directly compare the new primary national standard to the California standard the units can be converted to ppm. In this case, the national standard of 75 ppb is identical to 0.075 ppm.

[k] The California Air Resources Board has identified lead and vinyl chloride as toxic air contaminants with no threshold of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.

Key:

$\mu g/m^3$ = micrograms per cubic meter

mg/m^3 = milligrams per cubic meter

ppm = parts per million

5.1.5 Global Study Area

Atmospheric GHGs play a critical role in determining the earth's surface temperature. Solar radiation enters the earth's atmosphere from space. Prominent GHGs contributing to the greenhouse effect are carbon dioxide (CO_2), methane, nitrous oxide, hydrofluorocarbons, chlorofluorocarbons, and sulfur hexafluoride. Sources of GHG emissions associated with existing operations include vehicles used for operation and maintenance of the dam and recreation areas, vehicles used by recreational visitors, and fossil fuel–powered boats on Shasta Lake. Human-caused emissions of these GHGs that exceed natural ambient concentrations are responsible for intensifying the greenhouse effect and have led to a trend of unnatural warming of the earth's climate, known as global climate change or global warming (Ahrens 2003).

To provide a method of quantifying GHG emissions, the standard unit of CO_2e, or CO_2 equivalent, was developed. The definition of CO_2e is "The quantity of a given GHG multiplied by its total global warming potential (GWP). This is the standard unit for comparing the degree of warming that can be caused by GHGs" (CCAR 2009). The GWP of a GHG is dependent on the lifetime, or persistence, of the gas molecule in the atmosphere compared to CO_2. The GWP of methane is 23; the GWP of nitrous oxide is 296. Therefore, methane and nitrous oxide are more potent GHGs than CO_2. Expressing emissions in CO_2e takes the contributions of all GHG emissions to the greenhouse effect and converts them to a single unit equivalent to the effect that would occur if only CO_2 were being emitted. The most common quantity unit for CO_2e is million metric tons (MMT). In some reports, CO_2e is written as CO_2E, and million metric tons is written as MMT CO_2E.

Climate change is a global phenomenon. GHGs are global pollutants, unlike criteria air pollutants and TACs, which are pollutants of regional and local concern. Whereas pollutants with localized air quality effects have relatively short atmospheric lifetimes (about 1 day), GHGs have long atmospheric lifetimes (1 year to several thousand years). GHGs persist in the atmosphere for long enough time periods to be dispersed around the globe. Although the exact lifetime of any particular GHG molecule is dependent on multiple variables and cannot be pinpointed, it is understood that more CO_2 is emitted into the atmosphere than is sequestered by ocean uptake, vegetation, and other forms of sequestration. Of the total annual human-caused CO_2 emissions, approximately 54 percent is sequestered through ocean uptake, uptake by Northern Hemisphere forest regrowth, and other terrestrial sinks within a year, whereas the remaining 46 percent of human-caused CO_2 emissions remains stored in the atmosphere (Seinfeld and Pandis 1998).

Effects of GHGs are borne globally, as opposed to localized air quality effects of criteria air pollutants and TACs. The quantity of GHGs that it takes to ultimately result in climate change is not precisely known; suffice it to say that the quantity is enormous, and no single project alone would be expected to measurably contribute to a noticeable incremental change in the global average temperature,

or to global, local, or micro climate. From the standpoint of CEQA, GHG effects related to global climate change are inherently cumulative.

Please see the *Air Quality and Climate Technical Report* for a discussion of GHG feedback mechanisms and uncertainty.

5.2 Regulatory Framework

Air quality in Shasta County is regulated by such agencies as the U.S. Environmental Protection Agency (EPA), the California Air Resources Board (ARB), and SCAQMD. Each of these agencies develops rules, regulations, policies, and/or goals to comply with applicable legislation. Although EPA regulations may not be superseded, both State and local regulations may be more stringent.

5.2.1 Federal

Criteria Air Pollutants

At the Federal level, EPA implements national air quality programs. EPA's air quality mandates are drawn primarily from the Federal Clean Air Act (CAA), which was enacted in 1970 and most recently amended in 1990.

The CAA required EPA to establish primary and secondary national ambient air quality standards, as shown in Table 5-2. The CAA also required each state to prepare an air quality control plan referred to as a State implementation plan (SIP). The Federal Clean Air Act Amendments of 1990 (CAAA) added requirements for states with nonattainment areas to revise their SIPs to incorporate additional control measures to reduce air pollution. The SIP is modified periodically to reflect the latest emissions inventories, planning documents, and rules and regulations of the air basins as reported by their jurisdictional agencies. EPA reviews all SIPs to determine whether they conform to the mandates of CAA and its amendments, and whether implementation will achieve air quality goals. If EPA determines a SIP to be inadequate, a Federal implementation plan that imposes additional control measures may be prepared for the nonattainment area. Failure to submit an approvable SIP or to implement the plan within the mandated time frame may result in the application of sanctions to transportation funding and stationary air pollution sources in the air basin.

Hazardous Air Pollutants

Air quality regulations also focus on TACs, or in Federal parlance, HAPs. In general, for those TACs that may cause cancer, there is no concentration that does not present some risk. In other words, there is no threshold level below which adverse health effects may not be expected to occur. This contrasts with the criteria air pollutants, for which acceptable levels of exposure can be determined and for which the ambient standards have been established (Table

5-2). Instead, EPA and ARB regulate HAPs and TACs, respectively, through statutes and regulations that generally require the use of the maximum available control technology or best available control technology for toxics to limit emissions. These statutes and regulations establish the regulatory framework for TACs.

EPA has programs for identifying and regulating HAPs. Title III of the CAAA directed EPA to promulgate national emissions standards for HAPs. National emissions standards for HAPs vary depending on the pollutant source type. The national emissions standards for HAPs for major stationary sources of HAPs could therefore be different than those for area sources. Major sources are defined as stationary sources with potential to emit more than 10 tons per year of any HAP or more than 25 tons per year of any combination of HAPs; all other sources are considered area sources. The emissions standards were to be promulgated in two phases. In the first phase (1992 to 2000), EPA developed technology-based emission standards designed to produce the maximum emission reduction achievable. These standards are generally referred to as requiring maximum available control technology. For area sources, the standards may be different, based on generally available control technology. In the second phase (2001 to 2008), EPA was required to promulgate health risk–based emissions standards, where deemed necessary, to address risks remaining after implementation of the technology-based national emission standards for HAPs standards.

The CAAA also required EPA to promulgate vehicle or fuel standards containing reasonable requirements that control toxic emissions of benzene and formaldehyde at a minimum. Performance criteria were established to limit mobile-source emissions of toxics, including benzene, formaldehyde, and 1,3-butadiene. In addition, Section 219 required the use of reformulated gasoline in selected areas with the most severe ozone nonattainment conditions to further reduce mobile-source emissions.

General Conformity

The 1990 amendments to CAA Section 176 require EPA to promulgate rules to ensure that Federal actions conform to the appropriate SIP. These rules are known as the General Conformity Rule (40 Code of Federal Regulations Parts 51.850–51.860 and 93.150–93.160). Any Federal agency responsible for an action in a nonattainment/maintenance area must determine whether that action conforms to the applicable SIP or is exempt from General Conformity Rule requirements.

Shasta County, where the proposed action would occur, is neither a nonattainment area nor a maintenance area for the national ambient air quality standards. Therefore, the General Conformity Rule is not applicable to the project.

Greenhouse Gases

Mandatory Greenhouse Gas Reporting Rule On September 22, 2009, EPA released its final Greenhouse Gas Reporting Rule (Reporting Rule). The Reporting Rule is a response to the fiscal year 2008 Consolidated Appropriations Act (House Bill 2764; Public Law 110-161), which required EPA to develop "… mandatory reporting of greenhouse gases above appropriate thresholds in all sectors of the economy…." The Reporting Rule applies to most entities that emit 25,000 metric tons (MT) CO_2e or more per year. Since 2010, facility owners have been required to submit an annual GHG emissions report with detailed calculations of facility GHG emissions. The Reporting Rule also mandates recordkeeping and administrative requirements for EPA to verify annual GHG emissions reports.

U.S. Environmental Protection Agency Endangerment and Cause or Contribute Findings On December 7, 2009, the EPA Administrator signed two distinct findings regarding GHGs under Section 202(a) of the CAA:

- **Endangerment Finding** – The current and projected concentrations of the six key well-mixed GHGs – CO_2, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride – in the atmosphere threaten the public health and welfare of current and future generations.

- **Cause or Contribute Finding** – The combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to GHG pollution, which threatens public health and welfare.

Council on Environmental Quality Draft NEPA Guidelines Because of uneven treatment of climate change under NEPA, the International Center for Technology Assessment, Natural Resources Defense Council, and Sierra Club filed a petition with the Council on Environmental Quality (CEQ) in March 2008. The petition requested that climate change analyses be included in all Federal environmental review documents. In October 2009, President Barack Obama signed Executive Order 13514, "Federal Leadership in Environmental, Energy, and Economic Performance." The goal of this executive order is "to establish an integrated strategy towards sustainability in the Federal Government and to make reduction of greenhouse gas emissions (GHG) a priority for Federal agencies" (FedCenter 2011).

In response to the petition and subsequent Executive Order 13514, CEQ issued guidance on including GHG emissions and climate change impacts in environmental review documents under NEPA. CEQ's guidance (issued February 18, 2010) suggests that Federal agencies consider opportunities to reduce GHG emissions caused by proposed Federal actions, adapt their actions to climate change impacts throughout the NEPA process, and address these issues in the agencies' NEPA procedures. The following are the two main

factors to consider when addressing climate change in environmental documentation:

- The effects of a proposed action and alternative actions on GHG emissions
- The impacts of climate change on a proposed action or alternatives

CEQ notes that "significant" national policy decisions with "substantial" GHG impacts require analysis of their GHG effects. That is, the GHG effects of a Federal agency's proposed action must be analyzed if the action would cause "substantial" annual direct emissions; would implicate energy conservation or reduced energy use or GHG emissions; or would promote cleaner, more efficient renewable-energy technologies. Qualitative or quantitative information on GHG emissions that is useful and relevant to the decision should be used when deciding among alternatives.

CEQ states that if a proposed action would cause direct annual emissions of more than 25,000 MT CO_2e, a quantitative and qualitative assessment may be meaningful to decision makers and the public. If annual direct emissions would be less than 25,000 MT CO_2e, Federal agencies are encouraged to consider whether the action's long-term emissions should receive similar analysis.

5.2.2 State

ARB coordinates and oversees State and local air pollution control programs in California and implements the California Clean Air Act (CCAA).

Criteria Air Pollutants

The CCAA, which was adopted in 1988, required ARB to establish California ambient air quality standards (Table 5-2). The CCAA requires that all local air districts in the state endeavor to achieve and maintain California ambient air quality standards by the earliest practical date. The act specifies that local air districts should particularly focus on reducing emissions from transportation and areawide sources, and authorizes districts to regulate indirect sources. Among ARB's other responsibilities are to oversee local air district compliance with California and Federal laws; approve local air quality plans; submit SIPs to EPA; monitor air quality; determine and update area designations and maps; and set emissions standards for new mobile sources, consumer products, small utility engines, off-road vehicles, and fuels.

Toxic Air Contaminants

TACs in California are regulated primarily through the Tanner Air Toxics Act (Assembly Bill (AB) 1807 (Statutes of 1983)) and the Air Toxics Hot Spots Information and Assessment Act (AB 2588 (Statutes of 1987)). AB 1807 sets forth a formal procedure for ARB to designate substances as TACs. Research, public participation, and scientific peer review must be completed before ARB can designate a substance as a TAC. To date, ARB has identified more than 21

TACs and has adopted EPA's list of HAPs as TACs. Most recently, diesel PM was added to the ARB list of TACs.

Once a TAC is identified, ARB adopts an airborne toxics control measure for sources that emit that particular TAC. If a safe threshold exists for a substance at which there is no toxic effect, the control measure must reduce exposure below that threshold. If there is no safe threshold, the measure must incorporate best available control technology to minimize emissions.

AB 2588 requires facilities that emit toxic substances above a specified level to do all of the following:

- Prepare a toxic emissions inventory
- Prepare a risk assessment if emissions are significant
- Notify the public of significant risk levels
- Prepare and implement risk reduction measures

Greenhouse Gases

Various statewide initiatives to reduce California's contribution to GHG emissions have raised awareness that, even though the various contributors to and consequences of global climate change are not yet fully understood, global climate change is under way, and real potential exists for severe adverse environmental, social, and economic effects in the long term. The most relevant laws and orders are discussed in more detail below.

California Environmental Quality Act and SB 97 CEQA requires lead agencies to consider the reasonably foreseeable adverse environmental effects of projects they are considering for approval. GHG emissions have the potential to adversely affect the environment because they contribute to global climate change. In turn, global climate change has the potential to raise sea levels, affect rainfall and snowfall, and affect habitat.

Senate Bill 97 Senate Bill (SB) 97 was enacted in August 2007 as part of the State budget negotiations and is codified at Section 21083.05 of the California Public Resources Code. SB 97 directs the Governor's Office of Planning and Research (OPR) to propose guidance in the State CEQA Guidelines "for the mitigation of GHG emissions or the effects of GHG emissions." SB 97 directed OPR to develop text for the State CEQA Guidelines by July 2009. This legislation also directed the State Resources Agency (now Natural Resources Agency) – the agency charged with adopting the State CEQA Guidelines – to certify and adopt such guidelines by January 2010. In April 2009, OPR prepared draft CEQA Guidelines amendments and submitted them to the Natural Resources Agency (see below). On July 3, 2009, the Natural Resources Agency began the rulemaking process established under the Administrative Procedure Act.

The Natural Resources Agency recommended amendments for GHGs to fit within the existing CEQA framework for environmental analysis, which calls for lead agencies to determine baseline conditions and levels of significance and evaluate mitigation measures. The amendments to the State CEQA Guidelines do not identify a threshold of significance for GHG emissions, nor do they prescribe assessment methodologies or specific mitigation measures. The amendments encourage lead agencies to consider many factors in performing a CEQA analysis, but preserve the discretion that CEQA grants lead agencies to make their own determinations based on substantial evidence.

Section 15064.4, "Determining the Significance of Impacts from Greenhouse Gas Emissions," of the State CEQA Guidelines encourages lead agencies to consider three factors to assess the significance of GHG emissions:

(1) Will the project increase or reduce GHGs as compared to the baseline?

(2) Will the project's GHG emissions exceed the lead agency's threshold of significance?

(3) Does the project comply with regulations or requirements to implement a statewide, regional, or local GHG reduction or mitigation plan?

These questions are addressed in Section 5.3.

Section 15064.4 also recommends that lead agencies make a good-faith effort, based on available information, to describe, calculate, or estimate the amount of GHG emissions associated with a project.

Section 15126.4, "Consideration and Discussion of Mitigation Measures Proposed to Minimize Significant Effects," of the State CEQA Guidelines lists considerations for lead agencies related to feasible mitigation measures to reduce GHG emissions. Among those considerations are the following:

- Project features, project design, or other measures that are incorporated into the project to substantially reduce energy consumption or GHG emissions

- Compliance with the requirements in a previously approved plan or mitigation program to reduce or sequester GHG emissions, when the plan or program provides specific requirements that will avoid or substantially lessen the potential impacts of the project

- Measures that sequester carbon or carbon-equivalent emissions

Section 15126.4 also specifies that where mitigation measures are proposed to reduce GHG emissions through off-site actions or purchase of carbon offsets, these mitigation measures must be part of a reasonable plan of mitigation that the relevant agency commits itself to implementing.

In addition, as part of the amendments and additions to the State CEQA Guidelines, a new set of environmental checklist questions (VII. Greenhouse Gas Emissions) was added to Appendix G of the State CEQA Guidelines. The new set asks whether a project would do either of the following:

a) Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment?

b) Conflict with any applicable plan, policy or regulation of an agency adopted for the purpose of reducing the emissions of greenhouse gases?

Preliminary Draft Staff Proposal: Recommended Approaches for Setting Interim Significance Thresholds for Greenhouse Gases under CEQA CEQA gives discretion to lead agencies to establish thresholds of significance based on individual circumstances. To assist in that exercise, and because OPR believes the unique nature of GHGs warrants investigation of a statewide threshold of significance for GHG emissions, OPR asked ARB technical staff to recommend a methodology for setting thresholds of significance. In October 2008, ARB released *Preliminary Draft Staff Proposal: Recommended Approaches for Setting Interim Significance Thresholds for Greenhouse Gases under the California Environmental Quality Act* (ARB 2008). This draft proposal included a conceptual approach for thresholds associated with industrial, commercial, and residential projects. For nonindustrial projects, the steps to presuming a less than significant climate change impact generally involve analyzing whether the project meets the following criteria (ARB 2008):

- Is exempt under existing statutory or categorical exemptions
- Complies with a previously approved plan or target
- Meets specified minimum performance standards
- Falls below an as-yet-unspecified annual emissions level

The performance standards focus on construction activities, energy and water consumption, generation of solid waste, and transportation. For industrial projects, the draft proposal recommends a tiered analysis procedure similar to the procedure for analyzing nonindustrial projects. However, for industrial projects a quantitative limit for less than significant impacts is established at approximately 7,000 MT CO_2e per year. These standards have not yet been adopted or finalized as a basis for evaluating the significance of a project's contribution to climate change.

Executive Order S-3-05 Executive Order S-3-05 made California the first state to formally establish GHG emissions reduction goals. Executive Order S-3-05 includes the following GHG emissions reduction targets for California:

- By 2010, reduce GHG emissions to 2000 levels.

- By 2020, reduce GHG emissions to 1990 levels.
- By 2050, reduce GHG emissions to 80 percent below 1990 levels.

The final emission target of 80 percent below 1990 levels would put the state's emissions in line with estimates of the required worldwide reductions needed to bring about long-term climate stabilization and avoidance of the most severe impacts of climate change (IPCC 2007).

Executive Order S-3-05 also dictated that the Secretary of the California Environmental Protection Agency coordinate oversight of efforts to meet these targets with all of the following:

- The Secretaries of the Business, Transportation, and Housing Agency; California Department of Food and Agriculture; and California Natural Resources Agency
- The Chairpersons of ARB and the California Energy Commission
- The President of the California Public Utilities Commission

This group was subsequently named the Climate Action Team.

As laid out in Executive Order S-3-05, the Climate Action Team has submitted biannual reports to the Governor and State legislature describing progress made toward reaching the targets. The Climate Action Team is finalizing its second biannual report on the effects of climate change on California's resources.

Assembly Bill 32 In 2006, California passed the California Global Warming Solutions Act of 2006 (AB 32; California Health and Safety Code, Sections 38500 et seq.). AB 32 further details and puts into law the midterm GHG reduction target established in Executive Order S-3-05 – reduce GHG emissions to 1990 levels by 2020. AB 32 also identifies ARB as the State agency responsible for the design and implementation of emissions limits, regulations, and other measures to meet the target.

The statute lays out the schedule for each step of the regulatory development and implementation, as follows:

- By June 30, 2007, ARB had to publish a list of early-action GHG emission reduction measures.
- Before January 1, 2008, ARB had to identify the current level of GHG emissions by requiring statewide reporting and verification of GHG emissions from emitters and identify the 1990 levels of California GHG emissions.

- By January 1, 2010, ARB had to adopt regulations to implement the early-action measures.

In December 2007, ARB approved the 2020 GHG emission limit (1990 level) of 427 MMT CO_2e. The 2020 target requires the reduction of 169 MMT CO_2e, or approximately 30 percent below California's projected "business-as-usual" 2020 emissions of 596 MMT CO_2e.

Also in December 2007, ARB adopted mandatory reporting and verification regulations pursuant to AB 32. The regulations became effective January 1, 2009, with the first reports covering 2008 emissions. The mandatory reporting regulations require reporting for major facilities, those that generate more than 25,000 MT CO_2e per year. To date ARB has met all of the statutorily mandated deadlines for promulgation and adoption of regulations.

Climate Change Scoping Plan On December 11, 2008, pursuant to AB 32, ARB adopted the *Climate Change Scoping Plan*. This plan outlines how emissions reductions will be achieved from significant sources of GHGs via regulations, market mechanisms, and other actions. Six key elements, outlined in the scoping plan, are identified below to achieve emissions reduction targets:

- Expand and strengthen existing energy efficiency programs and building and appliance standards.

- Achieve a statewide renewable energy mix of 33 percent.

- Develop a California cap-and-trade program that links with other Western Climate Initiative partner programs to create a regional market system.

- Establish targets for transportation-related GHG emissions for regions throughout California, and pursue policies and incentives to achieve those targets.

- Adopt and implement measures pursuant to existing State laws and policies, including California's clean car standards, goods movement measures, and the Low Carbon Fuel Standard.

- Create targeted fees, including a public goods charge on water use, fees on high-GWP gases, and a fee to fund the administrative costs of the State's long-term commitment to AB 32 implementation.

The *Climate Change Scoping Plan* also recommended 39 measures that were developed to reduce GHG emissions from key sources and activities while improving public health, promoting a cleaner environment, preserving natural resources, and ensuring that the impacts of the reductions would be equitable and avoid disproportionately affecting low-income and minority communities.

These measures also put California on a path to meet the long-term 2050 goal of reducing statewide GHG emissions to 80 percent below 1990 levels. The measures in the approved scoping plan are being developed and will be in place by 2012.

Executive Order S-13-08 Executive Order S-13-08, issued November 14, 2008, directs the California Natural Resources Agency, DWR, OPR, the California Energy Commission, the State Water Resources Control Board, the California Department of Parks and Recreation, and California's coastal management agencies to participate in planning and research activities to advance California's ability to adapt to the effects of climate change. The order specifically directs agencies to work with the National Academy of Sciences to initiate the first California sea-level-rise assessment and to review and update the assessment every 2 years after completion; immediately assess the vulnerability of California's transportation system to sea level rise; and to develop a climate change adaptation strategy for California.

California Climate Change Adaptation Strategy Developed through cooperation and partnership among multiple State agencies, the 2009 *California Climate Adaptation Strategy* summarizes the best known science on climate change effects. The strategy describes effects of climate change on seven specific sectors—public health, biodiversity and habitat, ocean and coastal resources, water management, agriculture, forestry, and transportation and energy infrastructure—and recommends ways to manage against those threats.

Governor's Office of Planning and Research Technical Advisory In June 2008, OPR published a technical advisory on CEQA and climate change to provide interim advice to lead agencies regarding the analysis of GHGs in environmental documents (OPR 2008). The advisory encourages lead agencies to identify and quantify the GHGs that could result from a proposed project, analyze impacts of those emissions to determine whether they would be significant, and identify feasible mitigation measures or alternatives that would reduce adverse impacts to a less than significant level. The advisory recognized that OPR would develop, and the Natural Resources Agency would adopt, amendments to the State CEQA Guidelines pursuant to SB 97. (See "California Environmental Quality Act and SB 97," above.)

The advisory provides OPR's perspective on the emerging role of CEQA in addressing climate change and GHG emissions. It recognizes that approaches and methodologies for calculating GHG emissions and determining their significance are rapidly evolving. OPR concludes in the technical advisory that climate change is ultimately a cumulative impact, and that no individual project could have a significant impact on global climate. Thus, projects must be analyzed with respect to the incremental impact of the project when added to other past, present, and reasonably foreseeable probable future projects. OPR recommends that lead agencies undertake an analysis, consistent with available

guidance and current CEQA practice, to determine cumulative significance (OPR 2008).

The technical advisory points out that neither CEQA nor the State CEQA Guidelines prescribe thresholds of significance or particular methodologies for performing an impact analysis. "This is left to lead agency judgment and discretion, based upon factual data and guidance from regulatory agencies and other sources where available and applicable" (OPR 2008). OPR states that "the global nature of climate change warrants investigation of a statewide threshold of significance for GHG emissions" (OPR 2008). Until such a standard is established, OPR advises that each lead agency should develop its own approach to performing an analysis for projects that generate GHG emissions (OPR 2008).

OPR sets out the following process for evaluating GHG emissions. First, agencies should determine whether GHG emissions may be generated by a proposed project, and if so, quantify or estimate the emissions by type or source. Calculation, modeling, or estimation of GHG emissions should include the emissions associated with vehicular traffic, energy consumption, water usage, and construction activities (OPR 2008).

Agencies should then assess whether the emissions are "cumulatively considerable" even though a project's GHG emissions may be individually limited. OPR states: "Although climate change is ultimately a cumulative impact, not every individual project that emits GHGs must necessarily be found to contribute to a significant cumulative impact on the environment" (OPR 2008). Individual lead agencies may undertake a project-by-project analysis, consistent with available guidance and current CEQA practice (OPR 2008).

Finally, if the lead agency determines that emissions are a cumulatively considerable contribution to a significant cumulative impact, the lead agency must investigate and implement ways to mitigate the emissions (OPR 2008). OPR (2008) states:

> *Mitigation measures will vary with the type of project being contemplated, but may include alternative project designs or locations that conserve energy and water, measures that reduce vehicle miles traveled by fossil-fueled vehicles, measures that contribute to established regional or programmatic mitigation strategies, and measures that sequester carbon to offset the emissions from the project.*

OPR concludes that "A lead agency is not responsible for wholly eliminating all GHG emissions from a project; the CEQA standard is to mitigate to a level that is "less than significant" (OPR 2008). Attachment 3 to the technical advisory includes a list of GHG reduction measures that can be applied on a project-by-project basis.

California Air Pollution Officers Association In January 2008, the California Air Pollution Control Officers Association issued a "white paper" on evaluating and addressing GHGs under CEQA (CAPCOA 2008). This resource guide was prepared to support local governments as they develop their climate change programs and policies. Though not a guidance document, the paper provides information about key elements of CEQA GHG analyses, including a survey of different approaches to setting quantitative significance thresholds. The following are some of the thresholds discussed:

- Zero (all emissions are significant)
- 900 MT CO_2e per year (90 percent market capture for residential and nonresidential discretionary development)
- 10,000 MT CO_2e per year (potential ARB mandatory reporting level for cap-and-trade program)
- 25,000 MT CO_2e per year (ARB's mandatory reporting level for the statewide emissions inventory)
- Unit-based thresholds, based on identifying thresholds for each type of new development and quantifying significance by a 90 percent capture rate

5.2.3 Regional and Local

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Shasta County Air Quality Management District SCAQMD is the primary local agency regulating air quality for all of Shasta County. SCAQMD attains and maintains air quality conditions in Shasta County through a comprehensive program of planning, regulation, enforcement, technical innovation, and promotion of the understanding of air quality issues. The clean-air strategy of SCAQMD is to prepare plans and programs for the attainment of ambient air quality standards, adopt and enforce rules and regulations, and issue permits for stationary sources. SCAQMD also inspects stationary sources, responds to citizen complaints, monitors ambient air quality and meteorological conditions, and implements other programs and regulations required by the CAA, CAAA, and CCAA.

Rules and Regulations All projects in Shasta County are subject to SCAQMD rules and regulations in effect at the time of construction. Specific rules applicable to the project may include the following:

- **Rule 2:1A: Permits Required** – Any person who is building, erecting, altering, or replacing any article, machine, equipment or other contrivance, or multicomponent system including same, portable or

stationary and who is not exempt under Section 42310 of the California Health and Safety Code, the use of which may cause the issuance of air contaminants, shall first obtain written authority for such construction from the Air Pollution Control Officer.

- **Rule 2:7: Conditions for Open Burning** – All material to be burned must be arranged so that it will burn with a minimum of smoke and must be reasonably free of dirt, soil, and visible surface moisture. All vegetative wastes to be burned shall be ignited only with approved ignition devices and shall be free of tires, illegal residential waste, tar paper, construction debris, and combustible and flammable waste. No burning shall cause emissions to be transported into smoke sensitive areas. No burning shall be conducted when such burns, in conjunction with present or predicted meteorology, could cause or contribute to a violation of an ambient air quality standard.

- **Rule 3:15: Cutback and Emulsified Asphalt** – A person shall not manufacture, sell, offer for sale, use, or apply for paving, construction, or maintenance of parking lots, driveways, streets, or highways any rapid- or medium-cure cutback asphalt, slow-cure cutback asphalt material that contains more than 0.5 percent by volume VOCs that boil at 500 degrees Fahrenheit (°F) (260 degrees Celsius) (°C) or less, or any emulsified asphalt material that contains more than 3.0 percent by volume of VOCs that evaporate at 500°F (260°C) or less.

- **Rule 3:16: Fugitive, Indirect, or Nontraditional Sources** – The Air Pollution Control Officer may place reasonable conditions upon any source, as delineated below, that will mitigate the emissions from such sources to below a level of significance or to a point that such emissions no longer constitute a violation of Health and Safety Code Sections 41700 and/or 41701: fugitive sources, indirect sources, and nontraditional sources.

- **Rule 3:22: Asbestos** – No person shall use or apply serpentine material for surfacing in California unless the material has been tested using ARB Test Method 435 and determined to have an asbestos content of 5 percent or less. A written receipt or other record documenting the asbestos content shall be retained by any person who uses or applies serpentine material for at least 7 years from the date of use or application, and shall be provided to the Air Pollution Control Officer, or his or her designate, for review upon request.

- **Rule 3:31: Architectural Coatings** – The developer or contractor is required to use coatings that comply with the VOC content limits specified in the rule.

Criteria Pollutants SCAQMD has adopted pollutant emission thresholds and mitigation requirements that are used in the analysis of project impacts. The thresholds and mitigation requirements are discussed below in Section 5.3.2, "Criteria for Determining Significance of Effects."

Attainment Plan Air quality planning in the NSVAB has been undertaken on a joint basis by the air districts in seven counties. The current plan, the *Northern Sacramento Valley Planning Area 2009 Triennial Air Quality Attainment Plan* (AQAP), is an update of plans prepared in 1994, 1997, 2000, 2003, and 2006. The purpose of the plan is to achieve and maintain healthful air quality throughout the air basin. The 2009 AQAP addresses the progress made in implementing the 2006 plan and proposes modifications to the strategies necessary to attain the California ambient air quality standards for the 1-hour ozone standard at the earliest practicable date.

The AQAP is based on each county's projected emission inventory, which includes stationary, areawide, and mobile sources. Emission inventories are based on general plans and anticipated development.

Toxic Air Contaminants At the local level, air pollution control or management districts may adopt and enforce ARB control measures. Under SCAQMD Rule V, "Additional Procedures For Issuing Permits To Operate For Sources Subject To Title V Of The Federal Clean Air Act Amendments Of 1990," Rule 2:1, "New Source Review," and Rule 2:1A, "Permits Required," all sources that possess the potential to emit TACs are required to obtain permits from the district. Permits may be granted to these operations if they are constructed and operated in accordance with applicable regulations, including new-source-review standards and air-toxics control measures. SCAQMD limits emissions and public exposure to TACs through a number of programs. SCAQMD prioritizes TAC-emitting stationary sources based on the quantity and toxicity of the TAC emissions and the proximity of the facilities to sensitive receptors.

Shasta County General Plan The Air Quality Element of the *Shasta County General Plan* (Shasta County 2004) contains objectives and policies aimed at protecting and improving Shasta County's air quality, meeting the requirements of the Federal CAA and CCAA, and integrating planning efforts (e.g., transit, land use) to reduce air pollution contaminants, among others.

Tehama County Air Pollution Control District The southern portion of the primary study area is in Tehama County. The Tehama County Air Pollution Control District is the primary local agency with respect to air quality for Tehama County. The Tehama County Air Pollution Control District has rules and regulations similar to those described for SCAQMD. The Tehama County Air Pollution Control District is in the NSVAB and is therefore a participant in NSVAB's 2003 AQAP.

Lower Sacramento River and Delta and CVP/SWP Service Areas

All areas of California are within the jurisdiction of an air pollution control district or an air quality management district. Each district has rules and regulations similar to those described above for SCAQMD. Districts that are classified as nonattainment for one or more criteria pollutants have attainment plans or similar documents as required by ARB. Most districts have guidance documents for the analysis of air quality impacts for CEQA compliance.

Global Study Area—Greenhouse Gases

There are no regional or local policies, regulations, or laws pertaining to GHG emissions.

5.3 Environmental Consequences and Mitigation Measures

5.3.1 Methods and Assumptions

Criteria Air Pollutants

The proposed SLWRI alternatives are quite complex. They consist of implementing construction activities for the dam structure; clearing the reservoir area that would be affected by the increase in pool height; relocating and modifying bridges, roads, utilities, and recreation areas; and completing other related tasks. At the current stage of project development (April 2011), project planning, design, and engineering is preliminary. Detailed development of construction plans and schedule is not anticipated until an alternative is selected and approved. However, potential air quality impacts from emissions of criteria pollutants may be assessed quantitatively by estimating emissions for major project elements and understanding the implications of additional emissions from project activities that are not quantified.

The URBEMIS2007 emissions model was used to generate estimates of construction activity emissions. The URBEMIS2007 software package, Version 9.2.4, is a calculation tool designed to estimate air pollutant emissions from land use development projects based on development type and size. The emissions factors and calculation methodologies contained in the URBEMIS2007 program were developed in cooperation with ARB and many air districts in California. Among the inputs to the model for construction analysis are the following:

- Types and quantities of construction equipment to be used and hours of use
- Areas of land to be graded
- Number of truck trips and trip distances for export of spoils and import of materials
- Volumes of buildings to be demolished

- Areas of buildings to be built
- Areas of land to be paved

Attachment 1 of the *Air Quality and Climate Technical Report* contains the worksheets generated by URBEMIS2007 documenting the input and output for this analysis.

The Sacramento Metropolitan Air Quality Management District's Road Construction Emissions Model, version 6.3.2, was used to estimate emissions from the Reading Island portion of the project proposed under CP4 and CP5. This model is used for linear projects, such as Reading Island, and uses emission factors from EMFAC2007 and OFFROAD2007 databases developed by ARB. Inputs in the Road Construction Emissions Model include construction equipment populations, material and soil hauling, and construction phase timelines.

For postconstruction activities, principal inputs are the number of vehicle trips and average trip distances. Attachment 1 of the *Air Quality and Climate Technical Report* contains the worksheets generated by the model URBEMIS2007 documenting the input and output for this analysis.

SCAQMD and the Tehama County Air Pollution Control District standards are discussed relative to impact thresholds.

Toxic Air Contaminants and Odors

TACs and odors are discussed in accordance with SCAQMD, ARB, and EPA policies and rules.

Global Warming

Emissions of CO_2 from construction activities and from recreational visitors' vehicles were calculated using the URBEMIS2007 program. Data on CO_2 emissions avoided by generation of electricity from Shasta Dam were obtained from Chapter 5 of the *Shasta Lake Water Resources Investigation Plan Formulation Report* (Reclamation 2007). Emissions of CO_2 from cleared and burned vegetation were estimated using the Carbon Online Estimator (COLE Development Group 2011). Indirect emissions from cement production and CO_2 absorption by water and vegetation are discussed but not quantified.

5.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an environmental impact statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially

substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on air quality and climate would be significant if project implementation would do any of the following:

- Conflict with or obstruct implementation of the applicable air quality plan
- Violate any air quality standard or contribute substantially to an existing or projected air quality violation
- Result in a cumulatively considerable net increase of a criteria air pollutant for which the project region is nonattainment under any applicable Federal or State ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors)
- Expose sensitive receptors to substantial pollutant concentrations
- Create objectionable odors affecting a substantial number or people
- Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment
- Conflict with any applicable plan, policy, or regulation of an agency adopted for the purpose of reducing the emissions of GHGs

As stated in Appendix G of the State CEQA Guidelines, the significance criteria established by the applicable air quality management or air pollution control district may be relied upon to make the above determinations. SCAQMD has adopted air quality thresholds (Table 5-3). These thresholds are based on SCAQMD New Source Review Rule 2:1. The thresholds and policy are published in the *Shasta County General Plan*.

Table 5-3. Shasta County Air Quality Management District's Air Quality Emission Thresholds

NO_X	ROG	PM_{10}	CO
Level A Thresholds			
25 lb/day	25 lb/day	80 lb/day	500 lb/day
Level B Thresholds			
137 lb/day	137 lb/day	137 lb/day	500 lb/day

Source: Shasta County 2004

Note:
These thresholds will be applied during the Shasta County Planning Division's CEQA review process. The CO thresholds do not appear in the general plan, but are included in SCAQMD policy.

Key:
CEQA = California Environmental Quality Act
CO = carbon monoxide
lb/day = pounds per day
NO_X = oxides of nitrogen
PM_{10} = respirable particulate matter
ROG = reactive organic gases
SCAQMD = Shasta County Air Quality Management District

The policy includes standard mitigation measures (SMM) and best available mitigation measures (BAMM). Briefly, the policy for applying SMMs and BAMMs is as follows:

- Apply SMM to all projects; this effort will help contribute to reducing cumulative effects.
- Apply SMM and appropriate BAMM when a project exceeds Level A thresholds.
- Apply SMM, BAMM, and special BAMM when a project exceeds Level B thresholds.
- If application of the above procedures will reduce project emissions below Level B thresholds, the project can proceed with an environmental determination of a mitigated negative declaration, assuming that other project impacts do not require more extensive environmental review.
- If project emissions cannot be reduced to below Level B thresholds, emission offsets will be required. If, after applying the emissions offsets, the project emissions still exceed the Level B threshold, an environmental impact report will be required before the project can be considered for action by the reviewing authority.

Thus, as recommended by SCAQMD, impacts of an alternative on air quality would be significant if either of the following would occur as a result of project implementation:

- Emissions of criteria air pollutants or precursors in Shasta County during construction or long-term operations would exceed the SCAQMD Level B thresholds of 137 pounds per day (lb/day) of ROG, NO_X, or PM_{10} and 500 lb/day of CO after the application of mitigation measures.

- Emissions of criteria air pollutants or precursors in Tehama County during construction or long-term operations would exceed 137 lb/day of ROG, NO_X, or PM_{10} after the application of mitigation measures.

SCAQMD has not adopted a numeric significance criterion for GHGs generated by nonindustrial projects. (However, two California air districts, the Bay Area Air Quality Management District and the South Coast Air Quality Management District, have adopted thresholds for GHG emissions generated by development projects.) No numeric thresholds adopted by any air district or by ARB would be applicable to the action alternatives. However, by adopting AB 32, the State has established GHG reduction targets. Further, the State has determined that GHG emissions, as they relate to global climate change, are a source of adverse environmental impacts in California and should be addressed under CEQA. AB 32 did not amend CEQA, although the legislation identifies the myriad environmental problems in California caused by global warming (Health and Safety Code, Section 38501(a)). SB 97, in contrast, did amend CEQA by requiring OPR to revise the State CEQA Guidelines to address the mitigation of GHG emissions or their consequences (California Public Resources Code, Sections 21083.05 and 21097).

Based on the size, scope, and purpose of this project, the following significance criteria will be used to determine the significance of GHG emissions from this project:

- Whether the project has the potential to conflict with or is consistent with the following plans to reduce or mitigate GHG emissions:

  – The six key elements of the *Climate Change Scoping Plan* (described previously)

  – ARB's 39 recommended actions in the *Climate Change Scoping Plan*

  – Regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of GHG emissions

- Whether the project is part of a plan that includes overall reductions in GHG emissions

- Whether the relative amounts of GHG emissions over the life of the project are small in comparison to the amount of GHG emissions for major facilities that are required to report such emissions (25,000 MT CO_2e per year)

- Whether the project has the potential to contribute to a lower carbon future, through factors such as the following:

  – The design of the proposed project is inherently energy efficient

  – All applicable best management practices that would reduce GHG emissions are incorporated into the project design

  – The project implements or funds its fair share of a mitigation strategy designed to alleviate climate change

  – There are process improvements or efficiencies gained by implementing the project

5.3.3 Topics Eliminated from Further Consideration

No topics related to air quality and climate change that are included in the significance criteria listed above were eliminated from further consideration. All relevant topics are analyzed below.

5.3.4 Direct and Indirect Effects

No-Action Alternative

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact AQ-1 (No-Action): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction No short-term, construction-related increases in emissions of criteria air pollutants or precursors at Shasta Lake or in the vicinity would result from implementation of the No-Action Alternative. No impact would occur.

Under the No-Action Alternative, no new facilities would be constructed at Shasta Lake or in the vicinity. No changes to Reclamation's existing facilities would occur that would directly or indirectly result in any increases in emissions of criteria air pollutants or precursors in this portion of the primary study area. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact AQ-2 (No-Action): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation No long-term operational increases in emissions of criteria air pollutants or precursors in the primary study area would

result from implementation of the No-Action Alternative. However, PM_{10} emissions are expected to continue increasing through 2020 because of increased growth in the area. This impact would be less than significant.

Under the No-Action Alternative, no changes to Reclamation's existing operations in the primary study area would occur that would directly or indirectly result in any increases in emissions of criteria air pollutants or precursors in the primary study area. According to ARB, emission levels for ROG, NO_X, and CO are trending downward from 1990 to 2020 in the project area even with increased population growth (ARB 2009). More stringent mobile-source emission standards, cleaner burning fuels, and new rules have largely contributed to this decline. However, PM_{10} emissions are expected to continue increasing through 2020 because of increased growth in the area and associated emissions (e.g., from travel on paved and unpaved roads). Thus, such emissions will likely be worse in the future. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact AQ-3 (No-Action): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations The No-Action Alternative would not change existing exposure of sensitive receptors to pollutants. No impact would occur.

Sensitive receptors in the primary study area are not currently exposed to substantial pollutant concentrations. There is no indication of circumstances under the No-Action Alternative that would change exposure levels. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact AQ-4 (No-Action): Exposure of Sensitive Receptors to Odor Emissions The No-Action Alternative would not change existing exposure of sensitive receptors to odors. No impact would occur.

Sensitive receptors in the primary study area are not currently exposed to substantial concentrations of odors. There is no indication of circumstances under the No-Action Alternative that would change the exposure. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact AQ-5 (No-Action): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction No short-term, construction-related increases in emissions of criteria air pollutants or precursors below Shasta Dam would result from implementation of the No-Action Alternative. No impact would occur.

The Gravel Augmentation Program (proposed under CP4 and CP5, as described below) would not be implemented under the No-Action Alternative. No new facilities would be constructed below Shasta Dam. Furthermore, no changes to Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increases in emissions of criteria air pollutants in this

portion of the primary study area. No impact would occur. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under the No-Action Alternative; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

Global Study Area

Impact AQ-6 (No-Action): Generation of Greenhouse Gases State goals to reduce project-related GHG emissions would not be implemented under this alternative; however, the No-Action Alternative would not obstruct or conflict with those goals. This impact would be less than significant.

Under the No-Action Alternative, no new facilities would be constructed. No changes to Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increases or decreases in GHG emissions. Therefore, no efforts would be made to reduce existing GHG emissions in the project vicinity under this alternative. Although the State of California's goals to reduce GHG emissions would not be implemented, the No-Action Alternative would not obstruct or conflict with those goals. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity

Impact AQ-1 (CP1): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction would result in short-term NO_X emissions that would exceed applicable SCAQMD thresholds, and could result in emissions that would exceed PM_{10} and ROG thresholds. This conclusion is based on calculations of estimated emissions for major elements of the project, and projection of additional emissions for other elements where calculation is not reasonable at the current level of project definition. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

Construction emissions are described as "short-term" or temporary in duration because they would cease when the dam raise and associated construction projects are completed. The emissions of ozone precursors ROG and NO_X are associated primarily with gas and diesel engine equipment exhaust from off-road equipment and on-road vehicles. Off-road equipment anticipated in the project includes construction equipment such as bulldozers, cranes, welders, water trucks, loaders, and concrete batch plants. An additional off-road source

would be engine exhaust from helicopters used to airlift wood from clearing operations. On-road vehicles include trucks that would bring materials to the project site and haul excavated spoils and materials cleared from lands away from the project site. An additional on-road source would be the vehicles used by workers commuting to and from the project site. Engine equipment exhaust also emits CO, PM_{10}, and $PM_{2.5}$.

The primary sources of PM_{10} and $PM_{2.5}$ emissions are fugitive dust from site preparation, vehicle travel on unpaved and paved roads, and storage piles. Emissions vary as a function of such parameters as soil silt content, soil moisture, wind speed, acreage of disturbance area, and vehicle miles traveled by construction vehicles on- and off-site. Burning of cleared vegetation would be a substantial source of particulate emissions. PM_{10} and $PM_{2.5}$ would also be emitted during the materials handling processes associated with operation of a concrete batch plant.

Major construction elements under CP1 would be the dam raise of 6.5 feet and the clearing of land that would be inundated by the larger full pool. Land-clearing equipment used would be based on the terrain, and would range from full-size bulldozers to smaller backhoes and hand tools. In steep terrain helicopters would be used for material removal. In addition, wing dams and reservoir dikes would be constructed; railroad and roadway bridges would be replaced; roads, structures, and utilities would be relocated; and excavation and loading would occur at borrow areas to provide materials for dam construction.

To provide an initial, partial estimate of daily emission rates, it was assumed that the following construction activities would occur concurrently for a 3-year-long period:

- Dam raise, requiring two cranes, four off-road trucks, three dozers, two welders, two water trucks, and four other pieces of diesel engine equipment
- Trucking of materials to the dam site, with approximately 58 round trips per day of 20 miles per trip
- Clearing of acreage around the reservoir at a rate of 1.5 acres per day, using one tractor, two loader/backhoes, one water truck, and seasonal helicopters
- Trucking of materials cleared from the land, with approximately 23 round trips per day of 20 miles per trip

Emissions were calculated using the URBEMIS2007 model described above in Section 5.3.1, “Methods and Assumptions.” The results are shown in Table 5-4. (URBEMIS air quality modeling outputs for the comprehensive plans are presented in Attachment 1 to the *Air Quality and Climate Technical Report*.) As

seen in Table 5-4, NO_X emissions for the selected activities would exceed the Shasta County Level B threshold of 137 lb/day, which would result in a significant impact.

Particulate emissions from operation of a concrete batch plant are not included in the above calculations. Batch plants must obtain operating permits from Shasta County Air Pollution Control District. The granting of a permit would assure that the impact of PM_{10} and $PM_{2.5}$ emissions from batch plant sources would be less than significant.

Table 5-4 represents the initial partial emissions scenario. It is very likely that many other project-related activities using diesel-engine equipment would occur concurrently with the dam raise and the land clearing. It is also possible that the intensity of the dam raise and land clearing would be greater than assumed for the calculations. For example, the calculations for the dam raise assume an 8-hour work day; however, it is likely that some construction activities, such as mass concrete pours, would require 16- to 24-hour work days. With increases in concurrent activities and intensity of activity, it is anticipated that ROG and PM_{10} emissions would exceed the Level A significance threshold, and the potential exists for ROG and PM_{10} emissions to exceed the Level B thresholds of 137 lb/day.

Based on the data in Table 5-4 and the preceding discussion, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. As a result, this impact would be significant.

The Shasta County standards require standard mitigation measures for all projects and additional mitigation measures when project emissions are anticipated to reach intermediate levels of 25 lb/day for ROG and NO_X, and 80 lb/day of PM_{10}. Mitigation for this impact that incorporates these mitigation measures is proposed in Section 5.3.5.

Table 5-4. Construction Emissions for Postulated Dam Raise and Land Clearing, 3-Year Construction Period – CP1[a]

Activity	Emissions—pounds per day				
	ROG	NO_X	CO	PM_{10}	$PM_{2.5}$
Dam Raise and Materials Trucking					
Off-road diesel	17	157	63	6	6
On-road diesel	2	37	12	2	1
Worker trips	<0.5	<0.5	5	<0.5	<0.5
Subtotal	20	194	81	8	7
Land Clearing and Spoils Trucking					
Fugitive dust	<0.5	<0.5	<0.5	30	6

[b] Years modeled were 2009, 2010, 2011.

Key:
CO = carbon monoxide
CP = Comprehensive Plan
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
SCAQMD = Shasta County Air Quality Management District

Impact AQ-2 (CP1): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAMQD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. Stationary sources could include emergency generators powered by

diesel engines or pumps, boilers, and major kitchen equipment. No new stationary sources of note are anticipated as part of the project. Replacement equipment that would emit pollutants is anticipated to be similar to equipment presently in operation.

Area sources include gas-fired building heating and hot water equipment, landscape maintenance equipment, and architectural coatings (paints, lacquers) used in maintenance. Area-source increases are anticipated to be negligible.

After completion of the dam raise, the principal sources of long-term emissions would be mobile sources; an increase in vehicle trips would result from increased recreational activity at Shasta Lake and the associated recreation areas. It is assumed that maintenance activity for the dam and recreation areas would not change markedly. No new stationary sources of emissions are anticipated as part of the project.

Enlarging Shasta Dam and including facilities to ensure that at least the existing recreation opportunities are maintained would affect recreation participation by increasing the reservoir's surface area throughout the year. Table 5-5 compares user days (visitor days) for each of the comprehensive plans to existing and future conditions. Studies are under way to identify increases in recreation facilities and recreation uses to be included in CP1. See the Economic Valuation Appendix for a full discussion of increases in user days.

Table 5-5. Average Annual Predicted Increase in User Days[a]

Item	CP1	CP2	CP3	CP4[b]	CP5
Increase in user days (thousands)	83	141	224	224	224

Source: Data compiled by EDAW (now AECOM) in 2008

Notes:
[a] All alternatives are to include features to, at minimum, maintain existing Shasta Lake recreation capacity.
[b] The extent of increased recreation due to added facilities is under development. Recreation use would surpass that for CP3 and CP5.

The increase in recreational opportunities and visitor days would generate vehicle trips for the travel of visitors to and from the Shasta Lake area. Increased vehicle emissions were calculated using the URBEMIS2007 model and the following assumptions:

- The average visitor stay is 2.5 days.
- The average number of visitors per vehicle is 2.5.
- The recreation season for most visitors is 180 days.
- The average one-way trip distance for visitors is 25 miles.
- The first year of operations is expected to be 2015 or later.

With these assumptions and the value of 83,000 increased visitor days from Table 5-5, there would be an increase of an average of 148 one-way trips per day under CP1. The results of the emissions calculations are shown in Table 5-6. Anticipated emissions would be less than the SCAQMD significance thresholds.

Table 5-6. Operations Emissions for Shasta Dam Raise, 2015 – CP1

Activity	Emissions—pounds per day				
	ROG	NO_X	CO	PM_{10}	$PM_{2.5}$
Vehicle trips for increase in recreational visitors	2	4	35	6	1
SCAQMD Level A Significance Thresholds	**25**	**25**	**500**	**80**	**None**
SCAQMD Level B Significance Thresholds	**137**	**137**	**500**	**137**	**None**

Source: Data compiled by EDAW (now AECOM) in 2008

Note: Totals may not add due to rounding.

Key:
CO = carbon monoxide
CP = Comprehensive Plan
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
SCAQMD = Shasta County Air Quality Management District

Based on the above analysis, operation under CP1 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD Level A thresholds. Consequently, long-term emissions during project operation under CP1 would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-3 (CP1): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

Pollutants of concern for exposure of sensitive receptors include CO, PM_{10} and $PM_{2.5}$, and TACs. Local exposure of CO may occur near severe congestion on major roadways. The project is not anticipated to generate areas of severe roadway congestion, nor would the project locate receptors near major roadways; no local CO impact would occur.

Sensitive receptors could be exposed to substantial amounts of PM_{10} and $PM_{2.5}$ if receptors were located near large areas of grading or earthmoving and dust generation was not controlled. Similarly, substantial exposure to particulates and other smoke-borne pollutants could result if receptors were near areas

where cleared brush would be burned. There are no sensitive receptors near the dam raise areas; however, there may be sensitive receptors near the some of the lands that would be cleared before inundation by the expanded reservoir. Dust control measures would be required for all land clearing activities; these measures would prevent most PM_{10} and $PM_{2.5}$ from reaching sensitive receptors. Similarly, smoke control measures would be required by SCAQMD Rule 2:7. The impact of exposure of sensitive receptors to PM_{10} and $PM_{2.5}$ would be less than significant.

The principal TAC of concern for project construction is diesel PM. Diesel PM would be generated in the exhaust of diesel engine construction equipment. The largest concentration of diesel engines would be located at the dam raise site. There are no sensitive receptors within one-half mile of the dam site, and sensitive receptors would not be exposed to diesel PM from that source. Diesel equipment would be used for land clearing operations, and there may be sensitive receptors near the land clearing. The dose to which receptors are exposed is the primary factor used to determine health risk (i.e., potential exposure to TAC emission levels that exceed applicable standards). Dose is a function of the concentration of a substance or substances in the environment and the duration of exposure to the substance. Dose is positively correlated with time, meaning that a longer exposure period would result in a higher exposure level for the maximally exposed individual. Thus, the risks estimated for a maximally exposed individual are higher if a fixed exposure occurs over a longer period of time. According to the Office of Environmental Health Hazard Assessment, health risk assessments, which determine the exposure of sensitive receptors to TAC emissions, should be based on a 70-year exposure period; however, such assessments should be limited to the period/duration of activities associated with the project. Thus, because the use of off-road construction equipment would be limited to a few days near any sensitive receptor, short-term construction activities would not result in exposure of sensitive receptors to substantial TAC emissions.

Project implementation is not expected to result in the operation of any new significant sources of TAC emissions after construction is complete. Thus, short-term construction and long-term operational sources would not expose sensitive receptors to substantial TAC concentrations. As a result, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP1): Exposure of Sensitive Receptors to Odor Emissions
Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

The occurrence and severity of odor impacts depend on numerous factors: the nature, frequency, and intensity of the source; wind speed and direction; and the presence of sensitive receptors. Although offensive odors rarely cause any

physical harm, they still can be very unpleasant, leading to considerable distress and often generating citizen complaints to local governments and regulatory agencies.

Diesel exhaust has some odor, but it dissipates rapidly from the source with an increase in distance. There are no sensitive receptors immediately adjacent to the project site and people would not be exposed to substantial odors in that area. At other work sites, construction equipment use would be intermittent and temporary, resulting in an odor impact that would be less than significant.

Project implementation would not develop any major sources of odor. The project does not include one of the common types of facilities that are known to produce odors such as a landfill or a coffee roaster. Thus, short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact AQ-5 (CP1): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction The Gravel Augmentation Program and habitat restoration at Reading Island proposed under CP4 and CP5 would not be implemented under CP1. No other project construction or long-term operation activities that would affect emissions of criteria air pollutants and precursors are planned in the Shasta Dam–to–Red Bluff area under CP1. Therefore, no impact would occur.

The Gravel Augmentation Program and habitat restoration at Reading Island (proposed under CP4 and CP5, as described below) would not be implemented under CP1. No new facilities would be constructed below Shasta Dam under this alternative, and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increases in criteria air pollutant emissions in this portion of the primary study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under CP1; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

Global Study Area
Impact AQ-6 (CP1): Generation of Greenhouse Gases Project construction activities would result in emission of a less than significant quantity of GHGs. Project operation would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

There are no established quantitative criteria under CEQA for determining a significant impact related to GHG emissions. The criteria suggested by various agencies principally address long-term emissions, and not the relatively short-term emissions of construction activities. One of the more commonly suggested mass emissions thresholds is 25,000 MT CO_2e per year. This value has been selected because it is the threshold established for mandatory emissions reporting for most sources in California under AB 32.

For an initial estimate of construction-phase GHG emissions, the URBEMIS model was used with the same assumptions that were used to estimate criteria pollutant emissions, as described above for Shasta Lake and vicinity (see Impact AQ-1 (CP1)). URBEMIS calculations found that the dam raise and land clearing activities would generate 2,283–3,938 tons per year of CO_2 for the 3 years of construction, which is equal to 2,071–3,572 MT. URBEMIS does not calculate emissions of GHGs other than CO_2; for emissions that are generated primarily by construction equipment, the CO_2e value would be 3–5 percent greater than the CO_2 value. As described above, there could be considerably more construction activity and more intense activity than assumed for the calculations. Further, the calculations are limited to CO_2 produced by construction equipment and on-road vehicles, and do not include CO_2 emissions attributed to processes such as making concrete or welding. Therefore, it is not unreasonable to assume that construction activities could emit GHGs on the order of 10,000 MT CO_2e per year.

GHG emissions of sequestered carbon in removed vegetation were calculated at 4,034 MT CO_2e per year for CP1. This calculation assumes that all vegetation removal, overstory removal, and relocation acreages (473 acres total) would be covered in 70-year-old stands of forest vegetation (Ponderosa pine, Douglas-fir, montane hardwood-conifer, and montane hardwood forest) and that all above-ground vegetation would be disposed of in a manner that releases the sequestered carbon into the atmosphere. All 473 acres would not be covered with 70-year forest as used in the model (ages would vary) or release all carbon to the atmosphere. Also, most utilities would be relocated in roadways, but separate relocation (and additional disturbance) was assumed in the estimated relocation acreages. This approach was applied to ensure that underestimating would not occur.

With implementation of CP1, increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated CO_2 emissions of 3,435 lb/day, as calculated with URBEMIS. The calculations assumed 180 days of visitor activity; the annual emissions would be 309 tons per year of CO_2. Vehicles emit other GHGs in addition to CO_2; the annual GHG emissions are estimated at 324 tons (approximately 294 MT) CO_2e.

Increasing the size of Shasta Dam and Shasta Lake would result in the ability to increase hydropower generation at Shasta generating facilities. Generation of electricity by hydropower reduces the need for fossil-fuel generation of

electricity and the GHG emissions that would occur with that generation. Raising Shasta Dam by 6.5 feet and implementing the operational strategy for CP1 would result in a net increase in power generation of 17 gigawatt-hours (GWh) per year (Table 5-7). This net generation estimate accounts for the energy required for pumping the increased water supplies. Fossil-fuel generation of 17 GWh of energy would produce an estimated 15,100 MT of CO_2, also shown in Table 5-7. Therefore, the increased generation of electricity at Shasta Dam would reduce the need to build facilities for fossil-fueled generation of 17 GWh per year in the global study area.

Table 5-7. Average Annual Hydropower Generation Benefits

Item	CP1	CP2	CP3	CP4	CP5
Net increased generation (GWh/year)	17	42	54	94	54
CO_2 displaced (1,000 metric tons)	15.1	37.5	48.2	83.4	48.2

Source: Data compiled by EDAW (now AECOM) in 2008

Key:
CO_2 = carbon dioxide
CP = Comprehensive Plan
GWh/year = gigawatt-hours per year

The results of the above analysis show that CP1 would result in short-term emissions of GHG for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam. The magnitude of the GHG "savings" for each year of operation, approximately 15,000 MT, would be greater than the potential annual construction emissions, which may be on the order of 14,034 MT (10,000 from exhaust emission, 4,034 from loss of carbon sequestered in vegetation). Further, construction emissions of 14,034 MT CO_2e per year would be less than the suggested significance threshold of 25,000 MT.

The GHG emissions from construction activities would be temporary in duration and mitigated to the extent feasible; therefore, such emissions would not conflict with State or regional planning efforts or emit GHG in excess of mandatory reporting standards. GHG emissions from long-term operations would likely have a net benefit as a result of increased hydroelectric generation and would thus also not conflict with planning efforts or mandatory reporting thresholds. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

In addition to the effects described above, the loss of vegetation presently in the area that would be inundated would likely result in a loss of CO_2 absorption by that vegetation, as well as increased emissions of decomposing material present in the lake as a result of increases volume. There may be some offset to this effect with increased surface area of Shasta Lake for absorption. These effects are speculative and infeasible to quantify at this time.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity

Impact AQ-1 (CP2): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction would result in short-term NO_X emissions that would exceed applicable SCAMQD thresholds, and could result in emissions that would exceed PM_{10} or ROG thresholds. This conclusion is based on calculations of estimated emissions for major elements of the project, and projection of additional emissions for other elements where calculation is not reasonable at the current level of project definition. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

This impact would be similar to Impact AQ-1 (CP1). CP2 would include a dam raise of 12.5 feet and land clearing of an area likely to be greater than for CP1. These are larger values than for CP1, but the construction period would be longer and not substantially more intense. The SCAQMD thresholds are based on maximum daily emissions, and the maximum daily activity is not anticipated to be extraordinarily greater with CP2 than with CP1. For the same reasons as described for CP1, this impact would be significant. Mitigation for this impact is proposed in Section 5.3.5.

Impact AQ-2 (CP2): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. This impact would be the same as Impact AQ-2 (CP1) for stationary and area sources and similar to Impact AQ-2 (CP1) for mobile sources. With CP2, there would be an annual increase of 141,000 visitor days, as was shown in Table 5-5, resulting in 251 average daily trips. The associated daily emissions are shown in Table 5-8.

Based on the above analysis, operation under CP2 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD Level A thresholds. Consequently, long-term emissions during project operation under CP2 would not violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 5-8. Operations Emissions for Shasta Dam Raise, 2015 – CP2

Activity	Emissions—pounds per day				
	ROG	NO_X	CO	PM_{10}	$PM_{2.5}$
Vehicle trips for increase in recreational visitors	4	7	59	11	2
SCAQMD Level A significance thresholds	25	25	500	80	None
SCAQMD Level B significance thresholds	137	137	500	137	None

Source: Data compiled by EDAW (now AECOM) in 2008

Key:
CO = carbon monoxide
CP = Comprehensive Plan
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
SCAQMD = Shasta County Air Quality Management District

Impact AQ-3 (CP2): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP2): Exposure of Sensitive Receptors to Odor Emissions Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact AQ-5 (CP2): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction The Gravel Augmentation Program and habitat restoration at Reading Island proposed under CP4 and CP5 would not be implemented under CP2. No other project construction or long-term operation activities that would affect emissions of criteria air pollutants and precursors are planned in the Shasta Dam–to–Red Bluff area under CP2. Therefore, no impact would occur.

This impact would be the same as Impact AQ-5 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento

River and Delta and CVP/SWP service areas under CP2; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

Global Study Area

Impact AQ-6 (CP2): Generation of Greenhouse Gases Project construction activities would result in a less than significant quantity of emission of GHG. Project operations would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

This impact would be similar to Impact AQ-6 (CP1) for construction and operations. With implementation of CP2, increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated CO_2 emissions of 5,825 lb/day, as calculated with URBEMIS. The annual GHG emissions are estimated at 550 tons (approximately 500 MT) CO_2e. This amount would be approximately 225 MT greater than CP1.

Raising Shasta Dam by 12.5 feet and implementing the operational strategy for CP2 would result in a net increase in power generation of 42 GWh per year (Table 5-7). Fossil-fuel generation of 42 GWh of energy would produce an estimated 37,500 MT CO_2, also shown in Table 5-7. Thus, CP2 would reduce the need to build facilities for fossil-fueled generation of 17 GWh per year in the global study area.

CP2 would result in short-term emissions of GHG for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam. The magnitude of the GHG "savings" for each year of operation, approximately 37,000 MT, would be greater than the potential annual construction emissions, which may be on the order of 10,000 MT from exhaust emissions and 5,910 MT from loss of carbon sequestered in existing vegetation. Further, construction emissions of 15,910 MT CO_2e per year would be less than the suggested significance threshold of 25,000 MT. It is concluded that the short-term impact would be less than significant, and that the overall net impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

Shasta Lake and Vicinity

Impact AQ-1 (CP3): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction would result in short-term NO_X emissions that would exceed applicable SCAQMD thresholds, and could result in emissions that would exceed PM_{10} or ROG thresholds. This conclusion is based on calculations of estimated emissions for major elements of the project, and projection of additional emissions for other elements where calculation is not reasonable at the current level of project definition. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated

during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

This impact would be similar to Impact AQ-1 (CP1). CP3 would include a dam raise of 18.5 feet and land clearing of approximately 1,000 acres. These are larger values than for CP1, but the construction period would be longer and not substantially more intense, considering the margins for increase discussed in Impact AQ-1 (CP1). The SCAQMD thresholds are based on maximum daily emissions, and the maximum daily activity is not anticipated to be substantially greater with CP3 than with CP1. For the same reasons as described for CP1, this impact would be significant. Mitigation for this impact is proposed in Section 5.3.5.

Impact AQ-2 (CP3): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. This impact would be the same as Impact AQ-2 (CP1) for stationary and area sources and similar to Impact AQ-2 (CP1 and CP2) for mobile sources. With CP3, there would be an annual increase of 224,000 visitor days, as was shown in Table 5-5, resulting in 398 average daily trips. The associated daily emissions are shown in Table 5-9. Overall trip levels would be greater than under CP1 and CP2, but emissions would remain below significance thresholds.

Table 5-9. Operations Emissions for Shasta Dam Raise, 2015—CP3

Activity	Emissions—pounds per day				
	ROG	NO_X	CO	PM_{10}	$PM_{2.5}$
Vehicle trips for increase in recreational visitors	6	11	94	17	3
SCAQMD Level A significance thresholds	25	25	500	80	None
SCAQMD Level B significance thresholds	137	137	500	137	None

Source: Data compiled by EDAW (now AECOM) in 2008

Key:
CO = carbon monoxide
CP = Comprehensive Plan
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
SCAQMD = Shasta County Air Quality Management District

Based on the above analysis, operation under CP3 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed SCAQMD Level A thresholds.

Consequently, long-term emissions during operation under CP3 would not violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-3 (CP3): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP3): Exposure of Sensitive Receptors to Odor Emissions Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact AQ-5 (CP3): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction The Gravel Augmentation Program and habitat restoration at Reading Island proposed under CP4 and CP5 would not be implemented under CP3. No other project construction or long-term operation activities that would affect emissions of criteria air pollutants and precursors are planned in the Shasta Dam–to–Red Bluff area under CP3. Therefore, no impact would occur.

This impact would be the same as Impact AQ-5 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under CP3; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

Global Study Area
Impact AQ-6 (CP3): Generation of Greenhouse Gases Project construction activities would result in a less than significant quantity of emission of GHGs. Project operations would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

This impact would be similar to Impact AQ-6 (CP1) for construction and operations. With implementation of CP3, increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and

estimated CO_2 emissions of 9,238 lb/day, as calculated with URBEMIS. The annual GHG emissions are estimated at 873 tons (approximately 792 MT) CO_2e.

Raising Shasta Dam by 18.5 feet and implementing the operational strategy for CP3 would result in a net increase in power generation of 54 GWh per year, as was shown in Table 5-7. Fossil-fuel generation of 54 GWh of energy would produce an estimated 48,500 MT of CO_2, also shown in Table 5-7. Thus, CP3 would reduce the need to build facilities for fossil-fueled generation of 17 GWh per year in the global study area.

CP3 would result in relatively small short-term emissions of GHGs for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam. The magnitude of the GHG "savings" for each year of operation, approximately 48,500 MT, would be greater than the potential annual construction emissions, which may be on the order of 10,000 MT from exhaust emissions and 8,163 MT from loss of carbon sequestered in existing vegetation. Further, construction emissions of 18,163 MT CO_2e per year would be less than the suggested significance threshold of 25,000 MT. It is concluded that the short-term impact would be less than significant, and that the overall net impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Shasta Lake and Vicinity

Impact AQ-1 (CP4): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction would result in short-term NO_X emissions that would exceed applicable SCAQMD thresholds, and could result in emissions that would exceed PM_{10} or ROG thresholds. This conclusion is based on calculations of estimated emissions for major elements of the project, and projection of additional emissions for other elements where calculation is not reasonable at the current level of project definition. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

This impact would be similar to Impact AQ-1 (CP3) and would be significant. Mitigation for this impact is proposed in Section 5.3.5.

Impact AQ-2 (CP4): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to

an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. This impact would be the same as Impact AQ-2 (CP1) for stationary and area sources and the same as Impact AQ-2 (CP3) for mobile sources. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-3 (CP4): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP4): Exposure of Sensitive Receptors to Odor Emissions Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact AQ-5 (CP4): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction The Gravel Augmentation Program proposed for areas along the upper Sacramento River would add to emissions of ROG, NO_X, and PM_{10} from project construction. Habitat restoration activities at Reading Island would also add ROG, NO_X, and PM_{10} emissions. However, these emissions separately and combined would add negligible amounts to annual emission levels. This impact would be less than significant.

The Gravel Augmentation Program proposed under CP4 would add an additional 1 lb/day of ROG, 16 lb/day of NO_X, and 1 lb/day of PM_{10} to project construction emission levels. Emissions from gravel augmentation would be from gravel material hauling consisting of approximately 18 trips per day, 40 miles round trip to sites identified to the south along the Sacramento River. Gravel augmentation would only occur for 2 months out of the year; therefore, these emissions would add negligible amounts to annual emission levels.

Habitat restoration at Reading Island proposed under CP4 would add an additional 6.7 lb/day of ROG, 50.1 lb/day of NO_X, and 12.4 lb/day of PM_{10} to project construction emission levels. During habitat restoration, emissions would be generated from removing vegetation from the Sacramento River's side channel, removing noxious invasive plant species from the island, minor

grading, and hauling away waste materials (approximately 25 trips per day). Restoration activities would occur for only 2 months for a total of 44 8-hour work days; therefore, these emissions would add negligible amounts to annual emission levels.

The combined emissions from the Gravel Augmentation Program and habitat restoration at Reading Island would be 7.7 lb/day of ROG, 76 lb/day of NO_X, and 13.4 lb/day of PM_{10}. These emissions are below SCAQMD's Level A thresholds of 25 lb/day of ROG, 25 lb/day of NO_X, and 80 lb/day of PM_{10}. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under CP4; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

Global Study Area

Impact AQ-6 (CP4): Generation of Greenhouse Gases Project construction activities would result in a less than significant quantity of emission of GHGs. Project operation would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

This impact would be similar to Impact AQ-6 (CP1) for construction and operations. With implementation of CP4, increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated CO_2 emissions of 9,238 lb/day, as calculated with URBEMIS. The annual GHG emissions are estimated at 872 tons (approximately 792 MT) CO_2e.

Raising Shasta Dam by 18.5 feet and implementing the operational strategy for CP4 would result in a net increase in power generation of 94 GWh per year (Table 5-7). Fossil-fuel generation of 94 GWh of energy would produce an estimated 83,400 MT CO_2 (Table 5-7). Thus, CP4 would reduce the need to build facilities for fossil-fueled generation of 17 GWh per year in the global study area.

CP4 would result in short-term emissions of GHGs for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam. The magnitude of the GHG "savings" for each year of operation, approximately 83,400 MT, would be greater than the potential annual construction emissions, which may be on the order of 10,000 MT from exhaust emissions and 8,163 MT from loss of carbon sequestered in existing vegetation. Further, construction emissions of 18,163 MT CO_2e per year would be less than the suggested significance threshold of 25,000 MT. It is concluded that the short-term impact would be less than significant, and that the

overall net impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Shasta Lake and Vicinity

Impact AQ-1 (CP5): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction would result in short-term NO_X emissions that would exceed applicable SCAQMD thresholds, and could result in emissions that would exceed PM_{10} or ROG thresholds. This conclusion is based on calculations of estimated emissions for major elements of the project, and projection of additional emissions for other elements where calculation is not reasonable at the current level of project definition. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

This impact would be similar to Impact AQ-1 (CP3) and would be significant. Mitigation for this impact is proposed in Section 5.3.5.

Impact AQ-2 (CP5): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. This impact would be the same as Impact AQ-2 (CP1) for stationary and area sources and similar to Impact AQ-2 (CP3) for mobile sources. With CP5, the annual increase in visitor days has not been estimated, as was shown in Table 5-5; however, visitor days are expected to surpass the 224,000 forecast for CP3 and CP4. For purposes of impact assessment, it was assumed that there would be an annual increase of 400,000 visitor days with CP5, resulting in 711 average daily trips. The associated daily emissions are shown in Table 5-10.

Based on the above analysis, operation of CP5 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD Level A thresholds. Consequently, long-term operational emissions would not violate an air quality standard or contribute substantially to an existing or projected air quality violation. As a result, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 5-10. Operations Emissions for Shasta Dam Raise, 2015 – CP5

Activity	Emissions—pounds per day				
	ROG	NO_X	CO	PM_{10}	$PM_{2.5}$
Vehicle trips for increase in recreational visitors	11	20	168	31	6
SCAQMD Level A significance thresholds	25	25	500	80	None
SCAQMD Level B significance thresholds	137	137	500	137	None

Source: Data compiled by EDAW (now AECOM) in 2008

Key:
CO = carbon monoxide
CP = Comprehensive Plan
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
SCAQMD = Shasta County Air Quality Management District

Impact AQ-3 (CP5): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP5): Exposure of Sensitive Receptors to Odor Emissions Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact AQ-5 (CP5): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction The Gravel Augmentation Program proposed for areas along the upper Sacramento River would add to emissions of ROG, NO_X, and PM_{10} from project construction. However, these emissions would add negligible amounts to annual emission levels. This impact would be less than significant.

This impact would be the same as Impact AQ-5 (CP4) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento

River and Delta and CVP/SWP service areas under CP5; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

Global Study Area

Impact AQ-6 (CP5): Generation of Greenhouse Gases Project construction activities would result in a less than significant quantity of emission of GHG. Project operation would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

This impact would be similar to Impact AQ-5 (CP1) for construction and for operations. With implementation of CP5, increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated CO_2 emissions of 16,503 lb/day, as calculated with URBEMIS. The annual GHG emissions are estimated at 1,560 tons (approximately 1,415 MT) CO_2e.

Raising Shasta Dam by 18.5 feet and implementing the operational strategy for CP5 would result in a net increase in power generation of 54 GWh per year, as was shown in Table 5-7. Fossil fuel generation of 54 GWh of energy would produce an estimated 48,500 MT CO_2, also shown in Table 5-7. Thus, CP5 would reduce the need to build facilities for fossil-fueled generation of 17 GWh per year in the global study area.

CP5 would result in short-term emissions of GHGs for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam. The magnitude of the GHG "savings" for each year of operation, approximately 48,500 MT, would be greater than the potential annual construction emissions, which may be on the order of 10,000 MT from exhaust emissions and 8,311 MT from loss of carbon sequestered in existing vegetation. Further, construction emissions of 18,311 MT CO_2e per year would be less than the suggested significance threshold of 25,000 MT. It is concluded that the short-term impact would be less than significant, and that the overall net impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

5.3.5 Mitigation Measures

Table 5-11 presents a summary of mitigation measures for air quality and climate.

Table 5-11. Summary of Mitigation Measures for Air Quality and Climate Change

		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact AQ-1: Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure AQ-1: Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact AQ-2: Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation	LOS before Mitigation	LTS	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS
Impact AQ-3: Exposure of Sensitive Receptors to Substantial Pollutant Concentrations	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact AQ-4: Exposure of Sensitive Receptors to Odor Emissions	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact AQ-5: Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction	LOS before Mitigation	NI	NI	NI	NI	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	NI	NI	NI	LTS	LTS
Impact AQ-6: Generation of Greenhouse Gases	LOS before Mitigation	LTS	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS

Notes:
LOS = level of significance
LTS = less than significant
NA = not applicable
NI = no impact
PS = potentially significant
SU = significant and unavoidable

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts AQ-2 (CP1), AQ-3 (CP1), AQ-4 (CP1), AQ-5, and AQ-6 (CP1). Mitigation is provided below for the remaining impact of CP1 on air quality.

Mitigation Measure AQ-1 (CP1): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels Reclamation (referred to below as "the project applicant" or "the applicant") and its primary construction contractor(s) will implement the mitigation measures listed below to reduce emissions of criteria air pollutants and precursors generated during construction.

Standard Mitigation Measures The following SCAQMD standard mitigation measures are applicable to all projects.

PM_{10} Controls

- Alternatives to open burning of vegetative material on the project site shall be used by the project applicant unless otherwise deemed infeasible by SCAQMD. Among suitable alternatives is chipping, mulching, or conversion to biomass fuel.

- The applicant shall be responsible for ensuring that all adequate dust control measures are implemented in a timely and effective manner during all phases of project development and construction.

- All material excavated, stockpiled, or graded shall be sufficiently watered to prevent fugitive PM_{10} dust emissions from leaving the property boundaries and causing a public nuisance or a violation of an ambient air standard. Watering shall occur at least twice daily with complete site coverage, preferably in the mid-morning and after work is completed each day.

- All areas (including unpaved roads) with vehicle traffic shall be watered periodically or dust palliatives applied for stabilization of fugitive PM_{10} dust emissions.

- All on site vehicles shall be limited to a speed of 15 miles per hour on unpaved roads.

- All land clearing, grading, earthmoving, or excavation activities on a project shall be suspended when winds are expected to exceed 20 miles per hour.

- All inactive portions of the development site shall be seeded and watered until a suitable grass cover is established.

- The applicant shall be responsible for applying Shasta County Department of Public Works–approved nontoxic soil stabilizers (according to manufacturers' specifications) to all inactive construction areas (previously graded areas that remain inactive for 96 hours) in accordance with the Shasta County Grading Ordinance.

- All trucks hauling dirt, sand, soil, or other loose material shall be covered or maintain at least 2 feet of freeboard (i.e., minimum vertical distance between top of the load and the trailer) in accordance with the requirements of California Vehicle Code Section 23114. This provision shall be enforced by local law enforcement agencies.

- All material transported off site shall be either sufficiently watered or securely covered to prevent a public nuisance.

- During initial grading, earthmoving, or site preparation, the project shall be required to construct a paved (or dust palliative–treated) apron, at least 100 feet in length, onto the project site from the adjacent paved road(s).

- Paved streets adjacent to the development site shall be swept or washed at the end of each day to remove excessive accumulations of silt and/or mud that may have accumulated as a result of activities on the development site.

- Adjacent paved streets shall be swept (water sweeper with reclaimed water recommended) at the end of each day if substantial volumes of soil materials have been carried onto adjacent public paved roads from the project site.

- Wheel washers shall be installed where project vehicles and/or equipment enter and/or exit onto paved streets from unpaved roads. Vehicles and/or equipment shall be washed before each trip.

- Before final occupancy, the applicant shall reestablish ground cover on the construction site through seeding and watering in accordance with the Shasta County Grading Ordinance.

Streets

- The project shall provide for temporary traffic control as appropriate during all phases of construction to improve traffic flow as deemed appropriate by the Shasta County Department of Public Works and/or the California Department of Transportation.

- Construction activities shall be scheduled that direct traffic flow to off-peak hours as much as practicable.

Energy Conservation For any new or relocated structures, the following features will be incorporated as much as practicable:

- The project shall provide for the use of energy-efficient lighting, including controls, and process systems such as water heaters, furnaces, and boiler units.

- The project shall use a central water heating system featuring the use of low-NO_X hot water heaters.

Best Available Mitigation Measures None of the SCAQMD BAMMs are appropriate for the project. Therefore, the following measures will be incorporated into the project:

- The project applicant will prepare and submit to SCAQMD for approval a plan demonstrating that the heavy-duty (equal to or greater than 50 horsepower) off-road vehicles to be used in the construction project, including owned, leased, and subcontractor vehicles, shall achieve a projectwide fleet-average 20 percent NO_X reduction and 45 percent particulate reduction compared to the most recent ARB fleet average at time of construction. Acceptable options for reducing emissions may include use of late-model engines, low-emission diesel products, alternative fuels, engine retrofit technology, after-treatment products, and/or other options as they become available.

- The project applicant will locate all construction equipment maintenance and staging areas at the farthest distance possible from nearby sensitive land uses.

- Idling of diesel-powered vehicles and equipment will not be permitted during periods of nonactive vehicle use. Diesel-powered engines will not be allowed to idle for more than 5 consecutive minutes in a 60-minute period when the equipment is not in use, occupied by an operator, or otherwise in motion, except under the following conditions:

  – When equipment is forced to remain motionless because of traffic conditions or mechanical difficulties over which the operator has no control

  – When it is necessary to operate auxiliary systems installed on the equipment, only when such system operation is necessary to accomplish the intended use of the equipment

- To bring the equipment to the manufacturer's recommended operating temperature
- When the ambient temperature is below 40ºF or above 85ºF
- When equipment is being repaired

Implementation of the above mitigation measure would reduce ROG, NO_X, and PM_{10} emissions from on-site heavy-duty equipment exhaust by approximately 5 percent, 20 percent, and 45 percent, respectively, and fugitive PM_{10} dust emissions by 75 percent. However, NO_X emissions generated during construction would still exceed the SCAQMD Level B threshold of 137 lb/day. Thus, this impact would be significant and unavoidable**.**

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts AQ-2 (CP2), AQ-3 (CP2), AQ-4 (CP2), AQ-5, and AQ-6 (CP2). Mitigation is provided below for the remaining impact of CP2 on air quality.

Mitigation Measure AQ-1 (CP2): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels This mitigation measure is identical to Mitigation Measure AQ-1 (CP1). For the reasons described above under Mitigation Measure AQ-1 (CP1), this impact would be significant and unavoidable.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impacts AQ-2 (CP3), AQ-3 (CP3), AQ-4 (CP3), AQ-5, and AQ-6 (CP3). Mitigation is provided below for the remaining impact of CP3 on air quality.

Mitigation Measure AQ-1 (CP3): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels This mitigation measure is identical to Mitigation Measure AQ-1 (CP1). For the reasons described above under Mitigation Measure AQ-1 (CP1), this impact would be significant and unavoidable.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts AQ-2 (CP4), AQ-3 (CP4), AQ-4 (CP4), AQ-5, and AQ-6 (CP4). Mitigation is provided below for the remaining impact of CP4 on air quality.

Mitigation Measure AQ-1 (CP4): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels This mitigation measure is identical to Mitigation Measure AQ-1 (CP1). For the reasons described above under Mitigation Measure AQ-1 (CP1), this impact would be significant and unavoidable.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts AQ-2 (CP5), AQ-3 (CP5), AQ-4 (CP5), AQ-5, and AQ-6 (CP5). Mitigation is provided below for the remaining impact of CP5 on air quality.

Mitigation Measure AQ-1 (CP5): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels This mitigation measure is identical to Mitigation Measure AQ-1 (CP1). For the reasons described above under Mitigation Measure AQ-1 (CP1), this impact would be significant and unavoidable.

5.3.6 Cumulative Effects

The effects of climate change on operations at Shasta Lake could potentially result in changes downstream. As described in the Climate Change Projection Appendix, climate change could result in higher reservoir releases in the future due to an increase in winter and early spring inflow into the lake from high intensity storm events. The change in reservoir releases could be necessary to manage for flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in downstream channel equilibrium.

Growth is likely to occur throughout the primary and extended study areas and some future projects are reasonably foreseeable, but substantial increases in emissions of criteria air pollutants or precursors in the primary and extended study areas are unlikely to make a cumulatively considerable contribution to an overall cumulatively significant impact on air quality. For cumulative effects of climate change on other resource areas, please see the "Cumulative Effects" sections in other chapters of this PDEIS.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Under the project alternatives (CP1–CP5), construction activities would result in short-term emissions of ROG, NO_X, and PM_{10} that without mitigation would exceed applicable SCAQMD thresholds. After implementing the best available and all feasible mitigation measures, ROG and PM_{10} emissions would not exceed applicable thresholds; and in combination with past, present, and reasonably foreseeable future projects, would not result in an overall cumulatively significant impact. Therefore, with mitigation, these emissions would not be cumulatively considerable. Emissions of NO_X, however, would still exceed the applicable SCAQMD threshold after implementation of the best available mitigation measures. These emissions would be cumulatively considerable, and this would be a cumulatively significant and unavoidable impact.

Operation of any of the action alternatives would not result in cumulatively considerable emissions of ROG, NO_X, and PM_{10}. Also, neither short-term construction nor long-term operational sources would expose sensitive receptors

to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, TACs, or odors. None of these emissions would be cumulatively considerable contributions to a significant cumulative impact of ROG, NO_X, and PM_{10}.

Lower Sacramento River and Delta and CVP/SWP Service Areas

The project alternatives would not generate any short-term or long-term air pollutant emissions in the extended study area. Therefore, there would be no cumulative air quality impact.

Global Study Area—Climate Change

As discussed in Section 5.1, "Affected Environment," of this chapter, climate change is a global phenomenon. All GHG emissions are considered cumulative. The impact analyses for Impacts AQ-6 (CP1), AQ-6 (CP2), AQ-6 (CP3), AQ-6 (CP4), and AQ-6 (CP5), in Section 5.3.4, "Direct and Indirect Effects," of this chapter are cumulative analyses. All five project alternatives (CP1–CP5) would result in short-term cumulative impacts that would be less than the suggested significance threshold for this cumulative effect, and therefore are considered to not make a cumulatively considerable incremental contribution to a significant cumulative impact, and would have beneficial long-term effects. For cumulative effects of climate change on other resource areas, please see the "Cumulative Effects" sections in other chapters of this PDEIS.

Chapter 6
Hydrology, Hydraulics, and Water Management

6.1 Affected Environment

The environmental setting section first presents background information and then describes storage and diversion facilities, and hydrology, hydraulics, and water management (H&H), including flood management, south Delta water levels, and groundwater resources. For a more in-depth description of the affected environment, see the *Hydraulics, Hydrology, and Water Management Technical Report*.

6.1.1 Storage Facilities

Facilities described below include Shasta Dam and Powerplant, Keswick Dam and Powerplant, Anderson-Cottonwood Irrigation District Diversion Dam, and Red Bluff Diversion Dam (RBDD).

Shasta Lake and Vicinity

This section describes storage facilities in the Shasta Lake area.

Shasta Dam and Powerplant Shasta Dam is a curved, gravity-type, concrete structure that rises 533 feet above the streambed with a total height above the foundation of 602 feet. The dam has a crest width of about 41 feet and a length of 3,460 feet. Shasta Reservoir has a storage capacity of 4,550,000 acre-feet, and water surface area at full pool of 29,600 acres. Maximum seasonal flood management storage space in Shasta Reservoir is 1.3 million acre-feet (MAF). Releases from Shasta Dam can be mad e through the power plant, over the spillway, or through the river outlets. The power plant has a maximum release capacity of nearly 20,000 cubic feet per second (cfs), the river outlets can release a maximum of 81,800 cfs at full pool, and the maximum release over the drum-gated spillway is 186,000 cfs.

Upper Sacramento River (Shasta Dam to Red Bluff)

This section describes storage facilities along the Upper Sacramento River.

Keswick Dam and Powerplant Keswick Dam is about 9 miles downstream from Shasta Dam. In addition to regulating outflow from the dam, Keswick Dam controls runoff from 45 square miles of drainage area. Keswick Dam is a concrete, gravity-type structure with a spillway over the center of the dam. The spillway has four 50- by 50-foot fixed wheel gates with a combined discharge capacity of 248,000 cfs at full or full pool elevation (587 feet). Storage capacity below the top of the spillway gates at full pool is 23,800 acre-feet. The

powerplant has a nameplate generating capacity of 105,000 kilowatts and can pass about 15,000 cfs at full pool.

6.1.2 Diversion Facilities

Below Keswick Dam, two diversion dams regulate flows on the Sacramento River, the Anderson-Cottonwood Irrigation District Diversion Dam and RBDD. The primary purpose of these two facilities is to divert water into canals for local agricultural use.

In the Delta, the CVP and SWP primarily make diversions through two pumping plants, the CVP C.W. "Bill" Jones (Jones) and SWP Harvey O. Banks (Banks) pumping plants. These two pumping plants supply water to the CVP/SWP service areas south of the Delta. While other diversion facilities are located between the RBDD and the Delta, they have less of an effect on project operations than those discussed above.

6.1.3 Hydrology and Hydraulics

The Sacramento Valley contains the Sacramento, Feather, and American River basins, covering an area of more than 24,000 square miles in the northern portion of the Central Valley. The Sacramento Valley encompasses three major drainage basins: the McCloud River, Pit River, and the Sacramento River in the north; the Delta in the south; the Sierra Nevada Mountains and Cascade Ranges in the east; and the Coast Range and Klamath Mountains in the west. Drainage in the northern portion of the Central Valley is provided by the Sacramento, Feather, and American Rivers, and major and minor streams and rivers that drain the east and west sides of the valley.

Shasta Lake and Vicinity

The most northern portion of the Sacramento River basin, upstream from Shasta Dam, is drained by the Pit River, the McCloud River, Squaw Creek, and the headwaters of the Sacramento River.

The four major tributaries to Shasta Lake are the Sacramento River, McCloud River, Pit River, and Squaw Creek, in addition to numerous minor tributary creeks and streams.

Upper Sacramento River (Shasta Dam to Red Bluff)

Flows in the Sacramento River in the 65-river-mile (RM) reach between Shasta Dam and Red Bluff (RM 244) are regulated by Shasta Dam and reregulated downstream at Keswick Dam (RM 302). In this reach, flows are influenced by tributary inflow. Major west side tributaries to the Sacramento River in this reach of the river include Clear and Cottonwood creeks. Major east side tributaries to the Sacramento River in this reach of the river include Battle, Bear, Churn, Cow, and Paynes creeks.

Lower Sacramento River and Delta

The Sacramento River enters the Sacramento Valley about 5 miles north of Red Bluff. From Red Bluff to Chico Landing (52 miles), the river receives flows from Antelope, Mill, Deer, Big Chico, Rock, and Pine creeks on the east side and Thomes, Elder, Reeds, and Red Bank creeks on the west side. From Chico Landing to Colusa (50 miles) the Sacramento River meanders through alluvial deposits between widely spaced levees. Stony Creek is the only major tributary in this segment of the river. There are no tributaries entering the Sacramento River between Stoney Creek and its confluence with the Feather River.

Floodwaters in the Sacramento River overflow the east bank at three sites in a reach referred to by the State as the Butte Basin Overflow Area. In this river reach, several Federal projects begin, including the Sacramento River Flood Control Project, Sacramento River Major and Minor Tributaries Project, and Sacramento River Bank Protection Project. Levees of the Sacramento River Flood Control Project begin in this reach, downstream from Ord Ferry on the west (RM 184), and downstream from RM 176 above Butte City on the east side of the river.

Shasta Reservoir is also operated to meet a flow requirement in the Sacramento River, at Wilkins Slough near Grimes (RM 125), also known as the Navigation Control Point. Downstream from Wilkins Slough, the Feather River, the largest east side tributary to the Sacramento River, enters the river just above Verona. Between Wilkins Slough and Verona, floodwater is diverted at two places in this segment of the river – Tisdale Weir into the Tisdale Bypass and Fremont Weir into the Yolo Bypass. The bypass system routes floodwater away from the mainstem Sacramento River to discharge into the Delta.

Below Verona, the Sacramento River flows 79 miles to the Delta, passing the City of Sacramento. The Yolo Bypass parallels this river reach to the west. Flows enter this river reach at various points. First, flows from the Natomas Cross Canal enter the Sacramento River approximately 1 mile downstream from the Feather River mouth. The American River flows into the Sacramento River in the City of Sacramento. When Sacramento River system flood flows are the highest, a portion of the flow is diverted into the Yolo Bypass at the Sacramento Weir about 3 miles upstream from the American River confluence in downtown Sacramento. At the downstream end, Yolo Bypass flows reenter the Sacramento River near Rio Vista. As the river enters the Delta, Georgiana Slough branches off from the mainstem of the Sacramento River, routing a portion of the flow into the central Delta.

The hydraulics of the Delta are complicated by tidal influences, a multitude of agricultural and municipal and industrial (M&I) diversions for use within the Delta itself, and by CVP and SWP exports. The principal factors affecting Delta hydrodynamics are (1) river inflow and outflow from the Sacramento River and San Joaquin River systems, (2) daily tidal inflow and outflow through San

Francisco Bay, and (3) export pumping from the south Delta, primarily through the Jones and Banks pumping plants.

The Jones Pumping Plant consists of six pumps, with a maximum export capacity of 4,600 cfs during the irrigation season, and 4,200 cfs during the winter nonirrigation season. Limitations at the Jones Pumping Plant are the result of a Delta-Mendota Canal freeboard constriction near O'Neill Forebay and current water demand in the upper sections of the Delta-Mendota Canal. The Jones Pumping Plant is at the end of an earth-lined intake channel about 2.5 miles long.

The SWP Banks Pumping Plant supplies water for the South Bay Aqueduct and the California Aqueduct, with an installed capacity of 10,300 cfs. Under current operational constraints, exports from Banks Pumping Plant are generally limited to a daily average of 6,680 cfs, except between December 15 and March 15, when exports can be increased by 33 percent of San Joaquin River flow. The Banks Pumping Plant exports water from the Clifton Court Forebay, a 31,000 acre-foot reservoir that provides storage for off-peak pumping, and moderates the effect of the pumps on the fluctuation of flow and stage in adjacent Delta channels.

Contra Costa Water District (CCWD) supplies CVP water to its users via a pumping plant at the end of Rock Slough. The Rock Slough diversion capacity of 350 cfs gradually decreases to 22 cfs at the terminus. CCWD also constructed and operates the 100,000 acre-foot Los Vaqueros Reservoir, which has an intake and pumping plant on the Old River for diverting surplus Delta flows to reservoir storage or contract water to CCWD users. Because tidal inflows are approximately equivalent to tidal outflows during each daily tidal cycle, tributary inflows and export pumping are the principal variables that define the range of hydrodynamic conditions in the Delta. Excess outflow occurs almost entirely during the winter and spring months. Average winter outflow is about 32,000 cfs, while the average summer outflow is 6,000 cfs.

CVP/SWP Service Areas

This section describes the hydrology and hydraulics of the CVP/SWP service areas south of the primary study area.

Downstream from the Jones Pumping Plant, CVP water flows in the Delta-Mendota Canal and can be either diverted by the O'Neill Pumping-Generating Plant into the O'Neill Forebay, or can continue down the Delta-Mendota Canal for delivery to CVP contractors. The O'Neill Pumping-Generating Plant consists of six pump-generating units, with a capacity of 700 cfs each.

The O'Neill Forebay is a joint CVP/SWP facility, with a storage capacity of about 56,000 acre-feet. In addition to its interactions with the Delta-Mendota Canal via the O'Neill Pumping-Generating Plant, it is a part of the SWP California Aqueduct. The O'Neill Forebay serves as a regulatory body for San

Luis Reservoir; the William R. Gianelli Pumping-Generating Plant, also a joint CVP/SWP facility, can pump flows from the O'Neill Forebay into San Luis Reservoir, and also make releases from San Luis Reservoir to the O'Neill Forebay for diversion to either the Delta-Mendota Canal or the California Aqueduct. Also, several water districts receive diversions directly from the O'Neill Forebay. The William R. Gianelli Pumping-Generating Plant consists of eight units, with 1,375 cfs of capacity each.

San Luis Reservoir provides offstream storage for excess winter and spring flows diverted from the Delta. It is sized to provide seasonal carryover storage, with a total capacity of 2,027,840 acre-feet. The CVP share of the storage is 965,660 acre-feet; the remaining 1,062,180 acre-feet are the SWP share. During spring and summer, water demands and schedules are greater than the capability of Reclamation and DWR to pump water from the Jones and Banks pumping plants; water stored in San Luis Reservoir is used to make up the difference. The CVP share of San Luis Reservoir is typically at its lowest in August and September, and at its maximum in April. The San Felipe Division of the CVP supplies water to customers in Santa Clara and San Benito counties from San Luis Reservoir. The operation of San Luis Reservoir has the potential to affect the water quality and reliability of these supplies if reservoir storage drops below 300 thousand acre-feet (TAF).

South of the O'Neill Forebay, the Delta-Mendota Canal terminates in the Mendota Pool, about 30 miles west of Fresno. From the Delta-Mendota Canal, the CVP makes diversions to multiple water users and refuges. Delta-Mendota Canal capacity at the terminus is 3,211 cfs. Parallel to the Delta-Mendota Canal, the San Luis Canal-California Aqueduct is a joint-use facility for the CVP and SWP. It begins on the southeast edge of the O'Neill Forebay and extends about 101.5 miles southeasterly to a point near Kettleman City. Water from the canal serves the San Luis Federal service area, mostly for agricultural purposes and for some M&I uses. The canal has a capacity ranging from 8,350 cfs to 13,100 cfs.

South of Banks Pumping Plant, the California Aqueduct flows into Bethany Reservoir, a 5,000-acre-foot forebay for the South Bay Pumping Plant. Exiting the Bethany Forebay, the California Aqueduct flows through a series of checks to the aforementioned O'Neill Forebay, and is either pumped into San Luis Reservoir or released to the San Luis Canal, the CVP/SWP joint-use portion of the California Aqueduct. Deliveries are made from the California Aqueduct to agricultural and M&I contractors.

6.1.4 Surface Water Supply

While water supply reliability is one of the two primary planning objectives of the SLWRI, operations for Shasta Reservoir are primarily focused on delivering water supply to CVP contractors. However, because of the interconnectivity of the CVP and SWP, water supply operations of the SWP could be affected by changes in operations of the CVP associated with the SLWRI.

CVP/SWP Service Areas

This section describes surface water supply to CVP and SWP contractors.

CVP Contractors At certain times of the year, operations of Shasta Reservoir are driven by water supply needs of the CVP contractors. The CVP provides water to settlement contractors in the Sacramento Valley, exchange contractors in the San Joaquin Valley, agricultural and M&I water service contractors in both the Sacramento and San Joaquin Valleys, and wildlife refuges both north and south of the Delta. At the beginning of each year, Reclamation evaluates hydrologic conditions throughout California and uses this information to forecast CVP operations, and to estimate the amount of water to be made available to the Federal water service contractors for the year.

The majority of the Federal water service contractors have service areas located south of the Delta. In general, allocations to CVP water service contractors south of the Delta are lower than allocations to service contractors in the Sacramento Valley. Because of water rights secured before construction of the CVP, Sacramento Valley settlement contractors and San Joaquin Valley exchange contractors have a higher level of reliability for their supplies; except in extremely dry years, when the water year type, as defined by the Shasta Hydrologic Index, is classified as critical, settlement and exchange contractors receive 100 percent of their contract amounts. In Shasta critical years, settlement and exchange contractors receive 75 percent of their contract amounts. A Shasta critical year is defined as a year when the total inflow to Shasta Reservoir is below 3.2 MAF, or the average inflow for a 2-year period is below 4.0 MAF and the total 2-year deficiency for deliveries is higher than 0.8.

SWP Contractors The CVP and SWP are intrinsically linked through the Delta; shared responsibilities under their respective water rights and coordinated operations agreements mean that a change in flow from one project could result in a flow change from the other. Accordingly, SWP water supply operations are discussed below.

The SWP operates under long-term contracts with public water agencies throughout California. These agencies, in turn, deliver water to wholesalers or retailers, or deliver it directly to agricultural and M&I water users (DWR 1999). The SWP contracts between DWR and individual State water contractors define several classifications of water available for delivery under specific circumstances.

6.1.5 Flood Management

This section describes major features of the flood management system in the primary and extended study areas, including reservoirs, levees, weirs, and bypasses. Historical operation of these facilities is also described.

Shasta Lake and Vicinity

Releases from Shasta Dam are often made for flood management. Releases for flood management either occur in the fall, beginning in early October, to reach the prescribed vacant flood space, or to evacuate space during or after a storm event to maintain the prescribed vacant flood space in the reservoir. During a storm event, releases for flood management occur either over the spillway during large events or through river outlets for smaller events. Between 1950 and 2006, flows over the spillway occurred in 12 years, or in 21 percent of years. During the same time interval, releases for flood management (either for seasonal space evacuation or during a flood event, and including spills over the spillway) occurred in about 37 years, or nearly 70 percent of the years.

Upper Sacramento River (Shasta Dam to Red Bluff)

Historically, the largest flood events along the upper Sacramento River have been from heavy rainfall, with a relatively smaller component of the flows coming from snowmelt in the upper basin. Flood management operations at Shasta Dam include forecasting runoff into Shasta Lake as well as runoff of unregulated creek systems downstream from Keswick Dam. A critical component of upper Sacramento River flood operations is the forecast of local runoff entering the Sacramento River between Keswick Dam and Bend Bridge near Red Bluff.

The unregulated creeks (major tributaries include Cottonwood, Cow, and Battle creeks) discharging into the Sacramento River between Keswick Dam and Bend Bridge can produce high runoff rates into the Sacramento River in short periods of time. During large flood events, the local runoff between Keswick Dam and Bend Bridge can exceed 100,000 cfs.

Lower Sacramento River and Delta

Flood management facilities along the lower Sacramento River and in the Delta include the levees, weirs, and bypasses of upper and lower Butte Basin, the Sacramento River between Colusa and Verona, and the Sacramento River between Verona and Collinsville. The levees, weirs, and bypasses are features of the Sacramento River Flood Control Project, which began operation in the 1930s and was significantly expanded in the 1950s.

When Sacramento River flows exceed between 90,000 and 100,000 cfs at Ord Ferry, water flows naturally over the banks of the river into Butte Basin. In addition to the Sacramento River overbank flows at Ord Ferry, the basin receives inflow over the Colusa and Moulton weirs and from tributary streams draining from the northeast, principally Cherokee Canal and Butte Creek. Before construction of the Feather River levees, Butte Basin also received overflows from the Feather River north of the Sutter Buttes. Outflows from Butte Basin move through the Sutter Bypass when the Sacramento River is high or through the Butte Slough outfall gates (RM 139) into the Sacramento River when the river is low.

The Sacramento River meanders through the 64 miles between Colusa (RM 143) and Verona (RM 79). The levee system continues along both sides of this river reach. The levee spacing (or channel width), east to west, is wider between the upstream sections, from RM 176 to RM 143 at Colusa, than the levee spacing downstream from Colusa. The Feather River, the largest east side tributary to the Sacramento River, enters the river just above Verona. Flood management diversions occur at two places in this segment of the river: at the Tisdale Weir and Fremont Weir.

Below Verona, the Sacramento River flows 79 miles to Collinsville, at the mouth of the Delta, passing the City of Sacramento along the way. The Yolo Bypass parallels this river reach to the west. Flows enter this river reach at various points. First, flows from the Natomas Cross Canal enter the Sacramento River approximately 1 mile downstream from the Feather River mouth (RM 80). The American River (RM 60), the southernmost major Sacramento River tributary, enters the river at the City of Sacramento. Flows in the Yolo Bypass reenter the river near Rio Vista (RM 12). As the river enters the Delta, Georgiana Slough branches off from the mainstream Sacramento River, routing flows into the central Delta. The one diversion point for flood management is at Sacramento Weir, where floodwaters are diverted from the Sacramento River through the Sacramento Bypass to the Yolo Bypass under the highest flow conditions.

CVP/SWP Service Areas

This section describes flood management facilities in the CVP/SWP service areas by river basin, including the Feather River, American River, San Joaquin River, and east side tributaries to the Delta (Littlejohns Creek, Calaveras River, and Mokelumne River).

The primary flood management feature of the Feather River basin is Oroville Reservoir, with a flood management reservation volume of 750 TAF. Oroville Reservoir releases are used to help meet the objective flow on the Feather River of 150,000 cfs, and in conjunction with New Bullards Bar Reservoir on the Yuba River, to meet an objective flow below the Yuba River confluence of 300,000 cfs. Levees line the Feather River from its confluence with the Sacramento River up to the City of Oroville (RM 63).

The lower American River is primarily protected from flooding by Folsom Dam. The Folsom Reservoir flood management reservation volume is variable, ranging from 400 TAF to 670 TAF. The objective release on the American River is 115,000 cfs; however, some damage to infrastructure along the American River occurs at flows above 20,000 cfs. The American River is leveed from its confluence with the Sacramento River to near the Carmichael Bluffs on the north bank, and to near the Sunrise Boulevard Bridge on the south bank (RM 19).

The San Joaquin River basin is protected by an extensive reservoir system, including the following:

- Friant Dam and Millerton Lake (RM 270), with a flood management reservation volume of 170 TAF.
- Big Creek Dam, on Big Creek, with a flood management reservation of 30.2 TAF.
- Hidden Dam and Hensley Lake on the Fresno River, with a flood management reservation of 65 TAF.
- Buchanan Dam and H.V. Eastman Lake on the Chowchilla River, with a flood management reservation of 45 TAF.
- Los Banos Detention Dam on Los Banos Creek, with a flood management reservation of 14 TAF.
- Merced County Stream Group Project, consisting of five dry dams (Bear, Burns, Owens, Mariposa, and Castle) and two diversion structures, with a total flood storage capacity of 30.5 TAF.
- New Exchequer Dam and Lake McClure on the Merced River, with a flood management reservation of 350 TAF.
- Don Pedro Dam and Lake on the Tuolumne River, with a flood management reservation of 340 TAF.
- New Melones Dam and Lake on the Stanislaus River, with a flood management reservation of 450 TAF.

The streams in the northern portion of the San Joaquin River basin, between the American and Stanislaus rivers, are commonly referred to as the eastside tributaries to the Delta. These rivers flow into the San Joaquin River within the boundaries of the Delta. Flood management features on the eastside tributaries to the Delta include the following:

- Farmington Dam and Reservoir on Littlejohns Creek, with a flood management reservation of 52 TAF.
- New Hogan Dam and Lake on the Calaveras River, with a flood management reservation of 165 TAF.
- Camanche Dam and Reservoir on the Mokelumne River, with a flood management reservation of 200 TAF.

6.1.6 South Delta Water Levels

This section discusses the variability of water levels in the south Delta, as part of CVP/SWP operations in the extended study area.

In the south Delta, decreases in water levels due to CVP and SWP export pumping are a concern for local agricultural diverters because during periods of low water levels, sufficient pump draft cannot be maintained and irrigation can be interrupted. Historically, the highest minimum stage in the Middle River typically occurs in February and is about 0.1 foot below mean sea level (msl). The lowest minimum stage typically occurs in August and is about 0.8 foot below msl. During dry and critical years, under existing conditions, the highest minimum stage in the Middle River typically occurs in April and is about 0.6 foot below msl. The lowest minimum stage typically occurs in September and is about 0.7 foot below msl (CALFED 2000a).

6.1.7 Groundwater Resources

The use and sustainable management of groundwater resources is an important component in meeting water demands in California. Information specific to groundwater resources includes groundwater levels and budget and groundwater quality.

Shasta Lake and Vicinity

Shasta Lake and vicinity are located in the foothill area northwest of the Redding groundwater basin. Small groundwater basins underlying Shasta Lake and vicinity do not have significant groundwater availability for use as a source of supply (Shasta County Water Agency 1998). Groundwater basins underlying Shasta County include the Fall River Valley groundwater basin, Lake Britton groundwater basin, and North Fork Battle Creek. Of these three groundwater basins, the Fall River Valley groundwater basin covers the largest area (54,800 acres) and groundwater extraction for agricultural use in this basin is the highest (approximately 19,000 acre-feet). Estimated groundwater extraction for M&I use in these subbasins ranges from 5 acre-feet to 240 acre-feet. Deep percolation from applied water is minor, ranging from 10 acre-feet to 4,800 acre-feet. Groundwater quality in Shasta Lake and vicinity is typically good. Total dissolved solids (TDS) concentrations in the Fall River Valley groundwater basin are low, ranging from 115 to 232 milligrams per liter (mg/L).

Upper Sacramento River (Shasta Dam to Red Bluff)

The upper Sacramento River study area extends from Redding to Red Bluff, and includes the Redding groundwater basin and the northern portion of the Sacramento groundwater basin.

The Redding groundwater basin underlies most of the upper Sacramento River area between Shasta Dam and Red Bluff. The basin is bordered on the north, east, and west by foothills, and on the south by the Sacramento Valley groundwater basin (Tehama GMP 1996). The foothill areas that constitute the eastern and western portions of Shasta and Tehama counties, adjacent to the

Redding groundwater basin, are designated as “highland” areas, noted for their relative scarcity of groundwater resources. DWR Bulletin 118 (2003b) subdivides the Redding groundwater basin into six subbasins: Anderson, Enterprise, Millville, Rosewood, Bowman, and South Battle Creek.

The Sacramento groundwater basin extends from the Redding groundwater basin to the San Joaquin Valley, and includes Tehama, Glenn, Butte, Yuba, Colusa, Placer, and Yolo counties.

In general, groundwater flows southeasterly on the west side of the Redding groundwater basin and southwesterly on the east side, toward the Sacramento River (Reclamation and DWR 2003). Historically, groundwater levels in the Redding groundwater basin have remained relatively stable, with no apparent long-term trend of declining or increasing levels. Generally, groundwater levels have a seasonal fluctuation of approximately 2 to 15 feet (Reclamation and DWR 2003). DWR has estimated the total quantity of groundwater storage in the Redding groundwater basin at approximately 6.9 MAF (Reclamation and DWR 2003).

In the northern portion of the Sacramento groundwater basin, the following three subbasins are included in upper Sacramento River study area: Red Bluff, Antelope, and Bend subbasins. Groundwater extraction in the Red Bluff subbasin is nearly 90,000 acre-feet.

Groundwater in the Redding area is of good quality, as shown by low TDS concentrations, ranging from 70 to 360 mg/L. This range is below the U.S. Environmental Protection Agency and California Environmental Protection Agency secondary drinking water standard of 500 mg/L and also below the agricultural water quality goal of 450 mg/L. Areas of high salinity and poor quality are generally found on the basin margins where groundwater is derived from marine sedimentary rock (Reclamation and DWR 2003).

Groundwater quality in the Sacramento groundwater basin is generally good, and sufficient for agricultural and M&I uses, with TDS levels ranging from 200 to 500 mg/L (Reclamation and DWR 2003). Localized groundwater quality issues occur as a result of natural water quality impairments at the north end of the Sacramento Valley, where marine sedimentary rocks containing brackish to saline water are near the surface (Reclamation and DWR 2003).

Lower Sacramento River and Delta

The groundwater basins underlying the lower Sacramento River and Delta areas include the Sacramento Valley groundwater basin, and North and South San Joaquin Valley groundwater basins.

In the Sacramento groundwater basin, groundwater flows inward from the edges of the basin and south parallel to the Sacramento River. Groundwater extraction in some local areas resulted in groundwater depressions and local groundwater

gradients (Reclamation and DWR 2003). Before the completion of CVP facilities (1964 through 1971), pumping along the west side of the basin caused groundwater levels to decline. In the Sacramento groundwater basin, a slight decline of 2 to 12 feet was experienced in groundwater levels as a result of the 1976 through 1977 and 1987 through 1994 droughts. This was followed by a recovery to predrought conditions of the early 1970s and 1980s. Generally, groundwater level data show an average seasonal fluctuation ranging from 2 to 15 feet. Groundwater production in the basin increased from 500,000 acre-feet in the 1940s to 2 MAF annually in the mid-1990s.

As mentioned, groundwater quality in the Sacramento groundwater basin is generally good, and sufficient for agricultural and M&I uses, with TDS levels ranging from 200 to 500 mg/L (Reclamation and DWR 2003).

CVP/SWP Service Areas

The groundwater basins underlying the CVP/SWP service areas include the San Joaquin Valley, Santa Clara Valley, Antelope Valley, Fremont Valley, Coastal Plain of Los Angeles, and Coastal Plain of Orange County groundwater basins, and multiple other smaller groundwater basins underlying areas that receive water from the CVP/SWP system.

The San Joaquin Valley Groundwater Basin is a regional basin and is the largest in California, extending approximately from the Delta to Bakersfield. Areas within the San Joaquin Valley Groundwater Basin are heavily groundwater-reliant. Groundwater accounts for about 30 percent of the annual supply used for agricultural and urban purposes (Reclamation and DWR 2003). Groundwater production in the north San Joaquin Valley Groundwater Basin alone increased from 1.5 MAF annually in the 1920s to more than 3.5 MAF annually in 1990 (Reclamation and DWR 2003). In the south San Joaquin Valley Groundwater Basin, groundwater production for agriculture rose from approximately 3.0 MAF per year in the 1920s to more than 5.0 MAF per year 1980s (Reclamation and DWR 2003). Much of the San Joaquin groundwater basin is in overdraft conditions due to extensive groundwater pumping and irrigation, although the extent of overdraft varies widely from region to region.

Groundwater quality throughout the San Joaquin Valley is in general suitable for most urban and agricultural uses. Average TDS concentrations range from 218 to 1,190 mg/L. Areas of high TDS concentration, primarily along the west side of the San Joaquin Valley, are the result of streamflow recharge that originates from marine sediments. High TDS concentrations are also seen in the trough of the Sacramento Valley due to concentration of salts resulting from evaporation and poor drainage (Reclamation and DWR 2003). Agricultural pesticides and herbicides have been detected in groundwater throughout the region, but primarily along the east side of the San Joaquin Valley, where soil permeability is higher and depth to groundwater is shallower. From 1994 to 2000, 523 public wells out of 689 wells sampled met the State primary maximum contamination levels for drinking water. The remaining wells have

constituents that exceed one or more maximum contamination levels (Reclamation and DWR 2003).

6.2 Regulatory Setting

The regulatory setting for this report includes Federal, State, and local applicable laws, regulations, standards, and plans.

6.2.1 Federal

The following Federal laws, regulations, standards, and plans are discussed as part of the regulatory setting:

- NMFS 1993 and 2004 Winter-Run Chinook salmon Biological Opinion (BO) (NMFS 1993, NMFS 2004)
- Central Valley Project Improvement Act (CVPIA) (Reclamation 1999)
- CVP long-term water service contracts
- Trinity River Record of Decision (ROD) (Reclamation 2000)
- Flow objective for navigation (Wilkins Slough)
- Flood management requirements

National Marine Fisheries Service 2004 Biological Opinion

The regulatory conditions for the SLWRI alternatives include BOs from the NMFS (2004) and USFWS (2005). In response to litigation, the 2004 and 2005 BOs were remanded to the USFWS and NMFS for revision, but were not vacated. The USFWS and NMFS released revised BOs in 2008 and 2009 (USFWS 2008, NMFS 2009), respectively; since the revised BOs continue to be locked in controversy and litigation, the 2004 and 2005 BOs are assumed to be govern operations for SLWRI analysis. Further revised BOs are anticipated before the release of the final version of this document; final analysis will consider conditions dictated by the BOs in place at that time.

In October 2004, NMFS issued the Long-Term BO for operation of the CVP and SWP for Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, and Central Valley steelhead (NMFS 2004). The BO includes a Reasonable and Prudent Alternative (RPA) that addresses CVP operations criteria for temperature control objectives. The Shasta-Trinity Division section of the 2004 RPA includes operational elements relating to temperature control objectives, as described in this section.

Under the current RPA, Reclamation must make its February 15 forecast of deliverable water based on an estimate of precipitation and runoff at least as

conservative as the 90 percent probability-of-exceedence forecast. Subsequent updates of water delivery commitments must also be based on the 90 percent probability of exceedence forecast or a more conservative value.

Under the current RPA, Reclamation must target a minimum end-of-water-year (September 30) carryover storage in Shasta Reservoir of 1.9 MAF. The 1.9 MAF Shasta Reservoir carryover target is intended to increase the probability of sufficient cold-water resources to maintain suitable water temperature conditions for the following water year winter-run incubation and spawning season needs.

The BO requires that Reclamation manage the cold-water supply within Shasta Reservoir and make cold-water releases from Shasta Reservoir to provide suitable habitat between Keswick Dam and Bend Bridge. Reclamation was instructed to target daily average Sacramento River water temperatures between Keswick Dam and Bend Bridge such that water temperatures not exceed 56 degrees Fahrenheit (°F) at compliance locations between Balls Ferry and Bend Bridge from April 15 through September 30, and not exceed 60°F at the same locations between Balls Ferry and Bend Bridge between October 1 and October 31, provided operations and temperature forecasts demonstrate the capability to achieve and sustain compliance. If conditions were not sufficient to support compliance at Balls Ferry, Reclamation was instructed to reinitiate consultation and convene the Sacramento River Temperature Task Group (SRTTG) to provide input regarding annual cold-water management alternatives before announcement of the CVP water service delivery allocations. Selection of downstream compliance locations is determined through an annual adaptive management process initiated by Reclamation in consultation with NMFS, with recommendations from the SRTTG, and based on a technical assessment of cold-water resources. The annual adaptive management process focuses efforts to analyze annual cold-water management flexibility to provide thermal protection to winter-run Chinook salmon, spring-run Chinook salmon, and steelhead, as envisioned in the State Water Resources Control Board (SWRCB) Order 90-5. The initial technical analysis considers the compliance location shown in Table 6-1, based on projected cold-water availability and spawning distribution in the upper Sacramento River (NMFS 2004).

Table 6-1. Relationship Between Shasta Cold-Water Volume and Sacramento River Water Temperature Compliance Location

May 1, Shasta Reservoir Cold-Water Volume Below 52°F	Compliance Location
<3.3 MAF	Balls Ferry
>3.3 MAF but <3.6 MAF	Jellys Ferry
>3.6 MAF	Bend Bridge

Key:
°F = degrees Fahrenheit
MAF = million acre-feet

In almost every year since 1993, Reclamation has reconsulted with NMFS to modify the compliance point or allow short-term fluctuation above the 56°F objective because of insufficient cold-water resources, extreme ambient air temperature events, or high downstream tributary flows of warm water. The reconsultation actions have been coordinated through the SRTTG to the extent possible. Decisions by Reclamation to reconsult, and resulting decisions by NMFS, have reflected the best available information on cold-water resources and locations of Chinook salmon spawning activity.

Central Valley Project Improvement Act

Reclamation's evolving mission was written into law on October 30, 1992, with the passage by Congress, and signing by President George H. W. Bush, of Public Law 102-575, the Reclamation Projects Authorization and Adjustment Act of 1992. Included in the law was Title 34, the CVPIA (Reclamation 1999). The CVPIA amended previous authorizations of the CVP to include fish and wildlife protection, restoration, and mitigation as project purposes having equal priority with irrigation and domestic water supply uses, and fish and wildlife enhancement having equal priority with power generation. Among the changes mandated by the CVPIA are the following:

- Dedicating 800,000 acre-feet annually to fish, wildlife, and habitat restoration.
- Authorizing water transfers outside the CVP service area.
- Implementing the Anadromous Fish Restoration Program.
- Creating a restoration fund financed by water and power users.
- Providing for the Shasta Dam temperature control device (TCD).
- Implementing fish passage measures at the RBDD.
- Planning to increase the CVP yield.
- Mandating firm water supplies for Central Valley wildlife refuges.
- Meeting Federal trust responsibility to protect fishery resources on the Trinity River.

The CVPIA is being implemented on a broad front. The Final Programmatic Environmental Impact Statement (Reclamation 1999) for the CVPIA analyzes projected conditions in 2022, 30 years from the CVPIA's adoption in 1992. The Final Programmatic Environmental Impact Statement was released in October 1999, and the CVPIA ROD was signed on January 9, 2001.

Operations of the CVP reflect provisions of the CVPIA, particularly Sections 3406 (b)(1), (b)(2), and (b)(3). The Department of the Interior Decision on Implementation of Section 3406 (b)(2) of the CVPIA, October 5, 1999, provides the basis for implementing upstream and Delta actions with CVP delivery capability. The Vernalis Adaptive Management Program assumes that San Joaquin River water will be acquired under Section 3406 (b)(3) to support increased Vernalis flows during certain times of the year. Similarly, the Anadromous Fish Restoration Program assumes Sacramento River water will be acquired under Section 3406 (b)(2).

Central Valley Project Long-Term Water Service Contracts

In accordance with CVPIA Section 3404c, Reclamation is renegotiating long-term water service contracts. As many as 113 CVP water service contracts located within the Central Valley of California may be renewed during this process. Reclamation issued a Notice of Intent for long-term contract renewal in October 1998. Environmental documentation was prepared on a regional basis. In February 2005, Reclamation issued decisions (a ROD or Finding of No Significant Impact) for renewing contracts of the Sacramento River, San Luis, and Delta-Mendota Canal divisions, the Sacramento River settlement contracts, and several individual contracts. Preparation of environmental documents for other divisions and contracts is ongoing.

Trinity River Record of Decision

Export of Trinity River water to the Sacramento basin provides increased water supply for the CVP and is a major source of CVP power generation. The amounts and timing of the Trinity exports are determined after consideration is given to forecasted Trinity water supply available and Trinity in-basin needs, including carryover storage. Trinity exports are also a key component of water temperature control operations on the upper Sacramento River.

Based on the December 19, 2000, Trinity River Mainstem ROD (Reclamation 2000), 368.6 to 815 TAF are allocated annually for Trinity River flows. After several challenges and injunctions, on July 13, 2004, the Ninth Circuit Court upheld the ROD flows for the Trinity River.

Flow Objective for Navigation (Wilkins Slough)

Historical commerce on the Sacramento River resulted in the requirement to maintain minimum flows of 5,000 cfs at Chico Landing to support navigation. There is currently no commercial traffic between Sacramento and Chico Landing, and USACE has not dredged this reach to preserve channel depths since 1972. However, long-time water users diverting from the river have set their pump intakes just below this level. Therefore, the CVP is operated to meet the navigation flow requirement of 5,000 cfs to Wilkins Slough under all but the most critical water supply conditions to facilitate pumping.

At flows below 5,000 cfs at Wilkins Slough, diverters have reported increased pump cavitation as well as greater pumping head requirements. Diverters

operate for extended periods at flows of 4,000 cfs at Wilkins Slough, but pumping operations are severely affected and some pumps become inoperable at flows lower than 4,000 cfs. Flows may drop as low as 3,500 cfs for short periods while changes are made in Keswick releases to reach target levels at Wilkins Slough, but using the 3,500 cfs rate as a target level for an extended period would have major impacts on diverters.

No criteria have been established that specify when the navigation minimum flow should be relaxed. However, the basis for Reclamation's decision to operate at less than 5,000 cfs is the increased importance of conserving water when water supplies are not sufficient to meet full contractual deliveries and other operational requirements.

Flood Management Requirements

Shasta Dam provides flood protection to the nearby communities of Redding, Anderson, Red Bluff, and Tehama, as well as to agricultural lands, industrial developments, and communities downstream along the Sacramento River. Shasta Dam is operated for an objective release of 100,000 cfs at Bend Bridge in Red Bluff, subject to consideration of the following:

- Releases are not to be increased more than 15,000 cfs or decreased more than 4,000 cfs in any 2-hour period.

- The 2,500-square-mile uncontrolled drainage area between Keswick Dam and Bend Bridge can produce flows well in excess of the design channel capacity of 100,000 cfs. These high-magnitude flows can occur very rapidly, requiring release changes based on official flow forecasts, and are complicated by the 8- to 12-hour travel time between Keswick Dam and Bend Bridge.

- Recently installed gages on major east side tributaries (Cow, Battle, and Paynes creeks) between Keswick Dam and Red Bluff are very helpful in coordinating operations of Shasta Dam and Reservoir with flows from uncontrolled downstream areas. The most critical flood forecast for the Sacramento River is that of local runoff entering the Sacramento River between Keswick Dam and Bend Bridge. As the Bend Bridge flow is projected to recede, Keswick Dam releases are increased to evacuate water stored in the flood management space in Shasta Reservoir.

The following constraints are considered when making release changes at Keswick Dam:

- The maximum capacity of the Shasta Powerplant is about 18,000 cfs, but this varies considerably with head. Maximum powerplant release is required when Shasta Reservoir storage encroaches on the flood

management space by 25 percent or less, with actual or forecasted inflows of 40,000 cfs or less.

- The capacity of the Keswick Powerplant is about 16,000 cfs, which represents a maximum release rate when no flood management space is being used. The Keswick Dam release must include discharge from the Spring Creek Powerplant, releases from Spring Creek Debris Dam, and local flows into Keswick Reservoir.

- Flows greater than 36,000 cfs begin to cause flood coordination efforts in the local Redding area to close riverfront roads and parks. These coordination efforts require some advance notice to increase Keswick releases above this rate.

All outflows from Shasta Dam flow into and through Keswick Reservoir, located about 5 miles west of Redding. Keswick Reservoir also receives inflow from the 45-square-mile drainage area of Whiskeytown Reservoir on Clear Creek.

Flood Management Space Requirements Shasta Reservoir capacity is 4,552 TAF, with a maximum objective release capacity of 79,000 cfs. The end-of-September storage target for Shasta Reservoir is 1,900 TAF, except in the driest 10 percent of water years, to conserve sufficient cold water for meeting temperature criteria for the winter-run Chinook incubation period (summer to early fall). Storage levels are lowest by October to provide sufficient flood protection and capture capacity during the following wet months. The storage target gradually increases from October to full pool in May. Storage is then withdrawn for high water demand (i.e., municipal, agricultural, fishery, and water quality uses) during summer.

A storage space of up to 1.3 MAF below a full pool elevation of 1,067 feet is also kept available for flood management purposes in the reservoir in accordance with the Shasta Dam and Lake Flood Control Diagram (USACE 1977) , as prescribed by USACE (USACE 1977) (see Exhibit B to the *Hydrology, Hydraulics, and Water Management Technical Report*). Under the diagram, flood management storage space increases from zero on October 1 to 1.3 MAF (elevation 1,018.55) on December 1 and is maintained until December 23. From December 23 to June 15, the required flood management space varies according to parameters based on the accumulation of seasonal inflow. This variable space allows for the storage of water for conservation purposes, unless it is required for flood management based on basin wetness parameters and the level of seasonal inflow. Daily flood management operation consists of determining the required flood storage space reservation, and scheduling releases in accordance with flood operations criteria.

Objective Flow The current regulation of Shasta Dam for flood management requires that releases be restricted to quantities that will not cause downstream

flows or stages to exceed, insofar as possible, (1) a flow of 79,000 cfs at the tailwater of Keswick Dam and (2) a stage of 39.2 feet for the Sacramento River at the Bend Bridge gaging station near Red Bluff (corresponding roughly to a flow of 100,000 cfs).

Tributary Inflows Shasta Lake collects flow in the upper Sacramento River watershed, but many uncontrolled tributaries enter the Sacramento River downstream from the dam. Stream gages have been added to major uncontrolled tributaries entering downstream from Shasta Lake (Cow, Battle, Cottonwood, and Thomes creeks). To a limited extent, operators of Shasta Dam can adjust releases containing these uncontrolled flows to try to reduce downstream peak flows. Accordingly, the influence of Shasta Dam and Reservoir operation on reducing peak flood flows diminishes downstream on the Sacramento River.

6.2.2 State

The following State laws, regulations, standards, and plans are discussed as part of the regulatory setting:

- SWRCB Orders 90-05 and 91-01
- 1960 DFG-Reclamation Memorandum of Agreement (DFG 1960)
- Water Quality Control Plan (WQCP) for the San Francisco Bay/San Joaquin Delta Estuary (SWRCB 1995)
- SWRCB Revised Water Right Decision 1641 (RD-1641) (SWRCB 2000)
- Coordinated Operations Agreement (COA) (Reclamation and DWR 1986)
- Groundwater regulations

State Water Resources Control Board Orders 90-05 and 91-1

In 1990 and 1991, SWRCB issued Water Right Orders 90-05 and 91-01 modifying Reclamation's water rights for the Sacramento River. The orders included a narrative water temperature objective for the Sacramento River, and stated that Reclamation shall operate Keswick and Shasta dams and the Spring Creek Powerplant to meet a daily average water temperature of 56°F at the RBDD in the Sacramento River during periods when higher temperatures would be harmful to fisheries.

Under the orders, the water temperature compliance point may be modified when the objective cannot be met at the RBDD. The SRTTG, a multiagency group, develops temperature operational plans for the Shasta and Trinity divisions of the CVP pursuant to SWRCB Water Rights Orders 90-5 and 91-1. These temperature plans consider the impacts to winter-run Chinook salmon

and other races of Chinook salmon from project operations. Previous plans have included releases of water from the low-level outlets at Shasta Dam and Trinity Dam, operation of the TCD, warm water releases, and manipulating the timing of Trinity River diversions through the Spring Creek Powerplant. Warm water releases from the upper level outlets have been made to conserve cold water in Shasta Lake for temperature control in the late summer and to induce winter-run Chinook salmon to spawn as far upstream as possible. The SRTTG typically first meets in the spring once the cold-water availability in Shasta Lake is known. In every year since the SWRCB issued the orders, those plans have included modifying the RBDD compliance point to make the best use of the cold-water resources based on the location of spawning Chinook salmon (NMFS 2004).

The water right orders also recommended construction of a TCD to improve management of the limited cold-water resources. Reclamation constructed the TCD on Shasta Dam in 1997. This device releases cool water from Shasta Lake through low-level river outlets that bypass the power plant. The TCD provides flexibility to Shasta Dam operations and allows downstream temperature goals to be consistently achieved (Reclamation 2004).

Reclamation operates the Shasta, Sacramento River, and Trinity River divisions of the CVP to meet, to the extent possible, the provisions of SWRCB Order 90-05 and 91-01 and the NMFS 2004 Operations Criteria and Plan BO, shown as in Table 1-33.

1960 California Department of Fish and Game-Reclamation Memorandum of Agreement

An April 5, 1960, Memorandum of Agreement between DFG and Reclamation (DFG 1960) originally established flow objectives in the Sacramento River for the protection and preservation of fish and wildlife resources. The agreement provided for minimum releases into the natural channel of the Sacramento River at Keswick Dam for normal and critically dry years. Since October 1981, Keswick Dam has been operated based on a minimum release of 3,250 cfs for normal years from September 1 through the end of February, in accordance with an agreement between DFG and Reclamation. This release schedule was included in Order 90-05, which maintains a minimum release of 3,250 cfs at Keswick Dam and the RBDD from September through the end of February in all water years, except critically dry years.

Water Quality Control Plan for the San Francisco Bay/San Joaquin Delta Estuary

The 1995 Bay-Delta WQCP (SWRCB 1995) established water quality control objectives for the protection of beneficial uses in the Delta. The 1995 WQCP identified (1) beneficial uses of the Delta to be protected, (2) water quality objectives for the reasonable protection of beneficial uses, and (3) a program of implementation for achieving the water quality objectives. Because these new beneficial objectives and water quality standards were more protective than

those of the previous SWRCB Water Right Decision 1485, the new objectives were adopted in 1995 through a water right order for operation of the CVP and SWP. Key features of the 1995 WQCP include estuarine habitat objectives for Suisun Bay and the western Delta (consisting of salinity measurements at several locations), export/inflow (E/I) ratios intended to reduce entrainment of fish at the export pumps, Delta Cross Channel gate closures, and San Joaquin River electrical conductivity (EC) and flow standards. The SWRCB adopted a new Bay-Delta WQCP on December 13, 2006. However, this new WQCP made only minor changes to the 1995 WQCP.

State Water Resources Control Board Revised Water Right Decision 1641

The 1995 Bay-Delta WQCP contains current water quality objectives. SWRCB RD-1641 (SWRCB 2000) and Water Right Order 2001-05 contain the current water right requirements to implement the 1995 WQCP. RD-1641 incorporates water right settlement agreements between Reclamation and DWR and certain water users in the Delta and upstream watersheds regarding contributions of flows to meet water quality objectives. However, SWRCB imposed terms and conditions on water rights held by Reclamation and DWR that require these two agencies, in some circumstances, to meet many of the water quality objectives established in the 1995 WQCP. RD-1641 also authorizes the CVP and SWP to use joint points of diversion (JPOD) in the south Delta, and recognizes the CALFED Bay-Delta Program (CALFED) Operations Coordination Group process for operational flexibility in applying or relaxing certain protective standards.

Delta Outflow Requirement Delta outflow, inflow that is not exported or diverted, is the primary factor controlling water quality in the Delta. When Delta outflow is low, seawater is able to intrude further into the Delta, impacting water quality at drinking water intakes. RD-1641 specifies minimum monthly Delta outflow objectives to maintain a reasonable range of salinity in the estuarine aquatic habitat based on the Net Delta Outflow Index (NDOI). The NDOI is a measure of the freshwater outflow and is determined from a water balance that considers river inflows, precipitation, agricultural consumptive demand, and project exports. The NDOI does not take into account the semidiurnal and spring-neap tidal cycles.

The monthly minimum values of the NDOI specified in RD-1641 depend on the water year type. Minimum flows are specified for the months of January and July to December. The outflow objectives from February to June are determined based on the X2[1] objective.

Delta Salinity Objectives Salinity standards for the Delta are stated in terms of EC (for protection of agricultural and fish and wildlife beneficial uses), and chloride (for protection of M&I uses). Compliance values vary with water year

[1] X2 is the most downstream location of either the maximum daily average or the 14-day running average of 2.64 millimhos per centimeter (mmhos/cm) isohaline, as measured in river kilometers from the Golden Gate Bridge.

and month. The salinity objectives at Emmaton on the Sacramento River, and at Jersey Point on the San Joaquin River, often control Delta outflow requirements during the irrigation season from April through August, requiring additional releases from upstream CVP and SWP reservoirs.

X2 Objective The location of X2, the 2 parts per thousand salinity unit isohaline at 1 meter above the bottom of the Sacramento River channel, is used as a surrogate measure of ecosystem health in the Delta. The X2 objective requires specific daily surface EC criteria to be met for a certain numbers of days each month, from February through June. Compliance can also be achieved by meeting a 14-day running average salinity or 3-day average outflow equivalent. These requirements were designed to provide improved shallow water habitat for fish species in the spring. Because of the relationship between seawater intrusion and interior Delta water quality, the X2 objective also improves water quality at Delta drinking water intakes.

Maximum Export/Inflow Ratio RD-1641 includes a maximum E/I standard to limit the fraction of Delta inflows that are exported. This requirement was developed to protect fish species and to reduce entrainment losses. Delta exports are defined as the combined pumping of water at Banks and Jones pumping plants. Delta inflows are the gaged or estimated river inflows. The maximum E/I ratio is 0.35 for February through June and 0.65 for the remainder of the year. If the January eight-river runoff index is less than 1.0 MAF, the February E/I ratio is increased to 0.45. The CVP and SWP have agreed to share the allowable exports equally if the E/I ratio is limiting exports.

Joint Point of Diversion The JPOD refers to the CVP and SWP use of each other's pumping facilities in the south Delta to export water from the Delta. The CVP and SWP have historically coordinated use of Delta export pumping facilities to assist with deliveries and to aid each other during times of facility failures. In 1978, by agreement with DWR, and with authorization from SWRCB, the CVP began using the SWP Banks Pumping Plant for replacement pumping (195 TAF per year) for pumping capacity lost at Jones Pumping Plant because of striped bass pumping restrictions in SWRCB Water Right Decision 1485. In 1986, Reclamation and DWR formally agreed that "either party may make use of its facilities available to the other party for pumping and conveyance of water by written agreement" and that the SWP would pump CVP water to make up for striped bass protection measures (Reclamation and DWR 1986).

Reclamation filed a number of temporary petitions with SWRCB to use Banks Pumping Plant for purposes other than replacement pumping and CVP deliveries that contractually relied on SWP conveyance. Such uses included deliveries to Cross Valley Contractors, the Musco Olive Company, and the San Joaquin National Cemetery. In RD-1641, the SWRCB conditionally approved the use of the JPOD in three separate stages:

- Stage 1 is the use of the JPOD to serve Cross Valley Canal contractors, the Musco Olive Company and the San Joaquin National Cemetery; to support a recirculation study; and to recover export reductions made to benefit fish. Authorization for Stage 1 JPOD pumping to recover export reductions prohibits the CVP and SWP from annually exporting more water than each would have exported without the use of each other's pumping facilities. Stage 1 pumping is subject to SWRCB approval of a water level response plan, and a water quality response plan.

- Stage 2 is the use of the JPOD for any purpose authorized in the water rights permits up to the limitations contained in the USACE permit. In addition to the Stage 1 requirements, Stage 2 pumping is subject to SWRCB approval of an operations plan to protect aquatic resources and other legal users of water.

- Stage 3 is the use of the JPOD for any purpose authorized under the water right permits up to the physical capacity of the export pumps. Stage 3 is subject to the operation of barriers or other means to protect water levels in the south Delta, an SWRCB-approved operations plan that adequately protects aquatic resources and other legal users of water, and certification of a project-level Environmental Impact Report by DWR for the South Delta Improvements Program.

It has been the policy of SWRCB that all water transfers must meet similar criteria and conditions, as set forth for the JPOD, and SWRCB has mandated a "response plan" evaluation process for real-time incremental export operations to determine the effects of water transfers and JPOD operations. SWRCB approval of the 2006 and 2007 Accord Pilot Programs included the provision that rediversion of transfer water at Banks and Jones pumping plants must be in compliance with the various plans under RD-1641 that are prerequisites for the use of the JPOD by Reclamation and DWR.

Reclamation and DWR have produced the following response plans:

- Water Level Response Plan to address incremental effects of additional export, at the time of the export, to water levels in the south Delta environment (Reclamation and DWR 2004a).

- Water Quality Response Plan to address incremental effects of additional export, at the time of the export, to water quality in the Delta, and south Delta specifically (Reclamation and DWR 2004b).

- Operations Plan to protect fish and wildlife, and other legal uses of water.

Coordinated Operations Agreement

The COA defines how Reclamation and DWR share their joint responsibility to meet Delta water quality standards and the water demands of senior water right holders, and how the two agencies share surplus flows (Reclamation and DWR 1986). The COA defines the Delta as being in either "balanced water conditions" or "excess water conditions." Balanced water conditions are periods when Delta inflows are just sufficient to meet water user demands within the Delta, outflow requirements for water quality and flow standards, and export demands. Under excess water conditions, Delta outflow exceeds the flow required to meet the water quality and flow standards. Typically, the Delta is in balanced water conditions from June to November, and in excess water conditions from December through May. However, depending on the volume and timing of winter runoff, excess or balanced water conditions may extend throughout the year.

With the goal of using coordinated management of surplus flows in the Delta to improve Delta export and conveyance capability, the COA received Congressional approval in 1986 and became Public Law 99-546. The COA, as modified by interim agreements, coordinates operations between the CVP and SWP, and provides for the equitable sharing of surplus water supply. The COA requires that the CVP and SWP operate in conjunction to meet State water quality objectives in the San Francisco Bay/Sacramento-San Joaquin River Delta (Bay-Delta) estuary, except as specified. Under this agreement, the CVP and SWP can each contract from the other for the purchase of surplus water supplies, potentially increasing the efficiency of water operations.

Since 1986, the COA principles have been modified to reflect changes in regulatory standards, facilities, and operating conditions. At its inception, the COA water quality standards were those of the 1978 WQCP; these were subsequently modified in the 1991 WQCP. The adoption of the 1995 WQCP by SWRCB superseded those requirements. The Environmental Water Account was established by CALFED in 2000 to protect the fish of the Bay-Delta estuary via changes in the operations of the CVP and SWP, without incurring uncompensated cost to the projects' water users. Evolution of the Clean Water Act over time has also impacted implementation of the COA.

Groundwater Regulations

Groundwater use is subject to limited statewide regulation; however, all water use in California is subject to constitutional provisions that prohibit waste and unreasonable use of water (SWRCB 1999). In general, groundwater is subject to a number of provisions in the Water Code. Assembly Bill 3030, Water Code Section 10750, commonly referred to as the Groundwater Management Act, permits local agencies to develop groundwater management plans (Reclamation and DWR 2003).

Other groundwater regulation is related primarily to water quality issues, which are addressed by several different State agencies, including SWRCB and nine

Regional Water Quality Control Boards, the California Department of Toxic Substances Control, Department of Pesticide Regulation, and Department of Health Services.

The California Legislature and Governor, as well as private citizens, have become increasingly concerned about recent public well closures regarding the detection of chemicals, such as methyl tertiary-butyl ether from gasoline, and various solvents from industrial sources. As a result of increased awareness of groundwater quality, the Supplemental Report of the 1999 Budget Act required SWRCB to develop a comprehensive ambient groundwater monitoring plan. To meet this mandate, SWRCB created the Groundwater Ambient Monitoring and Assessment (GAMA) Program. The primary objective of the GAMA Program is to assess water quality and relative susceptibility of groundwater resources. The GAMA Program has two sampling components: the California Aquifer Susceptibility Assessment for addressing public drinking water wells, and the Voluntary Domestic Well Assessment Project for addressing private drinking water wells.

The GAMA Program is being directed by the SWRCB Division of Water Quality, Land Disposal Section, Groundwater Special Studies Unit. The Voluntary Domestic Well Assessment Project samples domestic wells for various constituents commonly found in domestic well water, and provides that information to domestic well owners. In addition, the Voluntary Domestic Well Assessment Project includes a public education component to aid the public in understanding water quality data and water quality issues affecting domestic water wells. The Voluntary Domestic Well Assessment Project focuses on specific areas, as resources permit. The focus areas are chosen based on existing knowledge of water quality and land use, in coordination with local environmental agencies. SWRCB incurs the costs of sampling and analysis, and results are provided to domestic well owners as quickly as possible.

6.2.3 Regional and Local

The following local laws, regulations, standards, and plans are discussed as part of the regulatory setting:

- Local surface water regulations (water supply master plans, general plans, habitat and conservation plans, land use ordinances)
- Local groundwater regulations (management plans, county ordinances)

Local Surface Water Regulations

Local surface water regulations include goals, objectives, and policies pertaining to the primary and extended study areas, including the following:

- Local water supply master plans
- County general plans

- City general plans
- Local habitat and conservation plans (i.e., Natomas Basin Habitat Conservation Plan)
- Local land-use ordinances

Local Groundwater Regulations

Local regulatory setting documents on groundwater resources in the study areas include local groundwater management plans and county ordinances. Table 6-2 lists current groundwater management plans and county ordinances that apply to agencies in the Redding and Sacramento groundwater basins. Groundwater management plans and county ordinances in the North and South San Joaquin groundwater basins are presented in Table 6-3. These documents typically involve provisions to limit or prevent groundwater overdraft, protect groundwater quality, and regulate transfers.

6.3 Environmental Consequences and Mitigation Measures

The purpose of this chapter is to provide information about the environmental consequences of the SLWRI study alternatives on hydraulics and hydrology, including water management, and impacts on existing facilities. This chapter describes the methods and assumptions, criteria for determining significant impacts, and impacts and mitigation measures associated with the H&H effects of each of the SWLRI alternatives. Implementation of the action alternatives considered in the study would affect the H&H of the Sacramento River, Feather River, American River, and the CVP/SWP systems. Impacts on the H&H of the CVP/SWP systems would translate to potential impacts on related surface and groundwater supplies available for CVP/SWP water users.

6.3.1 Methods and Assumptions

A suite of modeling tools was used to evaluate the potential impacts of the No-Action Alternative and various SLWRI action alternatives on the H&H of the

project, and to quantify potential benefits. CalSim-II was used to simulate CVP and SWP operations, determining the surface water flows, storages, and deliveries associated with each alternative. A detailed description of CalSim-II is included in Chapter 2 of the Modeling Appendix. Delta Simulation Model 2 (DSM2) was used to simulate Delta hydrodynamics, providing the data used to discuss the water-level-related impacts of each alternative. A detailed description of DSM2 and the assumptions used in the SLWRI analysis are included in Chapter 8 of the Modeling Appendix. Analysis and modeling results are summarized below; more detailed results of the CalSim-II output can be found in Attachment A of the *Hydrology, Hydraulics, and Water Management Technical Report*. Attachment B of the *Hydrology, Hydraulics, and Water Management Technical Report* contains detailed results of the DSM2 modeling.

CalSim-II

CalSim-II is the application of the Water Resources Integrated Modeling System software to the CVP/SWP. This application was jointly developed by Reclamation and DWR for planning studies relating to CVP/SWP operations. The primary purpose of CalSim-II is to evaluate the water supply reliability of the CVP and SWP at current and/or future levels of development (e.g., 2005, 2030), with and without various assumed future facilities, and with different modes of facility operations. Geographically, the model covers the drainage basin of the Delta, and CVP/SWP exports to the San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California.

CalSim-II typically simulates system operations for an 83-year period using a monthly time step. The model assumes that facilities, land use, water supply contracts, and regulatory requirements are constant over this period, representing a fixed level of development (e.g., 2005, 2030). The historical flow record of October 1921 to September 2003, adjusted for the influences of land use changes and upstream flow regulation, is used to represent the possible range of water supply conditions. Major Central Valley rivers, reservoirs, and CVP/SWP facilities are represented by a network of arcs and nodes. CalSim-II uses a mass balance approach to route water through this network. Simulated flows are mean flows for the month; reservoir storage volumes correspond to end-of-month storage.

CalSim-II models a complex and extensive set of regulatory standards and operations criteria. Descriptions of both are contained in Chapter 2 of the Modeling Appendix. The hydrologic analysis conducted for this PDEIS used the Common Assumptions Common Modeling Package Version 8D CalSim-II models, which are the best available hydrological modeling tools, to approximate system-wide changes in storage, flow, salinity, and reservoir system reoperation associated with the SLWRI alternatives. Although CalSim-II is the best available tool for simulating system-wide operations, the model also contains simplifying assumptions in its representation of the real system. CalSim-II's predictive capability is limited and cannot be readily applied to

analyzing flood flows and hourly, daily, or weekly time steps for hydrologic conditions. The model, however, is useful for comparing the relative effects of alternative facilities and operations within the CVP/SWP system.

A general external review of the methodology, software, and applications of CalSim-II was conducted in 2003 (Close et al. 2003). Recently, an external review of the San Joaquin River Valley CalSim-II model was also conducted (Ford et al. 2006). Several limitations of the CalSim-II models were identified in these external reviews. The main limitations of the CalSim-II models are as follows:

- Model uses a monthly time step
- Accuracy of the inflow hydrology is uncertain
- Model lacks a fully explicit groundwater representation

In addition, Reclamation, DWR, and external reviewers have identified the need for a comprehensive error and uncertainty analysis for various aspects of the CalSim-II model. DWR has issued the CalSim-II Model Sensitivity Analysis Study (DWR 2005) and Reclamation has recently completed a similar sensitivity and uncertainty analysis for the San Joaquin River basin (Reclamation and DWR 2006a). This information will improve understanding of model results.

Despite these limitations, monthly CalSim-II model results remain useful for comparative purposes. It is important to differentiate between "absolute" or "predictive" modeling applications and "comparative" applications. In "absolute" applications, the model is run once to predict a future outcome; errors or assumptions in formulation, system representation, data, operational criteria, etc., all contribute to total error or uncertainty in model results. In "comparative" applications, the model is run twice, once to represent a base condition (no-action) and a second time with a specific change (action) to assess the change in the outcome due to the input change. In the comparative mode (the mode used for this PDEIS), the difference between the two simulations is of principal importance. Most potential errors or uncertainties affecting the "no-action" simulation also affect the "action" simulation in a similar manner; as a result, the effect of errors and uncertainties on the difference between the simulations is reduced. However, not all limitations are fully eliminated by the comparative analysis approach; small differences between the alternatives and the bases of comparison are not considered to be indicative of an effect of the alternative.

DSM2

DSM2 is a branched 1-dimensional model used to simulate hydrodynamics, water quality, and particle tracking in a network of riverine or estuarine channels. The hydrodynamic module can simulate channel stage, flow, and

water velocity. The water quality module can simulate the movement of both conservative and nonconservative constituents. DWR uses the model to perform operational and planning studies of the Delta.

IMpact analysis for PLANning studies of the Delta is typically performed for a 72-year period (1922 to 1994). In model simulations, EC is typically used as a surrogate for salinity. Results from CalSim-II are used to define Delta boundary inflows. CalSim-II-derived boundary inflows include the Sacramento River flow at Hood, the San Joaquin River flow at Vernalis, inflow from the Yolo Bypass, and inflow from the eastside streams. In addition, Net Delta Outflow from CalSim-II is used to calculate the salinity boundary at Martinez.

Details of the model, including source codes and model performance, are available from the DWR Bay-Delta Office, Modeling Support Branch, Web site. Documentation on model development is discussed in annual reports to SWRCB (*Methodology for Flow and Salinity Estimates in the Sacramento-San Joaquin Delta and Suisun Marsh*, by the Delta Modeling Section of DWR) (DWR 2009).

6.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an environmental impact statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The significance criteria were developed based on the guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on hydraulics, hydrology, and water management would be significant if project implementation would cause the results in the second column of Table 6-4 to occur. Simulated stream flow and reservoir storage data, generated as part of the hydrology, hydraulics and water management impact assessment, were used in the impact assessments for groundwater, hydropower, flood control, water quality, fisheries, terrestrial biology, recreation, and cultural resources. Accordingly, a detailed description of changes in flow and storage resulting from each of the SLWRI alternatives is included in addition to the impact analysis.

Table 6-4. Impact Indicators and Significance Criteria for Water Management

Impact Indicator	Significance Criterion
Flood management	Increase frequency or severity of damaging flood flows, as indicated by the following: • Increase frequency of daily flows above 100,000 cfs on the Sacramento River below Bend Bridge • Place housing or other structures within a 100-year flood hazard area as mapped on a Federal flood hazard boundary or Flood Insurance Rate Map or other flood hazard delineation map • Place within a 100-year flood hazard area structures that would impede or redirect flood flows
Water Supply Reliability	Reduce water supply reliability to the following CVP/SWP contractors: • North-of-Delta CVP Water Service Contractors or Refuges • South-of-Delta CVP Water Service Contractors or Refuges • SWP Table A Contractors south of the Delta
Water levels in the south Delta [1]	Reduce water surface elevation, relative to the basis of comparison, with sufficient frequency and magnitude to adversely affect south Delta water users' abilities to divert water during the irrigation season.
X2 location	Increase in X2 that adversely affects CCWD's ability to fill Los Vaqueros Reservoir: • Movement of X2 location to west of Chipps Island from February through May • Movement of X2 location to west of Collinsville during December, January, and June
Delta excess water conditions	Reduction in the duration of Delta excess conditions during the November-to-June period that adversely affects CCWD's ability to fill Los Vaqueros Reservoir.
Groundwater resources	A change in groundwater level or quality that would adversely affect users, as indicated by the following: • A change in groundwater level resulting in long-term overdraft conditions for the groundwater basins • A change groundwater quality resulting in substantially adverse effects to designated beneficial uses of groundwater.

Note:
[1] Changes in south Delta water levels are estimated using the DSM2 Model.

Key
CCWD = Contra Costa Water District
cfs = cubic feet per second
Delta = Sacramento-San Joaquin Delta

Significance statements are relative to both existing conditions (2005) and future conditions (2030) unless stated otherwise.

Flood Management

To prevent an increase in flood damages in the study area, the SLWRI must not cause a significant increase in the frequency or magnitude of flood flows on the Sacramento River. The current regulation of Shasta Dam for flood control requires that releases be restricted to quantities that will not cause downstream flows or stages to exceed, insofar as possible, (1) a flow of 79,000 cfs at the tailwater of Keswick Dam, and (2) a stage of 39.2 feet at the Sacramento River Bend Bridge gaging station near Red Bluff (corresponding roughly to a flow of 100,000 cfs). Because of the uncontrolled nature of the inflows between Keswick Dam and Bend Bridge, the 100,000 cfs flow objective at Bend Bridge

is the critical objective for minimizing flood damage. It is also important to ensure that the project does not increase potential flood damages by locating any new facilities within the 100-year floodplain or in a location that could impede or redirect flood flows, thereby potentially increasing damage to other property.

Water Supply Reliability

To prevent a decrease in water supply, the SLWRI must not cause a significant reduction in water supply reliability to CVP and SWP contractors. A significant reduction in reliability would be a reduction in average annual or average dry and critical year reliability of a magnitude and frequency that could not reliably be replaced from other sources, such as groundwater pumping or water transfers. Also, it is recognized that there is limited flexibility to change water usage between months, so monthly reliability is considered in addition to average annual delivery volumes.

The CVP provides water to a range of contract types; Settlement and Exchange contractors have the highest degree of reliability due to water rights senior to the CVP. Due to their high priority, these contractors would not be affected by any of the SLWRI alternatives. Water service contractors and refuges are subject to shortages according to water availability and their geographic location; due to conveyance constraints, south-of-Delta water service contractors and refuges have a lower degree of reliability than north-of-Delta water service contractors and refuges. While the SWP has several contractors north of the Delta, the vast majority of recipients of SWP water supplies are south of the Delta. SWP contractors have several types of water in their contract; the Table A contracts (DWR 2003a) are most susceptible to variability of supply.

South Delta Water Levels

Water levels in the south Delta are influenced to varying degrees by natural tidal fluctuations, San Joaquin River flows, barrier operations, CVP and SWP export pumping, local agricultural diversions and drainage return flows, channel capacities, siltation, and dredging. When the CVP and SWP are exporting water, water levels in local channels can be drawn down, particularly during low water years. The South Delta Water Agency and local farmers in the south and central Delta have interests in maintaining the water levels so that their siphons and pumps, which are installed at fixed locations in the Delta, can continue to be used for irrigation diversions. The SLWRI alternatives could affect the ability of the South Delta Water Agency to divert water if changes in Delta operations reduce Delta channel water levels during the irrigation season, from April to October.

The South Delta Temporary Barriers Program was initiated by DWR in 1991 to improve water conditions in the south Delta and to provide design data for permanent gates. Since 1991, DWR has seasonally installed four barriers. Three barriers, located on the Middle River, Grant Line Canal, and Old River,

ensure adequate water levels and water quality for agricultural diversions. The barriers are constructed from rock fill and incorporate overflow weirs and gated culverts. These barriers are installed in spring and removed in fall. A fourth barrier is seasonally installed at the Head of the Old River for fish control. The existing seasonal barriers (and proposed permanent tidal gates) significantly affect water levels in the south Delta. In October 2005, Reclamation and DWR released a DEIS for the South Delta Improvements Program (Reclamation 2005). This DEIS discusses the proposed operation and evaluates the impacts of the proposed permanent tidal and fish control gates in the south Delta. The Final Environmental Impact Statement/Environmental Impact Report for the South Delta Improvements Program was released in December 2006 (Reclamation and DWR 2006b) but the document has not yet been certified.

To evaluate water level effects, modeling results were examined for sites in the vicinity of three monitoring locations. South Delta agricultural irrigation users are primarily concerned with the water level at low-low tide because this is the minimum water surface elevation they experience. The impact analysis considers the maximum change in water elevation at the low-low tide for each day of each month. Channel tidal levels at three south Delta locations have been selected to describe the possible impacts of the SWLRI alternatives on south Delta tidal hydraulics. The three locations are as follows:

- **Old River at Tracy Boulevard Bridge (Road Bridge).** This station is a tidal level and EC monitoring location, and is upstream from the temporary barrier and proposed permanent barrier just east (upstream) from the Delta-Mendota Canal intake and fish facility.

- **Grant Line Canal Above the Grant Line Canal Barrier.** This station is upstream from the temporary barrier on Grant Line Canal and upstream from the proposed permanent tidal gate.

- **Middle River near the Howard Road Bridge.** This station is located just upstream from the temporary barrier near Victoria Canal and the proposed permanent tidal gate.

A change in water level of greater than 0.1 foot during the irrigation season of April to October, at a level of recurrence substantially adversely affecting south Delta water users, is considered to be significant.

X2 Location

CCWD depends almost entirely on the Delta for water supply. CCWD's raw water system consists of three Delta pumping plants (Mallard Slough, Rock Slough, and Old River), and a 100 TAF reservoir (Los Vaqueros). The pumping plants on Rock Slough and on the Old River are the primary source for CCWD. The third intake at Mallard Slough is used only when water quality conditions in the western Delta permit, usually following a prolonged period of surplus Delta outflow. Water diverted at the Old River Pumping Plant is either

used directly or stored in Los Vaqueros Reservoir for later use. CCWD's current operational priority is to fill Los Vaqueros Reservoir with high quality water whenever possible.

CCWD diversions to fill Los Vaqueros Reservoir are constrained by the Delta Smelt BO (NMFS 2004; USFWS 2005), as subsequently modified by agreements among CCWD, USFWS, DFG, and SWRCB. From February through May, the BO precondition for filling the reservoir is that the X2 location is west of Chipps Island. In December, January, and June, the X2 location must be west of Collinsville. Filling Los Vaqueros Reservoir is unconstrained in December if no delta smelt are present at the diversion location. Through agreement with DFG and USFWS, the X2 restrictions on filling Los Vaqueros Reservoir have subsequently been modified for a temporary trial period through 2010 to conform with X2 requirements specified in RD-1641.

For the impact analysis, it is assumed that from February to June, the X2 requirement for filling Los Vaqueros Reservoir will be met by Reclamation and DWR as part of their responsibilities under RD-1641.[2] Changes in simulated Delta conditions are considered to be potentially significant only for the months of December and January, and only when all of the following conditions are met:

- The Delta is not in balanced condition[3]
- Under the basis of comparison, X2 is west of Collinsville
- Under the SLWRI alternatives, X2 is east of Collinsville

It is noted that Reclamation and DWR are not authorized to use the JPOD when the Delta is in excess conditions, and when such diversions would cause the location of X2 to shift upstream and prevent CCWD from filling Los Vaqueros Reservoir under its water right permits.

Delta Excess Water Conditions

Changes from Delta excess water conditions to balanced conditions could adversely affect CCWD's ability to fill Los Vaqueros Reservoir. Under SWRCB Water Right Decision 1629, filling Los Vaqueros Reservoir is restricted to the parts of the period from November 1 to June 30 when the Delta is in excess water conditions. Changes in simulated Delta conditions are

[2] When the Eight River Index is less than 8.1 MAF, the RD-1641 X2 requirements for May and June are relaxed, potentially impacting filling of Los Vaqueros Reservoir. Model simulations show that this would occur eight times during the historical record for water years 1922 to 1994, but in these circumstances the Delta would be in balanced water conditions.

[3] Balanced water conditions are periods when it is agreed by Reclamation and DWR that releases from upstream reservoirs plus unregulated flows approximately equal the water supply needed to meet Sacramento Valley in-basin uses plus required Delta outflows and exports (Reclamation and DWR 1986).

considered to be potentially significant if during this period the following conditions are met:

- Under the basis of comparison, the Delta is in excess conditions
- Under the SLWRI alternatives, the Delta is in balanced conditions

Groundwater Resources

Impacts on groundwater resources would be considered significant if actions related to the SLWRI alternatives would cause the groundwater resources impacts described in Table 6-4. Improvements in water supply reliability under the SLWRI alternatives may affect groundwater levels, budget, and quality in the primary and extended study areas. In general, potential impacts of the SLWRI in the primary and extended study areas would result from a reduction in water extraction due to increased surface water supply reliability. Currently, CVP and SWP water users in the primary and extended study areas pump groundwater to supplement surface water supply.

Potential impacts on groundwater resources, particularly groundwater levels, budget, and water quality, are evaluated qualitatively based on changes in surface water supply. This approach is based on the assumption that the actual reduction in groundwater extraction would be proportional to the increase in surface water supply reliability that would occur in the study areas under the SLWRI alternatives. Changes in groundwater pumping in the study areas would be relatively small compared to the estimated millions of acre-feet of annual groundwater pumping. Nevertheless, the SLWRI alternatives would have a positive, albeit limited, impact by reducing reliance on groundwater in the study areas. Because effects on groundwater basins would be limited and positive, groundwater impacts are discussed qualitatively.

6.3.3 Direct and Indirect Effects

This section describes the environmental consequences of the SLWRI alternatives, and proposed mitigation measures for any impacts determined to be significant or potentially significant. All alternatives are compared to a basis of comparison. For the existing condition (2005 level of development), a CalSim-II simulation for the existing condition is used. Similarly, the future condition (2030 level of development) uses a CalSim-II simulation of the No-Action/No-Project Alternative as a basis of comparison. Each of the alternatives is simulated using the same level of development so that any changes from the basis of comparison in H&H can be attributed to the alternative.

Alternatives Description

The six SLWRI alternatives are described in the following subsections.

No-Action Alternative NEPA and CEQA require the analysis of a baseline alternative, representing a scenario in which the project is not implemented. For

all Federal feasibility studies of potential water resources projects, the NEPA No-Action Alternative is intended to account for existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area by 2030. Reasonably foreseeable actions include actions with current authorization, complete funding for design and construction, and complete environmental permitting and compliance.

Under CEQA, the No-Project Alternative is similar to NEPA's No-Action Alternative, but it involves the review of two scenarios: the Existing Condition baseline, which represents only current conditions at the time the Notice of Preparation is published, and "reasonably foreseeable" future conditions without the project (which is equivalent to the NEPA No-Action Alternative). Table 2-1 of the Modeling Appendix describes the Existing Condition, and shows what actions were assumed to be part of the Future Condition (or No-Project/No-Action Alternative).

For the SLWRI, under the No-Action Alternative, the Federal Government would take reasonably foreseeable actions, as defined above, but would take no additional action toward implementing a specific plan to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water reliability issues in California. This alternative is used as a basis of comparison to determine effects of the action alternatives under future conditions.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability CP1 focuses on increasing water supply reliability while contributing to increased anadromous fish survival, actions that are consistent with the 2000 CALFED ROD (CALFED 2000b). In addition to the common features above, CP1 primarily consists of raising Shasta Dam 6.5 feet, an elevation change that increases the reservoir's full pool by 8.5 feet, and enlarges the total storage space in the reservoir by 256,000 acre-feet. Under this plan, Shasta Dam normal operational guidelines would continue essentially unchanged, with the additional storage retained for water supply reliability. This scenario helps to reduce future water shortages through increasing drought and average year water supply reliability. This plan would also include the potential to revise the operational rules for flood control for Shasta Dam and Reservoir, which could benefit flood damage reduction and recreation. Reservoir reoperation would likely include increasing the bottom of the flood control pool elevation based on increased dam height and reservoir capacity. The increased Shasta Reservoir pool depth and volume would also contribute to maintaining lower seasonal water temperatures for anadromous fish on the upper Sacramento River.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability As with CP1, this comprehensive plan focuses on enlargement of Shasta Dam and Lake consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increased water supply reliability

and increased anadromous fish survival. In addition to the common features above, CP2 consists of raising Shasta Dam 12.5 feet, an elevation change that increases the full pool by 14.5 feet, and enlarges the total storage space in the reservoir by 443,000 acre-feet. This alternative would help reduce future shortages by increasing drought and average year water supply reliability. The increased cold-water pool also would contribute to improved seasonal water temperatures for anadromous fish on the upper Sacramento River.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability CP3 is similar to CP1 and CP2. It focuses on the greatest practical enlargement of Shasta Dam and Lake consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increased water supply reliability and increased anadromous fish survival. In addition to the common features above, CP3 consists of raising Shasta Dam 18.5 feet, an elevation change that increases the full pool by 20.5 feet, and enlarges the total storage space in the reservoir by 634,000 acre-feet to 5.19 MAF. This comprehensive plan would help reduce future shortages by increasing water supply reliability in relatively dry years. The increased pool depth and volume would also contribute to improving seasonal water temperatures for anadromous fish on the upper Sacramento River.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability The primary function of CP4 is to address anadromous fish survival, while still improving water supply reliability. It focuses on increasing the volume of cold water available to the Shasta Lake TCD through reservoir reoperations, and on raising Shasta Dam by 18.5 feet. As with CP3 and the common features above, this raise would increase the full pool by 20.5 feet and enlarge total reservoir storage space by 634,000 acre-feet. This additional storage space would expand Shasta Reservoirs cold-water supply available to the TCD by 378,000 acre-feet, a feature that would help improve cooler water temperatures in the upper Sacramento River.

CP5 – 18.5-Foot Dam Raise, Combination Plan CP5 would address both the primary and secondary planning objectives. CP5 includes enlarging Shasta Dam 18.5 feet, which is consistent with the objectives of the 2000 CALFED ROD, and also includes the common features above. In addition, CP5 includes (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing either additional or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. Specific environmental restoration features and increased recreation components are presented in the Alternatives Description portion of the PDEIS and the Draft Feasibility Report.

Changes to CVP/SWP Operations

Each of the SWLRI alternatives would have similar impacts on CVP and SWP operations compared to either the existing condition or the No-Action

Alternative. However, the magnitude of the impacts would vary according to the alternative. Detailed tables of the estimated monthly flows and storages associated with each alternative, in addition to changes from the bases of comparison, are included in Attachment A of the *Hydrology, Hydraulics, and Water Management Technical Report*. Results are summarized below.

The analysis assumed that the SLWRI alternatives would not alter existing operational rules or protocols; no formal changes to CVP or SWP operating criteria and associated with the SLWRI. At a base level, each action alternative would store some additional flows behind Shasta Dam during periods when the flows would have otherwise been released downstream. The resulting increase in storage would then be used to both create an expanded cold-water pool, thus benefiting fisheries, and for subsequent release downstream when there are opportunities to put the water to beneficial use.

Reductions in Shasta releases under the various SLWRI alternatives would typically occur during winter (November through March) in relatively wet years, and increases in releases would typically occur in the late spring and summer (June through September) of drier years. Shasta Dam typically makes releases for one of six purposes:

- Flood management
- Sacramento River flow requirements both below Keswick and at Wilkins Slough
- Sacramento River water temperature requirements at Bend Bridge
- Delta water quality requirements
- Senior water rights along the Sacramento River
- CVP water supply contracts needs both north and south of the Delta

However, release for one purpose may also be sufficient for meeting another; for instance, releases for Sacramento River water temperatures may also be used to both meet Delta water quality requirements and for export to south-of-Delta contractors. While releases for flood management purposes typically occur in winter, water temperature and water quality requirements exist year-around. Releases for water supply purposes primarily occur in late spring, summer, and early fall.

For the SLWRI alternatives, existing water quality and temperature requirements would typically be met in most years; therefore, additional water in storage would primarily be released for water supply purposes. Accordingly, minimal increases in flow would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Table 6-5 summarizes monthly flows and changes below Shasta Dam. Releases from Shasta Dam would typically be increased in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage would be used to capture additional runoff rather than releasing to the downstream river.

Table 6-5. Simulated Monthly Average Sacramento River Flows Below Shasta Dam

Storage in Shasta Reservoir fluctuates greatly throughout a year; storage is typically highest at the end of winter, in April and May, as the need for flood control reservation space in the reservoir is reduced. Storage is typically at its lowest in September and October, after the irrigation season and before the winter refill begins. As a result of the increased storage capacity attributed to each alternative, and the flow reductions described above, Shasta Reservoir storage would be generally higher under the SLWRI alternatives than under the existing condition or the No-Action Alternative (future condition). This additional storage would typically be greatest in the winter (February or March), and would be lowest at the end of summer (September or October), as shown in Table 6-6, consistent with Shasta Reservoir's current operation. Additional runoff captured by the increased storage increment would typically remain in

storage until it could be used to meet one of the purposes described above. Conversely, under either of the bases of comparison, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Therefore, increased releases would typically be made on a schedule providing increased reliability of deliveries to water service contractors, typically in July through October of relatively dry years.

A key indicator of water temperature benefits of the SLWRI alternatives to the Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Reservoir before the water temperature operation season, about May through October. As previously described, Shasta Reservoir generally reaches its maximum storage during late April or early May. Also, the cold-water pool volume in the lake accumulates during the winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for each dam raise alternative should also result in an incremental increase in the cold-water pool volume.

Reclamation operates the Shasta Dam TCD to manage water temperatures in the Sacramento River to (1) improve habitat for the endangered winter-run Chinook salmon and other threatened runs, (2) withdraw warmer surface water in the

winter and spring to preserve cold-water storage for release during the temperature operation season, and (3) enable power generation to continue while controlling release temperatures, which eliminates the need to bypass the powerplant penstocks via the low-level river outlets. Generally, to accomplish these temperature objectives during the temperature operation season, the TCD functions to select water temperatures in the 47 degrees Fahrenheit (˚F) to 52˚F range. Therefore, a good index of the temperature-related benefits of the alternative is the volume of the cold-water pool less than 52˚F at the end of April. In the context of historical project operation, reservoir storage and cold-water pool conditions in mid-spring represent the available cold-water "bank" managed throughout the temperature operation season (July through October), as prescribed by the SRTTG. The simulated end-of-April volume of water less than 52˚F for the two bases of comparison, and the change in cold-water pool volume for each of the SLWRI alternatives, are shown by Sacramento Valley Index in Table 6-7. As expected, the higher dam raise alternatives generally reflect a larger cold-water pool volume.

Table 6-7. Simulated Average Volume of Water Less than 52˚F in Shasta Reservoir at the End of April

Downstream from Shasta Dam, the Sacramento River combines with releases from Trinity Reservoir through Whiskeytown Reservoir and the Spring Creek Tunnel above Keswick Dam. Because of the connected nature of Shasta Reservoir and Trinity Reservoir for meeting instream flow requirements and water supply demands below Keswick Dam, changes in Shasta Reservoir operations would possibly result in changes to operations of Trinity Reservoir. Table 6-8 shows changes in Trinity Reservoir storage that would result from SLWRI alternatives. These changes are very small relative to the reservoir storage and should not result in noticeable changes at Trinity Reservoir. To limit the effect of the enlarged Shasta Reservoir on Trinity Reservoir operations, the relationship in CalSim-II between Shasta Reservoir storage and Trinity Reservoir exports to the Sacramento River was modified through interpolation to approximately maintain the export level of the basis of comparison in the action alternatives.

Below Keswick Dam, Sacramento River flows would be increasingly affected by tributary inflows rather than releases from Shasta Lake. Table 6-9 shows the simulated monthly average tributary inflows to the Sacramento River between Keswick Dam and the RBDD. The tributary inflows are consistent between the 2005 and 2030 levels of development simulations and for each alternative. Below the RBDD, flow changes associated with the SLWRI alternatives would be considerably smaller relative to total flow in the river. Comparing the flows in Table 6-5 and Table 6-10 for the existing condition and No-Action Alternative, the tributary influence on river flow becomes apparent. Similarly, with increases in flow for the existing condition and No-Action Alternative, the influence of the SLWRI alternatives on the flow in the river would be reduced.

TAF = thousand acre-feet

In addition to the multiple tributary inflows between Keswick Dam and Red Bluff, downstream flows on the Sacramento River would be affected by diversions above the RBDD. Specifically, contractors off the Tehama-Colusa Canal receive supplies from above the RBDD. Since contractors off the Tehama-Colusa Canal are all water service contractors, and thus would be subject to delivery shortages when CVP storage is low, the SLWRI alternatives would result in increased deliveries to the Tehama-Colusa Canal contractors in relatively dry years. Table 6-11 shows simulated diversions from the RBDD to the Tehama-Colusa Canal in dry and critical years. Agricultural diversions typically occur between April and September, with some additional diversions in March and October; accordingly, deliveries on the Tehama-Colusa Canal increase in the agricultural diversion months, but see no changes in months with little or no irrigation.

While Tehama-Colusa Canal water users are the primary recipient of CVP water service contract deliveries north of the Delta, other north-of-the-Delta users are subject to changes in water supply, including wildlife refuges. Average monthly deliveries to CVP water service contractors and refuges north of the Delta are included in Table 6-12.

Table 6-12. Simulated Monthly Average Deliveries to North-of-Delta CVP Water Service Contractors and Refuges

As would be expected, the change in deliveries increases with the greater enlargement volumes, and increases in deliveries are much greater in the dry and critical years than in average years, corresponding to the increased likelihood of shortages during drier periods. Table 6-13 shows average deliveries in dry and critical years.

As described in Chapter 1 of the *Hydrology, Hydraulics, and Water Management Technical Report*, during high flow periods, Sacramento River flows below Red Bluff can be diverted into the Sutter Bypass near Ord Ferry, or from the Moulton, Colusa, or Tisdale weirs. Similarly, flows can be diverted into the Yolo Bypass from the Fremont and Sacramento weirs. Table 6-15 shows the recurrence of annual spills over the various Sacramento Valley weirs into the Sutter and Yolo bypasses.

Table 6-15. Simulated Number of Years of Sacramento Valley Weir Spill

As the Sacramento River nears the Delta, the basis-of-comparison flow would increase considerably so that flow changes associated with SLWRI alternatives would be immeasurable in most months. Table 6-16 shows the simulated monthly average Sacramento River flow below Freeport. Flow changes due to each alternative are very small compared to the bases of comparison; average monthly flow changes are typically between 0 percent and 2 percent. Larger flow increases are due to operations specifically for export; since conditions typically only allow for increased exports in July and August, the majority of the benefits are observed during those months.

Table 6-16. Simulated Monthly Average Sacramento River Flows Below Freeport

Because of the interconnected nature of CVP and SWP operations for meeting shared Sacramento River flow requirements and Delta water quality obligations, changes in Shasta Reservoir operations could potentially affect operations of both Oroville Reservoir on the Feather River and Folsom Reservoir on the American River. For example, an increase in Shasta Reservoir releases may create opportunities for increased SWP export of releases from Oroville Reservoir by improving Delta water quality. An increase in releases from Oroville Reservoir would result in a decrease in storage. Tables 6-17 and 6-18 show simulated end-of-month storage at Oroville Reservoir and Feather River flow below the Thermalito Afterbay, respectively.

Similarly, an increase in Shasta Reservoir releases in a particular month may result in improved Delta water quality, allowing for a possible reduction in CVP releases from the American River, and a corresponding increase in Folsom Reservoir storage. Tables 6-19 and 6-20 show simulated end-of-month storage at Folsom Reservoir and on the American River near the H-Street Bridge, respectively.

TAF = thousand acre-feet

The Delta is the confluence of the Sacramento, San Joaquin, Cosumnes, Calaveras, and Mokelumne rivers in addition to several other smaller streams and creeks. As the "central hub" of California's water supplies, minor changes in operations in one region could result in other minor changes throughout the system. As previously described, changes in operations associated with the SLWRI alternatives could possibly result in minor changes in operations to other CVP and SWP facilities. While New Melones Reservoir on the Stanislaus River is operated by the CVP to meet water quality requirements in the South Delta and lower San Joaquin River, and could potentially be affected by changes in Sacramento River flow or Delta exports, simulations indicate the SLWRI alternatives would not result in any changes to New Melones operations. (See Attachment A of the *Hydrology, Hydraulics, and Water Management Technical Report*, for details about New Melones Reservoir and Stanislaus River operations.)

Besides potentially changing exports to south-of-Delta water users, changes in Delta inflow could also be reflected in changes in Delta outflow. Changes in Sacramento River flow, as shown above in Table 6-16, are typically reflected as a combination of Delta outflow and export. Table 6-21 shows changes in Delta outflow associated with each alternative.

Table 6-21. Simulated Monthly Average Change in Delta Outflow

The CVP and SWP divert water via the Jones Pumping Plant and the Banks Pumping Plant, respectively. The increased water supply made available from the SLWRI alternatives would typically be moved through the Jones Pumping Plant; however, under each of the bases of comparison, capacity at Jones is often fully used in the wetter years, leaving little ability to export available water. Accordingly, while unmet CVP demand south of the Delta may exist in some relatively wet years, conveyance restrictions would limit opportunities to export available water in those years. In drier years, however, typically capacity is available for increased exports through the Jones Pumping Plant. Thus, there are greater increases in average annual pumping volumes in those years. Table 6-22 shows the average annual exports through Jones Pumping Plant.

Recipients of exports through the Jones Pumping Plant include San Joaquin Valley Exchange Contractors, Federal wildlife refuges, and water service contractors. Since the Exchange Contractors have substantially higher levels of reliability of delivery compared to the refuges and water service contractors, their deliveries will not change under any of the SLWRI alternatives. Deliveries to the refuges and water service contractors would increase with an enlargement of Shasta Dam. Table 6-24 shows monthly average deliveries to the CVP south-of-Delta refuges and water service contractors.

As would be expected, while there are some increases in deliveries when all years are averaged, the increases in deliveries in SVI dry and critical years are much greater, as shown in Table 6-25. This is primarily due to several factors, including increased available capacity at the Jones Pumping Plant in dry and critical years, and because of the CVP shortage policies, there is a substantially increased demand in dry and critical years. None of the SLWRI alternatives will provide a noticeable change in deliveries in relatively wet years because contractors are typically already receiving their full contract amount in those years.

TAF = thousand acre-feet

When evaluating project effects on water supply reliability, CVP south-of-Delta allocations are a valuable indicator of benefits resulting from each alternative. Tables 6-26 and 6-27 show the simulated annual allocations to south-of-Delta agricultural and M&I refuges and water service contractors for the existing condition and the No-Action Alternative, and the simulated change in allocation for each of the SLWRI alternatives. Simulated allocations are calculated by dividing annual deliveries of each contract type by the demand. The contract period for CVP allocations is assumed to be March through February; the assumed simulated demand for each contract type is as follows:

- **Agricultural water service contractors** – 1,987.2 TAF/year (both 2005 and 2030 level of development).

- **M&I water service contractors** – 164.2 TAF/year (both 2005 and 2030 level of development).

- **Federal refuges** – 304.6 TAF/year (2005 level of development)/281.1 TAF/year (2030 level of development).

Tables 6-26 and 6-27 show that while allocations would typically increase, there could also be years with small decreases in allocations. Simulations of CP2 with a 2030 level of development indicate an average decrease in allocations; however, as indicated in Table 6-24, there would be an average annual increase in deliveries. This apparent contradiction is likely due to differences in averaging methodology for the two tables. More important than the average annual change in allocation is the increase in allocation in years with low allocations under either the existing condition or No-Action Alternative, such as in 1928, 1944, and 1976. Some decreases in allocations would occur in years in the latter parts of prolonged droughts. This is likely due to changes in CalSim-II north-of-Delta reservoir storage–water supply relationships.

While the Banks Pumping Plant typically provides water supply to SWP contractors, the SLWRI alternatives may provide opportunities for increased CVP and SWP exports through the Banks Pumping Plant by improving Delta water quality (i.e., salinities). Furthermore, CVP/SWP water rights in the Delta (RD-1641) provide opportunities for the CVP to export its supplies through the Banks Pumping Plant under certain conditions. Accordingly, there would be increases in exports at the Banks Pumping Plant under the SLWRI alternatives, but since the Banks Pumping Plant export capacity would be fully used less often than the Jones Pumping Plant, increases in exports would be relatively similar in average annual and SVI dry and critical years. Table 6-28 shows average annual exports through Banks Pumping Plant for the various SLWRI alternatives.

Table 6-28. Simulated Monthly Average Exports Through the Banks Pumping Plant

Month	Existing Condition (2005)				Future Condition (2030)

cfs = cubic feet per second

CP = Comprehensive Plan

TAF = thousand acre-feet

As described in Chapter 1 of the *Hydrology, Hydraulics, and Water Management Technical Report*, the SWP delivers water supplies to contractors both north and south of the Delta, and makes all of its exports through the Banks Pumping Plant. Because of the increased exports described in Table 2-25, it is reasonable to expect a similar increase in deliveries to SWP contractors south of the Delta. Of the approximately 4.2 MAF of Table A contracts, about 4 MAF are held by contractors south of the Delta. Table 6-29 shows the average monthly increases in SWP Table A deliveries to contractors south of the Delta.

Since a large portion of the SWP Table A demands south of the Delta are for M&I use, the monthly pattern of deliveries is fairly even throughout the year, compared to the CVP contractors, who are primarily agricultural, and only require water supply during the irrigation season.

Table 6-29. Simulated Monthly Average Deliveries to SWP Table A Contractors South of the Delta

Month	Existing Condition (2005)				Future Condition (2030)

Notes:

Simulation period: 1922-2003

(%) indicates percent change from either existing condition or No-Action Alternative

Key:

Alt = alternative

cfs = cubic feet per second

CP = Comprehensive Plan

SWP = State Water Project

TAF = thousand acre-feet

In SVI dry and critical years, SWP Table A deliveries are relatively lower because of less available water supply. In these periods, the ability of the SWP to deliver more water under the SLWRI alternatives would be improved because of increased releases from Shasta Reservoir improving Delta water quality. Table 6-30 shows the SWP Table A deliveries to south-of-Delta contractors in SVI dry and critical years.

Differences in timing between exports through the Jones and Banks pumping plants and deliveries to CVP and SWP contractors would be due to the ability of both projects to store water in San Luis Reservoir during winter months, and to use that storage to augment Delta exports in summer months with releases from San Luis Reservoir. (Attachment A of the *Hydrology, Hydraulics, and Water Management Technical Report*, includes information about San Luis Reservoir storage.

Table 6-30. Simulated Monthly Average Deliveries to SWP Table A Contractors South of the Delta in Dry and Critical Years

Month	Existing Condition (2005)				Future Condition (2030)			
	Existing Condition (cfs)	Change from Base			No-Action Alt (cfs)	Change from Base

Changes in Delta export operations could also result in changes in reservoir operations south of the Delta along the San Joaquin River. Any changes in operations of South-of-Delta reservoirs would be reflected in changes in San Joaquin River flows near its confluence with the Delta. The San Joaquin River at Vernalis is commonly used as the downstream end of the San Joaquin River. Table 6-31 shows simulated San Joaquin River flow at Vernalis. According to modeling, the SLWRI alternatives do not affect San Joaquin River flows at Vernalis.

Table 6-31. Simulated Monthly Average San Joaquin River flows at Vernalis

SWP = State Water Project

TAF = thousand acre-feet

No-Action Alternative

Under the No-Action Alternative, Shasta Dam would not be modified, and the CVP would continue operating similar to the existing condition. Changes in regulatory conditions and water supply demands would result in differences in flows on the Sacramento River and at the Delta. Possible changes include the following:

- Firm Level 2 Federal refuge needs
- Implementation of the Sacramento Area Water Forum Agreement on the American River
- Increased CCWD contract supply and water rights
- SWP deliveries based on full Table A amounts
- Use of the Delta-Mendota Canal–California Aqueduct Intertie
- Implementation of the San Joaquin River Salinity Management Program
- CVP use of Banks Pumping Plant to move 50,000 acre-feet/year of Level 2 refuge water
- Implementation of permanent operable Delta barriers

For a complete list of the differences between the No-Action Alternative and the existing conditions, see Table 2-1 in the Modeling Appendix.

Each of these changes could result in different operations of Shasta Reservoir, and could result in impacts to the various impact indicators. As described above, modeling indicates that the No-Action Alternative would continue to meet water supply demands at levels of compliance similar to the existing conditions, and would not result in any appreciable changes in water supply reliability.

Shasta Lake and Vicinity The significance criteria for H&H are not expected to apply in the Shasta Lake and Vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (No-Action): Change in Frequency of Flows Above 100,000 cfs on the Sacramento River Below Bend Bridge Flood management operations would not change under the No-Action Alternative as compared to the existing condition. There would be no impact.

Flood management operations at Shasta Dam would not be expected to change under the No-Action Alternative as compared to the existing condition.

Therefore, the recurrence of flows above 100,000 cfs on the Sacramento River below Bend Bridge would be expected to be the same.

Therefore, Impact H&H-1 (No-Action) would have no impact. Mitigation is not required for the No-Action Alternative.

Impact H&H-2 (No-Action): Place Housing or Other Structures Within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map No new structures will be built in the 100-year flood plain. Therefore, there would be no impact.

No new structures would be built in the flood plain under the No-Action Alternative, and flood management operations at Shasta Dam would not be expected to change under the No-Action Alternative as compared to the existing condition.

Therefore, Impact H&H-2 (No-Action) would have no impact. Mitigation is not required for the No-Action Alternative.

Impact H&H-3(No-Action): Place Within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows No new structures will be built in the 100-year flood plain. Therefore, there would be no impact.

No new structures would be built in the flood plain under the No-Action Alternative, and flood management operations at Shasta Dam would not be expected to change under the No-Action Alternative compared to the existing condition.

Therefore, Impact H&H-3 (No-Action) would have no impact. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta

Impact H&H-4 (No-Action): Change in Water Levels in the Old River near Tracy Road Bridge Water levels in the Old River near Tracy Road Bridge could be substantially lower under the No-Action Alternative than the existing condition. Therefore, this impact would be potentially significant.

As shown in Table 6-32, there will be some noticeable differences in water level in the Old River near the Tracy Road Bridge. These differences are due to the construction of permanent operable barriers rather than the temporary barriers included in the existing condition. Specifically, the permanent barriers will use different gate operations than the temporary barriers, resulting in typically decreased water levels under the No-Action Alternative.

Therefore, Impact H&H-4 (No-Action) would be potentially significant. Mitigation is not required for the No-Action Alternative.

Table 6-32. Simulated Monthly Maximum 15-Minute Change in Water Levels at Various Locations in the South Delta at Low-Low Tide

Month	Change from Existing Condition		
	Old River near Tracy Road Bridge (feet)	Grant Line Canal near the Grant Line Canal Barrier (feet)	Middle River near the Howard Road Bridge (feet)
April	-0.38 (11)	-0.79 (14)	-1.26 (30)
May	-2.66 (63)	-2.55 (68)	-1.72 (36)
June	-3.38 (73)	-3.05 (72)	-1.24 (68)
July	-3.06 (73)	-2.72 (73)	-1.10 (72)
August	-2.76 (73)	-2.46 (73)	-1.13 (73)
September	-2.38 (73)	-1.76 (73)	-1.15 (73)
October	-2.09 (73)	-2.14 (73)	-1.16 (73)

Source: Common Assumptions Common Modeling Package Version 8D DSM2 2005 and 2030 simulations (Node 071_0, 206_5533, and 129_0)

Notes:

Simulation period: 1922-1994

Number in parentheses indicates number of months with a maximum decrease in water level exceeding 0.1 foot

Impact H&H-5 (No-Action): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Water levels in the Grant Line Canal near the Grant Line Canal Barrier could be substantially lower under the No-Action Alternative than the existing condition. Therefore, this impact would be potentially significant.

Similar to Impact H&H-4, as shown in Table 6-32, water levels under the No-Action Alternative will typically be lower than under the existing condition because of differences in operation of south Delta barriers.

Therefore, Impact H&H-5 (No-Action) would be potentially significant. Mitigation is not required for the No-Action Alternative. *Impact H&H-6 (No-Action): Change in Water Levels in the Middle River near the Howard Road Bridge* Water levels in the Middle River near Howard Road Bridge could be substantially lower under the No-Action Alternative than the existing condition. Therefore, this impact would be potentially significant.

Similar to Impact H&H-4, as shown in Table 6-32, water levels under the No-Action Alternative will typically be lower than under the existing condition because of differences in operation of south Delta barriers.

Therefore, Impact H&H-6 (No-Action) would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact H&H-7 (No-Action): Change in X2 Position X2 Position would not change from west of either Collinsville or Chipps Island, whichever is the controlling location, from the existing condition to the No-Action Alternative. Therefore, there would be no impact.

Examination of simulation output indicates that compared to the existing condition there would be no months when the No-Action Alternative would cause the X2 position to shift westward from either Collinsville or Chipps Island, depending on the applicable standard, to east of the respective location.

Therefore, there would be no impact for Impact H&H-7 (No-Action Alternative). Mitigation is not required for the No-Action Alternative.

Impact H&H-8 (No-Action): Change in Recurrence of Delta Excess Conditions
The No-Action Alternative could result in a change of recurrence of Delta excess conditions at a frequency potentially impacting CCWD's ability to fill Los Vaqueros Reservoir. Therefore, this impact would be potentially significant.

As shown in Table 6-33, the No-Action Alternative would cause many changes from excess to balanced conditions compared to the existing condition.

Because of the large number of occurrences, Impact H&H-8 (No-Action) would be potentially significant. Mitigation is not required for the No-Action Alternative.

Table 6-33. Simulated Number of Years the Delta Changes from Excess to Balanced Condition

Number of Years the Delta Changes from Excess to Balanced Conditions Compared to Existing Condition											
Jan	**Feb**	**Mar**	**Apr**	**May**	**Jun**	**Jul**	**Aug**	**Sep**	**Oct**	**Nov**	**Dec**
63 (76%)	55 (66%)	49 (59%)	59 (71%)	60 (72%)	26 (31%)	5 (6%)	9 (11%)	22 (27%)	18 (22%)	32 (39%)	46 (55%)

Notes:
Simulation Period: 1922-2003
Number in parentheses indicates percentage of months Delta condition change occurs

CVP/SWP Service Areas

Impact H&H-9 (No-Action): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to north-of-Delta CVP water service contractors and refuges would be greater under the No-Action Alternative relative to the existing condition, but there may be potentially large decreases in certain months. Therefore, this impact would be potentially significant.

As shown in Table 6-34, average annual deliveries under the No-Action Alterative to North-of-Delta CVP water service contractors and refuges would be greater than under existing conditions, but April deliveries could potentially decrease by 5 percent under both average annual and dry and critical years.

Therefore, Impact H&H-9 (No-Action) would be potentially significant. Mitigation is not required for the No-Action Alternative.

Table 6-34. Simulated Monthly Average Deliveries and Percent Change of Deliveries to North-of-Delta CVP Water Service Contractors and Refuges

Month	Change from Existing Conditions	
	Average All Years (cfs (%))	Dry and Critical Years (cfs (%))
October	53 (18%)	52 (19%)
November	47 (17%)	46 (17%)
December	28 (10%)	28 (10%)
January	13 (5%)	13 (5%)
February	12 (4%)	10 (4%)
March	2 (1%)	3 (1%)
April	-15 (-5%)	-13 (-5%)
May	24 (8%)	7 (2%)
June	45 (16%)	15 (5%)
July	60 (21%)	22 (8%)
August	64 (23%)	33 (12%)
September	56 (20%)	42 (15%)
Total (TAF)	24 (8%)	16 (6%)

Notes:

Simulation period: 1922-1994. Change as measured from either existing condition or No-Action Alternative. Dry and critical years as defined by the Sacramento Valley Index

Key:

cfs = cubic feet per second

TAF = Thousand acre-feet

Impact H&H-10 (No-Action): Change in Deliveries to South-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to south-of-Delta CVP water service contractors and refuges would increase under the No-Action Alternative relative to the existing condition, but there may be potentially large average .decreases in some months. Therefore, this impact would be potentially significant.

As shown in Table 6-35, annual deliveries to South-of-Delta CVP water service contractors and refuges would increase by 8 percent and 6 percent in average annual and dry and critical years, respectively. However, average April deliveries under both average annual and dry and critical years could decrease by 5 percent on average.

Therefore, Impact H&H-10 (No-Action) would be potentially significant. Mitigation is not required for the No-Action Alternative.

Table 6-35. Simulated Monthly Average Deliveries and Percent Change of Deliveries to South-of-Delta CVP Water Service Contractors and Refuges

Month	Change from Existing Conditions	
	Average All Years (cfs (%))	Dry and Critical Years (cfs (%))
October	-63 (-4%)	-63 (-4%)
November	-42 (-2%)	-42 (-3%)
December	-9 (-1%)	-8 (-1%)
January	30 (2%)	29 (2%)
February	45 (3%)	42 (3%)
March	53 (3%)	2 (0%)
April	52 (3%)	-2 (0%)
May	37 (2%)	-18 (-1%)
June	87 (5%)	-4 (0%)
July	142 (8%)	30 (2%)
August	91 (5%)	14 (1%)
September	-37 (-2%)	-60 (-4%)
Total (TAF)	23 (1%)	-5 (0%)

Key:

cfs = cubic feet per second

TAF = thousand acre-feet

Impact H&H-11 (No-Action): Change in Deliveries to SWP Table A Contractors South of the Delta Average annual deliveries to SWP Table A contractors south of the Delta would increase, but average deliveries in some month could decrease, therefore, this impact would be potentially significant.

As shown in Table 6-36, average annual and monthly deliveries to SWP Table A contractors south of the Delta would increase under the No-Action Alternative relative to existing conditions when averaging all years. However, when averaging dry and critical years, there are decreases in average deliveries in June, July, and August of 3 percent, 2 percent, and 1 percent, respectively.

Therefore, Impact H&H-11 (No-Action) would be potentially significant. Mitigation is not required for the No-Action Alternative.

Table 6-36. Simulated Monthly Average Deliveries and Percent Change of Deliveries to SWP Table A Contractors South-of-Delta

Month	Change from Existing Conditions	
	Average All Years (cfs (%))	Dry and Critical Years (cfs (%))
October	68 (2%)	76 (2%)
November	226 (6%)	210 (6%)
December	400 (10%)	340 (9%)
January	1,049 (26%)	401 (11%)
February	1,793 (44%)	665 (18%)
March	1,019 (25%)	308 (9%)
April	721 (18%)	126 (4%)
May	790 (19%)	216 (6%)
June	249 (6%)	-118 (-3%)
July	296 (7%)	-98 (-3%)
August	258 (6%)	-43 (-1%)
September	187 (5%)	29 (1%)
Total (TAF)	420 (10%)	125 (3%)

Source: Common Assumptions Common Modeling Package, version 8D CalSim-II 2005 and 2030 simulations (Nodes DEL_SWP_PAG and DEL_SWP_PMI)

Notes:

Simulation period: 1922-1994. Change as measured from either existing condition or No-Action Alternative. Dry and critical years as defined by the Sacramento Valley Index

Key:

cfs = cubic feet per second

TAF = Thousand acre-feet

Impact H&H-12(No-Action): Change in Groundwater Changes in groundwater levels under the No-Action Alternative as compared to the existing condition would not be noticeable. Therefore, this impact would be less than significant.

As shown in Tables 6-12, 6-13, 6-24, 6-25, 6-29, and 6-30, surface water deliveries to CVP and SWP contractors would be expected to increase for the No-Action Alternative compared to the existing condition. However, these increases in deliveries are likely associated with increases in demands rather than increases in water supply. Therefore, while groundwater pumping would still be required, groundwater usage in the CVP/SWP service area would not be expected to change noticeably.

Thus, Impact H&H-12 (No-Action) would be less than significant. Mitigation is not required for the No-Action Alternative.*Impact H&H-13 (No-Action): Change in Groundwater Quality* Changes in groundwater quality under the No-Action Alternative as compared to the existing condition would not be noticeable. Therefore, this impact would be less than significant.

As shown in Tables 6-12, 6-13, 6-24, 6-25, 6-29, and 6-30, surface water deliveries to CVP and SWP contractors would be expected to increase for the No-Action Alternative compared to the existing condition. However, these increases in deliveries are likely associated with increases in demands rather than increases in water supply. Therefore, while groundwater pumping would still be required, groundwater usage in the CVP/SWP service area would not be expected to change noticeably.

Thus, Impact H&H-13 (No-Action) would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Operations under CP1 would be similar to the bases of comparison, but Shasta Reservoir would be raised by 6.5 feet, and would have 256 TAF increased storage. With the enlarged storage capacity, at Shasta Reservoir, there would be minor changes in operations. This section describes the environmental consequences of CP1.

Shasta Lake and Vicinity The significance criteria for H&H are not expected to apply in the Shasta Lake and Vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (CP1): Change in Frequency of Flows Above 100,000 cfs on the Sacramento River Below Bend Bridge CP1 would slightly reduce the frequency of flows greater than 100,000 cfs. Therefore, this impact would be beneficial.

SLWRI modeling uses a monthly time step, which is inappropriate for flood control analysis. However, flood management operations for downstream objectives would not change with an increase in reservoir storage. While a slight decrease in recurrence of high flows would be possible, CP1 would not increase the frequency of flows above 100,000 cfs.

Therefore, Impact H&H-1 (CP1) would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP1): Place Housing or Other Structures Within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map No new structures would be built downstream from Shasta Dam. Therefore, there would be no impact.

All project construction would be done at the Shasta Dam site, and while the reservoir area would be expanded, any structures located within the reservoir area would be removed. Since reservoir operations for downstream objectives would not change, no additional structures downstream from the dam would be located within the 100-year flood hazard area.

Therefore, there would be no impact for Impact H&H-2 (CP1). Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP1): Place Within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows No new structures would be built downstream from Shasta Dam. Therefore, there would be no impact.

All project construction would be done at the Shasta Dam site, and while the reservoir area would be expanded, any structures located within the reservoir area would be removed. Since reservoir operations for downstream objectives would not change, no additional structures downstream from the dam would be located within the 100-year flood hazard area which would impede or redirect flood flows.

Therefore, there would be no impact for Impact H&H-3 (CP1). Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact H&H-4 (CP1): Change in Water Levels in the Old River near Tracy Road Bridge Delta export operations associated with CP1 would result in increased Delta exports during some months. Accordingly, there would be a possibility of changes in south Delta water levels at times. This impact would be less than significant.

During the agricultural season (April through October), the maximum change in water level at low-low tide compared to the existing condition exceeds 0.1 foot in 2 months, May and June, 1954. As shown in Table 6-37, compared to the No-Action Alternative, CP1 would result in water level changes in excess of 0.1 foot in 15 months during the agricultural season, representing 3 percent of months in the irrigation season. The greatest decrease would be 0.27 foot in July 1930.

Because of the rare incidence of maximum water level changes exceeding 0.1 foot, Impact H&H-4 (CP1) would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-37. Simulated Monthly Maximum 15-Minute Change in Old River Water Levels near Tracy Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP1 (2005) Change (feet)	CP1 (2030) Change (feet)
April	-0.06 (0)	-0.13 (2)
May	-0.14 (1)	-0.13 (1)
June	-0.13 (1)	-0.16 (2)
July	-0.09 (0)	-0.27 (5)
August	-0.06 (0)	-0.13 (2)
September	-0.04 (0)	-0.18 (2)
October	-0.04 (0)	-0.13 (1)

Source: Common Assumptions Common Modeling Package Version 8D DSM2 2005 and 2030 simulations (Node 071_0)

Notes:

Simulation period: 1922-1994

Number in parentheses indicates number of months with a maximum decrease in water level exceeding 0.1 foot

Key:

CP = Comprehensive Plan

Impact H&H-5 (CP1): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Similar to Impact H&H-4 (CP1), CP1 would have the potential to affect water levels in the Grant Line Canal above the Grant Line Canal Barrier. This impact would be less than significant.

As shown in Table 6-38, maximum monthly changes in minimum daily water level associated with CP1 would exceed 0.1 foot in 2 months during the irrigation season, June 1987 and July 1955, compared to the existing condition. When compared to the No-Action Alternative, maximum monthly changes in excess of 0.1 foot occur in 10 months during the irrigation season, representing 2 percent of months.

Because of the low incidence of changes in water level greater than 0.1 foot, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-38. Simulated Monthly Maximum 15-Minute Change in the Grant Line Canal Water Levels near the Grant Line Canal Barrier at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP1 (2005) Change (feet)	CP1 (2030) Change (feet)
April	-0.05 (0)	-0.12 (1)
May	-0.11 (1)	-0.13 (1)
June	-0.11 (1)	-0.15 (1)
July	-0.09 (0)	-0.21 (3)
August	-0.07 (0)	-0.13 (1)
September	-0.04 (0)	-0.16 (2)
October	-0.05 (0)	-0.11 (1)

CP = Comprehensive Plan

Impact H&H-6 (CP1): Change in Water Levels in the Middle River near the Howard Road Bridge This impact is similar to both Impacts H&H-4 (CP1) and H&H-5 (CP1), and would be less than significant.

As shown in Table 6-39, maximum monthly changes in minimum daily water levels in the Middle River near the Howard Road Bridge would exceed 0.1 foot in 2 months compared to the existing condition, and in 16 months compared to the No-Action Alternative. A change in 16 months out of the 73 year period of record represents 3 percent of the months during the irrigation season.

Because of the low incidence of changes in water level greater than 0.1 foot, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-39. Simulated Monthly Maximum 15-Minute Change in Middle River Water Levels near the Howard Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP1 (2005) Change (feet)	CP1 (2030) Change (feet)
April	-0.04 (0)	-0.13 (2)
May	-0.08 (0)	-0.12 (1)
June	-0.12 (1)	-0.13 (2)
July	-0.10 (1)	-0.24 (5)
August	-0.04 (0)	-0.15 (3)
September	-0.02 (0)	-0.17 (2)
October	-0.02 (0)	-0.12 (1)

Key:

CP = Comprehensive Plan

Impact H&H-7 (CP1): Change in X2 Position Changes in X2 position from west of either Collinsville or Chipps Island, depending on the applicable standard, would be extremely rare, so this impact would be less than significant.

Examination of simulation output indicates that compared to the existing condition, there would be no months when the No-Action Alternative would cause the X2 position to shift from either west of Collinsville or Chipps Island, depending on the applicable standard, to east of the respective location.

Compared to the No-Action Alternative, there would be 1 month, December 1929, when the X2 position would change from west to east of Collinsville. Under the No-Action Alternative, the X2 position would be at 80.97 kilometers (km), and under CP1, it would be at 81.05 km, a 0.08 km shift.

Because of the extremely rare occurrence and the very low magnitude of change, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP1): Change in Recurrence of Delta Excess Conditions Changes from excess to balance Delta conditions would be very rare, so this impact would be less than significant.

As shown in Table 6-40, CP1 would cause one February, one March and one September to switch from excess to balanced Delta conditions when compared to the existing condition, and three Julys, two Augusts, and one each of January, June, September, November, and December when compared to the No-Action Alternative.

Because of the low number of occurrences, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact H&H-9 (CP1): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges Average annual and monthly deliveries would increase under both existing and future conditions. Therefore, this impact would be beneficial.

As shown in Table 6-41, average annual and average monthly deliveries under both existing and future conditions would increase relative to the basis of comparison when averaging all years, and dry and critical years.

Therefore, Impact H&H-9 (CP1) would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-11 (CP1): Change in Deliveries to SWP Table A Contractors South of the Delta Average annual deliveries would increase under both existing and future conditions, but there could be some less than significant decreases in monthly deliveries under future conditions. Therefore, this impact would be less than significant.

As shown in Table 6-43, average annual deliveries to SWP Table A contractors south of the Delta would increase under Alternative CP1 in both existing and future conditions relative to the bases of comparison in both average years and in dry and critical years. Under existing conditions, the average monthly deliveries would increase in all months, but there could be some decreases in deliveries under Alternative CP1 relative to the No-Action Alternative under Future Conditions in both average annual and dry and critical years. These decreases would be less than 1 percent, and would therefore not be significant.

Therefore, Impact H&H-11 (CP1) would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Key:

cfs = cubic feet per second

CP = Comprehensive Plan

TAF = Thousand acre-feet

Impact H&H-12 (CP1): Change in Groundwater Levels CP1 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. Therefore, this impact would be beneficial for groundwater levels.

With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP1. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. With less groundwater pumping, groundwater basins that are in overdraft conditions would be anticipated to recover as a result of increasing groundwater levels.

Accordingly, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP1): Change in Groundwater Quality CP1 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping could improve groundwater quality. Therefore, this impact would be less than significant for groundwater quality.

This impact would be beneficial for groundwater levels and less than significant for groundwater quality. With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP1. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. Because CP1 would have a positive, albeit limited, impact by reducing reliance on groundwater, it is anticipated that the impacts of CP1 on groundwater quality would be also limited.

Accordingly, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Operations under CP2 would be similar to CP1, except the Shasta Dam and Reservoir enlargement would be 12.5 feet and 443 TAF, respectively, rather than 6.5 feet and 256 TAF, respectively. With the increased storage capacity at Shasta Reservoir, there would be minor changes in operations. However, all impacts would be similar to those observed under CP1. This section describes the environmental consequences of CP2.

Shasta Lake and Vicinity The significance criteria for H&H are not expected to apply in the Shasta Lake and Vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (CP2): Change in Frequency of Flows Above 100,000 cfs on the Sacramento River Below Bend Bridge This impact would be similar to Impact H&H-1 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP2): Place Housing or Other Structures Within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map This impact would be the same as Impact H&H-2 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP2): Place Within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows This impact would be the same as Impact H&H-3 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact H&H-4 (CP2): Change in Water Levels in Old River near Tracy Road Bridge Impact H&H-4 (CP2) would be very similar to Impact H&H-4 (CP1), except the amount of annual exports would be slightly greater under CP2. This impact would be less than significant.

Table 6-44, shows maximum monthly changes in minimum daily Old River water levels near Tracy Road Bridge. Under the existing condition, CP2 would result in 3 months during the irrigation season when the maximum change in water level at low-low tide would exceed 0.1 foot. Compared to the No-Action Alternative, there would be 24 months with maximum changes in water levels exceeding 0.1 foot. A change of 24 months represents less than 5 percent of the irrigation season during the period of record.

Because of the low incidence of changes in minimum daily water level exceeding 0.1 foot, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-44. Simulated Monthly Maximum 15-Minute Change in Old River Water Levels near Tracy Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP2 (2005) Change (feet)	CP2 (2030) Change (feet)
April	-0.06 (0)	-0.30 (3)
May	-0.14 (1)	-0.13 (2)
June	-0.13 (1)	-0.16 (2)

Impact H&H-5 (CP2): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Impact H&H-5 (CP2) would be very similar to Impact H&H-5 (CP1), except the amount of Delta exports would be slightly greater under CP2. This impact would be less than significant.

Table 6-45 shows maximum monthly changes in minimum daily Grant Line Canal water levels above the Grant Line Canal Barrier. Under existing condition, CP2 would result in 4 months during the irrigation season when the maximum change in water level at low-low tide would exceed 0.1 foot. Compared to the No-Action Alternative, there would be 15 months with maximum changes in water levels exceeding 0.1 foot. A change of 15 months represents less than 3 percent of the irrigation season during the period of record.

Because of the low incidence of changes in minimum daily water level exceeding 0.1 foot, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-45. Simulated Monthly Maximum 15-Minute Change in Grant Line Canal Water Levels near the Grant Line Canal Barrier at Low-Low Tide

Impact H&H-6 (CP2): Change in Water Levels in the Middle River near the Howard Road Bridge Impact H&H-6 (CP2) would be very similar to Impact H&H-6 (CP1), except the amount of Delta export would be slightly greater under CP2, resulting in slightly different south Delta water levels. This impact would be less than significant.

Table 6-46 shows maximum monthly changes in minimum daily Middle River water levels near the Howard Road Bridge. Under the existing condition, CP2 would result in 2 months during the irrigation season when the maximum change in water level at low-low tide would exceed 0.1 foot. Compared to the No-Action Alternative, there would be 21 months with maximum changes in water levels exceeding 0.1 foot. A change of 21 months represents 4 percent of the irrigation season during the period of record.

Because of the low incidence of changes in minimum daily water level exceeding 0.1 foot, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-46. Simulated Monthly Maximum 15-Minute Change in Middle River Water Levels near the Howard Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP2 (2005) Change (feet)	CP2 (2030) Change (feet)

Impact H&H-7 (CP2): Change in X2 Position Changes in X2 position from west of either Collinsville or Chipps Island, depending on the applicable standard, would be extremely rare, so this impact would be less than significant.

Similar to Impact H&H-7 (CP1) examination of simulation output indicates that compared to the existing condition, there would be no months when the No-Action Alternative would cause the X2 position to shift from either west of Collinsville or Chipps Island, depending on the applicable standard, to east of the respective location. Compared to the No-Action Alternative, there would be 1 month, December 1929, when the X2 position would change from west to east of Collinsville. Under the No-Action Alternative, the X2 position would be at 80.97 km, and under CP2, it would be at 81.04 km, a 0.07 km shift.

Because of the extremely rare occurrence and the very low magnitude of change, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP2): Change in Recurrence of Delta Excess Conditions Changes from excess to balance Delta conditions would be very rare, so this impact would be less than significant.

As shown in Table 6-47, CP2 would cause one February and one September to change from excess to balanced Delta conditions when compared to the existing condition, and three Julys, two Augusts, and one each of January, June, September, and November when compared to the No-Action Alternative.

Because of the low number of occurrences, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-10 (CP2): Change in Deliveries to South-of-Delta CVP Water Service Contractors and Refuges Impact H&H-10 (CP2) would be similar to Impact H&H-10 (CP1) except the increase in deliveries would be greater under CP2. Therefore, this impact would be beneficial.

As shown in Table 6-49, average annual and average monthly deliveries under both existing and future conditions would increase relative to the basis of comparison when averaging all years, and dry and critical years.

Therefore, Impact H&H-10 (CP2) would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

TAF = Thousand acre-feet

As shown in Table 6-50, average annual deliveries to SWP Table A contractors south of the Delta would increase under Alternative CP2 in both existing and future conditions relative to the bases of comparison in both average years and in dry and critical years. Under existing conditions, the average monthly deliveries would increase in all months, but there could be some decreases in deliveries under Alternative CP2 relative to the No-Action Alternative under

future conditions in both average annual and dry and critical years. These decreases would be less than 1 percent, and would therefore not be significant.

Therefore, Impact H&H-11 (CP2) would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-50. Simulated Monthly Average Deliveries and Percent Change of Deliveries to SWP Table A Contractors South-of-Delta

Month	Existing Condition (2005)				Future Condition (2030)

CP = Comprehensive Plan

TAF = Thousand acre-feet

Impact H&H-12 (CP2): Change in Groundwater Levels CP2 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. Therefore, this impact would be beneficial for groundwater levels.

With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP2. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. With less groundwater pumping, groundwater basins

that are in overdraft conditions would be anticipated to recover as a result of increasing groundwater levels.

Accordingly, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP2): Change in Groundwater Quality CP2 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping could improve groundwater quality. Therefore, this impact would be less than significant for groundwater quality.

With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP2. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. Because CP2 would have a positive, albeit limited, impact by reducing reliance on groundwater, it is anticipated that the impacts of CP2 on groundwater quality would be also limited.

Accordingly, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Operations under CP3 would be similar to CP1, except the Shasta Dam and Reservoir enlargement would be 18.5 feet and 634 TAF, respectively, rather than 6.5 feet and 256 TAF, respectively. With the increased storage capacity of Shasta Reservoir, there would be minor changes in operations. However, all impacts would be similar to those observed under CP1. This section describes the environmental consequences of CP3.

Shasta Lake and Vicinity The significance criteria for H&H are not expected to apply in the Shasta Lake and Vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (CP3): Change in Frequency of Flows Above 100,000 cfs on the Sacramento River Below Bend Bridge This impact would be similar to Impact H&H-1 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP3): Place Housing or Other Structures Within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map This impact

would be the same as Impact H&H-2 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP3): Place Within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows This impact would be the same as Impact H&H-3 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact H&H-4 (CP3): Change in Water Levels in Old River near Tracy Road Bridge Impact H&H-4 (CP3) would be very similar to Impact H&H-1 (CP1), except export amounts would be slightly higher under CP3, resulting in slightly different water levels. This impact would be less than significant.

Table 6-51 shows the maximum monthly change in minimum daily Old River water levels near Tracy Road Bridge. Under existing condition, Alternative CP3 would result in 4 months during the irrigation season when the maximum change in water level at low-low tide would exceed 0.1 foot. Compared to the No-Action Alternative, there would be 33 months with maximum changes in water levels exceeding 0.1 foot. A change of 33 months represents 6 percent of the irrigation season during the period of record.

Because of the low incidence of changes in minimum daily water level exceeding 0.1 foot, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-51. Simulated Monthly Maximum 15-Minute Change in Old River Water Levels near Tracy Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP3 (2005) Change (feet)	CP3 (2030) Change (feet)
April	-0.07 (0)	-0.32 (4)
May	-0.14 (1)	-0.14 (2)
June	-0.13 (2)	-0.16 (2)
July	-0.11 (1)	-0.26 (10)
August	-0.08 (0)	-0.26 (6)
September	-0.06 (0)	-0.18 (6)

Key:

CP = Comprehensive Plan

Impact H&H-5 (CP3): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Impact H&H-2 (CP3) would be very similar to Impact H&H-5 (CP1), except Delta export amounts would be slightly higher under CP3. This impact would be less than significant.

Table 6-52 shows the maximum monthly change in minimum daily Grant Line Canal water levels above the Grant Line Canal Barrier. Under the existing condition, CP3 would result in 6 months during the irrigation season when the maximum change in water level at low-low tide would exceed 0.1 foot. Compared to the No-Action Alternative, there would be 26 months with maximum changes in water levels exceeding 0.1 foot. A change of 26 months represents 5 percent of the irrigation season during the period of record.

Because of the low incidence of changes in minimum daily water level exceeding 0.1 foot, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-52. Simulated Monthly Maximum 15-Minute Change in Tyrant Line Canal Water Levels near the Grant Line Canal Barrier at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP3 (2005) Change (feet)	CP3 (2030) Change (feet)
April	-0.07 (0)	-0.25 (3)
May	-0.11 (1)	-0.13 (1)
June	-0.11 (2)	-0.10 (0)
July	-0.11 (3)	-0.25 (11)

Impact H&H-6 (CP3): Change in Water Levels in the Middle River near the Howard Road Bridge Impact H&H-6 (CP3) would be very similar to Impact H&H-6 (CP1), except Delta export amounts would be slightly higher under CP3, resulting in slightly different south Delta water levels. Changes in water levels would be very rare; therefore, this impact would be less than significant.

Table 6-53 shows maximum monthly changes in minimum daily Middle River water levels near the Howard Road Bridge. Under the existing condition, CP3 would result in 4 months during the irrigation season when the maximum change in water level at low-low tide would exceed 0.1 foot. Compared to the No-Action Alternative, there would be 30 months with maximum changes in water levels exceeding 0.1 foot. A change of 30 months represents less than 6 percent of the irrigation season during the period of record.

Because of the low incidence of changes in minimum daily water level exceeding 0.1 foot, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-53. Simulated Monthly Maximum 15-Minute Change in Middle River Water Levels near the Howard Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP3 (2005) Change (feet)	CP3 (2030) Change (feet)

Impact H&H-7 (CP3): Change in X2 Position Changes in X2 position from west of either Collinsville or Chipps Island, depending on the applicable standard, would be extremely rare, so this impact would be less than significant.

Similar to Impact H&H-7 (CP1), examination of simulation output indicates that compared to the existing condition there would be no months when the No-Action Alternative would cause the X2 position to shift from either west of Collinsville or Chipps Island, depending on the applicable standard, to east of the respective location. Compared to the No-Action Alternative, there would be 1 month, December 1929, when the X2 position would change from west to east of Collinsville. Under the No-Action Alternative, the X2 position would be at 80.97 km, and under CP3, it would be at 81.05 km, a 0.08 km shift.

Because of the extremely rare occurrence and the very low magnitude of change, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP3): Change in Recurrence of Delta Excess Condition Changes from excess to balance Delta conditions would be very rare, so this impact would be less than significant.

As shown in Table 6-54, CP3 would cause three Februarys and one September to change from excess to balanced Delta conditions when compared to the existing condition, and three Julys, two Augusts, and one each of January, June, September, and November when compared to the No-Action Alternative.

Because of the low number of occurrences, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-54. Simulated Number of Years the Delta Changes from Excess to Balanced Condition

	Number of Years the Delta Changes from Excess to Balanced Conditions Compared to Existing Condition or No-Action Alternative											
	Jan	**Feb**	**Mar**	**Apr**	**May**	**Jun**	**Jul**	**Aug**	**Sep**	**Oct**	**Nov**	**Dec**

TAF = Thousand acre-feet

Impact H&H-11 (CP3): Change in Deliveries to SWP Table A Contractors South of the Delta Impact H&H-11 (CP3) would be similar to Impact H&H-11 (CP1) except the increase in average annual deliveries would be greater, and potential decreases in average monthly deliveries in some months could be slightly larger under CP3. Therefore, this impact would be less than significant.

As shown in Table 6-57, average annual deliveries to SWP Table A contractors south of the Delta would increase under Alternative CP2 in both existing and future conditions relative to the bases of comparison in both average years and in dry and critical years. Under existing conditions, the average monthly deliveries would increase in all months, but there could be some decreases in deliveries under Alternative CP3 relative to the No-Action Alternative under future conditions in both average annual and dry and critical years. These decreases would be around 1 percent, and would therefore not be significant.

Therefore, Impact H&H-11 (CP3) would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-57. Simulated Monthly Average Deliveries and Percent Change of Deliveries to SWP Table A Contractors South-of-Delta

Month	Existing Condition (2005)				Future Condition (2030)			
	Average All Years		Dry and Critical Years		Average All Years		Dry and Critical Years	
	Existing Condition (cfs)	CP3 Change (cfs (%))	Existing Condition (cfs)	CP3 Change (cfs (%))	No-Action Alternative (cfs)	CP3 Change (cfs (%))	No-Action Alternative (cfs)	CP3 Change (cfs (%))

TAF = Thousand acre-feet

Impact H&H-12 (CP3): Change in Groundwater Levels CP3 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. Therefore, this impact would be beneficial for groundwater levels.

With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP3. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. With less groundwater pumping, groundwater basins that are in overdraft conditions would be anticipated to recover as a result of increasing groundwater levels.

Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP3): Change in Groundwater Quality CP3 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping could improve groundwater quality. Therefore, this impact would less than significant for groundwater quality.

With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP3. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. Because CP3 would have a positive, albeit limited, impact by reducing reliance on groundwater, it is anticipated that the impacts of CP3 on groundwater quality would be also limited.

Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

CP4 would differ from the No-Action Alternative primarily through a 634 TAF enlargement of Shasta Reservoir, with 256 TAF operated for water supply reliability, and 378 TAF of the storage dedicated to anadromous fish survivability, through an increase in available cold water for release to the Sacramento River. This section describes the environmental consequences of CP4.

Shasta Lake and Vicinity The significance criteria for H&H are not expected to apply in the Shasta Lake and Vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact H&H-1 (CP4). Change in Frequency of Flows Above 100,000 cfs on the Sacramento River Below Bend Bridge This impact would be similar to Impact H&H-1 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP4). Place Housing or Other Structures Within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map This impact would be the same as Impact H&H-2 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP4). Place Within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows This impact would be the same as Impact H&H-3 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta
Impact H&H-4 (CP4). Change in Water Levels in Old River near Tracy Road Bridge This impact would be the same as Impact H&H-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-5 (CP4). Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier This impact would be the same as Impact H&H-5 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-6 (CP4). Change in Water Levels in Middle River near the Howard Road Bridge This impact would be the same as Impact H&H-6 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-7 (CP4): Change in X2 Position This impact would be the same as Impact H&H-7 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP4): Change in Recurrence of Delta Excess Conditions
This impact would be the same as Impact H&H-8 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas
Impact H&H-9 (CP4): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges This impact would be the same as Impact

H&H-9 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-10 (CP4): Change in Deliveries to South-of-Delta CVP Water Service Contractors and Refuges This impact would be the same as Impact H&H-10 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-11 (CP4): Change in Deliveries to SWP Table A Contractors South of the Delta This impact would be the same as Impact H&H-11 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-12 (CP4). Change in Groundwater Levels This impact would be the same as Impact H&H-12 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP4). Change in Groundwater Quality This impact would be the same as Impact H&H-13 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise Combination Plan

CP5 would differ from the No-Action Alternative primarily through a 634 TAF enlargement of Shasta Reservoir with additional recreation facilities at Shasta Lake and environmental restoration to the lower ends of the Shasta Lake tributaries. This section describes the environmental consequences of CP5.

Shasta Lake and Vicinity The significance criteria for H&H are not expected to apply in the Shasta Lake and Vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (CP5). Change in Frequency of Flows Above 100,000 cfs on the Sacramento River Below Bend Bridge This impact would be similar to Impact H&H-1 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP5): Place Housing or Other Structures Within a 100-year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map This impact would be the same as Impact H&H-2 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP5): Place Within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows This impact would be the same as Impact H&H-3 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact H&H-4 (CP5). Change in Water Levels in Old River near Tracy Road Bridge This impact would be the same as Impact H&H-4 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-5 (CP5): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier This impact would be the same as Impact H&H-5 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-6 (CP5): Change in water levels in Middle River near the Howard Road Bridge This impact would be the same as Impact H&H-6 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-7 (CP5): Change in X2 Position This impact would be the same as Impact H&H-7 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed..

Impact H&H-8 (CP5): Change in Recurrence of Delta Excess Conditions This impact would be the same as Impact H&H-8 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact H&H-9 (CP5): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges This impact would be the same as Impact H&H-9 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-10 (CP5): Change in Deliveries to South-of-Delta CVP Water Service Contractors and Refuges This impact would be the same as Impact H&H-10 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-11 (CP5): Change in Deliveries to SWP Table A Contractors South of the Delta This impact would be the same as Impact H&H-11 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-12 (CP5): Change in Groundwater Levels This impact would be the same as Impact H&H-12 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP5): Change in Groundwater Quality This impact would be the same as Impact H&H-13 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

6.3.4 Mitigation Measures

Table 6-58 presents a summary of the impacts related to hydrology, hydraulics, and water management. No significant impacts have been identified, and therefore no mitigation measures are proposed.

No-Action Alternative

No feasible mitigation is available to reduce the impacts of changes in level of development or new facility construction. Therefore, these potential impacts would remain significant and unavoidable.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are required for this alternative.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are required for this alternative.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are required for this alternative.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

No mitigation measures are required for this alternative.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation measures are required for this alternative.

Table 6-58. Summary of Mitigation Measures for Hydrology, Hydraulics, and Water Management

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5

LTS = less than significant
NI = No Impact
PS = potentially significant

6.3.5 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences" discusses overall cumulative impacts of the project alternatives and, including the relationship to CALFED Programmatic Cumulative Impacts Analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria.

This section provides an analysis of overall cumulative impacts of the project alternatives with other past, present, and reasonably foreseeable future projects producing related impacts.

The projects listed in the quantitative analysis section of Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences" are included in the 2030 level of development alternatives above. Accordingly, quantitative effects of the projects combined with the SLWRI alternatives are described in the Environmental Consequences section. The discussion below focuses on the qualitative effect of the SLWRI alternatives and the other past, present, and reasonably foreseeable future projects.

The effects of climate change on operations at Shasta Lake could potentially result in changes to hydrology, hydraulics, and water management. As described in the Climate Change Projection Appendix, climate change could result in higher reservoir releases in the winter and early spring due to an increase in runoff during these times. The change in winter and early spring releases could necessitate managing flood events resulting from potentially larger storms. Similarly, climate change could result in lower reservoir inflows and Sacramento tributary flows during the late spring and summer due to a decreased snow pack. This reduction in inflow and tributary flow could result in Shasta Lake storage being reduced due to both a reduced ability to capture flows, and an increased need to make releases to meet downstream requirements.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As described in Section 6.3.3 above, CP1 would not result in potentially significant impacts.

When combined with other past, present, and reasonably foreseeable future projects, it is likely there would be a change in flows in the Sacramento River. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, a new project or program along the Sacramento River and in the Delta could potentially affect the hydraulics, hydrology, and water resources of CP1. For instance, if the Shasta River Water Reliability Study (SRWRS) were implemented, Shasta Reservoir would be reoperated, resulting in changes to the Sacramento River flow regime and Delta inflow. However, with the implementation of the other past, present, and

reasonably foreseeable future projects, it is reasonable to assume there would not be a reduction in flow requirements, or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Even though regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP1 combined with other projects could result in changes to water levels during the irrigation season at a magnitude and frequency that would affect south Delta water users. Accordingly, it is possible that CP1 combined with a number of other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and Delta outflow are primarily products of Delta inflow and export pumping. A previously mentioned, CP1 combined with other projects could result in changes to Delta inflow and export pumping. While CP1 results in very rare changes to either the X2 position or Delta outflow of a magnitude affecting CCWD's ability to fill Los Vaqueros Reservoir, and result in less than significant impacts to the X2 position, it is possible CP1 combined with other projects could result in potentially significant and unavoidable impacts.

As previously described, CP1 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is extremely unlikely that CP1, when combined with other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to the bases of comparison. Accordingly, there would not be an effect on groundwater levels or groundwater quality. Therefore, CP1, combined with other projects, would likely have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect Shasta Reservoir's ability to fill its flood management obligations. Consequently, when combined with CP1, the cumulative effect would be no impact or a beneficial effect on flood management.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP1 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Potential impacts associated with flood management, water supply, south Delta water levels, and groundwater management would be less than significant under CP1. Therefore, even with the addition of anticipated effects of climate change, CP1 would not have a significant cumulative effect, and could be potentially beneficial.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As described in Section 6.3.3 above, CP2 would not result in potentially significant impacts.

When combined with the other past, present, and reasonably foreseeable future projects, it is likely there would be a change in flows in the Sacramento River. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, a new project or program along the Sacramento River and in the Delta could potentially affect the hydraulics, hydrology, and water resources of CP2. For instance, if the SRWRS were implemented, Shasta Reservoir would be reoperated, resulting in changes to the Sacramento River flow regime and Delta inflow. However, with the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume there would not be a reduction in flow requirements, or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Even though regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP2 combined with other projects could result in changes to water levels during the irrigation season at a magnitude and frequency that would affect south Delta water users. Accordingly, it is possible that CP2 combined with other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and Delta outflow are primarily products of Delta inflow and export pumping. A previously mentioned, CP2 combined with other projects could result in changes to Delta inflow and export pumping. While CP2 results in very rare changes to either the X2 position or Delta outflow of a magnitude affecting CCWD's ability to fill Los Vaqueros Reservoir, and result in less–than-significant impacts to the X2 position, it is possible CP2 combined with other projects could result in potentially significant and unavoidable impacts.

As previously described, CP2 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is extremely unlikely that CP2, when combined with other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to the bases of comparison. Accordingly, there would not be an effect on groundwater levels or groundwater quality. Therefore, CP2, combined with other projects, would likely have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect Shasta Reservoir's ability to fill its flood management

obligations. Consequently, when combined with CP2, the cumulative effect would be no impact or a beneficial effect on flood management.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP2 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Potential impacts associated with flood management, water supply, south Delta water levels, and groundwater management would be less than significant under CP2. Therefore, even with the addition of anticipated effects of climate change, CP2 would not have a significant cumulative effect, and could be potentially beneficial.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

As described in Section 6.3.3 above, CP3 would not result in potentially significant impacts.

When combined with the other past, present, and reasonably foreseeable future projects, it is likely there would be a change in flows in the Sacramento River. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, a new project or program along the Sacramento River and in the Delta could potentially affect the hydraulics, hydrology, and water resources of CP3. For instance, if the SRWRS were implemented, Shasta Reservoir would be reoperated, resulting in changes to the Sacramento River flow regime and Delta inflow. However, with the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume there would not be a reduction in flow requirements, or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Even though regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP3 combined with other projects could result in changes to water levels during the irrigation season at a magnitude and frequency that would affect south Delta water users. Accordingly, it is possible that CP3 combined with other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and Delta outflow are primarily products of Delta inflow and export pumping. A previously mentioned, CP3 combined with other projects could result in changes to Delta inflow and export pumping. While CP3 results in very rare changes to either the X2 position or Delta outflow of a magnitude affecting CCWD's ability to fill Los Vaqueros Reservoir, and result in less than significant impacts to the X2 position, it is possible CP3 combined

with other projects could result in potentially significant and unavoidable impacts.

As previously described, CP3 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is extremely unlikely that CP3, when combined with a number of other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to the bases of comparison. Accordingly, there would not be an effect on groundwater levels or groundwater quality. Therefore, CP3, combined with a number of other projects, would likely have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect Shasta Reservoir's ability to fill its flood management obligations. Consequently, when combined with CP3, the cumulative effect would be no impact or a beneficial effect on flood management.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP3 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Potential impacts associated with flood management, water supply, south Delta Water levels, and groundwater management would be less than significant under CP3. Therefore, even with the addition of anticipated effects of climate change, CP3 would not have a significant cumulative effect, and could be potentially beneficial.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

As described in Section 6.3.3 above, CP4 would not result in potentially significant impacts.

When combined with the other past, present, and reasonably foreseeable future projects, it is likely there would be a change in flows in the Sacramento River. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, a new project or program along the Sacramento River and in the Delta could potentially affect the hydraulics, hydrology, and water resources of CP4. For instance, if the SRWRS were implemented, Shasta Reservoir would be reoperated, resulting in changes to the Sacramento River flow regime and Delta inflow. However, with the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume there would not be a reduction in flow requirements, or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Even though regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP4 combined with other projects could result in changes to water levels during the irrigation season at a magnitude and frequency that would affect south Delta water users. Accordingly, it is possible that CP4 combined with other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and Delta outflow are primarily products of Delta inflow and export pumping. A previously mentioned, CP4 combined with other projects could result in changes to Delta inflow and export pumping. While CP4 results in very rare changes to either the X2 position or Delta outflow of a magnitude affecting CCWD's ability to fill Los Vaqueros Reservoir, and result in less than significant impacts to the X2 position, it is possible CP4 combined with other projects could result in potentially significant and unavoidable impacts.

As previously described, CP4 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is extremely unlikely that CP4, when combined with other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to the bases of comparison. Accordingly, there would not be an effect on groundwater levels or groundwater quality. Therefore, CP4, combined with other projects, would likely have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect Shasta Reservoir's ability to fill its flood management obligations. Consequently, when combined with CP4, the cumulative effect would be no impact or a beneficial effect on flood management.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP4 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Potential impacts associated with flood management, water supply, south Delta water levels, and groundwater management would be less than significant under CP4. Therefore, even with the addition of anticipated effects of climate change, CP4 would not have a significant cumulative effect, and could be potentially beneficial.

CP5 – 18.5-Foot Dam Raise, Combination Plan

As described in Section 6.3.3 above, CP5 would not result in potentially significant impacts.

When combined with the other past, present, and reasonably foreseeable future projects, it is likely there would be a change in flows in the Sacramento River.

Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, a new project or program along the Sacramento River and in the Delta could potentially affect the hydraulics, hydrology, and water resources of CP5. For instance, if the SRWRS were implemented, Shasta Reservoir would be reoperated, resulting in changes to the Sacramento River flow regime and Delta inflow. However, with the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume there would not be a reduction in flow requirements, or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Even though regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP5 combined with other projects could result in changes to water levels during the irrigation season at a magnitude and frequency that would affect south Delta water users. Accordingly, it is possible that CP5 combined with other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and Delta outflow are primarily products of Delta inflow and export pumping. A previously mentioned, CP5 combined with other projects could result in changes to Delta inflow and export pumping. While CP5 results in very rare changes to either the X2 position or Delta outflow of a magnitude affecting CCWD's ability to fill Los Vaqueros Reservoir, and result in less than significant impacts to the X2 position, it is possible CP5 combined with other projects could result in potentially significant and unavoidable impacts.

As previously described, CP5 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is extremely unlikely that CP5, when combined with other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to the bases of comparison. Accordingly, there would not be an effect on groundwater levels or groundwater quality. Therefore, CP5, combined with other projects, would likely have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect Shasta Reservoir's ability to fill its flood management obligations. Consequently, when combined with CP5, the cumulative effect would be no impact or a beneficial effect on flood management.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP5 would potentially diminish these effects and allow Shasta Lake to capture some

of the increased runoff in the winter and early spring for release in late spring and summer. Potential impacts associated with flood management, water supply, south Delta water levels, and groundwater management would be less than significant under CP5. Therefore, even with the addition of anticipated effects of climate change, CP5 would not have a significant cumulative effect, and could be potentially beneficial.

Chapter 7
Water Quality

7.1 Affected Environment

This section describes the affected environment related to water quality for the dam and reservoir modifications proposed under the SLWRI. For more detail, please see the *Water Quality Technical Report*.

7.1.1 Overview of Water Quality Conditions

Surface water quality in the study area is affected by natural runoff, agricultural return flows, abandoned mines, construction, logging, grazing, operations of flow-regulating facilities, urbanization, and recreation. This section discusses key water quality constituents of concern (temperature, sediments, and metals), the factors influencing their concentrations, and the regulatory objectives associated with maintaining beneficial uses.

The following discussion provides an overview of water quality and its relationship to beneficial uses throughout the primary and secondary study areas. This section is followed by discussions of key water quality parameters that influence beneficial uses to varying degrees within the study areas; temperature, sediment and metals.

Shasta Lake and Vicinity

This section addresses water quality in the Shasta Lake and vicinity portion of the primary study area. It focuses on the six arms of Shasta Lake and tributaries that enter into Shasta Lake from the surrounding watersheds.

Water quality in this portion of the primary study area generally meets the standards for beneficial uses identified in the *Water Quality Control Plan for the Sacramento River and San Joaquin River Basins* (Basin Plan) (CVRWQCB 2009). The quality of surface waters in Shasta County is generally considered good, although some water bodies are affected by nonpoint pollution sources that influence surface water quality: high turbidity from controllable sediment discharge sources (e.g., land development and roads); high concentrations of nitrates and dissolved solids from range and agricultural runoff or septic tank failures; contaminated street and lawn runoff from urban areas, roads, and railroads; acid mine drainage and heavy metal discharges from historic mining and processing operations; and warm-water discharges into cold-water streams.

The quality of water in underground basins and water-bearing soils is also considered generally good throughout most of Shasta County. Potential hazards

to groundwater quality involve nitrates and dissolved solids from agricultural and range practices and septic tank failures. The ability of soils in Shasta County to support septic tanks and on-site wastewater treatment systems is generally severely limited, particularly on older valley terrace soils and certain loosely confined volcanic soils in the eastern portions of the county (CVRWQCB 2009).

The surface water quality of streams and lakes draining the Shasta-Trinity National Forest (STNF) and adjacent private lands generally meets standards for beneficial uses defined by the Basin Plan (CVRWQCB 2009). There are, however, some areas where the water quality does not meet the standards during periods of storm runoff because of past management activities, or as a result of drainage from historic mining and processing operations. The cumulative impacts of successive activities, such as road construction and timber harvesting on private and National Forest lands, also contribute to the degradation of water quality in the STNF (USFS 1995). Within this portion of the primary study area, most of the road construction and timber harvest activities occur on private lands.

Shasta Dam and Shasta Lake constitute the “keystone of the Central Valley Project.” Approximately 6.2 million acre-feet of water flows annually into Shasta Lake from the Sacramento River, McCloud River, and Pit River drainages. A favorable inflow-outflow relationship of 1.4 to 1 results in good water quality, both in the lake and downstream (USFS 1996), although Shasta Lake is considered an impaired water body due to heavy metal accumulations (e.g., cadmium, copper and zinc) at locations throughout the reservoir (CVRWQCB 2009).

Nutrient inputs and bacteria are not of concern in the Sacramento River and McCloud River arms (USFS 1998); however, they could be an issue in the Pit River Arm as a result of runoff from agricultural and range lands in the upper Pit River watershed. Within Little Backbone Creek, Dry Creek, and the Squaw Creek Arm, the waters are locally limited by low pH and elevated concentrations of heavy metals caused by drainage from abandoned mines (CVRWQCB 2003a). In addition, data suggest that sediment and turbidity locally affect beneficial uses, mainly contact recreation. A recent 2-year study conducted by the State Water Resources Control Board (SWRCB) sampled mercury accumulations in fish at a number of locations throughout Shasta Lake. This study documented elevated levels of mercury in some specimens (Davis et al. 2010).

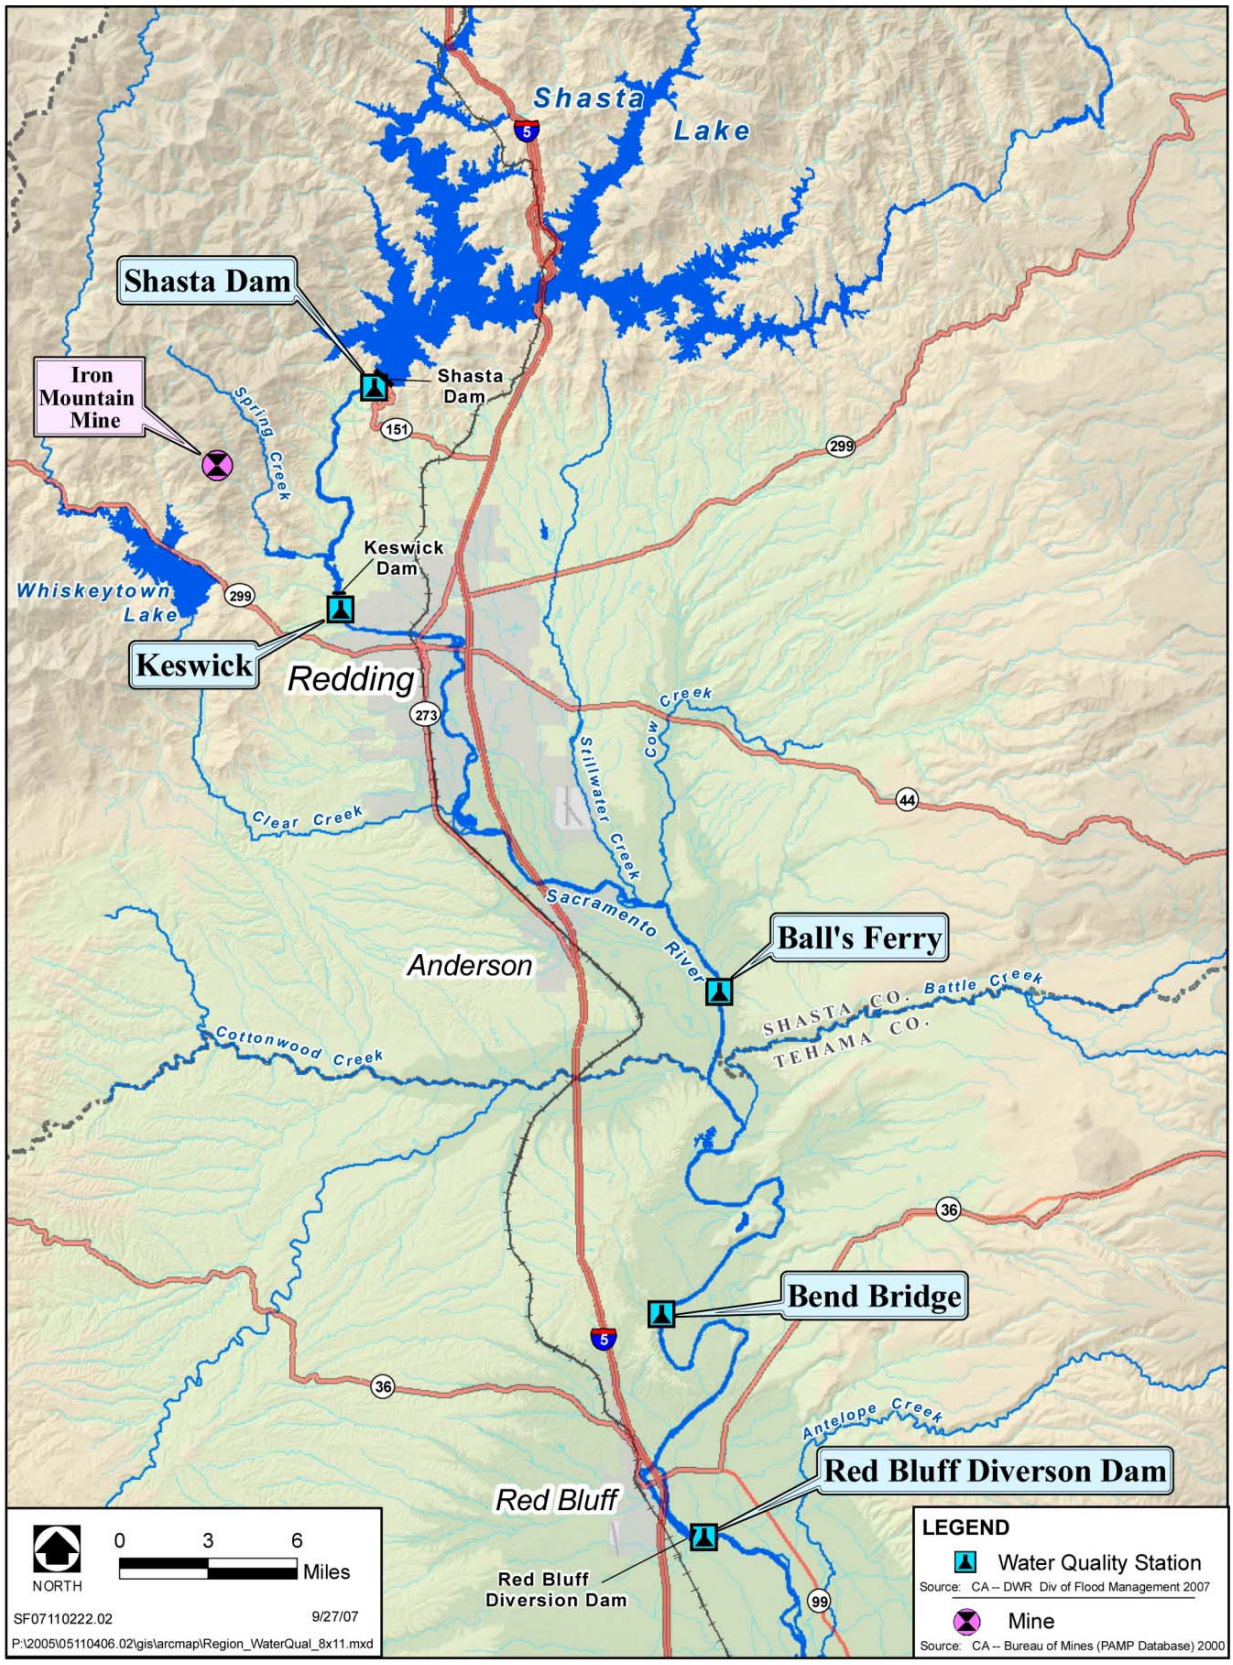

Figure 7-1. Upper Sacramento River Primary Study Area

Upper Sacramento River (Shasta Dam to Red Bluff)

Tributaries to the Upper Sacramento River, and place names referred to in the text are shown in Figure 7-1. The main sources of water in the Sacramento River below Keswick Dam are rain and snowmelt that collect in upstream reservoirs and are released in response to water needs or flood control. The quality of surface water downstream from Keswick Dam is also influenced by other human activities along the Sacramento River downstream from the dam, including agricultural, historical mining, and municipal and industrial (M&I) inputs.

The quality of water in the Sacramento River is relatively good. Only during conditions of stormwater-driven runoff are water quality objectives typically not met (Domagalski et al. 2000). Water quality issues within the primary study area of the Sacramento River include the presence of mercury, pesticides such as organochlorine pesticides, trace metals, turbidity, and toxicity from unknown origin (CALFED 2000a).

Water quality in the Sacramento River and its major tributaries above Red Bluff Diversion Dam (RBDD) is generally good (Table 7-1). Nutrients such as nitrate were found to be low throughout the Sacramento River basin (Domagalski and Dileanis 2000, as cited in Domagalski et al. 2000). Water temperature is a principal water quality issue in the upper Sacramento River between Keswick Dam and RBDD.

Table 7-1. Summary of Conventional Water Quality Constituents Collected in the Sacramento River at Red Bluff from 1996 to 1998

Constituent (unit)	Water Quality Objective	Average Measurement
Conventional Physical and Chemical Constituents		
Temperature	< 2.5ºF [a]	52.7ºF
Conductivity (µS/cm)	–	116
Dissolved Oxygen (mg/L)	7.0 [b]	10.7
Dissolved Oxygen Saturation (%)	85 [b]	99
pH (standard unit)	6.5 to 8.5 [c]	7.8
Alkalinity (mg/L $CaCO_3$)	–	48.3
Total Hardness (mg/L $CaCO_3$)	–	46.6
Suspended Sediment (mg/L)	–	38.8
Calcium (mg/L)	narrative [d]	10.3
Magnesium (mg/L)	–	5.0
Sodium (mg/L)	–	5.8
Potassium (mg/L)	–	1.1
Chloride (mg/L)	500 [e]	2.4

Table 7-1. Summary of Conventional Water Quality Constituents Collected in the Sacramento River at Red Bluff from 1996 to 1998 (contd.)

Constituent (unit)	Water Quality Objective	Average Measurement
Conventional Physical and Chemical Constituents		
Sulfate (mg/L)	500 [e]	4.5
Silica (mg/L)	–	20.5
$NO_2 + NO_3$ (mg/L N)	$NO_3 < 10$ [f]	0.12
Total Phosphorus (mg/L P)	–	0.0477
Trace Metals		
Arsenic (µg/L)	50 [g]	1.0
Chromium (µg/L)	180 [g]	1.0
Copper (µg/L)	5.1 [g]	1.6
Mercury (µg/L)	0.050 [g]	0.0045
Nickel (µg/L)	52 [g]	1.2
Zinc (µg/L)	120 [g]	2.3
Organic Pesticides		
Molinate (ng/L)	13,000 [h]	< 60
Simazine (ng/L)	3,400 [i]	< 22
Carbofuran (mg/L)	40,000 [e], 500 [i]	< 31
Diazinon (mg/L)	51 [j]	< 28
Carbaryl (ng/L)	700 [k]	< 41
Thiobencarb (ng/L)	1,000 [a]	< 38
Chlorpyrifos (ng/L)	14 [J]	< 25
Methidathion (ng/L)	–	< 38

ng/L = nanograms per liter
NO_2 = nitrate
NO_3 = nitrite
ºF = degrees Fahrenheit
P = phosphorus

Although all trace metals shown in Table 7-1 were well below their established water quality objectives, one of the principal water quality issues in the upper

Sacramento River portion of the primary study area is acid mine drainage and associated heavy-metal contamination from the Spring Creek drainage and other abandoned mining sites. It should be noted that the U.S. Geological Survey (USGS) study detected mercury, but it did not exceed the criterion of ambient level specified in the California Toxics Rule; however, California Toxics Rule levels for mercury are not protective to prevent the high concentration of mercury found in fish tissue. In addition to heavy metal contamination, the Central Valley Regional Water Quality Control Board (CVRWQCB) determined that the 25-mile reach of the Sacramento River from Keswick Dam downstream to Cottonwood Creek is impaired because the water periodically contains levels of dissolved cadmium, copper, and zinc that exceed levels identified to protect aquatic organisms. The 26-mile reach from Keswick Dam to Red Bluff is listed for unknown sources of toxicity (CVRWQCB 2007a).

Lower Sacramento River and Delta

Water quality in the lower Sacramento River is affected by agricultural runoff, acid mine drainage, stormwater discharges, water releases from dams, diversions, and urban runoff. However, the flow volumes generally provide sufficient dilution to prevent excessive concentrations of contaminants in the river.

Several total maximum daily loads (TMDL) are currently proposed for the lower Sacramento River. In addition, the Sacramento River downstream from RBDD to Knights Landing is listed as an impaired water body under Section 303(d) of the Clean Water Act (CWA) for mercury and unknown toxicity. Elevated metals and pesticide levels have been found at some sites in the Sacramento River Valley downstream from Knights Landing. The parameters of concern in the Sacramento River from Knights Landing to the Delta include diazinon, mercury, and unknown sources of toxicity (CVRWQCB 2007a, 2007b).

Water quality in the Delta is highly variable temporally and spatially. It is a function of complex circulation patterns that are affected by inflows, pumping for Delta agricultural operations and exports, operation of flow control structures, and tidal action. The existing water quality problems of the Delta system may be categorized as presence of toxic materials, eutrophication and associated fluctuations in dissolved oxygen, presence of suspended sediments and turbidity, salinity, and presence of bacteria (SWRCB 1999).

The Delta waterways within the area under CVRWQCB jurisdiction are listed as impaired on the U.S. Environmental Protection Agency's (EPA) 303(d) list for dissolved oxygen, electrical conductivity (EC), dichlorodiphenyl-trichloroethane, mercury, Group A pesticides, diazinon and chlorpyrifos, and unknown toxicity (CVRWQCB 2003b). The area of the Delta that is under the jurisdiction of the San Francisco Bay Regional Water Quality Control Board (RWQCB) is listed as impaired for mercury, chlordane, selenium, dichlorodiphenyl-trichloroethane, dioxin compounds, polychlorinated biphenyl

compounds, dieldrin, nickel, exotic species, and furan compounds (SFBRWQCB 2007).

Organic carbon in the Delta originates from runoff from agricultural and urban land, drainage water pumped from Delta islands that have soils with high organic matter, runoff and drainage from wetlands, wastewater discharges, and primary production in Delta waters. Delta agricultural drainage can also contain high levels of nutrients, suspended solids, organic carbon, minerals (salinity), and trace chemicals such as organophosphate, carbamate, and organochlorine pesticides.

Salinity is also an important water quality constituent in the Delta. Salinity in the Delta is the result of tidal exchange with San Francisco Bay, variations in freshwater inflow from the San Joaquin and Sacramento rivers, agricultural and urban exports/diversions, and agricultural return flows. During dry conditions, seawater intrusion is the primary factor influencing Delta salinity and can adversely affect agricultural and municipal uses. The highest concentrations typically occur in late summer or early fall.

CVP/SWP Service Areas

The CVP and SWP service areas are affected by water quality from the Delta. Water quality concerns of particular concern are those related to salinity and drinking-water quality. Salinity is an issue because excessive salinity may adversely affect crop yields and require more water for salt leaching, may require additional M&I treatment, may increase salinity levels in agricultural soils and groundwater, and is the primary water quality constraint to recycling wastewater (CALFED 2000b).

Constituents that affect drinking-water quality include bromide, natural organic matter, microbial pathogens, nutrients, total dissolved solids (TDS), hardness, alkalinity, pH, organic carbon, disinfection byproducts, and turbidity.

7.1.2 Sediment

Shasta Lake and Vicinity

Sediment-caused turbidity is one of the limiting water quality issues for Shasta Lake and its tributaries. It is a noticeable recurring water quality problem that affects beneficial uses, including recreation and fisheries. Within the reservoir, turbid water results from clay- and silt-sized soil particles suspended in the water column. Under certain conditions, inflow to the Pit Arm appears to be influenced by water quality conditions upstream from Shasta Lake, but monitoring data are not available to adequately document this phenomenon.

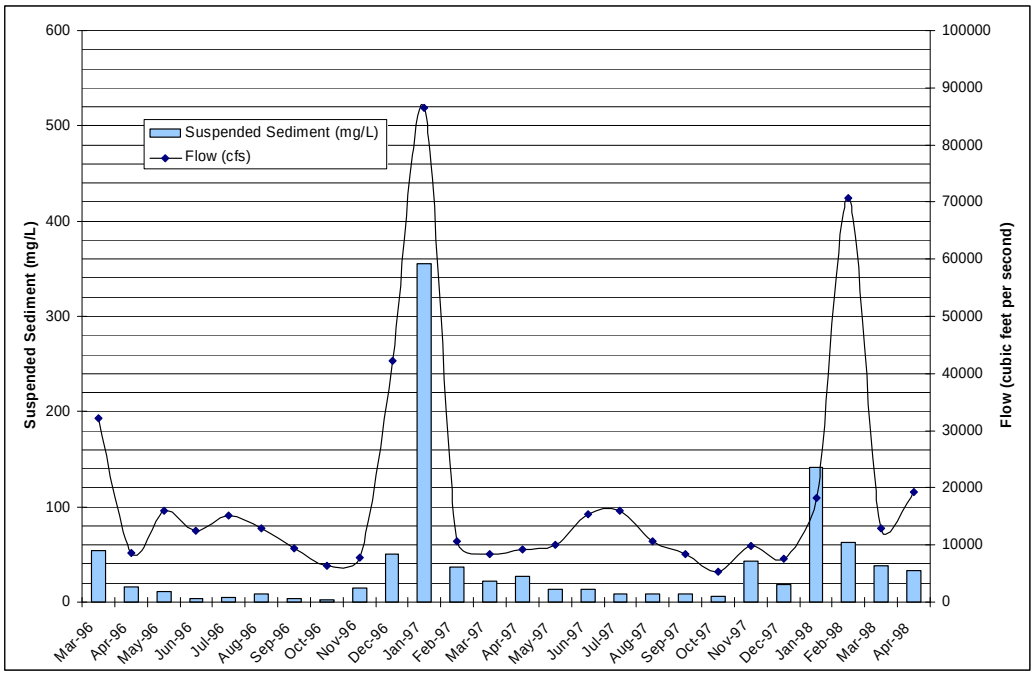
Before the construction of Shasta Dam, the widespread loss of vegetation caused by historic copper mining and smelting operations resulted in large-scale erosion, particularly in the watersheds that are tributary to the Main Body of Shasta Lake and the Squaw Creek Arm. In addition to sediment sources from

upland areas, including roads and historic mining features, the construction and operation of Shasta Dam continue to influence erosional processes that introduce sediment into Shasta Lake, causing turbid conditions that are visible to the casual observer.

Nonpoint sources of fine sediment that increase turbidity in Shasta Lake include sediment discharge from tributaries, wave-related erosion below and adjacent to the fluctuating water surface, and surficial erosion of exposed surfaces as the lake levels fluctuate (USFS 1996). Erosion of the fine-textured soil and rock types that constitute much of the shoreline is a predominant factor in causing turbidity. The turbid water is noticeable along the shoreline throughout the year, but typically increases during wind and runoff events. Plumes of turbid water entering from tributaries are also visible periodically throughout the year. The fluctuation of lake levels, combined with various wave-generating processes, also influences the degree and location of erosion-related turbidity. Turbidity and, to a lesser degree, sediment suspended in the water column influence recreational uses of the lake, including fishing, swimming, and boating, by decreasing the clarity of the water along the shoreline.

Although some amount of fine sediment is transported downstream from Shasta Dam, the size and location of the reservoir provide an efficient sediment trap for material typically mobilized as bedload. Additional discussion of erosional processes is provided in Chapter 4, “Geology, Geomorphology, Minerals, and Soils.”

Upper Sacramento River (Shasta Dam to Red Bluff)



Rates of loading and discharge of suspended sediment within the upper Sacramento River watershed have been altered by activities such as mining, smelting, agriculture, urbanization, and dam construction. The storage and diversion of water within reservoirs for either hydroelectric or other purposes can affect sediment yield, downstream sediment levels, and transport characteristics. In particular, dams such as Shasta can trap sediment and result in the depletion of coarse sediments needed by fisheries. This has resulted in the creation of gravel replenishment programs on the upper Sacramento River as part of the Central Valley Project Improvement Act restoration program.

Historic hydraulic gold mining has probably had the greatest effect on sediment yield in the Sacramento River watershed (Wright and Schoellhamer 2004). During the late 1800s, such mining introduced mass quantities of silt, sand, and gravel into the Sacramento River system. Suspended sediment was washed downstream into the Delta. Current sediment transport patterns in the Sacramento River watershed are greatly affected by the trapping of sediment in reservoirs such as Shasta Lake (Wright and Schoellhamer 2004).

Characteristics of peak-flow events are fundamental regulators of sediment mobilization, bed scour, riparian recruitment, and bank erosion. However, upstream sediment supply rates and sediment load distribution also affect

suspended sediment loading (CALFED 2003). The upper Sacramento River contributes little coarse sediment from erosion because it is bounded by erosion-resistant bedrock and terrace deposits (Stillwater Sciences 2006). Therefore, today there is a decreasing trend in suspended sediment in the Sacramento River (Wright and Schoellhamer 2004).

USGS assessed concentrations of suspended sediment in the Sacramento River at Big Bend above Red Bluff from February 1996 to April 1998 (USGS 2000a). Concentrations of suspended sediment ranged from 3 milligrams per liter (mg/L) to 355 mg/L, with an average of 38.8 mg/L (see Figure 7-2).

Source: USGS 2000a

Figure 7-2. Concentrations of Suspended Sediment and Associated Flows in the Sacramento River above Big Bend near Red Bluff

Lower Sacramento River and Delta

Delivery of suspended sediment from the Sacramento River to the Delta and finally to San Francisco Bay decreased by about one-half during the period 1957 to 2001 (Wright and Schoellhamer 2004). Factors contributing to this trend in sediment yield included the depletion of erodible sediment from hydraulic mining in the late 1800s, trapping of sediment in reservoirs, riverbank protection, altered land uses, and levee construction.

Sediment supply to the Sacramento and San Joaquin river watersheds has declined over recent years because dams on rivers and other water management actions have resulted in less sediment transport (CALFED 2000c), although agricultural drainage in the Delta often contains high levels of suspended sediments (Reclamation and DWR 2005). Sediments that include fine sands,

silts, and clays are transported by rivers and the Yolo Bypass into the Delta. Coarser materials are deposited at points higher up in the river basins. The sands typically are transported in the bed load, while the clays and silts move the suspended load. The suspended load is composed of generally finer materials moving downstream in the water column. Sediment loads from the Sacramento River are higher than those from the San Joaquin River (Reclamation and DWR 2005).

Hydraulic gold mining, particularly through the major westerly flowing tributaries such as the American, Feather, Yuba, and Bear rivers, may also affect sediment transport in the extended study area. USGS found that the Sacramento River is the primary supplier of suspended sediment to the Delta.

CVP/SWP Service Areas

Some suspended sediments are transported within the CVP and SWP service areas, but turbidity and sedimentation are not issues within the service areas (CALFED 2000c).

7.1.3 Temperature

Shasta Lake and Vicinity

Water temperature is an important water quality parameter affecting the beneficial uses of Shasta Lake and its tributaries, including contact and noncontact recreation and aquatic organisms. Within the reservoir, water temperature commonly controls the growth of algae and the rate of biochemical processes. Shasta Lake periodically stratifies and a thermocline develops on an annual basis, although turnover is incomplete and the lake has not been known to freeze over (Bartholow et al. 2001). Strong stratification of the reservoir occurs during summer at a depth of 10 to 15 meters. This stratification isolates the epilimnion from nutrients available in the deeper hypolimnion, segregating spring and fall algal blooms when water temperatures might otherwise support algal production in the euphotic zone, the zone close to the surface that provides opportunities for photosynthesis. The period of stratification generally overlaps with the peak recreation season (May to September), when surface water temperatures are comfortable for contact recreation activities. During fall, the stratification dissipates and the surface water temperature is reduced.

Shasta Dam operations greatly influence the annual and seasonal water temperature of the reservoir. The wetness of a given water year or series of years generally controls the mean annual water temperature. The current temperature regime of Shasta Lake is related to CVP operational requirements, including those necessary to optimize the water temperatures in the Sacramento River downstream from Keswick Dam. Overall, the tributaries that enter Shasta Lake meet the Basin Plan water quality objective for temperature.

Upper Sacramento River (Shasta Dam to Red Bluff)

Water temperature in the Sacramento River from Shasta Dam to Keswick Dam is determined primarily by Shasta Dam releases. Shasta Dam release flows are then mixed with flows from Whiskeytown Reservoir at Keswick Reservoir and released into the upper Sacramento River.

Water temperature for rivers within the Sacramento River basin is reportedly maintained consistent with regulatory requirements (e.g., NMFS biological opinion (BO)) most of the time, but temperature management can be difficult during low-flow periods (USGS 2000a). Historically, low-flow events and a lack of flexibility in dam operations can cause water temperatures to periodically approach critical levels for sustaining juvenile salmon populations. In addition to low flows, high water temperatures released from reservoirs, coupled with natural instream warming, can cause elevated river water temperatures (Vermeyen 1997).

There are a number of water quality objectives for the upper Sacramento River. The Basin Plan specifies that water temperature shall not be elevated above 56 degrees Fahrenheit (°F) from Keswick Dam to Hamilton City (+9). In addition, the Basin Plan specifies that at no time or place shall the temperature of cold or warm intrastate waters be increased more than 5°F above natural receiving-water temperature (CVRWQCB 2009). Keswick Dam releases are managed to meet temperature control requirements.

According to the 2004 BO for CVP and SWP operations for the Sacramento River winter-run Chinook salmon, the Sacramento River water temperatures will be below 56°F at compliance locations between Balls Ferry and Bend Bridge from April 15 through September 30, and not in excess of 60°F at the same compliance locations between Balls Ferry and Bend Bridge from October 1 through October 31. On December 15, 2008, USFWS issued a BO on the Operations Criteria and Plan (OCAP) for delta smelt and its critical habitat governing the coordinated operations of the CVP and SWP. On June 4, 2009, NMFS issued the NMFS OCAP BO for listed anadromous fishes and marine mammal species and their critical habitats governing the long-term operations of the CVP and SWP. On May 18, 2010, in *The Consolidated Salmonid Cases*, Judge Oliver Wanger concluded that NMFS likely violated the Federal Endangered Species Act by failing to rely on the "best available science" when drafting its June 4, 2009, BO. Similarly, on May 27, 2010, Judge Wanger concluded that USFWS violated NEPA in failing to conduct environmental review before establishing pumping restrictions to protect delta smelt. The BOs and their requirements remain in litigation and are subject to change.

Before 1997, to help meet the needs of Federally listed winter-run Chinook salmon, cold water was released from low outlets at Shasta Dam. These cold-water releases bypassed hydropower facilities, causing the loss of power revenues. To achieve water temperature objectives in the Sacramento River without interrupting power generation, Reclamation constructed a temperature

control device (TCD) on Shasta Dam that became operational in 1997. The TCD allows selective withdrawal of water from different reservoir depths without bypassing power generation, provides flexibility to Shasta Dam operations, and allows downstream temperature goals to be consistently achieved (Reclamation 2004).

Historical Sacramento River water temperatures below Shasta Dam were analyzed from January 1991 through December 2005. The data set indicates that average temperatures vary seasonally, ranging from 47.9°F in February to 55.7°F in November. Water temperatures below Keswick Dam were analyzed for January 1990 through December 2006. Like the temperatures below Shasta Dam, average temperatures below Keswick Dam vary seasonally, ranging from 47.8°F in February to 54.9°F in November. Summer and fall temperatures typically increase by about 7°F. Water temperatures just downstream from Keswick Dam are influenced by releases from Shasta Lake and Whiskeytown Reservoir and Keswick Dam operations.

Lower Sacramento River and Delta

Water temperature in the Sacramento River at Colusa varies seasonally, ranging from 47.5°F to 67.5°F. Water temperatures gradually increase through the spring and summer and reach an average of about 65°F. Water temperature in the Sacramento River at Freeport varies seasonally, ranging from 48.7°F to 72.1°F (USGS 2000).

Water temperature in the Delta is influenced only slightly by water management activities (i.e., dam releases) (Reclamation and DWR 2005). The 2004 and 2009 BOs for Sacramento River winter-run Chinook salmon are among the most influential factors governing Shasta releases, in terms of both quantity and timing (NMFS 2004, 2009). The BOs sets temperature requirements below Keswick Dam for April through October. In years when CVP facilities cannot be operated to meet required temperature and storage objectives, Reclamation reinitiates consultation with NMFS (Reclamation 2004a).

CVP/SWP Service Areas

Water quality in the CVP and SWP service areas, including water temperature, is affected by fluctuations of water quality in the Delta, which in turn are influenced by water quality in the San Joaquin River, CVP and SWP export pumping rates, local agricultural diversions and drainage water, and the Sacramento River (CALFED 2000c).

7.1.4 Metals

Shasta Lake and Vicinity

Certain areas of Shasta Lake have been identified as impaired by toxic metal pollutants. For this reason, Shasta Lake is listed on the CWA Section 303(d) list of impaired water bodies. For water bodies on the Section 303(d) list, the CWA requires the development of TMDL allocations for the pollutants of concern. A

TMDL allocation must estimate the total maximum daily load, with seasonal variations and a margin of safety, for all suitable pollutants and thermal loads, at a level that would ensure protection and propagation of a balanced population of indigenous fish, shellfish, and wildlife. Table 7-2 shows the potential sources of pollution within specific areas of Shasta Lake, along with the TMDL priority and the estimated affected area of the pollutants.

Table 7-2. 303(d) List of Water Quality Limited Segments, Shasta Lake, 2006

Pollutant	Potential Sources	TMDL Priority	Estimated Area Affected
Horse Creek (from Rising Star Mine to Squaw Creek Arm of Shasta Lake)			
Cadmium	Resource extraction	Low	0.52 mile
Copper	Resource extraction	Low	0.52 mile
Lead	Resource extraction	Low	0.52 mile
Zinc	Resource extraction	Low	0.52 mile
Area where West Squaw Creek enters Squaw Creek Arm of Shasta Lake			
Cadmium	Resource extraction	Low	20 acres
Copper	Resource extraction	Low	20 acres
Zinc	Resource extraction	Low	20 acres

Source: SWRCB 2006

Key:
TMDL = total maximum daily load

Waters discharged by stream channels draining the areas disturbed by the mining of sulfide ore deposits are generally acidic and contain high concentrations of dissolved metals, including iron, copper, and zinc. The streams with the highest metal concentrations are Flat, Little Backbone, Spring, Squaw, Horse, and Zinc creeks (USGS 1978). Dissolved metals concentrations discharged by these streams violate water quality objectives (CVRWQCB 2003b). The sources of the metals are surface and groundwater discharge from underground mines and waters flowing through open pits, tunnels, mine tailings, waste rock, and tertiary deposits that include modern alluvium along the shoreline. Interaction with sulfide minerals and erosion of metal-rich material commonly result in low pH readings and high metal concentrations.

The sources of the metals in the two areas identified in Table 7-2 are associated with the Bully Hill/Rising Star mining complex adjacent to the Squaw Creek Arm. Although the mines are no longer operational and remedial action continues, these areas are a documented source of metals and continue to be subject to an abatement order issued by the CVRWQCB. A containment structure constructed sometime during the early 1900s has filled with sediment

downstream from the Bully Hill Mine. No information is available on the character of the material stored behind this earth fill dam. In 2006, North State Resources, Inc., conducted a Phase 1 Site Assessment of an area adjacent to, but over a small divide from, the Bully Hill Mine. This assessment documented elevated levels of sulfide minerals in sediment samples and extremely low pH values in surface waters draining the mine (NSR 2007).

Tributaries to the Main Body of Shasta Lake are also a source of metals, along with acid mine drainage from a number of mines in the Dry Creek and Little Backbone watersheds. In addition to runoff from the historic workings (i.e., adits and portals), there are a number of large tailing deposits that are currently leaching various metals into tributaries to Shasta Lake (CVRWQCB 2003a).

Between 2002 and 2003, the CVRWQCB conducted an investigation intended to increase the understanding of the relationship between elevated metal concentrations (dissolved copper and zinc) in discharges from Shasta Dam and the temporal and spatial distribution of these metals within and upslope of Shasta Lake (CVRWQCB 2003a). Specifically, this investigation attempted to answer two questions:

- Why do these elevated metal concentrations appear seasonally?
- Are the concentrations somehow related to the operation of the temperature control device that is attached to the upstream face of Shasta Dam?

In 2003, the CVRWQCB issued an interim report that provided data and limited analysis at 17 sites upstream from Shasta Dam. The data set included 412 discrete samples and included 1,043 specific chemical analyses for various chemical constituents (CVRWQCB 2003b). The interim report offers the following conclusion: “This study shows a direct correlation between dissolved copper concentrations in the upper water column near the dam and dissolved copper concentrations immediately downstream from the dam in the winter months.” The report goes on to suggest that this correlation may somehow be related to the operation of the temperature control device as it relates to the seasonal thermocline that develops in Shasta Lake (CVRWQCB 2003b).

Upper Sacramento River (Shasta Dam to Red Bluff)

A major source of metals to the Sacramento River is drainage from inactive mines in the Iron Mountain area of the West Shasta mining district. During mining and smelting activities from the 1880s to the 1960s, Iron Mountain’s acid mine drainage discharged directly to Spring Creek, a Sacramento River tributary upstream from Redding (USGS 2000b).

USGS conducted a water quality assessment of trace metal concentrations in the Sacramento River at Big Bend above Red Bluff from February 1996 to May 1998 (USGS 2000b). Although metals concentrations are a serious water quality

concern in the project area, metals did not exceed water quality objectives during the study period.

The CVRWQCB has determined that the 25-mile segment of the upper Sacramento River between Keswick Dam and Cottonwood Creek near Balls Ferry in Shasta County is impaired because of levels of dissolved cadmium, copper, and zinc that exceed water quality standards (CVRWQCB 2002). The impairment results primarily from inactive mines in the upper Sacramento River watershed, predominantly the Iron Mountain site upstream from Keswick Dam and other mines upstream from Shasta Dam.

Water quality enhancement actions at the mines and improved coordination of the Spring Creek and Keswick Reservoirs have resulted in a notable decrease in the number of water quality targets exceeded in the past 10 years. However, metal loading remains high enough to cause periodic exceedences (CVRWQCB 2002). The sediments found in the Spring Creek Arm of Keswick Reservoir contain high levels of copper and zinc, which settled out of the contaminated stormwater runoff from the Iron Mountain Mine Superfund site. In 2009 and 2010, EPA dredged and removed contaminated sediments at this location with the goal of protecting the downstream Sacramento River ecosystem during storm events, when contaminated sediments can become mobilized and carried downstream. EPA expects that dredging the contaminated sediments will eliminate the last major threat that contamination from the Iron Mountain Mine poses to human health and the environment (EPA 2009).

High mercury concentrations in the Sacramento River correlate with concentrations of suspended sediment and high flows, because much of the mercury is transported adsorbed to suspended sediments (Domagalski et al. 2000). In May 2000, EPA adopted a water quality objective for total mercury for the Sacramento River watershed of 50 nanograms per liter (30-day average). In a USGS study of mercury levels along the Sacramento River at Big Bend above Red Bluff, conducted from February 1996 to May 1998, mercury levels were consistently below the EPA criterion of 50 nanograms per liter (USGS 2000b).

Lower Sacramento River and Delta

The downstream tributaries Cache Creek and Putah Creek are known to be substantial sources of mercury to the Sacramento River. The Sacramento River from Knights Landing to the Delta is listed as impaired on EPA's 303(d) list for mercury (CVRWQCB 2002).

The Delta waterways within the area under CVRWQCB jurisdiction are listed on EPA's 303(d) list as impaired for mercury from agriculture and historic mining, while the western Delta, under the jurisdiction of the San Francisco Bay RWQCB, is listed as impaired for mercury, nickel, and selenium. The primary sources of mercury are abandoned mine sites in the upper watershed that drain into the lower Sacramento River and Delta. The City of Sacramento is also the

largest urban source of nitrogen, mercury, and assorted other urban waste products. Selenium concentrations are attributed to agriculture and oil refiners, while the primary source of nickel is unknown (SWRCB 2006).

CVP/SWP Service Areas

Water quality in the CVP and SWP service areas is affected by fluctuations of water quality in the south Delta, which in turn are influenced by water quality in the San Joaquin River, CVP and SWP export pumping rates, local agricultural diversions and drainage water, and the Sacramento River (CALFED 2000c).

7.1.5 Salinity

The following discussion of the affected environment in the study area with regard to salinity is limited to a discussion of conditions in the lower Sacramento River and Delta portion of the extended study area because of the potential effects of salinity in this geographic area on beneficial uses. Salinity is particularly important in the Delta, which is influenced by tidal exchange with San Francisco Bay; during low-flow periods, seawater intrusion results in increased salinity.

Lower Sacramento River and Delta

The following are recognized water quality issues in the Delta (Reclamation and DWR 2005):

- High salinity from Suisun Bay intrudes into the Delta during periods of low Delta outflow. Salinity can adversely affect agricultural, M&I, and recreational uses.

- Delta exports contain elevated concentrations of disinfection byproduct precursors (e.g., dissolved organic carbon), and the presence of bromide increases the potential for formation of brominated compounds in treated drinking water.

- Agricultural drainage in the Delta contains high levels of nutrients, suspended solids, dissolved organic carbon and minerals (salinity), and agricultural chemicals (pesticides).

- Synthetic organic chemicals and heavy metals have bioaccumulated in Delta fish and other aquatic organisms, occasionally exceeding standards for food consumption.

- The San Joaquin River delivers relatively poor-quality water to the Delta; agricultural drainage is a major source of salts and pollutants. Because the south Delta receives a substantial portion of water from the San Joaquin River, the influence of this relatively poor San Joaquin River water quality is greatest in the south Delta channels and in CVP and SWP exports.

Trends in Delta water quality reflect the effects of river inflows, tidal exchanges with San Francisco Bay, diversions, and pollutant releases. The north Delta tends to have better water quality primarily because of inflow from the Sacramento River. The quality of water in the west Delta is strongly influenced by tidal exchange with San Francisco Bay; during low-flow periods, seawater intrusion results in increased salinity. In the south Delta, water quality tends to be poorer because of the combination of inflows of poorer water quality from the San Joaquin River, discharges from Delta islands, export pumping, seasonal agricultural barriers, and effects of diversions that can sometimes increase seawater intrusion from San Francisco Bay.

The Sacramento and San Joaquin rivers contribute approximately 61 percent and 33 percent, respectively, to TDS concentrations within the Delta from tributary inflows. TDS concentrations are relatively low in the Sacramento River, but because of its large volumetric contribution, the river provides the majority of the TDS load supplied by tributary inflow to the Delta (DWR 2001). Although actual flow from the San Joaquin River is lower than flow from the Sacramento River, TDS concentrations in San Joaquin River water average approximately seven times the TDS concentrations in the Sacramento River.

7.2 Regulatory Framework

Several regulatory authorities at the Federal, State, and local levels control the flow, quality, and supply of water in California either directly or indirectly. This section focuses on laws related directly to the water quality aspect of the project.

Management of the Delta is partly determined by Federal and State regulations developed to protect both human and environmental beneficial uses. Primary institutional and regulatory influences on the use and management of the Delta consist of the CVP; the SWP; direct Delta diverters, including Contra Costa Water District (CCWD), Solano County Water Agency, and the City of Stockton Metropolitan Area; San Francisco Bay water quality needs; and multiple regulations governing protection of endangered species.

At the State level, the SWRCB and the RWQCBs regulate and monitor Delta water quality. Nine regional boards oversee water quality in California. Two of these, the CVRWQCB and San Francisco Bay RWQCB, oversee Delta water quality. EPA also plays an important role under the auspices of the CWA and the Safe Drinking Water Act (SDWA). The California Department of Public Health has an interest in the Delta because the Delta is the source of drinking water for more than 23 million Californians. DWR extensively monitors Delta water quality as part of its Municipal Water Quality Investigations program; in cooperation with Reclamation, DWR monitors Delta water quality under the SWRCB's compliance monitoring requirements.

At the local level, water agencies that divert from the Delta have both strong interest in and influence on Delta water quality management. These agencies include CCWD, Solano County Water Agency, and City of Stockton Metropolitan Area.

Two agencies with key planning roles in the Delta are the California Bay-Delta Authority and the Delta Protection Commission. The California Bay-Delta Authority became a State agency in January 2003, and is responsible for implementing the CALFED Bay-Delta Program (CALFED). State legislation created the Delta Protection Commission in 1992 with the goal of developing regional policies for the Delta to protect and enhance existing land uses. In 2000, the commission was made a permanent State agency. The Delta Protection Commission comments on applications for CALFED ecosystem restoration grants that affect the Delta, and participates in meetings with other CALFED agencies to provide input to CALFED management decisions.

7.2.1 Federal

Safe Drinking Water Act

The SDWA was established to protect the quality of drinking water in the United States. The SDWA authorized EPA to set national health-based standards for drinking water and requires many actions to protect drinking water and its sources, including rivers, lakes, reservoirs, springs, and groundwater wells. Furthermore, the SDWA requires all owners or operators of public water systems to comply with primary (health-related) standards. EPA has delegated to the California Department of Public Health, Division of Drinking Water and Environmental Management, the responsibility for administering California's drinking-water program. California Department of Public Health is accountable to EPA for program implementation and for adopting standards and regulations that are at least as stringent as those developed by EPA. Contaminants of concern relevant to domestic water supply are defined as those that pose a public health threat or that alter the aesthetic acceptability of the water. These types of contaminants are regulated by EPA primary and secondary maximum contaminant levels that are applicable to treated water supplies delivered to the distribution system. maximum contaminant levels and the process for setting these standards are reviewed triennially.

Clean Water Act

The CWA is the major Federal legislation governing the water quality aspects of the project. The objective of the act is "to restore and maintain the chemical, physical, and biological integrity of the nation's waters." The CWA establishes the basic structure for regulating discharge of pollutants into the waters of the United States and gives EPA the authority to implement pollution control programs such as setting wastewater standards for industries. In certain states such as California, EPA has delegated authority to state agencies.

Section 303 This section of the CWA requires states to adopt water quality standards for all surface waters of the United States. The three major components of water quality standards are as follows:

- **Designated uses** – Uses that society, through the Federal and State governments, determines should be attained in the water body, such as supporting communities of aquatic life, supplying water for drinking, irrigating crops and landscaping, and industrial purposes, and recreational uses (e.g., fishing, swimming, boating).

- **Water quality criteria** – Levels of individual pollutants or water quality characteristics, or descriptions of conditions of a water body that, if met, will generally protect the designated use of the water. Water quality criteria must be scientifically consistent with attainment of designated uses, which means that only scientific considerations can be taken into account when determining what water quality conditions are consistent with meeting a given designated use. Economic and social impacts are not considered when developing water quality criteria.

- **Antidegradation policy** – Designed to prevent deterioration of existing levels of good water quality (see the "Antidegradation Policy" section below for more information).

Where multiple uses exist, water quality standards must protect the most sensitive use. In California, EPA has given the SWRCB and its nine RWQCBs the authority to identify beneficial uses and adopt applicable water quality objectives.

Section 303(d) of the CWA requires states and authorized Native American tribes to develop a list of water quality–impaired segments of waterways. The list includes waters that do not meet water quality standards necessary to support the beneficial uses of that waterway, even after point sources of pollution have installed the minimum required levels of pollution control technology. Only waters impaired by "pollutants," not those impaired by other types of "pollution" (e.g., altered flow and/or channel modification), are to be included on the list. (Pollutants include clean sediments, nutrients (e.g., nitrogen and phosphorus), pathogens, acids/bases, temperature, metals, cyanide, and synthetic organic chemicals.)

Section 303(d) of the CWA also requires states to maintain a listing of impaired water bodies so that a TMDL can be established. A TMDL is a plan to restore the beneficial uses of a stream or to otherwise correct an impairment. It establishes the allowable pollutant loadings or other quantifiable parameters (e.g., pH or temperature) for a water body and thereby provides the basis for the establishment of water quality-based controls. The calculation for establishment of TMDLs for each water body must include a margin of safety to ensure that

the water body can be used for the purposes the State has designated. Additionally, the calculation also must account for seasonal variation in water quality. The CVRWQCB develops TMDLs for the Sacramento River (see discussion on the Porter-Cologne Water Quality Control Act below). Sedimentation/siltation impacts are the primary water quality parameters of concern with construction projects.

Reductions in pollutant loading are achieved by implementing strategies authorized by the CWA, such as the following, which are discussed in more detail below.

- **Section 401** – This section of the CWA requires Federal agencies to obtain certification from the State or Native American tribes before issuing permits that would result in increased pollutant loads to a water body. The certification is issued only if such increased loads would not cause or contribute to exceedences of water quality standards.

- **Section 402** – This section creates the National Pollutant Discharge Elimination System (NPDES) permit program. This program covers point sources of pollution discharging into a surface water body.

- **Section 404** – This section regulates the placement of dredged or fill materials into wetlands and other waters of the United States.

Section 401 – Water Quality Certification This section of the CWA requires an applicant for any Federal license or permit (e.g., a Section 404 permit) that may result in a discharge into waters of the United States to obtain a certification from the State that the discharge would comply with provisions of the CWA. The SWRCB and RWQCBs administer this program. The SWRCB issues Section 401 certifications for projects that would take place in two or more regions. Any condition of a Section 401 certification (or water quality certification) would be incorporated into the USACE permit.

For the primary study area the CVRWQCB has jurisdiction, while the extended study area encompasses the San Francisco Bay, Central Coast, Los Angeles, Lahontan, Colorado River Basin, Santa Ana, and San Diego RWQCBs. A Section 401 certification would not be required from the RWQCBs within the extended study area because no construction would occur in the extended study area.

Section 402 – National Pollutant Discharge Elimination System All point sources that discharge into waters of the United States must obtain an NPDES permit under provisions of Section 402 of the CWA. As with Section 401, the SWRCB and RWQCBs are responsible for implementing the NPDES permitting process at the State and regional levels, respectively.

The NPDES permit process also provides a regulatory mechanism for controlling nonpoint-source pollution created by runoff from construction and industrial activities, and general and urban land use, including runoff from streets. Projects involving construction activities (e.g., clearing, grading, or excavation) involving land disturbance greater than one acre must file a notice of intent with the appropriate RWQCB(s) to indicate their intent to comply with the General Permit for Discharges of Stormwater Associated with Construction Activity (Construction General Permit Order 2009-0009-DWQ, which went into effect and replaced Order 99-08-DWQ on July 1, 2010). This general permit establishes conditions to minimize sediment and pollutant loadings and requires preparation and implementation of a stormwater pollution prevention plan (SWPPP) before construction. The SWPPP is intended to help identify the sources of sediment and other pollutants, and to establish best management practices (BMP) for stormwater and nonstormwater source control and pollutant control. A sediment monitoring plan must be included in the SWPPP if the discharges occur directly to a water body listed on the Section 303(d) TMDL list for sediment.

For the primary study area the CVRWQCB has jurisdiction. A NPDES would not be required from the RWQCBs within the extended study area because no construction would occur.

Section 404 – Discharge of Dredged or Fill Material into Waters of the United States Section 404 deals with one broad type of pollution – the placement of dredged or fill material into "waters of the United States." Jurisdictional limits of these features are typically noted by the ordinary high-water mark. Isolated ponds or seasonal depressions had been previously regulated as waters of the United States. However, in *Solid Waste Agency of Northwestern Cook County v. United States Army Corps of Engineers et al.* (January 8, 2001), the U.S. Supreme Court ruled that certain "isolated" wetlands (e.g., nonnavigable, isolated, and intrastate) do not fall under the jurisdiction of the CWA and are no longer under USACE jurisdiction. (Although isolated wetlands may not be under Federal regulation, they are regulated by the State of California (see Porter-Cologne Water Quality Control Act discussion below).) Some circuit courts (e.g., *U.S. v. Deaton*, 2003; *U.S. v. Rapanos*, 2003; *Northern California River Watch v. City of Healdsburg*, 2006), however, have ruled that Solid Waste Agency of Northwestern Cook County does not prevent CWA jurisdiction if a "significant nexus" such as a hydrologic connection exists. The hydrologic connection may be human-made (e.g., roadside ditch) or a natural tributary to navigable waters, or direct seepage from the wetland to the navigable water, a surface or underground hydraulic connection. An ecological connection (e.g., the same bird, mammal, and fish populations are supported by both the wetland and the navigable water) and changes to chemical concentrations in the navigable water caused by water from the wetland may also constitute a significant nexus.

The discharge of dredge or fill generally includes the following activities:

- Placement of fill that is necessary for the construction of any structure or infrastructure in a water of the United States
- The building of any structure, infrastructure, or impoundment requiring rock, sand, dirt, or other material for its construction
- Site-development fills for recreational, industrial, commercial, residential, or other uses
- Causeways or road fills
- Dams and dikes
- Artificial islands
- Property protection and/or reclamation devices such as riprap, groins, seawalls, breakwaters, and revetments
- Beach nourishment
- Levees
- Fill for structures such as sewage treatment facilities, intake and outfall pipes associated with powerplants, and subaqueous utility lines
- Placement of fill material for construction or maintenance of any liner, berm, or other infrastructure associated with solid waste landfills
- Placement of overburden, slurry, or tailings or similar mining-related materials
- Artificial reefs

USACE regulations and policies mandate avoiding the filling of wetlands unless it can be demonstrated that no practicable alternatives (to filling wetlands) exist. There are four basic processes for obtaining Section 404 authorization from USACE. Because of its scale and potential impact, this project would require an individual permit.

For the primary study area, USACE's Sacramento District has jurisdiction, while the extended study area encompasses the San Francisco and Los Angeles Districts of USACE.

Antidegradation Policy

The antidegradation policy, established in 1968 and revised in 2005 (Title 40, Section 131.12 of the Code of Federal Regulations), is designed to protect

existing uses and water quality and national water resources, as authorized by Section 303(c) of the CWA. At a minimum, the policy and implementation methods must be consistent with the following:

- Existing instream water uses and the level of water quality necessary to protect the existing uses shall be maintained and protected.

- Where the quality of the waters exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water, that quality shall be maintained and protected unless the State finds that allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located. In allowing such degradation or lower water quality, the State shall assure water quality adequate to protect existing uses fully. Further, the State shall assure that there shall be achieved the highest statutory and regulatory requirements for all new and existing point sources and all cost-effective and reasonable BMPs for nonpoint source control.

- Where high-quality waters constitute an outstanding National resource, such as waters of National and State parks and wildlife refuges and waters of exceptional recreational or ecological significance, that water quality shall be maintained and protected.

Although the quality of water in the upper Sacramento River is relatively good, water quality problems do occur, including the presence of mercury, pesticides such as organochlorine pesticides, trace metals, turbidity, and toxicity from unknown origin (CALFED 2000a).

The CWA requires states to maintain a listing of impaired water bodies so that a TMDL can be established. A TMDL is a plan to restore the beneficial uses of a stream or to otherwise correct an impairment. The most prevalent contaminants in the Sacramento River basin are for organophosphate pesticides (agricultural runoff) and trace metals (acid mine drainage), for which TMDLs currently are being considered. Only during conditions of stormwater-driven runoff are water quality objectives typically not met (Domagalski et al. 2000).

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF is guided by various laws, regulations, and policies that provide the framework for all levels of planning. These include regional guides, the *Shasta-Trinity National Forest Land and Resource Management Plan*, and site-specific planning documents, such as this document.

The *Shasta-Trinity National Forest Land and Resource Management Plan* provides guidance for managing National Forest System lands in the STNF. The development of a Forest land and resource management plan (LRMP) occurs within the framework of regional and national USFS planning. The LRMP

includes forest goals; forest objectives, including forest-wide prescription assignment by acres, outputs, and activities; and forest standards and guidelines. Forest goals state the management philosophy of the LRMP, and the Forest objectives describe the purpose of the management prescriptions. The Forest-wide management prescriptions apply a management theme to specific types of land (e.g., wilderness, roaded high-density recreation).

In essence, this LRMP requires that projects authorized by the STNF be designed and implemented in a manner that maintains the existing conditions or implements actions to restore biological and physical processes within their natural range of variability.

Water Quality
Goals (LRMP, p. 4-6)

- Maintain or improve water quality and quantity to meet fish habitat requirements and domestic use needs.
- Maintain water quality to meet or exceed applicable standards and regulations.

Standards and Guidelines (LRMP, p. 4-25)

- Implement BMPs for protection or improvement of water quality, as described in "Water Quality Management for National Forest System Lands in California," for applicable management activities. Determine specific practices or techniques during project level planning using information obtained from on-site soil, water, and geology investigations.

Best Management Practices
Standards and Guidelines (LRMP, Appendix E)

- STNF water quality BMPs were developed in compliance with Section 208 of the Federal CWA, Public Law 92-500, as amended and are certified by the RWQCB and approved by EPA. The following BMPs are applicable to the proposed action:

Road Building and Site Construction
Standards and Guidelines (LRMP, Appendix E, pp. E-2 through E-3)

- General guidelines for the location and design of roads
- Erosion control plan
- Timing of construction activities
- Road slope stabilization (preventive practice)
- Road slope stabilization (administrative practice)

- Dispersion of subsurface drainage from cut and fill slopes
- Control of road drainage
- Construction of stable embankments
- Minimization of sidecast material
- Servicing and refueling equipment
- Control of construction in riparian management zones
- Controlling in-channel excavation
- Diversion of flows around construction sites
- Bridge and culvert installation
- Disposal of right-of-way and roadside debris
- Specifying riprap composition
- Maintenance of roads
- Road surface treatment to prevent loss of materials
- Traffic control during wet periods
- Surface erosion control at facility sites

Recreation

Standards and Guidelines (LRMP, Appendix E, p. E-3)

- Sampling and surveillance of designated swimming sites
- On-site interdisciplinary sanitary surveys will be conducted to augment the sampling of swimming waters
- Documentation of water quality data
- Control of sanitation facilities
- Control of refuse disposal
- Protection of water quality within developed and dispersed recreation areas

U.S. Bureau of Land Management

The U.S. Bureau of Land Management's Resource Management Plan, which is its plan for managing Federal lands in Shasta County, was amended by the 1994 Record of Decision (ROD) for the Northwest Forest Plan (Final Supplemental Environmental Impact Statement (EIS) for Amendments to Forest Service and Bureau of Land Management Planning Documents within the Range of the Northern Spotted Owl). This amendment required preparation of Watershed Analysis prior to initiating U.S. Bureau of Land Management activities. As a party to the Northwest Forest Plan, U.S. Bureau of Land Management, like USFS, is also required to ensure that projects are consistent with the Aquatic Conservation Strategy.

Biological Opinions on the Long-term Central Valley Project and State Water Project Operations Criteria and Plan

During the past 6 years, NMFS and USFWS BOs regarding effects of the proposed OCAP have been revised twice. On October 22, 2004, NMFS issued a BO regarding effects of the proposed OCAP for the CVP in coordination with the SWP on winter-run Chinook salmon, spring-run Chinook salmon, Central Valley steelhead, Southern Oregon/Northern California Coast Coho salmon, and Central California Coast steelhead and their designated critical habitat. On February 16, 2005, USFWS issued a BO regarding effects of the proposed OCAP on delta smelt. The 2004 and 1995 BOs supersede the prior BOs issued by NMFS and USFWS, and contain reasonable and prudent measures and terms and conditions that specify fisheries monitoring actions, spawning gravel augmentation, forecasting of deliverable water, management of cold-water supply within reservoirs, temperature monitoring, adaptive management processes to analyze annual cold-water management, minimization of flow fluctuations, passage at RBDD, operation of gates in the Delta, fish screening at pumping facilities, and numerous other effects minimization measures. In response to litigation, the 2004 and 2005 BOs were remanded to USFWS and NMFS for revision, but were not vacated. USFWS and NMFS released revised BOs in 2008 and 2009, respectively. These revised BOs are in litigation.

7.2.2 State

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act (Porter-Cologne Act) is California's statutory authority for the protection of water quality. Under the act, the State must adopt water quality policies, plans, and objectives protecting the State's waters for the use and enjoyment of the people. Obligations of the SWRCB and RWQCBs to adopt and periodically update their basin plans are set forth in the act. A basin plan identifies the designated beneficial uses for specific surface water and groundwater resources, applicable water quality objectives necessary to support the beneficial uses, and implementation programs that are established to maintain and protect water quality from degradation for each of the RWQCBs. The act also requires waste dischargers to notify the RWQCBs of their activities through the filing of reports of waste

discharge and authorizes the SWRCB and RWQCBs to issue and enforce waste discharge requirements (WDR), NPDES permits, Section 401 water quality certifications, or other approvals. The RWQCBs also have authority to issue waivers to reports of waste discharge/WDRs for broad categories of "low threat" discharge activities that have minimal potential for adverse water quality effects when implemented according to prescribed terms and conditions.

The CVRWQCB Basin Plan (originally published in 1998, last revised in September 2009) (CVRWQCB 2009) regulates waters of the State located within the primary study area. The CVRWQCB Basin Plan covers an area including the entire Sacramento and San Joaquin river basins, involving an area bounded by the crests of the Sierra Nevada on the east and the Coast Ranges and Klamath Mountains on the west. The area covered in the CVRWQCB Basin Plan extends some 400 miles, from the California/Oregon border southward to the headwaters of the San Joaquin River, encompassing a substantial portion of the extended study area. The beneficial uses of the Sacramento River are as follows (CVRWQCB 2009):

- Municipal and domestic supply
- Irrigation and stock watering
- Service supply
- Power
- Contact recreation and canoeing and rafting
- Other noncontact recreation
- Freshwater habitat (warm and cold)
- Migration habitat (warm and cold)
- Spawning habitat (warm and cold)
- Wildlife habitat
- Navigation

The Basin Plan recognizes Shasta Reservoir (i.e., Shasta Lake) as a discrete water body and identifies a number of specific beneficial uses:

- Municipal and domestic supply
- Agricultural supply
- Hydropower generation

- Water contact recreation
- Noncontact recreation
- Freshwater habitat (warm and cold)
- Spawning, reproduction, and/or early development
- Wildlife habitat

The CVRWQCB has also promulgated water quality objectives for all surface waters in the Sacramento and San Joaquin River basins (CVRWQCB 2009) for the following:

- Bacteria levels
- Biostimulatory substances
- Chemical constituents
- Color
- Dissolved oxygen
- Floating material
- Methylmercury
- Oil and grease
- pH
- Pesticides
- Radioactivity
- Salinity
- Sediment
- Settleable material
- Suspended material
- Tastes and odors
- Temperature
- Toxicity
- Turbidity

Primary Study Area The CVRWQCB determined that the 25-mile reach of the Sacramento River from Keswick Dam downstream to Cottonwood Creek is impaired because the water periodically contains levels of dissolved cadmium, copper, and zinc that exceed levels identified to protect aquatic organisms.

Consequently, the CVRWQCB developed a TMDL program for dissolved cadmium, copper, and zinc loading into the upper Sacramento River because of these exceedences of water quality standards (CVRWQCB 2002) and has proposed implementing the water quality objectives listed in Table 7-3 as numeric targets for this TMDL. No other TMDLs have been finalized for this area (CVRWQCB 2007a).

Table 7-3. Proposed TMDL Numeric Targets for Dissolved Cadmium, Copper, and Zinc for a 25-Mile Segment of the Upper Sacramento River between Keswick Dam and Cottonwood Creek near Balls Ferry in Shasta County

Metals	Acute Numeric Target (μg/L)	Chronic Numeric Target (μg/L)
Cadmium	0.22	0.22
Copper	5.6	4.1
Zinc	16	16

Source: CVRWQCB 2002

Key:
μg/L = micrograms per liter
TMDL = total maximum daily load

Extended Study Area The Sacramento River downstream from RBDD was listed as an impaired water body under Section 303(d) of the CWA. The parameters of concern in this reach included diazinon, mercury, and unknown sources of toxicity (CVRWQCB 2003b). TMDLs under development for the Sacramento River are for diazinon, methylmercury, and chlorpyrifos (CVRWQCB 2007b). The extended study area encompasses the San Francisco, Central Coast, Los Angeles, Lahontan, Colorado River Basin, Santa Ana, and San Diego RWQCBs.

Clean Water Act Section 401 Water Quality Certification

The CVRWQCB, under the auspices of the SWRCB, requires that a project proponent obtain a CWA Section 401 water quality certification in conjunction with the Section 404 permits granted by USACE. Because the project would have the potential to affect water quality in Shasta Lake, the CVRWQCB is likely to impose water quality limitations on the project through WDRs. Reclamation will prepare and submit to the CVRWQCB a request for water quality certification before development of the project. A likely condition of the water quality certification is preparation of an erosion and sedimentation control plan and a spill prevention and containment plan.

Waste Discharge Permit

The CVRWQCB controls the discharge of wastes to surface waters from industrial processes or construction activities through the NPDES permit process. WDRs are established in the permit to protect beneficial uses. The

CVRWQCB will require an application for a waste discharge permit for the project.

Industrial Stormwater General Permit

The Industrial Stormwater General Permit (General Industrial Permit) is an NPDES permit that regulates discharges associated with 10 broad categories of industrial activities. This permit requires implementation of management measures that will achieve the performance standard of best available technology economically achievable and best conventional pollutant control technology. This permit also requires development of a SWPPP and a monitoring plan. Through the SWPPP, sources of pollutants are to be identified and the means to manage the sources to reduce stormwater pollution are described.

Stormwater Pollution Prevention Plan

The General Industrial Permit includes provisions for developing a SWPPP to maximize the potential benefits of pollution prevention and sediment- and erosion-control measures at construction sites. Developing and implementing a SWPPP would provide Reclamation with the framework for reducing soil erosion and minimizing pollutants in stormwater during project construction.

Water Quality Control Plan for the Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California

The *Water Quality Control Plan for the Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California* (Thermal Plan) sets limits for "thermal waste" and "elevated temperature waste" discharged into coastal and interstate waters and enclosed bays and estuaries of California (SWRCB no date). Estuarine waters are considered to extend from "…a bay or the open ocean to the upstream limit of tidal action" (SWRCB no date). This definition includes the Delta as defined by Section 12220 of the California Water Code, as well as portions of the Sacramento River that are subject to tidal action. Generally, the Basin Plan defines temperature objectives in two parts (CVRWQCB 2009):

> *At no time or place shall the temperature of COLD or WARM intrastate waters be increased more than 5°F above natural receiving water temperature.*
>
> *The temperature shall not be elevated above 56°F in the reach from Keswick Dam to Hamilton City nor above 68°F in the reach from Hamilton City to the I Street Bridge during periods when temperature increases will be detrimental to the fishery.*

The first water quality standards for the Delta were adopted in May 1967, when the State Water Rights Board (predecessor to the SWRCB) released Water Right Decision 1275 (D-1275), approving water rights for the SWP while setting agricultural salinity standards as terms and conditions. Since then, these

requirements were changed in 1971 under Water Right Decision 1379 (D-1379), and again in 1978 under Water Right Decision 1485 and the Water Quality Control Plan (WQCP) for the Delta and Suisun Marsh (1978 WQCP). In May 1995, SWRCB adopted a new Bay-Delta WQCP, and it was implemented through SWRCB Revised Water Rights Decision 1641 (D-1641) in March 2000.

1995 Water Quality Control Plan

The 1995 *Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary* (SWRCB 1995) established water quality control measures that contribute to the protection of beneficial uses in the Delta. The 1995 WQCP identified (1) beneficial uses of the Delta to be protected, (2) water quality objectives for the reasonable protection of beneficial uses, and (3) a program of implementation for achieving the water quality objectives. The 1995 WQCP superseded the *Water Quality Control Plan for Salinity* (adopted in May 1991) and the *Water Quality Control Plan for the Sacramento-San Joaquin Delta and Suisun Marsh* that was adopted in August 1978.

The 1995 WQCP was developed as part of the December 15, 1994, Bay-Delta Accord, which committed the CVP and SWP to new Delta habitat objectives. Because these new beneficial objectives and water quality standards were more protective than those of the previous Water Right Decision 1485, the new objectives were adopted by amendment in 1995 through a Water Rights Order for operation of the CVP and SWP. One key feature of the 1995 WQCP was the estuarine habitat ("X2") objectives for Suisun Bay and the western Delta. The X2 objective required specific daily or 14-day surface EC criteria, or 3-day averaged outflow requirements to be met for a certain number of days each month, February through June. These requirements were designed to provide improved shallow water habitat for fish species in spring. Because of the relationship between seawater intrusion and interior Delta water quality, the X2 criteria also improved water quality at Delta drinking water intakes. Other new elements of the 1995 WQCP included export-to-inflow ratios intended to reduce entrainment of fish at the export pumps, Delta Cross Channel gate closures, and San Joaquin River EC and flow standards.

Water Right Decision 1641

D-1641 and Water Rights Order 2001-05 contain the current water right requirements to implement the 1995 WQCP. D-1641 incorporates water right settlement agreements between Reclamation and DWR and certain water users in the Delta and upstream watersheds regarding contributions of flows to meet water quality objectives. However, Reclamation and/or DWR are responsible for ensuring that objectives are met in the Delta. D-1641 also authorizes the CVP and SWP to use joint points of diversion (JPOD) in the south Delta, and recognizes the CALFED Operations Coordination Group process for operational flexibility in applying or relaxing certain protective standards. The additional exports allowed under the JPOD could result in additional degradation of water quality for water users in the south and central Delta. The

JPOD also could affect water levels in the south Delta and endangered fish species.

In February 2006, SWRCB issued notice to Reclamation and DWR that each agency is responsible for meeting the objectives in the interior south Delta, as described in D-1641. The SWRCB order requires Reclamation and DWR to comply with a detailed plan and time schedule that will bring them into compliance with their respective permit and license requirements for meeting interior south Delta salinity objectives by July 1, 2009. The SWRCB order also revised the previously issued (July 1, 2005) Water Quality Response Plan approval governing Reclamation's and DWR's use of each other's respective point of diversion in the south Delta. Additionally, the order specifies that JPOD operations are authorized pursuant to the 1995 WQCP, and that Reclamation and DWR may conduct JPOD diversions, provided that both agencies are in compliance with all conditions of their respective water right permits and licenses at the time the JPOD diversions would occur (SWRCB 2006).

Municipal and Industrial Water Quality Objectives

In the 1978 WQCP, the SWRCB set two objectives that it believed would provide reasonable protection for M&I beneficial uses of Delta waters from the effects of salinity intrusion. The first objective established a year-round maximum mean daily chloride concentration measured at five Delta intake facilities, including CCWD's Pumping Plant Number 1, of 250 mg/L for the reasonable protection of municipal beneficial uses. This objective was consistent with the EPA secondary maximum contaminant level for chloride of 250 mg/L, and is based only on aesthetic (taste) considerations. The second objective established a maximum mean daily chloride concentration of 150 mg/L (measured at either CCWD Pumping Plant No. 1 or the San Joaquin River at the Antioch water works intake) for the reasonable protection of industrial beneficial uses (specifically manufacture of cardboard boxes by Gaylord Container Corporation in Antioch). This requirement is in effect for a minimum of between 155 and 240 days each calendar year, depending on the water year type.

In the 1991 WQCP, the SWRCB reviewed the water quality objectives for M&I use contained in the 1978 WQCP, and reviewed potential new objectives for trihalomethanes and other disinfection byproducts, including bromides. The SWRCB concluded that technical information regarding trihalomethanes and other disinfection byproducts was not sufficient to set a scientifically sound objective. Accordingly, the SWRCB continued the existing objectives for chloride concentration, and until development of more information about these constituents, set a water quality "goal" for bromides of 0.15 mg/L (150 micrograms per liter). The SWRCB also noted that the 150 mg/L chloride objective was maintained in part because it provides ancillary protection for other M&I uses in the absence of objectives for trihalomethanes and other disinfection byproducts.

These objectives remained unchanged in the 1995 WQCP. The SWRCB and CVRWQCB basin plans specify water quality objectives to protect designated beneficial uses, including municipal drinking-water supply. The CVRWQCB is also currently developing a Central Valley drinking-water policy that may lead to regulations limiting the discharge of bromide, organic carbon, pathogens, and other drinking water constituents of concern. The CVRWQCB took the important step of adopting resolutions in July 2004 (Resolution No. R5-2004-0091) and in July 2010 (Resolution No. R5-2010-0079) supporting development of the policy. Resolution No. R5-2010-0079 directed CVRWQCB staff to develop and bring a comprehensive drinking water policy to the board within 3 years (i.e., by 2013).

Coordinated Operations Agreement

The Coordinated Operations Agreement defines how Reclamation and DWR share their joint responsibility to meet Delta water quality standards and meet the water demands of senior water right holders. The Coordinated Operations Agreement defines the Delta as being in either "balanced water conditions" or "excess water conditions." Balanced conditions are periods when Delta inflows are just sufficient to meet water user demands within the Delta, outflow requirements for water quality and flow standards, and export demands. Under excess conditions, Delta outflow exceeds the flow required to meet the water quality and flow standards. Typically, the Delta is in balanced water conditions from June to November, and in excess water conditions from December through May. However, depending on the volume and timing of winter runoff, excess or balanced conditions may extend throughout the year.

During excess water conditions, but during periods when Delta outflow is still relatively low, additional Delta diversions can degrade the water quality needed to meet drinking water standards, even when SWRCB M&I objectives are being met.

7.2.3 Local

The primary study area is located within both Shasta and Tehama counties, while the extended study area includes the following counties: Glenn, Butte, Colusa, Sutter, Yolo, Yuba, Sacramento, Napa, Solano, San Francisco, Contra Costa, San Joaquin, Alameda, Santa Clara, Stanislaus, Santa Cruz, San Benito, Merced, Madera, Fresno, Tulare, King, Kern, Santa Barbara, Ventura, Los Angeles, San Bernardino, Orange, Riverside, San Diego, and Imperial. Each of these counties has a general plan that includes general policies to protect water quality, water supply, water resources, and watersheds. There are no specific local requirements that are pertinent to this analysis.

Water quality protection measures are included in the *Shasta County General Plan*. The county's goal is to protect all aspects of water quality in the county. The county defines erosion and downstream sedimentation as geologic hazards that must be prevented as part of grading and site development. The Shasta County Grading Ordinance sets requirements for grading and erosion control,

including prevention of sedimentation or damage to off-site property. Grading permits require a vested map and the following information:

- A detailed grading plan
- Geological studies, if the project is located within an area that is prone to slippage, or has highly erodible soils or known geologic hazards
- Detailed drainage or flood control information as required by the Department of Public Works
- A final development plan, if the project is located in a zone or district that requires a final development plan
- A noise analysis, if the project is located in the vicinity of a high-noise-generating use

The water quality protection goal included in the Open Space and Conservation Element of the *Tehama County General Plan* (Tehama County 2009) is to ensure that water supplies are of sufficient quality and quality, now and into the future, to serve the needs of Tehama County (Goal OS-1). Policies in support of this goal include sound watershed management, protection of surface water quality and streamflows, and protection of groundwater quality through the minimization of erosion and prevention of intrusion of wastes into water supplies.

7.3 Environmental Consequences and Mitigation Measures

7.3.1 Methods and Assumptions

A combination of water quality monitoring data and computer modeling was used to aid in the evaluation of potential impacts of the project alternatives on water quality. Anticipated construction practices and materials, location, and duration of construction were also evaluated.

To evaluate potential Delta water quality impacts, the analysis relied on quantitative modeling tools to simulate conditions that would be expected to occur under the SLWRI alternatives compared to the bases of comparison (existing conditions without project, and future conditions without project). The analysis of potential impacts on water quality in the Delta includes an analysis of potential impacts on water quality for all in-Delta water users. Delta parameters used in the evaluation include simulated changes in X2 location, Delta outflow, export-to-inflow ratio, salinity, and chloride ion concentrations.

The water quality impact assessment focuses on EC, measured in millimhos per centimeter (mmhos/cm), and chloride ion concentration in mg/L, as indicators of Delta water quality because they are the primary water quality constituents most

likely to be affected by changes in Delta outflow and pumping operations. EC also is the parameter for which considerable monitoring data are available, and which has been used to calibrate the modeling tools used to simulate Delta water quality conditions.

A suite of modeling tools was used to evaluate the potential impacts of existing conditions, and the No-Action and other SLWRI alternatives on the Delta water quality of the project, and to quantify potential benefits. CalSim-II was used to simulate CVP and SWP operations, determining surface water flows, storages, and deliveries associated with each alternative. (A detailed description of CalSim-II is included in Chapter 2 of the Modeling Appendix.) Delta Simulation Model 2 (DSM2) was used to simulate the hydrodynamics of the Delta, providing the data used in discussion of the water-quality-related impacts of each alternative. (A detailed description of DSM2 and the assumptions used in the SLWRI analysis are included in Chapter 8 of the Modeling Appendix.) Summaries of the analysis and modeling results are provided below. (More detailed results of the CalSim-II output can be found in Attachment A of the *Hydrology, Hydraulics, and Water Management Technical Report*.) Attachment A of the *Water Quality Technical Report* contains more detailed DSM2 output.

To understand the effects of the alternatives under both existing and future conditions, each alternative was modeled using two different assumptions about level of development (2005 and 2030) and compared to the appropriate baseline modeling results to determine the character and extent of impacts.

CalSim-II

CalSim-II is the application of the Water Resources Integrated Modeling System software to the CVP/SWP. This application was jointly developed by Reclamation and DWR for planning studies relating to CVP/SWP operations. The primary purpose of CalSim-II is to evaluate the water supply reliability of the CVP and SWP at current or future levels of development (e.g., 2005, 2030), with and without various assumed future facilities, and with different modes of facility operations. Geographically, the model covers the drainage basin of the Delta, and CVP/SWP exports to the Bay Area, San Joaquin Valley, Central Coast, and Southern California.

CalSim-II typically simulates system operations for an 83-year period using a monthly time step. The model assumes that facilities, land use, water supply contracts, and regulatory requirements are constant over this period, representing a fixed level of development (e.g., 2005, 2030). The historical flow record of October 1921 to September 2003, adjusted for the influences of land use changes and upstream flow regulation, is used to represent the possible range of water supply conditions. Major Central Valley rivers, reservoirs, and CVP/SWP facilities are represented by a network of arcs and nodes. CalSim-II uses a mass balance approach to route water through this network. Simulated flows are mean flows for the month; reservoir storage volumes correspond to end-of-month storage.

CalSim-II models a complex and extensive set of regulatory standards and operations criteria. (Descriptions of both are contained in Chapter 2 of the Modeling Appendix.) The hydrologic analysis presented for this EIS used the Common Assumptions Common Modeling Package version 8D CalSim-II models, which are the best available hydrological modeling tools, to approximate the changes in storage, flow, salinity, and reservoir system reoperation associated with the SLWRI alternatives. Although CalSim-II is the best available tool for simulating system-wide operations, the model also contains simplifying assumptions in its representation of the real system.

A general external review of the methodology, software, and applications of CalSim-II was conducted in 2003 (Close et al. 2003). Recently, an external review of the San Joaquin River Valley CalSim-II model was also conducted (Ford et al. 2006). Several limitations of the CalSim-II models were identified in these external reviews. The main limitations of the CalSim-II models are as follows:

- Model uses a monthly time step
- Accuracy of the inflow hydrology is uncertain:
  - Model lacks a fully explicit groundwater representation

Reclamation, DWR, and the external reviewers have identified the need for a comprehensive error and uncertainty analysis for various aspects of the CalSim-II model. DWR has issued a CalSim-II Model Sensitivity Analysis Study (DWR 2005), and Reclamation is currently embarking on a similar sensitivity and uncertainty analysis for the San Joaquin River basin. This information will improve understanding of the model results.

Despite these limitations, the monthly CalSim-II model results remain useful for comparative purposes. It is important to differentiate between “absolute” or “predictive” modeling applications and “comparative” applications. In “absolute” applications, the model is run once to predict a future outcome and errors or assumptions in formulation, system representation, data, operational criteria, etc., all contribute to total error or uncertainty in model results. In “comparative” applications, the model is run twice, once to represent a base condition (no-project) and a second time with a specific change (project) to assess the change in the outcome because of the input change. In this mode (the mode used for this EIS), the difference between the two simulations is of principal importance. Potential errors or uncertainties that exist in the “no-project” simulation are also present in the “project” simulation such that their impacts are reduced when assessing the change in outcomes. The SLWRI analysis is a comparative analysis.

DSM2

DSM2 is a branched 1-dimensional model for simulation of hydrodynamics, water quality, and particle tracking in a network of riverine or estuarine

channels (DWR 2002). The hydrodynamic module can simulate channel stage, flow, and water velocity. The water quality module can simulate the movement of both conservative and nonconservative constituents. The model is used by DWR to perform operational and planning studies of the Delta.

Impact analyses for planning studies of the Delta are typically performed for a 72-year period (1922 to 1994). In model simulations, EC is typically used as a surrogate for salinity. Results from CalSim-II are used to define Delta boundary inflows. CalSim-II-derived boundary inflows include the Sacramento River flow at Hood, San Joaquin River flow at Vernalis, inflow from the Yolo Bypass, and inflow from the eastside streams. In addition, Net Delta Outflow from CalSim-II is used to calculate the salinity boundary at Martinez.

Details of the model, including source codes and model performance, are available from the DWR Bay-Delta Office, Modeling Support Branch Web site (http://modeling.water.ca.gov/delta/models/dsm2/index.html). Documentation on model development is discussed in annual reports on Methodology for Flow and Salinity Estimates in the Sacramento-San Joaquin Delta and Suisun Marsh submitted to the SWRCB by the DWR Delta Modeling Section.

Sediment

The potential impacts from sediment in terms of erosion and geomorphology are analyzed in Chapter 4, “Geology, Geomorphology, Minerals, and Soils.”

Temperature

The analysis presented in Chapter 6, “Hydrology, Hydraulics, and Water Management,” assumed that the SLWRI alternatives would not alter existing operational rules or protocols and that there would be no formal changes to CVP or SWP operating criteria. Each action alternative would include storing some additional flows behind Shasta Dam during periods when the flows would have otherwise been released downstream. The resulting increase in storage would be used both to create an expanded cold-water pool (CWP), thus benefiting fisheries, and for subsequent release downstream when there are opportunities to put the water to beneficial use.

HEC-5Q temperature modeling was used to simulate flow and temperature for the Sacramento River system above RBDD. This model was updated to better represent the upper Sacramento River system with an emphasis on operation of the Shasta TCD. CalSim-II results were used as flow inputs to the HEC-5Q model. Temperature results are presented in Chapter 11, “Fisheries and Aquatic Ecosystems.” The water quality impacts analysis for temperature based on those results is summarized below.

Metals

Water quality data available for Shasta Lake and its tributaries were used to assess the impacts related to the discharge of metals into Shasta Lake. Available

monitoring data for the Sacramento River were used to assess the impacts of metals in Keswick Reservoir and the Sacramento River downstream.

7.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an environmental impact statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

Overall Impact Indicators for Water Quality

The significance criteria described below were developed based on guidance provided by the State CEQA Guidelines for use in assessing potential impacts on water quality; they also consider the context and intensity of the environmental effects as required under NEPA. These significance criteria were applied to the qualitative assessment and quantitative modeling results and used to determine impact significance. The analysis of water quality impacts and benefits focuses on temperature, metals, and sediment, because they are important water quality constituents in the both the primary and extended study areas.

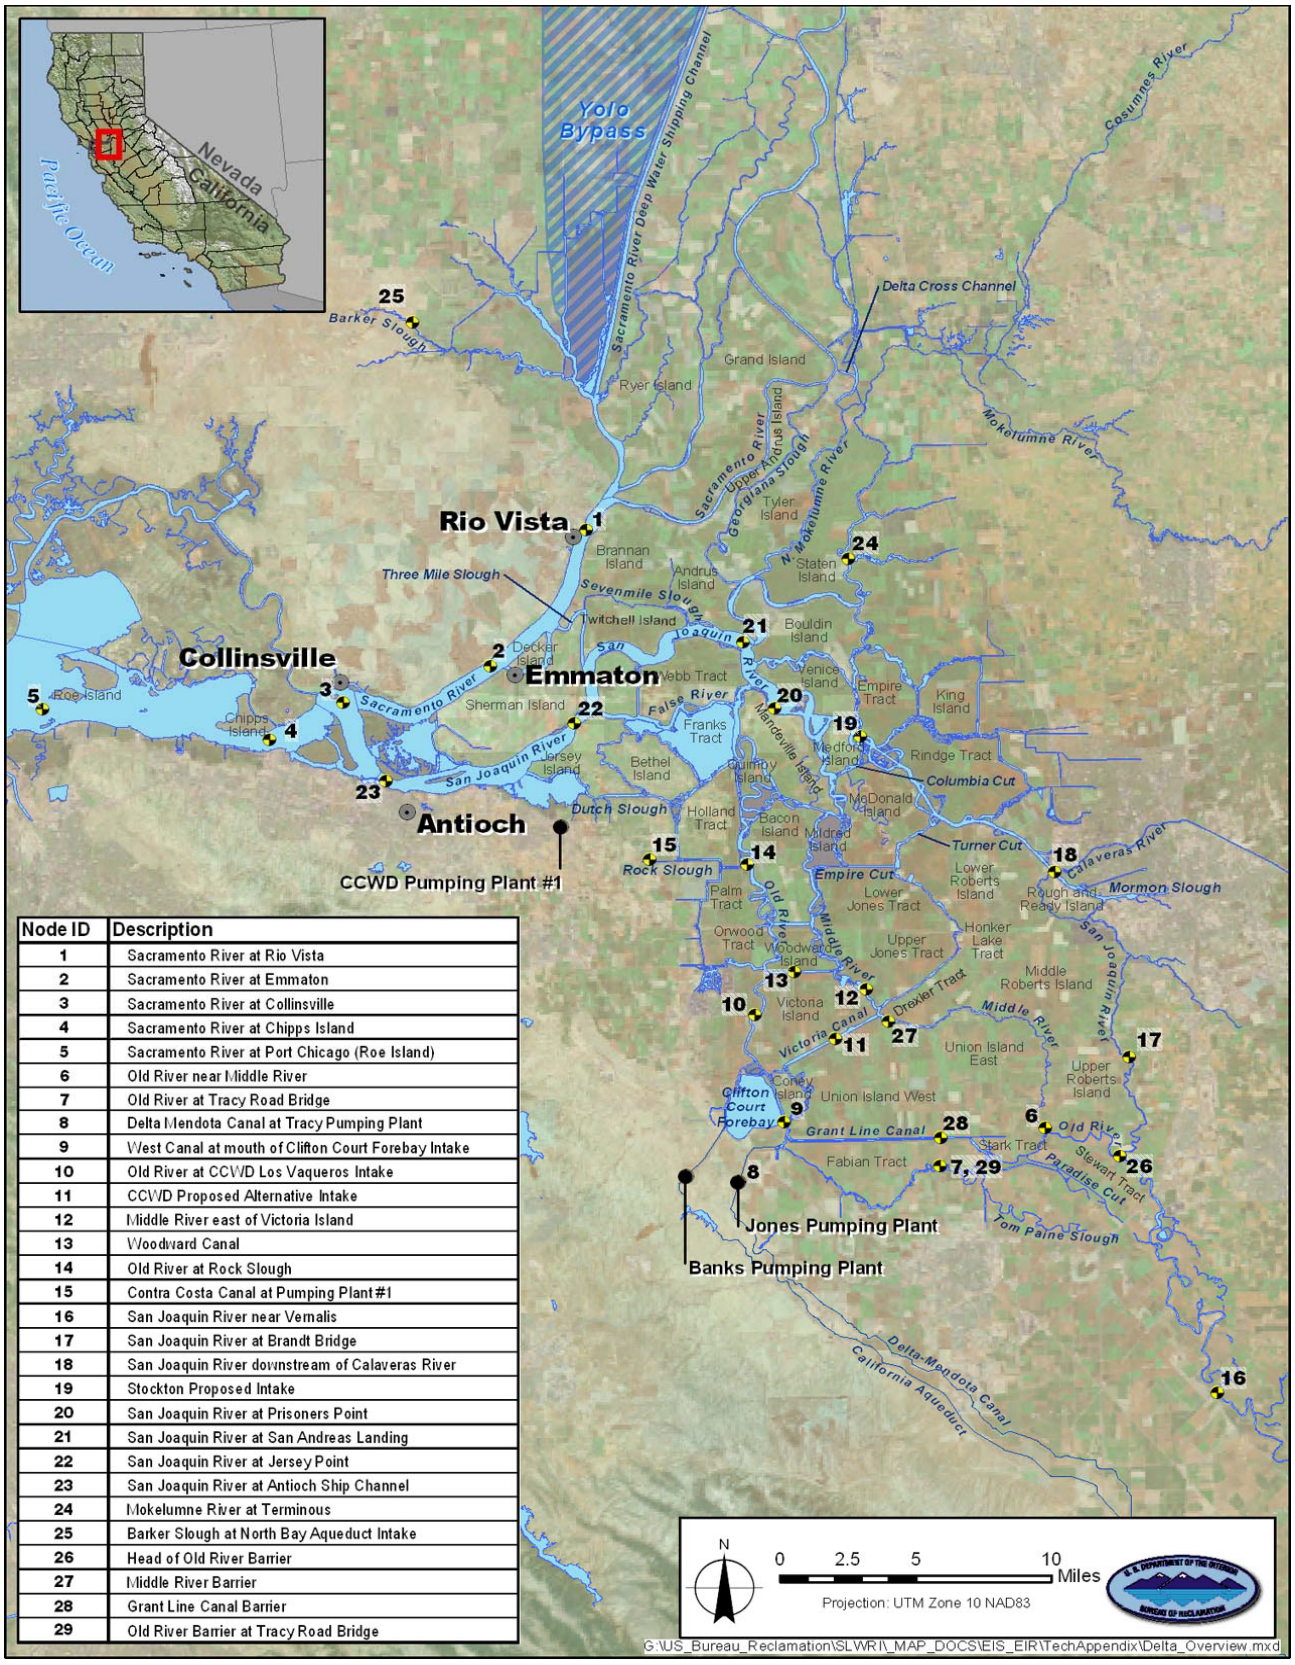
The impact significance criteria for Delta water quality variables that have regulatory objectives or numerical standards, such as those contained in the 1995 WQCP, are developed from the general considerations listed below.

Impacts of an alternative on water quality would be significant if project implementation would do any of the following:

- Violate existing water quality standards or otherwise substantially degrade water quality
- Result in substantial water quality changes that would adversely affect beneficial uses
- Result in substantive undesirable impacts on public health or environmental receptors

Significance statements are relative to both existing conditions (2005) and future conditions (2030) unless stated otherwise.

Impact Indicators for Delta Salinity



If changes in salinity within the Delta during months of increased pumping would result in an increase in salinity, relative to the basis of comparison, of sufficient frequency and magnitude over the long term to adversely affect designated beneficial uses, to increase the frequency that existing regulatory standards are exceeded, or to substantially degrade water quality at the locations below, then the impact would be considered significant:

- Sacramento River at Collinsville
- San Joaquin River at Jersey Point
- Sacramento River at Emmaton
- Old River at Rock Slough
- Delta-Mendota Canal at Jones Pumping Plant
- West Canal at mouth of the Clifton Court Forebay
- San Joaquin River at Vernalis
- Old River near Tracy Road Bridge
- Old River at Middle River
- San Joaquin River at Brandt Bridge

Figure 7-3 shows the major Delta islands, waterways, water quality control stations, and M&I intakes within the Delta.

Salinity Salinity-related water quality impacts associated with the operational component of the SLWRI alternatives were assessed at several locations in the Delta. EC was used as a surrogate for salinity. Using the assumptions discussed above, and detailed in Chapter 6 of the Modeling Appendix, the DSM2 model calculated changes in monthly mean EC values for the alternatives, relative to the bases of comparison. Monthly EC results were derived for a 73-year simulation period, extending from 1922 through 1994.

DSM2 model output was used to evaluate potential changes in salinity under the SWLRI alternatives, relative to the bases of comparison: changes equal to or greater than 5 percent in long-term monthly average EC values and average monthly EC values by water year type, and compliance with water quality standards, including the number of occurrences during which an EC compliance standard was met or exceeded.

Node ID	Description
1	Sacramento River at Rio Vista
2	Sacramento River at Emmaton
3	Sacramento River at Collinsville
4	Sacramento River at Chipps Island
5	Sacramento River at Port Chicago (Roe Island)
6	Old River near Middle River
7	Old River at Tracy Road Bridge
8	Delta Mendota Canal at Tracy Pumping Plant
9	West Canal at mouth of Clifton Court Forebay Intake
10	Old River at CCWD Los Vaqueros Intake
11	CCWD Proposed Alternative Intake
12	Middle River east of Victoria Island
13	Woodward Canal
14	Old River at Rock Slough
15	Contra Costa Canal at Pumping Plant #1
16	San Joaquin River near Vernalis
17	San Joaquin River at Brandt Bridge
18	San Joaquin River downstream of Calaveras River
19	Stockton Proposed Intake
20	San Joaquin River at Prisoners Point
21	San Joaquin River at San Andreas Landing
22	San Joaquin River at Jersey Point
23	San Joaquin River at Antioch Ship Channel
24	Mokelumne River at Terminous
25	Barker Slough at North Bay Aqueduct Intake
26	Head of Old River Barrier
27	Middle River Barrier
28	Grant Line Canal Barrier
29	Old River Barrier at Tracy Road Bridge

Figure 7-3. Major Delta Islands, Waterways, Water Quality Control Stations, and Municipal and Industrial Intakes

Changes in salinity were evaluated in the Delta during months of increased pumping under the alternatives, relative to the bases of comparison. Potential significant impacts could occur if salinity increases were of sufficient frequency and magnitude over the long term to adversely affect designated beneficial uses, to exceed existing regulatory standards, or to substantially degrade water quality.

Delta water quality is directly controlled by existing Delta water quality objectives (SWRCB 1995) for M&I, agricultural, and fish and wildlife uses that are incorporated in SWRCB D-1641 (SWRCB 2000). The 1995 WQCP objectives vary with month and water year type. Also, the 1995 WQCP objectives may only apply for some months and at some locations.

Applicable EC objectives were evaluated for the agricultural diversion season of April through August at Emmaton and Jersey Point, and during the entire year at each of the CVP/SWP export locations, and three south Delta locations. Increases in EC values that result in exceedence of the objective at specified locations in the Delta were considered to be significant water quality impacts. Monthly changes in EC values are also considered to be significant if they exceeded 10 percent of the applicable objective.

Impact Indicators for X2 Position

If a change in mean monthly position of X2, relative to the bases of comparison, would be of sufficient frequency and magnitude to adversely affect water quality, then it shall be considered a significant impact.

The X2 parameter represents the geographical location of the 2 parts per thousand near-bottom salinity isohaline in the Delta, which is measured in distance upstream from the Golden Gate Bridge in Suisun Bay (Jassby et al. 1995). The location of the estuarine salinity gradient is regulated during the months of February through June by the location of the X2 objective in the 1995 WQCP. During this time period, the X2 location must remain downstream from the confluence of the Sacramento and San Joaquin rivers[1] at Collinsville for the entire 5-month period. The X2 objective also specifies the number of days each month that that location of X2 must be downstream from Chipps Island or downstream from Roe Island.[2]

Estuarine EC objectives (i.e., X2) specified in the 1995 WQCP are applicable at Chipps Island during February through June for most years. The maximum EC objective at Chipps Island is 2.640 mmhos/cm (corresponding to a 2 parts per thousand salinity at Chipps Island) and must be satisfied for a specified number of days each month, depending on the previous month's Eight River Index (a measure of runoff in the Sacramento and San Joaquin valleys).

[1] Also referred to as Collinsville.
[2] Also referred to as the Port Chicago EC monitoring station.

7.3.3 Topics Eliminated from Further Consideration

The comprehensive plans include measures to remove or abandon on-site wastewater treatment facilities (e.g., septic tanks and/or drain fields) in conjunction with relocation activities. Several wastewater treatment packages will be developed to ensure that management of effluent from lakeshore developments is consistent with requirements of Federal, State, and local agencies. Only minor project-related effects on nutrients are expected to occur in either the primary study area or the extended study area; therefore, potential effects on the study area related to nutrients are not discussed further in this EIS.

7.3.4 Direct and Indirect Effects

No-Action Alternative

Shasta Lake and Vicinity Under the No-Action Alternative, the full-pool elevation of Shasta Lake would not be increased, and no ground-disturbing activities associated with construction would occur. Therefore, there would be no short-term increases in turbidity and suspended sediment in Shasta Lake and tributary streams. Ongoing impacts of sediment on beneficial uses would remain consistent with those that occur periodically under baseline conditions.

Under the No-Action Alternative, the operation of Shasta Dam would continue to influence the amount and duration of exposed shoreline below the maximum elevation of the reservoir. As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils," the shoreline would continue to erode, and impacts to beneficial uses, namely recreation and to some extent, the warm-water fishery along the shoreline of Shasta Lake, would be ongoing. In addition to active areas of shoreline erosion, sediment would continue to periodically be transported into Shasta Lake from tributaries as a result of other ongoing actions within the project area. Wave action and nearshore currents would continue to remobilize sediment that is typically visible as turbid plumes of water along portions of the shoreline. Sediment and turbidity would remain consistent with baseline conditions.

Reclamation operates the Shasta Dam TCD to manage water temperatures in the upper Sacramento River to (1) improve habitat for the endangered winter-run Chinook salmon and other threatened runs; (2) withdraw warmer surface water in the winter and spring to preserve cold-water storage for release during the temperature operation season; and (3) enable power generation to continue while controlling release temperatures, thereby eliminating the need to bypass the power plant penstocks via the low-level river outlets. Generally, to accomplish these temperature objectives during the temperature operation season, the TCD functions to select water temperatures in the 47˚F to 52˚F range. Therefore, a good index of the temperature-related benefits of the alternative is the volume of the CWP with a water temperature lower than 52˚F at the end of April.

In the context of historical project operation, reservoir storage and CWP conditions in mid-spring represent the available cold-water "bank" managed throughout the temperature operation season (July through October), as prescribed by Reclamation and implemented by Central Valley Operations.

Under the No-Action Alternative, no new facilities associated with raising Shasta Dam would be constructed within the vicinity of Shasta Lake; therefore, there would be no short-term changes in the temperature regime of waters within Shasta Lake or its tributaries.

Under the No-Action Alternative, Shasta Dam would continue to be operated consistent with current regulatory requirements with respect to storage and release of water to the upper Sacramento River. As described in Chapter 6, "Hydrology, Hydraulics, and Water Management," the temperature profile within Shasta Lake would not be changed under the No-Action Alternative. Therefore, there would be no change in the temperature regime of waters within Shasta Lake or its tributaries. Periodic changes in water temperature on a seasonal or interannual basis would be consistent with those that occur under baseline conditions.

Under the No-Action Alternative, no new facilities associated with raising Shasta Dam would be constructed in the vicinity of Shasta Lake. Metal concentrations in the Main Body and the Squaw Creek Arm would continue to be within the range of variability that currently exists with respect to the ongoing discharge and potential storage of heavy metals associated with historic mining and smelting operations. Concentrations of metals, specifically copper and zinc, that may persist within the water column of Shasta Lake would continue to remain in suspension at locations and levels similar to baseline conditions. Ongoing remediation of historic mining properties at locations in the Dry Creek, Little Backbone, Squaw Creek, and Horse Creek watersheds are anticipated to reduce the amount of acid mine drainage into Shasta Lake over time, thereby reducing metal concentrations in the water column.

Upper Sacramento River (Shasta Dam to Red Bluff) Under the No-Action Alternative, no new facilities would be constructed at Shasta Lake; thus there would be no construction-related degradation of water quality. In addition, there would be no changes in releases at Shasta or other CVP reservoirs as a result of a Shasta Lake enlargement that would either adversely affect or improve water quality. It is anticipated that if the project alternatives were not implemented, current operations to meet existing regulatory requirements would be continued. The ability to comply with existing temperature requirements would not be improved. Analysis of flow and temperature modeling results indicates little change in flows or compliance with temperature objectives on the upper Sacramento River between existing conditions and the future No-Action Alternative conditions. Remediation activities at Iron Mountain Mine and other mine sites over the last several years, as well as dredging of contaminated sediment in the Spring Creek Arm of Keswick Reservoir in 2009 and 2010,

would be expected to maintain or reduce the likelihood of future exceedences of the TMDL numeric targets below Keswick Dam. Therefore, there would be no impacts on water quality in the primary study area associated with the No-Action Alternative.

Lower Sacramento River and Delta and CVP/SWP Service Areas Under the No-Action Alternative, Shasta Dam would not be modified, and the CVP and SWP would continue operating similarly to existing conditions. Changes in regulatory conditions and water supply demands would result in differences in flows on the Sacramento River and the Delta. However, the No-Action Alternative would not, in itself, result in any changes in Delta water quality. Modeling indicates that the No-Action Alternative would continue to meet water quality requirements at levels of compliance similar to existing conditions, and would not result in any appreciable degradation of water quality.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability while contributing to increased survival of anadromous fish. Seven measures are included, to some degree, in all of the comprehensive plans:

- Enlarge Shasta Lake's cold-water pool
- Modify the TCD
- Increase conservation storage
- Reduce demand
- Modify flood control operations
- Increase public safety at Shasta Dam
- Modify hydropower facilities

In addition to these common features, CP1 consists primarily of raising Shasta Dam 6.5 feet, an elevation change that would increase the reservoir's full pool elevation by 8.5 feet and would enlarge the total storage space in the reservoir by 256 thousand acre-feet (TAF). Under this plan, operational guidelines for Shasta Dam would continue unchanged, with the additional storage retained for water supply reliability. This scenario would help to reduce future water shortages by increasing the reliability of the water supply in drought and average years. The increased pool depth and volume would also contribute to maintaining lower seasonal water temperatures for anadromous fish on the upper Sacramento River.

Shasta Lake and Vicinity

Impact WQ-1 (CP1): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses The construction-related

activities described in Chapter 2, “Alternatives,” would result in short-term changes in the amount of exposed area that would be subject to erosion. In addition to the clearing of vegetation in various areas to accommodate relocation activities, about 500 acres of vegetation in parts of the new inundation area would be cleared. Removal of vegetation would reduce the amount of effective ground cover (e.g., duff, large woody debris), thereby increasing the potential for short-term erosion and sedimentation along the shoreline.

The relocation activities would result in exposing as many as 3,337 acres to some amount of soil disturbance. These effects are described in more detail in Chapter 4, “Geology, Geomorphology, Minerals, and Soils.” The disturbed sites would have the potential to contribute sediments to nearby water bodies.

Although the environmental protection measures and BMPs described in Chapter 2, “Alternatives.” are intended to reduce the potential effects of introducing sediment into Shasta Lake and its tributaries, CP1 would affect water quality by increasing the levels of turbidity and suspended sediment in the receiving waters at levels that could be inconsistent with the Basin Plan. These increased levels of turbidity and suspended sediment could affect the beneficial uses of Shasta Lake and/or its tributaries. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP1): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under CP1, construction activities associated with enlarging Shasta Dam as well as the relocation actions would result in sizeable areas that would be subject to surface disturbance, including jurisdictional waters within the influence zone of this alternative. Efforts to document jurisdictional waters associated with relocation areas are ongoing. This information will be included if available in the Final EIS, as well as in the Section 404 permitting package, prior to issuance of a ROD.

Environmental commitments and BMPs for the various construction and relocation activities (e.g., bridge replacement, boat ramp construction, demolition of facilities) have been incorporated into CP1. These activities could include removal of riparian vegetation, thereby exposing water bodies to increased solar radiation for various time periods. As described in Chapter 2, “Alternatives,” a riparian revegetation program would be implemented at all construction and relocation sites as applicable to ensure that shade is quickly reestablished after construction is completed.

As described in Chapter 2, “Alternatives,” although the TCD may not be operational for some period of time during construction, project sequencing would ensure that changes to water temperature and associated limnological conditions would be consistent with those that occur periodically under the No-Action Alternative associated with maintenance and outage periods.

Because of the large water surface area of Shasta Lake, coupled with the isolated and discrete nature of the relocation activities on the tributaries, temporary construction-related effects are not expected to modify water temperature in a manner that would have a negative effect on beneficial uses or result in a water quality violation. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP1): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under CP1, there would be no construction activities that would disturb locations known to contain elevated metal concentrations in either sediments or the water column. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP1): Long-Term Sediment Effects That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Under CP1, the exposure of an additional 1,227 acres of shoreline surrounding Shasta Lake would result in a potential for increased wave-related shoreline erosion (see Chapter 4, "Geology, Geomorphology, Minerals, and Soils"). As the reservoir is lowered during summer and fall, the exposed surface area would also be subject to surficial erosion processes that could mobilize and transport sediment to the newly expanded Shasta Lake. Although environmental commitments and BMPs are incorporated into the project description, the project would result in an incremental increase in the delivery of suspended sediment and turbidity to the receiving waters. The amount of sediment that could be delivered is not quantifiable because of the size of the lake and the number of variables that influence sediment transport and delivery. This impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP1): Long-Term Temperature Effects That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries The analysis presented in Chapter 6, "Hydrology, Hydraulics, and Water Management," assumed that the existing CVP or SWP operating criteria would not be changed from an annual perspective and that the action alternatives would increase storage on a monthly basis. Reductions in releases would typically occur during winter (November through March) in relatively wet years, and increases in releases would typically occur in the late spring and summer (June through September) of drier years. CP1 would store some additional flows behind Shasta Dam during periods when the flows would have otherwise been released downstream. The resulting increase in storage would then be used both to create an expanded CWP available for carryover storage, thus benefiting fisheries, and for subsequent release to support beneficial uses downstream. On average, CP1 would provide about a 5 percent increase in annual storage.

Table 7-4 shows the simulated monthly change in storage for CP1 as a percent increase above the No-Action Alternative.

Table 7-4. Simulated Average End-of-Month Shasta Lake Storage – CP1

Month	Existing Condition (TAF)	CP1 (TAF)	CP1 % Increase
Oct	2,671	144	5.4%
Nov	2,690	148	5.5%
Dec	2,815	160	5.4%
Jan	3,067	165	5.4%
Feb	3,291	175	5.3%
Mar	3,624	175	4.8%
Apr	3,919	170	4.3%
May	3,950	171	4.3%
Jun	3,642	169	4.6%
Jul	3,187	162	5.1%
Aug	2,879	150	5.2%
Sep	2,782	145	5.2%

TAF = thousand acre-feet

Under CP1, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-4 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

As illustrated in Table 7-4, the increase in storage provided by CP1 fluctuates greatly throughout a year; storage is typically highest at the end of winter, in April and May, as the need for flood control reservation space in the reservoir is reduced. Storage is typically at its lowest in September and October, after the irrigation season and before the winter refill begins. This additional storage would typically be greatest in winter (February or March), and would be lowest at the end of summer (September or October), which is consistent with Shasta Reservoir's current operation. Additional runoff captured by the increased storage increment would typically remain in storage and available to support beneficial uses downstream. Conversely, if there were insufficient water in storage to meet downstream demands, the first increment to be reduced would be deliveries to water service contractors. As such, increased releases would typically be made on a schedule providing increased reliability of deliveries to

water service contractors, typically in July through October of relatively dry years.

A key indicator of the water temperature benefits of CP1 to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake prior to the water temperature operation season, about May through October. As previously described, Shasta Lake generally reaches its maximum storage during late April or early May. Also, the CWP volume in the lake accumulates during winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP1 should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52˚F for the No-Action Alternative and the change in CWP volume for CP1 is shown, by Sacramento Valley Index (SVI) year type, in Table 7-5.

In addition to illustrating the average change in available CWP, Table 7-5 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall, would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although there would be a meaningful increase in the active storage and carryover storage of the CWP, this increase is considered a less than significant impact. Mitigation for this impact is not needed, and thus not proposed.

Table 7-5. Simulated Average Volume of Water Less than 52˚F in Shasta Lake at the End of April – CP1

SVI Year Type	Existing Condition (TAF)	CP1 (TAF)	CP1 % Increase
Average of All Years	1,577	90	5.7%
Wet	1,807	137	7.6%
Above Normal	1,721	110	6.4%
Below Normal	1,743	72	4.1%
Dry	1,451	71	4.9%
Critical	928	16	1.7%

Impact WQ-6 (CP1): Long-Term Metals Effects That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries The increase in storage associated with CP1 would result in modifying the depth and thickness of the thermocline in Shasta Lake. The level of change would be correlated to a number of parameters, including carryover storage, climatic conditions, and the timing and duration of stratification (Bartholow et al. 2001). A study conducted by the CVRWQCB in 2002 and 2003 suggests that there is a direct correlation between dissolved copper concentrations in the upper levels of Shasta Lake near the dam and dissolved copper concentrations in the waters immediately downstream from the power plant (CVRWQCB 2003a). This study concluded that there appears to be a correlation between operation of the TCD and concentration of dissolved metals within the thermocline; an increase in available storage, however, would increase the opportunity to dilute metals concentrations below current levels.

Within the Squaw Creek Arm, two depositional features associated with historic copper mining and smelting operations are immediately adjacent to the shoreline of Shasta Lake in the general vicinity of the Bully Hill Mine. As mapped, these two sites appear to have about 7,300 cubic yards of material that could be subjected to shoreline and surficial erosional processes, with a high potential for delivery to Shasta Lake. This impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact WQ-7 (CP1): Temporary Construction-Related Sediment Effects on the Upper Sacramento River That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

As described in Impact WQ-1 (CP1), ground-disturbing activities associated with construction could cause soil erosion and sedimentation of local drainages and eventually the Sacramento River. Construction activities could also discharge waste petroleum products or other construction-related substances that could enter these waterways/facilities in runoff. The environmental protection measures and BMPs described in Chapter 2, “Alternatives,” are intended to reduce the potential effects of introducing sediment into Shasta Lake and into downstream releases to the upper Sacramento River; however, CP1 would affect water quality by increasing the levels of turbidity and suspended sediment in the receiving waters at levels that could be inconsistent with the Basin Plan. These increased levels of turbidity and suspended sediment could affect the beneficial uses of the upper Sacramento River. Therefore, this temporary impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP1): Temporary Construction-Related Temperature Effects on the Upper Sacramento River That Would Cause Violations of Water Quality

Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

As described for Impact WQ-2 (CP1), changes to water temperature and associated limnological conditions in Shasta Lake would be consistent with those that occur periodically under the No-Action Alternative associated with maintenance and outage periods. Therefore, water temperatures in the upper Sacramento River, which are related to releases from Shasta Lake, would not be expected to be modified during construction in a manner that would negatively affect beneficial uses or result in a water quality violation. This temporary impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP1): Temporary Construction-Related Metal Effects on the Upper Sacramento River That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

As described in Impact WQ-3 (CP1), there would be no construction activities that would disturb locations known to contain elevated metal concentrations in either sediments or the water column of Shasta Lake. Because water quality in the upper Sacramento River is related to the quality of releases from Shasta Lake, metals concentrations would not be expected to be modified during construction in a manner that would negatively affect beneficial uses or result in a water quality violation. This temporary impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP1): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment, because modeling results have indicated that CP1 would cause little change in average mean monthly flow, and could cause a decrease in peak flows that are associated with increased sediment transport. This impact would be less than significant.

Long-term effects on water quality could be caused by changes in the size and timing of releases from the reservoir associated with CP1. The analysis used flow data from hydrologic modeling as an indicator of effects on sediment and metals.

For CP1, fall and winter flows on the upper Sacramento River would be reduced in some years, and summer flows would increase in many years. In addition,

retention of winter flows would reduce or eliminate some overbank flood events in the upper Sacramento River. Because the reservoir would be able to store additional water during high-flow periods, in some years wintertime peak flows would be reduced as a result of the project. High-flow events transport sediments and can produce bank erosion and meander.

The Basin Plan specifies that changes to suspended sediment loading and discharge rates cannot cause nuisance or adversely affect beneficial uses (CVRWQCB 2007b). Under both existing and future conditions, analysis of modeling results indicates that the generally small changes in average mean monthly flow from CP1 are unlikely to have a significant effect on sediment transport within the upper Sacramento River. In addition, it appears that CP1 would reduce wintertime peak flow events, which may reduce sediment loading and discharge rates. Beneficial uses that may be beneficially affected include municipal and domestic supply, irrigation and stock watering, service supply, power, contact recreation and canoeing and rafting, other noncontact recreation, and navigation. However, there could be varying effects on beneficial uses concerning habitat, such as freshwater and spawning habitat. These impacts are explored further in Chapter 11, “Aquatic and Fisheries Ecosystems,”. Because the project would cause little change in average mean monthly flow, and a potential decrease in peak flows, the water quality impact of CP1 related to sediment would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP1): Long-Term Temperature Effects That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP1 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the cold-water pool in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact of CP1 on water quality measured as temperature would be beneficial.

The temperature analysis used temperature modeling; the analysis was limited to using monthly average flows by the modeling tools used. CP1 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critically dry years. This would be accomplished by raising Shasta Dam 6.5 feet, thus increasing the depth of the cold-water pool in Shasta Lake and resulting in an increase in seasonal cold-water volume below the thermocline (i.e., layer of greatest water temperature and density change). Cold water released from Shasta Dam influences water temperature conditions in the Sacramento River between Keswick Dam and RBDD, with effects diminishing downstream.

This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, “Fisheries and Aquatic Resources.”

Analysis of temperature modeling results indicates that CP1 would improve compliance with the temperature requirements on the Sacramento River. The 2009 BO for CVP and SWP operations and their effects on the Sacramento River winter-run Chinook salmon require that Sacramento River water temperatures be below 56°F at compliance locations between Balls Ferry and Bend Bridge from April 15 through September 30, and not in excess of 60°F at the same compliance locations in during October. Currently, this standard is not always met, particularly in dry and critically dry years. CP1 would reduce the amount of daily exceedences of the 2009 BO standards under both existing and future conditions. Table 7-6 provides a summary of modeled reductions in exceedences over the 82-year modeling period under each of the alternatives.

Based on this analysis, the impact of CP1 on water quality measured as temperature would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP1): Long-Term Metals Effects That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant.

Table 7-6. Modeled Reduction in Daily Exceedences of Sacramento River Temperature Requirements (as Defined by the 2004 Biological Opinion for CVP and SWP Operations and Their Effects on the Sacramento River Winter-Run Chinook Salmon) for April 1 – October 31

Comprehensive Plan	Existing Conditions (2005)		Future Conditions (2030)	
	Balls Ferry	Bend Bridge	Balls Ferry	Bend Bridge
CP1	10%	4%	14%	5%
CP2	15%	6%	19%	8%
CP3 and CP5	18%	8%	24%	11%
CP4	37%	13%	40%	15%

CVP = Central Valley Project
SWP = State Water Project

The analysis used flow data from hydrologic modeling as an indicator of effects on sediment and metals. The Sacramento River and its tributaries upstream from Keswick Dam are the primary source of metals to the lower Sacramento River (USGS 2000b). Shasta Lake is also listed as impaired for metals. As described

in Impact WQ-6 (CP1), a study conducted by the CVRWQCB in 2002 and 2003 suggests that there is a direct correlation between dissolved copper concentrations in the upper levels of Shasta Lake near the dam and dissolved copper concentrations in the waters immediately downstream from the power plant (CVRWQCB 2003a).

The 25-mile reach of the Sacramento River from Keswick Dam downstream to Cottonwood Creek is impaired for cadmium, copper, and zinc. The CVRWQCB developed a TMDL program for these constituents in the upper Sacramento River because of exceedences of water quality standards. Heavy metals such as copper, zinc, mercury, lead, and cadmium are water quality parameters that are impairing beneficial uses. Natural mineral deposits and historical mining practices are a source of metals, including mercury, within Shasta Lake and the upper Sacramento River. High metals concentrations in the Sacramento River correlate with concentrations of suspended sediment and high flows because metals are transported adsorbed to suspended sediments (USGS 2000b; Domagalski et al. 2000).

Under both existing and future conditions, the generally small changes in average mean monthly flow from the project predicted by modeling are unlikely to have a significant effect on metals within the upper Sacramento River and would not be expected to result in exceedences of the dissolved metals numeric targets established in the TMDL (as shown in Table 7-3). Remediation activities at Iron Mountain Mine and other mine sites over the last several years, as well as dredging of contaminated sediment in the Spring Creek Arm of Keswick Reservoir in 2009 to 2010, are also expected to reduce the likelihood of future exceedences of the TMDL numeric targets below Keswick Dam.

However, as described in Impact WQ-6 (CP1), two depositional features associated with historic copper mining and smelting operation within the Squaw Creek Arm of Shasta Lake could be subjected to shoreline and surficial erosional processes, with a high potential for delivery to Shasta Lake and subsequent delivery to the upper Sacramento River. Therefore, the water quality impact of CP1 related to metals in the upper Sacramento River would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact WQ-13 (CP1): Temporary Construction-Related Sediment Effects on the Extended Study Area That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

Construction would only temporarily influence water quality in the primary study area. Construction effects are anticipated to be localized and would be further minimized with appropriate BMPs. Therefore, construction is not anticipated to affect water quality conditions downstream in the extended study

area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP1): Temporary Construction-Related Temperature Effects on the Extended Study Area That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses As described in Impact WQ-13 (CP1), construction is not anticipated to affect water temperature in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP1): Temporary Construction-Related Metal Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses As described in Impact WQ-13 (CP1), construction is not anticipated to affect metals in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP1): Long-Term Sediment Effects That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Water quality effects of CP1 could influence the extended study area, but effects would diminish with distance into the study area. Water quality effects are attenuated by multiple factors including flow from tributaries, stormwater runoff, and municipal and agricultural discharges, as described below.

Because the Sacramento River is the primary supplier of suspended sediment to the Delta, sediment loading and discharge rates from the upper Sacramento River could affect water quality and beneficial uses in the extended study area. However, changes in sediment loading in the upper Sacramento River would be less than significant and changes in the extended study area would be even smaller. Therefore, the impact on sediment would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP1): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Analysis of temperature modeling shows little to no change in temperature at RBDD caused by CP1. This suggests that there would be no changes in temperature beyond RBDD as a result of CP1. This conclusion is further supported by the operational experience of the CVP, which indicates that the 60-mile stretch of river between Keswick Dam and Red Bluff is the extent to which the Shasta-Trinity Division can control temperatures through normal operations of the CVP. Therefore, no temperature effects are anticipated in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP1): Long-Term Metals Effects That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended

Study Area CP1 would alter the operations of Shasta Lake. Increases in metals concentrations can result from changes in flows that cause increases in concentrations of suspended sediments during high-flow periods. The reduction in frequency and magnitude of peak flow events resulting from CP1 would suggest a beneficial impact for metals; however, as described in Impact WQ-6 (CP1), two depositional features associated with historic copper mining and smelting operation within the Squaw Creek Arm of Shasta Lake could be subjected to shoreline and surficial erosional processes, with the potential for delivery to Shasta Lake and subsequent delivery to the Sacramento River. Therefore, the water quality impact of CP1 related to metals in the lower Sacramento River could be potentially significant, because operation of the project could add substantial additional amounts of metal to the river system. Mitigation for this impact is proposed in Section 7.3.5.

Salinity CP1 would differ from the No-Action Alternative primarily through a 256-TAF enlargement of Shasta Lake. Potential impacts, which are evaluated below, include the following:

- Delta salinity on the Sacramento River at Collinsville
- Delta salinity on the San Joaquin River at Jersey Point
- Delta salinity on the Sacramento River at Emmaton
- Delta salinity on the Old River at Rock Slough
- Delta water quality on the Delta-Mendota Canal at Jones Pumping Plant
- Delta water quality on the West Canal at the mouth of the Clifton Court Forebay
- Delta salinity on the San Joaquin River at Vernalis
- Delta salinity on the San Joaquin River at Brandt Bridge
- Delta salinity on the Old River near the Middle River
- Delta salinity on the Old River at Tracy Road Bridge
- X2 position

Impact WQ-19a (CP1): Delta Salinity on the Sacramento River at Collinsville Operations for CP1 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. Similarly, on a percentage basis, all increases

in salinity would be less than 10 percent; this would be within the range of natural variability. This impact would be less than significant.

The water quality requirement on the Sacramento River at Collinsville is specified in D-1641, and is defined for all year types, from October through April. The D-1641 objectives for the Sacramento River at Collinsville are defined in Table 7-7.

Table 7-7. D-1641 Water Quality Objectives for the Sacramento River at Collinsville

Months	Year-Type	Value (mmhos/cm)
October	All	19.0
November–December	All	15.5
January	All	12.5
February–March	All	8.0
April–May	All	11.0

Source: SWRCB 2000

Notes:
Year types defined by Sacramento Valley Index.
The requirement is the maximum monthly average of both daily high tide EC values or demonstration that equivalent or better protection will be provided at the location.

Key:
D-1641 = Revised Water Right Decision 1641
EC = electrical conductivity
mmhos/cm = millimhos per centimeter (unit of EC)

As shown in Table 7-8, operations for CP1 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. Similarly, on a percentage basis, all increases in salinity would be less than 10 percent; this would be within the range of natural variability. Table 7-9 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Collinsville in the period of simulation. The operation of CP1 would not result in any additional violations of the salinity standards for the Sacramento River at Collinsville under both Existing and Future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP1): Delta Salinity on the San Joaquin River at Jersey Point
On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months in an average year. Moreover, CP1 would not increase the EC at Jersey Point. This impact would be less than significant.

The water quality requirement on the San Joaquin River at Jersey Point is specified in D-1641 as two components. The first component of the requirement begins on April 1, and extends through a year-type–dependent date. The second component of the Jersey Point requirement begins at the end of the first component, and ends on August 15. The numerical requirement of the second component is dependent on the year type. Objectives for the San Joaquin River at Jersey Point are defined in Table 7-10.

Table 7-10. D-1641 Water Quality Objectives for the San Joaquin River at Jersey Point

Year Type	0.45 EC April 1 to the Date Shown	EC from Date Shown to August 15 (mmhos/cm)
Wet	August 15	0.45
Above Normal	August 15	0.45
Below Normal	June 20	0.74
Dry	June 15	1.35
Critical	April 1	2.20

Source: SWRCB 2000.

Note:
Year types defined by Sacramento Valley Index. While requirement in D-1641 is the maximum 14-day running average of mean daily EC, modeling uses a monthly average.

Key:
D-1641 = Water Right Decision 1641
EC = electrical conductivity
mmhos/cm = millimhos per centimeter

While Table 7-11 shows EC for all months, the Jersey Point water quality requirement is only defined for April 1 through August 15. On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months in an average year. Moreover, CP1 would not increase the EC at Jersey Point. Table 7-12 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Jersey Point in the period of simulation. CP1 would result in a slight increase in the frequency of violations (4 percent) during August under the Existing Conditions and up to 6 percent during June under the Future Conditions. Overall, the frequency of exceedence of salinity standards for the San Joaquin River at Jersey Point under CP1 would be similar to those under Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP1): Delta Salinity on the Sacramento River at Emmaton
On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months on an average annual basis; moreover, CP1 would not increase the EC at Emmaton during this period by more than 0.2 percent. This impact would be less than significant.

Similar to the water quality requirement on the San Joaquin River at Jersey Point, the water quality requirement on the Sacramento River at Emmaton is specified in D-1641 as two components. The first component of the requirement begins on April 1, and extends through a year-type-dependent date. The second component of the Emmaton requirement begins at the end of the first component, and ends on August 15. The numerical requirement of the second

component is dependent on the year type. Objectives for the Sacramento River at Emmaton are defined in Table 7-13.

Note:
Year types defined by Sacramento Valley Index. While requirement in D-1641 is the maximum 14-day running average of mean daily EC, modeling uses a monthly average.

Key:
D-1641 = Water Right Decision 1641
EC = electrical conductivity
mmhos/cm = millimhos per centimeter

While Table 7-14 shows the EC for all months, the Emmaton water quality requirement is only defined for April 1 through August 15. On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months on an average annual basis; moreover, CP1 would not increase the EC at Emmaton during this period by more than 0.2 percent. Table 7-15 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Emmaton in the period of simulation. Operations of CP1 would not result in any additional violation of salinity standards between October and March. Between April and September, CP1 would result in a decrease in the frequency of violations when compared to the baseline values under the Existing and Future conditions, except in June and August when there would be a slight increase under the Future Conditions. Overall, the compliance of standards for the Sacramento River at Emmaton would be similar to the baseline levels under both Existing and Future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Key:
CP = Comprehensive Plan

Impact WQ-19d (CP1): Delta Salinity on the Old River at Rock Slough On an average annual basis, all months except October through January under both the Existing Condition and Future Condition would be less than 150 mg/L. In dry and critical years, only October and November would exceed the standard under the Existing Condition, and October through February would exceed the standard in the Future Condition. In average annual years, CP1 would not increase chlorides by more than 1.2 percent, and even in that instance, the standard would be met. For dry and critical years, larger increases in chlorides would occur in November and December under the Existing Condition. However, the change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. This impact would be less than significant.

Rock Slough is the location of the CCWD diversion for the Contra Costa Canal. The actual requirement location is at Contra Costa Canal Pumping Plant No. 1, but in DSM2, the location is measured in the Old River at Rock Slough. The requirements, as defined in D-1641, specify a minimum number of days during the calendar year that the maximum mean daily chloride concentration of 150

mg/L must be maintained. Objectives for the Contra Costa Canal Pumping Plant No. 1 are defined in Table 7-16.

Table 7-16. D-1641 Water Quality Objective for Contra Costa Canal Pumping Plant No. 1

Year Type	Number of Days Each Calendar Year Chlorides Less Than or Equal to 150 mg/L
Wet	240
Above Normal	190
Below Normal	175
Dry	165
Critical	155

Source: SWRCB 2000

Note:
Year-types defined by Sacramento Valley Index. Maximum mean daily 150 mg/L Cl- for at least the number of days shown.

Key:
Cl- = chlorides
D-1641 = Water Right Decision 1641
mg/L = milligram per liter

The standard for chlorides at the Contra Costa Canal is defined by the number of days with less than 150 mg/L of chloride. The analysis of modeling output is limited to monthly average chlorides. However, on an average annual basis, all months except October through January under both the Existing Condition and Future Condition would be less than 150 mg/L. In dry and critical years, only October and November would exceed the standard under the Existing Condition, and October through February would exceed the standard in the Future Condition. As shown in Table 7-17, in average annual years, CP1 would not increase chlorides by more than 1.2 percent, and even in that instance (August under the Existing Condition), the standard would be met. For dry and critical years, larger increases in chlorides would occur in November and December under the Existing Condition. However, the change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. Table 7-18 shows the number of days simulated chloride values exceeded the standards of 250 mg/L for the Old River at Rock Slough in the period of simulation. CP1 would result in fewer violations compared to the basis of comparison under the Existing Conditions. Overall, CP1 would not alter the compliance level for Old River at Rock Slough observed under both Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19e (CP1): Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. CP1 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

The Jones Pumping Plant is the primary point of export for the CVP water supply south of the Delta. The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. Table 7-19 shows both the chloride and EC concentration requirements.

Table 7-20 shows the simulated chloride concentrations and Table 7-21 shows the EC for the Delta-Mendota Canal at Jones Pumping Plant.

Table 7-22 shows the number of days simulated chloride values exceeded the standards of 250 mg/L for the Delta-Mendota Canal at the Jones Pumping Plant in the period of simulation. As seen in Table 7-22, there would be no additional violations throughout the year except during February. Even in February, chloride values under CP1 would be similar to the baseline values under both Existing and Future conditions.

As evidenced by Table 7-22, the 250 mg/L chloride concentration would not be exceeded on an average annual or dry and critical year basis. Furthermore, chloride concentrations would typically be lower under CP1 than under the basis of comparisons.

Similar to the chloride concentrations, the average annual and dry and critical year averages under the basis of comparison would be under the requirement in all months. CP1 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-23 shows the number of months simulated EC values exceeded the standards for the Delta-Mendota Canal at the Jones Pumping Plant in the period of simulation. CP1 would not result in any additional violations of the salinity standards except during February. Even in February, CP1 would not change the baseline compliance levels under both Existing and Future conditions.

Impact WQ-19f (CP1): Delta Water Quality on the West Canal at the Mouth of the Clifton Court Forebay The 250 mg/L chloride concentration at the West Canal would not be exceeded on an average annual or dry and critical year basis. Furthermore, chloride concentrations would typically be lower under CP1 than under the basis of comparisons. CP1 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

Clifton Court Forebay is the source of water supply for the Banks Pumping Plant and SWP exports south of the Delta. Similar to the Delta-Mendota Canal at Jones Pumping Plant, the water quality requirement on the West Canal at the mouth of the Clifton Court Forebay has two components, a chloride requirement and an EC requirement. Table 7-24 shows both the chloride and EC concentration requirements.

Source: Common Assumptions Common Modeling Package, version 8D, DSM2 Existing and Future simulations (Node CHSWP003)

Note:
Simulation period: 1922-1994. Change as measured from either Existing Condition or No-Action Alternative. Dry and critical years as defined by the Sacramento Valley Index.

Key:
CP = Comprehensive Plan

Impact WQ-19g (CP1): Delta Salinity on the San Joaquin River at Vernalis On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP1 would not measurably change the EC on the San Joaquin River at Vernalis. This impact would be less than significant.

To protect water quality in the south Delta, D-1641 includes a salinity objective at several locations on the San Joaquin River and on the Old River. The objective is the same for all four locations: the San Joaquin River at Airport Way Bridge in Vernalis, the San Joaquin River at Brandt Bridge, the Old River near the Middle River, and the Old River at Tracy Road Bridge. The water quality requirement is a maximum 30-day average of mean daily EC. Table 7-29 shows the south Delta water quality requirement.

Table 7-29. D-1641 South Delta Water Quality Objective

Year Type	Months	EC Standard (mmhos/cm)
All	April–August	0.7
All	September–March	1.0

Source: SWRCB 2000

Note:
Year types defined by Sacramento Valley Index. While requirement in D-1641 is the maximum 30-day running average of mean daily EC, modeling uses a monthly average. San Joaquin River at Vernalis measured at the Airport Way Bridge.

Key:
D-1641 = Water Right Decision 1641
EC = electrical conductivity
mmhos/cm = millimhos per centimeter

On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP1 would not measurably change the EC on the San Joaquin River at Vernalis, as shown in Table 7-30. Table 7-31 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Vernalis in the period of simulation. CP1 would not change the baseline compliance levels under both Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19h (CP1): Delta Salinity on the San Joaquin River at Brandt Bridge Impact WQ-19h (CP1) would be the same as Impact WQ-19g (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP1 would not measurably change EC on the San Joaquin River at Brandt Bridge. This impact would be less than significant.

As previously mentioned, D-1641 contains a south Delta water quality requirement applicable at several locations, including on the San Joaquin River at Brandt Bridge. Table 7-29 contains the water quality requirement standards.

Impact WQ-19i (CP1): Delta Salinity on the Old River near the Middle River
Impact WQ-19i (CP1) would be similar to Impact WQ-19g (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP1 would not measurably change EC on the Old River near the Middle River. This impact would be less than significant.

As previously mentioned, D-1641 contains a south Delta water quality requirement applicable at several locations, including on the Old River near the Middle River. Table 7-29 contains the water quality requirement standards.

Impact WQ-19i (CP1) would be similar to Impact WQ-19g (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP1 would not measurably change EC on the Old River near the Middle River, as shown in Table 7-34. Table 7-35 shows the number of months simulated EC values exceeded the standards for the Old River near the Middle

River in the period of simulation. The compliance of salinity standards for the Old River near the Middle River would not change under CP1 except in July under Existing Conditions. In July, CP1 would result in 8 months of violation of salinity standards as compared to 7 months for the baseline under the Existing Conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-34. Simulated Monthly Average Salinity and Percent Change for the Old River near the Middle River

Note:
Simulation period: 1922-1994. Change as measured from either Existing Condition or No-Action Alternative. Dry and critical years as defined by the Sacramento Valley Index.

Key:
CP = Comprehensive Plan

Impact WQ-20 (CP1): X2 Position CP1 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 kilometer (km) under either the Existing Condition or Future Condition. While several months may be out of compliance under the bases of comparison, the change resulting from CP1 would not increase the amount out of compliance. This impact would be less than significant.

Table 7-38 shows the simulated monthly average X2 position for CP1 compared to the Existing Condition and Future Condition baselines. CalSim-II calculates the X2 position on a 1-month delay; the values shown have been corrected to accurately reflect the X2 position for the specified month.

CP1 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the Existing Condition or Future Condition. While several months may be out of compliance under the bases of comparison, the change resulting from CP1 would not increase the amount out of compliance.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Like CP1, CP2 focuses on enlarging Shasta Dam and Shasta Lake consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increasing water supply reliability, increasing survival of anadromous fish, and improving water quality. In addition to the common features, CP2 consists of raising Shasta Dam 12.5 feet, an elevation change that would increase the full pool elevation by 14.5 feet and enlarge the total storage space in the reservoir by 443 TAF. This alternative would help reduce future shortages by increasing the reliability of the water supply in drought and average years. The increased CWP would also contribute to improved seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity

Impact WQ-1 (CP2): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-1 (CP1). However, the construction-related activities described in Chapter 2, "Alternatives," would result in about 500 more acres of exposed shoreline than CP1 and in about the same number of relocation acres (3,337) that would be subject to erosion. This alternative is similar to, but somewhat larger than CP1. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP2): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses Similar to CP1, construction activities associated with enlarging Shasta Dam as well as the relocation actions would result in sizeable areas that would be subject to surface disturbance, including jurisdictional waters within the influence zone of CP2. Efforts to document jurisdictional waters associated with relocation areas are ongoing. This information will be included, if available, in the Final EIS, as well as in the Section 404 permitting package, prior to issuance of a ROD.

Environmental commitments and BMPs for the various construction and relocation activities (e.g., bridge replacement, boat ramp construction, demolition of facilities) have been incorporated into CP2. These activities could include removal of riparian vegetation, thereby exposing water bodies to increased solar radiation for various time periods. A riparian revegetation program will be implemented at all construction and relocation sites as applicable to ensure that shade is quickly reestablished after construction is completed.

As described in Chapter 2, "Alternatives," although the TCD may not be operational for some period of time during construction, project sequencing will ensure that changes to water temperature and associated limnological conditions will be consistent with those that occur periodically under the No-Action Alternative associated with maintenance and outage periods.

Because of the large water surface area of Shasta Lake, coupled with the isolated and discrete nature of the relocation activities on the tributaries, temporary construction-related effects are not expected to modify water temperature in a manner that would have a negative effect on beneficial uses or result in a water quality violation. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP2): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-3 (CP1). There would be no construction activities that would disturb locations known to

contain elevated metal concentrations in either sediments or the water column. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP2): Long-Term Sediment Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to WQ-4 (CP1), except that the exposure of an additional 1,735 acres of shoreline surrounding Shasta Lake would result in a potential for increased wave-related shoreline erosion (see Chapter 4, "Geology, Geomorphology, Minerals, and Soils"). This would be a potentially significant impact. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP2): Long-Term Temperature Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, this alternative would increase storage on a monthly basis although it would vary by water year. Table 7-39 shows the simulated monthly change in storage for CP2 as a percent increase above the No-Action Alternative. On average, CP2 would provide almost a 9 percent increase in the end-of-month storage on an annual basis.

Table 7-39. Simulated Average Increased End-of-Month Shasta Lake Storage – CP2

Month	Existing Condition (TAF)	CP2 (TAF)	CP2 % Increase
Oct	2,671	263	9.8%
Nov	2,690	265	9.9%
Dec	2,815	284	10.1%
Jan	3,067	288	9.4%
Feb	3,291	299	9.1%
Mar	3,624	301	8.3%
Apr	3,919	295	7.5%
May	3,950	295	7.5%
Jun	3,642	293	8.0%
Jul	3,187	282	8.8%
Aug	2,879	271	9.4%
Sep	2,782	269	9.7%

Source: Common Assumptions Common Modeling Package Version 8D CalSim-II 2005 and 2030 simulations (Node S4+S44)

Note:
Simulation period: 1922–2003

Key:
TAF = thousand acre-feet

Under CP2, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-39 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Similar to CP1, the increase in storage provided by CP2 fluctuates greatly throughout a year. A key indicator of water temperature benefits of CP2 to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake prior to the water temperature operation season, about May through October. Similar to CP1, the CWP volume in the lake accumulates during the winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP2 should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52˚F for the No-Action Alternative and the change in CWP volume for CP2 is shown, by SVI year type, in Table 7-40.

Table 7-40. Simulated Average Volume of Water Less than 52˚F in Shasta Lake at the End of April – CP2

SVI Year Type	Existing Condition (TAF)	CP2 (TAF)	CP2 % Increase
Average of All Years	1,577	152	9.6%
Wet	1,807	237	13.1%
Above Normal	1,721	182	10.6%
Below Normal	1,743	130	7.5%
Dry	1,451	111	7.6%
Critical	928	22	2.4%

Source: Common Assumptions Common Modeling Package Version 8D SRWQM 2005 and 2030 simulations

Note:
Simulation period: 1922-2003
Year types as defined by the Sacramento Valley Index

Key:
SVI = Sacramento Valley Index
TAF = thousand acre-feet

In addition to illustrating the average change in available CWP, Table 7-40 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although there would be a meaningful increase in active storage and carryover storage of the CWP, this increase is considered a less than significant impact. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-6 (CP2): Long-Term Metals Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, the increase in storage associated with this alternative would not result in modifying the depth and thickness of the thermocline that persists in Shasta Lake.

Within the Squaw Creek Arm, two depositional features associated with historic copper mining and smelting operations are immediately adjacent to the shoreline of Shasta Lake in the general vicinity of the Bully Hill Mine. As mapped, these two sites appear to have about 7,300 cubic yards of material that could be subjected to shoreline and surficial erosional processes at slightly higher elevations on the features than CP1with a high potential for delivery to Shasta Lake. Under CP2, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact WQ-7 (CP2): Temporary Construction-Related Sediment Effects on the Upper Sacramento River That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

This impact would be the same as Impact WQ-7 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP2): Temporary Construction-Related Temperature Effects on the Upper Sacramento River That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

This impact would be identical to Impact WQ-8 (CP1). For the same reasons as described for Impact WQ-8 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP2): Temporary Construction-Related Metal Effects on the Upper Sacramento River That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

This impact would be identical to Impact WQ-9 (CP1). For the same reasons described for Impact WQ-9 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP2): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment, because modeling results have indicated that CP2 would cause little change in average mean monthly winter flows during some years, which could slightly reduce sediment transport. This impact would be less than significant.

This impact would be similar to Impact WQ-10 (CP1) because the extent of the effect of CP2 on sediment would be similar to but slightly greater than that for CP1 (i.e., CP2 would have greater potential to reduce erosional processes and sediment transport in the upper Sacramento River). For the same reasons as described for Impact WQ-10 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP2): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP2 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the cold-water pool in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact of CP2 on water quality measured as temperature would be beneficial.

CP2 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critically dry years. Raising Shasta Dam 12.5 feet would increase the cold-water pool and benefit seasonal water temperatures along the upper Sacramento River. This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, “Fisheries and Aquatic Ecosystems.”

Analysis of temperature modeling results indicates that under both existing and future conditions, CP2 would have a beneficial effect on temperature within the upper Sacramento River, with a slight decrease in average monthly water temperature during summer. Decreased temperatures would improve compliance with the temperature objectives for the upper Sacramento River in the 2004 and 2009 BOs (NMFS 2004, 2009). CP2 would reduce temperature exceedences at Balls Ferry by 15 percent under existing conditions and 19 percent under future conditions. At the Bend Bridge compliance station, CP2 would reduce temperature exceedences by 6 percent under existing conditions and 8 percent under future conditions. Table 7-6 summarizes the temperature modeling results.

Based on this analysis, the impact of CP2 on water quality measured as temperature would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP2): Long-Term Metals Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant.

This impact would be similar to Impact WQ-12 (CP1) because the extent of the effect of CP2 on metals would be similar to but slightly greater than that for CP1. For the same reasons as described for CP1, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
CP2 would differ from the No-Action Alternative primarily through a 443 TAF enlargement of Shasta Lake. The impacts described below are the same as described for CP1.

Impact WQ-13 (CP2): Temporary Construction-Related Sediment Effects on the Extended Study Area That Would Cause Violations of Water Quality Standards Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

This impact would be similar to Impact WQ-13 (CP1). For the same reasons as described for Impact WQ-13 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP2): Temporary Construction-Related Temperature Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-14 (CP1). For the same reasons as described for Impact WQ-14 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP2): Temporary Construction-Related Metal Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-15 (CP1). For the same reasons as described for Impact WQ-15 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP2): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Project implementation could affect water quality in the extended study area, but effects would diminish with distance. This impact would be less than significant.

This impact would be similar to Impact WQ-16 (CP1). For the same reasons as described for Impact WQ-16 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP2): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-17 (CP1). For the same reasons as described for Impact WQ-17 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP2): Long-Term Metals Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-18 (CP1). For the same reasons as described for Impact WQ-18 (CP1), this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-19a (CP2): Delta Salinity on the Sacramento River at Collinsville Impact WQ-19a (CP2) would be similar to Impact WQ-19a (CP1). As shown in Table 7-41, operations for CP2 result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. Similarly, on a percentage basis, all increases in salinity would be less than 1 percent; this would be within the range of natural variability. Table 7-42 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Collinsville in the period of simulation. The operation of CP2 would not result in any violation of the salinity standards under both Existing and Future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP2): Delta Salinity on the San Joaquin River at Jersey Point On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months in an average year. Moreover, CP2 would not increase the EC at Jersey Point. This impact would be less than significant.

Impact WQ-19b (CP2) would be similar to Impact WQ-19b (CP1). As shown in Table 7-43, the basis of comparison would meet the requirement on an average basis in both average years and in dry and critical years. Furthermore, all changes during April through August would be less than 1 percent. Table 7-44 shows the number of months simulated EC values exceeded the standards for San Joaquin River at Jersey Point in the period of simulation. CP2 would result in a slight increase in the frequency of violations (2 percent) during August under the Existing Conditions and up to 6 percent during June under the Future Conditions. Overall, frequency of violation of salinity standards for the San Joaquin River at Jersey Point under CP2 would be similar to those under Existing and Future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP2): Delta Salinity on the Sacramento River at Emmaton
On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months on an average annual basis; moreover, CP2 would not increase the EC at Emmaton during this period by more than 0.2 percent. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP2) would be similar to Impact WQ-19c (CP1). While Table 7-45 shows EC for all months, the Emmaton water quality requirement is only defined for April 1 through August 15. On an average monthly basis, for the basis of comparison, EC would meet requirements in all months on an average annual basis. Moreover, CP2 would not increase EC at Emmaton during this period by more than 0.2 percent. Table 7-46 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Emmaton in the period of simulation. Operations of CP2 would not result in any violation of salinity standards between October and March. Between April and September, CP2 would result in a decrease in the frequency of violations when

compared to the baseline values under the Existing and Future conditions, except in June and August when there would be a slight increase, under the Future Conditions. Overall, the compliance of salinity standards for the Sacramento River at Emmaton would be very similar to the baseline levels under both Existing and Future conditions.

Impact WQ-19d (CP2): Delta Salinity on the Old River at Rock Slough On an average annual basis, all months except October through January under both the Existing Condition and Future Condition would be less than 150 mg/L. In dry and critical years, only October and November would exceed the standard under the Existing Condition, and October through February would exceed the standard in the Future Condition. In average annual years, CP2 would not increase chlorides by more than 1.2 percent, and even in that instance, the standard would be met. For dry and critical years, larger increases in chlorides would occur in November and December under the Existing Condition. However, the change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. This impact would be less than significant.

Impact WQ-19d (CP2) would be similar to Impact WQ-19d (CP1). The standard for chlorides at the Contra Costa Canal is defined by the number of days with less than 150 mg/L chloride. The analysis of modeling output is limited to monthly average chlorides. However, on an average annual basis, all months except October through January under both the Existing Condition and

Future Condition would be less than 150 mg/L. As shown in Table 7-47, in dry and critical years, October through February exceed the standard in both the Existing Condition and Future Condition. In average annual years, CP2 would not increase chlorides by more than 1.2 percent, and even in the month of the largest increase (August under the Existing Condition), the standard would be met. For dry and critical years, larger increases in chlorides occur in November and December under the Existing Condition. However, the change in chloride concentration would not affect compliance with the requirement; it would already be exceeded under the basis of comparison. Table 7-48 shows the number of days simulated chloride values exceeded the standards of 250 mg/L for the Old River at Rock Slough in the period of simulation. On an annual average basis, CP2 would result in fewer violations compared to the Existing Conditions. Dry and Critical years would see a slight increase (2 percent) in violations of chloride standards for CP2 under the Existing Conditions. Overall, CP2 would not alter the compliance level observed under the Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19e (CP2): Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. CP2 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

Impact WQ-19e (CP2) would be similar to Impact WQ-19e (CP1). Table 7-49 shows simulated chloride concentrations and Table 7-50 shows EC for the Delta-Mendota Canal at Jones Pumping Plant.

The 250 mg/L chloride concentration would not be exceeded on an average annual or dry or critical year basis. Furthermore, chloride concentrations would typically be lower under CP2 than under the basis of comparisons.

Key:
CP = Comprehensive Plan
EC = electrical conductivity
mg/L = milligrams per liter

Similar to the chloride concentrations, the average annual and dry and critical year averages under the basis of comparison would be under the requirement in all months. CP2 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent.

Table 7-49 shows the number of days simulated chloride values exceeded the standards of 250 mg/L for the Delta-Mendota Canal at the Jones Pumping Plant in the period of simulation. As seen in Table 7-49, there would be no additional violations throughout the year except during February. Even in February, chloride values under CP2 would be similar to the baseline values under both Existing and Future conditions.

Table 7-51 shows the number of months simulated EC values exceeded the standards for the Delta-Mendota Canal at the Jones Pumping Plant in the period of simulation. CP2 would not result in any additional violations of the salinity standards except during February. Even in February, CP2 would not change the baseline compliance levels under both Existing and Future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19f (CP2): Delta Water Quality in the West Canal at the Mouth of the Clifton Court Forebay The 250-mg/L chloride concentration at the West Canal would not be exceeded on an average annual or dry and critical year basis. Furthermore, chloride concentrations would typically be lower under CP2 than under the basis of comparisons. CP2 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

Impact WQ-19f (CP2) would be similar to Impact WQ-19f (CP1). Table 7-52 shows simulated chloride concentrations and Table 7-53 shows EC for the West Canal at the mouth of the Clifton Court Forebay.

The 250 mg/L chloride concentration would not be exceeded on an average annual or dry or critical year basis. Furthermore, chloride concentrations would typically be lower under CP2 than under the basis of comparisons.

Similar to the chloride concentrations, the average annual and dry and critical year averages under the basis of comparison would be under the requirement in

all months. CP2 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent.

Table 7-54 shows the number of days simulated chloride values exceeded the standards of 250 mg/L for the West Canal at the Clifton Court Forebay in the period of simulation. As seen in Table 7-54, there would be no additional violations throughout the year except during February. Even in February, CP2 would not change the baseline compliance levels under both Existing and Future conditions.

Table 7-55 shows the number of months simulated EC values exceeded the standards for West Canal at the Clifton Court Forebay in the period of simulation. CP2 would not result in any additional violations of the salinity standards except during February. Even in February, CP2 would not change the baseline compliance levels under both Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19i (CP2): Delta Salinity on the Old River near the Middle River
Impact WQ-19i (CP2) would be similar to Impact WQ-19i (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP2 would not measurably change EC on the Old River near the Middle River. This impact would be less than significant.

Impact WQ-19i (CP2) would be similar to Impact WQ-19i (CP1). On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months in both average years and in dry and critical years. Moreover, CP2 would not measurably change EC on the Old River near the Middle River, as shown in Table 7-60. Table 7-61 shows the number of months simulated EC values exceeded the standards for the Old River near the Middle River in the period of simulation. As shown in Table 7-61, the compliance of salinity standards for the Old River near the Middle River would not change under CP2 when compared to the Existing Conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP2): X2 Position CP2 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the Existing Condition or Future Condition. While several months may be out of compliance under the bases of comparison, the change resulting from C2 would not increase the amount out of compliance. This impact would be less than significant.

Impact WQ-20 (CP2) would be similar to Impact WQ-20 (CP1). Table 7-64 shows the simulated monthly average X2 position for CP2 as compared to the Existing Condition and Future Condition baselines. CalSim-II calculates the X2 position on a 1-month delay; the values shown have been corrected to accurately reflect the X2 position for the specified month.

CP2 would not change average monthly X2 in either average years or in dry or critical years by more than 0.1 km under either the Existing Condition or the Future Condition. While several months may be out of compliance under the bases of comparison, the change resulting from CP2 would not increase the amount out of compliance.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

CP3 is similar to CP1. CP3 would differ from the No-Action Alternative primarily through a 634 TAF enlargement of Shasta Lake. The impacts described below are the same as for CP1. CP3 focuses on the greatest practical enlargement of Shasta Dam and Reservoir consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increasing water supply reliability, increasing survival of anadromous fish, and improving water quality. In addition to the common features, CP3 consists of raising Shasta Dam 18.5 feet, an elevation change that would increase the full pool elevation by 20.5 feet and enlarge the total storage space in the reservoir by 634 TAF to 5.19 million acre-feet. This comprehensive plan would help reduce future shortages by increasing the reliability of the water supply in drought and average years. The increased pool depth and volume would also contribute to

improving seasonal water temperatures for anadromous fish on the upper Sacramento River.

Shasta Lake and Vicinity

Impact WQ-1 (CP3): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-1 (CP1). However, the construction-related activities described in Chapter 2, "Alternatives," would result in about 1,270 more acres of exposed shoreline than CP1 and in about the same number of relocation acres (3,337) that would be subject to erosion. This alternative is similar to, but somewhat larger than, CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP3): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses Similar to CP1, construction activities associated with enlarging Shasta Dam as well as the relocation actions would result in sizeable areas that would be subject to surface disturbance, including jurisdictional waters within the influence zone of CP3. Efforts to document jurisdictional waters associated with relocation areas are ongoing. This information will be included if available in the Final EIS, as well as in the Section 404 permitting package, prior to issuance of a ROD.

Environmental commitments and BMPs for the various construction and relocation activities (e.g., bridge replacement, boat ramp construction, demolition of facilities) have been incorporated into CP3. These activities could include removal of riparian vegetation, thereby exposing water bodies to increased solar radiation for various time periods. A riparian revegetation program will be implemented at all construction and relocation sites as applicable to ensure that shade is quickly reestablished after construction is completed.

As described in Chapter 2, "Alternatives," although the TCD may not be operational for some period of time during construction, project sequencing will ensure that changes to water temperature and associated limnological conditions will be consistent with those that occur periodically under the No-Action Alternative associated with maintenance and outage periods.

Because of the large water surface area of Shasta Lake, coupled with the isolated and discrete nature of the relocation activities on the tributaries, temporary construction-related effects are not expected to modify water temperature in a manner that would have a negative effect on beneficial uses or result in a water quality violation. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP3): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-3 (CP1). There would be no construction activities that would disturb locations known to contain elevated metal concentrations in either sediments or the water column. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP3): Long-Term Sediment Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to WQ4 (CP1), except that the exposure of about 2,498 acres of shoreline surrounding Shasta Lake would result in a potential for increased wave-related shoreline erosion compared to the No-Action Alternative (see Attachment 1 of the *Water Quality Technical Report*). Therefore, this impact is potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP3): Long-Term Temperature Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, this alternative would increase storage on a monthly basis, although it would vary by water year. Table 7-65 illustrates the monthly change in simulated storage for CP3 as a percent increase above the No-Action Alternative. On average, CP3 represents almost a 13-percent increase in the end-of-month storage on an annual basis.

Table 7-65. Simulated Average Increased End-of-Month Shasta Lake Storage – CP3 and CP5

Month	Existing Condition (TAF)	CP3 & CP5 (TAF)	CP3 & CP5 % Increase
Oct	2,671	377	14.1%
Nov	2,690	374	13.9%

Note:
Simulation period: 1922-2003

Key:
TAF = thousand acre-feet

Under CP3 existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-65 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Similar to CP1, the increase in storage provided by CP3 fluctuates greatly throughout a year. A key indicator of water temperature benefits of CP3 to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake before the water temperature operation season, about May through October. Similar to CP1, the CWP volume in the lake accumulates during winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP3 should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52˚F for the No-Action Alternative and the change in CWP volume for CP3 is shown, by SVI, in Table 7-66.

Table 7-66. Simulated Average Volume of Water Less than 52˚F in Shasta Lake at the End of April – CP3 and CP5

SVI Year Type	Existing Condition (TAF)	CP3 & CP5 (TAF)	CP3 & CP5 % Increase
Average of All Years	1,577	220	14.0%
Wet	1,807	349	19.3%
Above Normal	1,721	284	16.5%
Below Normal	1,743	214	12.3%
Dry	1,451	130	9.0%
Critical	928	17	1.8%

Note:
Simulation period: 1922-2003
Year types as defined by the Sacramento Valley Index

Key:
SVI = Sacramento Valley Index
TAF = thousand acre-feet

In addition to illustrating the average change in available CWP, Table 7-66 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall, would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although there is a meaningful increase in active storage and carryover storage of the CWP, this increase is considered a less than-significant impact. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-6 (CP3): Long-Term Metals Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, the increase in storage associated with this alternative would not result in modifying the depth and thickness of the thermocline that persists in Shasta Lake.

Within the Squaw Creek Arm, two depositional features associated with historic copper mining and smelting operations are immediately adjacent to the shoreline of Shasta Lake in the general vicinity of the Bully Hill Mine. As mapped, these two sites appear to have about 7,300 cubic yards of material that could be subjected to shoreline and surficial erosional processes with an increase in reservoir elevations resultant related to CP3.

Under CP3, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact WQ-7 (CP3): Temporary Construction-Related Sediment Effects on the Upper Sacramento River That Would Cause Violations of Water Quality

Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

This impact would be the same as Impact WQ-7 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP3): Temporary Construction-Related Temperature Effects on the Upper Sacramento River That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

This impact would be identical to Impact WQ-8 (CP1). For the same reasons as described for Impact WQ-8 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP3): Temporary Construction-Related Metal Effects on the Upper Sacramento River That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

This impact would be identical to Impact WQ-9 (CP1). For the same reasons as described for Impact WQ-9 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP3): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment, because modeling results have indicated that CP3 would cause little change in average mean monthly flow, and could cause a decrease in peak flows that are associated with increased sediment transport. This impact would be less than significant.

This impact would be similar to Impact WQ-10 (CP1) because the extent of the effect of CP3 on sediment would be similar to that for CP1. For the same reasons as described for Impact WQ-10 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP3): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP3 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the cold-water pool in

Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact of CP3 on water quality measured as temperature would be beneficial.

CP3 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critically dry years. Raising Shasta Dam 18.5 feet would increase the cold-water pool and benefit seasonal water temperatures along the upper Sacramento River. This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, "Fisheries and Aquatic Resources."

Analysis of temperature modeling results indicates that CP3 would have a beneficial effect on temperature within the upper Sacramento River, with a slight decrease in average monthly water temperature during summer under both existing and future conditions. Decreased temperatures would improve compliance with the temperature objectives for the upper Sacramento River in the 2004 BO. CP3 would reduce temperature exceedences at Balls Ferry by 18 percent under existing conditions and 24 percent under future conditions. At the Bend Bridge compliance station, CP3 would reduce temperature exceedences by 8 percent under existing conditions and 11 percent under future conditions. Table 7-6 summarizes the temperature modeling results.

Based on this analysis, the impact of CP3 on water quality measured as temperature would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP3): Long-Term Metals Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant.

This impact would be similar to Impact WQ-12 (CP3) because the extent of the effect of CP3 on metals would be similar to that for CP1. For the same reasons as described for Impact WQ-12 (CP1), this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact WQ-13 (CP3): Temporary Construction-Related Sediment Effects on the Extended Study Area That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

This impact would be similar to Impact WQ-13 (CP1). For the same reasons described for Impact WQ-13 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP3): Temporary Construction-Related Temperature Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-14 (CP1). For the same reasons described for Impact WQ-14 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP3): Temporary Construction-Related Metal Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-15 (CP1). For the same reasons described for Impact WQ-15 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP3): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Project implementation could affect water quality in the extended study area, but effects would diminish with distance. This impact would be less than significant.

This impact would be similar to Impact WQ-16 (CP1). For the same reasons as described for Impact WQ-16 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP3): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-17 (CP1). For the same reasons as described for Impact WQ-17 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP3): Long-Term Metals Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-18 (CP1). For the same reasons as described for Impact WQ-18 (CP1), this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-19a (CP3): Delta Salinity on the Sacramento River at Collinsville Operations for CP3 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. Similarly, on a percentage basis, all increases in salinity would be less than 10 percent; this would be within the range of natural variability. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19a (CP3) would be similar to Impact WQ-19a (CP1). As shown in Table 7-67, operations for CP3 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. Similarly, on a percentage basis, all increases in salinity would be less than 1 percent; this would be within the range of natural variability. Table 7-68 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Collinsville in the period of simulation. The operation of CP3 would not result in any violation of the salinity standards under both Existing and Future conditions.

Impact WQ-19b (CP3): Delta Salinity on the San Joaquin River at Jersey Point
On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months in an average year. Moreover, CP3 would not increase the EC at Jersey Point. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP3) would be similar to Impact WQ-19b (CP1). As shown in Table 7-69, the basis of comparison would meet the requirement on an average basis in both average years and in dry and critical years. Furthermore, all changes during April through August would be less than 1 percent. Table 7-70 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Jersey Point in the period of simulation. CP3 would result in a slight increase in the frequency of violations (2 percent) during August under the Existing Conditions. Overall, frequency of violation of salinity standards for the San Joaquin River at Jersey Point under CP3 would be similar to those under Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP3): Delta Salinity on the Sacramento River at Emmaton
On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months on an average annual basis; moreover, CP3 would not increase the EC at Emmaton during this period by more than 0.2 percent. This impact would be less than significant.

Impact WQ-19c (CP3) would be similar to Impact WQ-19c (CP1). While Table 7-71 shows EC for all months, the Emmaton water quality requirement is only defined for April 1 through August 15. On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months on an average annual basis. Moreover, CP3 would not increase EC at Emmaton during this period by more than 0.2 percent. Table 7-72 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Emmaton in the period of simulation. Operations of CP3 would not result in any violation of salinity standards between October and March. Between April and September, CP3 would result in a decrease in the frequency of violations when compared to the baseline values under the Existing and Future conditions. Overall, the compliance of salinity standards for the Sacramento River at

Emmaton would be very similar to the baseline levels under both Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Source: Common Assumptions Common Modeling Package, version 8D, DSM2 Existing and Future simulations (Node RSAC092)

Note:
Simulation period: 1922-1994. Change as measured from either Existing Condition or No-Action Alternative. Dry and critical years as defined by the Sacramento Valley Index.

Key:
CP = Comprehensive Plan

Impact WQ-19d (CP3): Delta Salinity on the Old River at Rock Slough On an average annual basis, all months except October through January under both the Existing Condition and Future Condition would be less than 150 mg/L. In dry and critical years, only October and November would exceed the standard under the Existing Condition, and October through February would exceed the standard in the Future Condition. In average annual years, CP3 would not increase chlorides by more than 1.2 percent, and even in that instance, the standard would be met. For dry and critical years, larger increases in chlorides would occur in November and December under the Existing Condition. However, the change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. This impact would be less than significant.

Impact WQ-19d (CP3) would be similar to Impact WQ-19d (CP1). The standard for chlorides at the Contra Costa Canal is defined by number of days with less than 150 mg/L chloride. The analysis of modeling output is limited to the monthly average chlorides. However, on an average annual basis, all months except October through January under both the Existing Condition and Future Condition, and September in dry and critical years, would be less than 150

mg/L. As shown in Table 7-73, in dry and critical years, October through February exceed the standard in both the Existing Condition and Future Condition. In average annual years, CP3 would not increase chlorides by more than 1.2 percent; however, in the month of the largest increase (September under the Existing Condition and Future Condition), the standard would be exceeded. For dry and critical years, larger increases in chlorides occur in November and December under Existing Condition. However, the change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. Table 7-74 shows the number of days simulated chloride values exceeded the standards of 250 mg/L for the Old River at Rock Slough in the period of simulation. Dry and critical years would see a slight increase (2 percent) in violations of chloride standards for CP3 under the Existing Conditions. Overall, CP3 would not alter the compliance level observed under both Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP = Comprehensive Plan

Impact WQ-19e (CP3): Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. CP3 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

Impact WQ-19e (CP3) would be similar to Impact WQ-19e (CP1). Table 7-75 shows the simulated chloride concentrations and Table 7-76 shows EC for the Delta-Mendota Canal at Jones Pumping Plant.

The 250-mg/L chloride concentration would be not exceeded on an average annual or dry critical year basis. Furthermore, chloride concentrations would typically be lower under CP3 than under the basis of comparisons.

Table 7-77 shows the number of days simulated chloride values exceeded the standards of 250 mg/L for the Delta-Mendota Canal at the Jones Pumping Plant in the period of simulation. As seen in Table 7-77, there would be no additional

violations throughout the year except during February. Even in February, chloride values under CP3 would be similar to the baseline values under both Existing and Future conditions.

Table 7-81 shows the number of days simulated chloride values exceeded the standards of 250 mg/L for the West Canal at the Clifton Court Forebay in the period of simulation. As seen in Table 7-81, there would be no additional violations throughout the year except during February. Even in February, CP3 would not change the baseline compliance levels under both Existing and Future conditions.

Table 7-82 shows the number of months simulated EC values exceeded the standards for the West Canal at the Clifton Court Forebay in the period of simulation. CP3 would not result in any additional violations of the salinity standards except during February. Even in February, CP3 would not change the baseline compliance levels under both Existing and Future conditions. Similar to the chloride concentrations, the average annual and dry and critical year averages under the basis of comparison would be under the requirement in all months. CP3 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19j (CP3): Delta Salinity on the Old River at Tracy Road Bridge
Impact WQ-19j (CP3) would be similar to Impact WQ-19j (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP3 would not measurably change EC on the Old River at Tracy Road Bridge. This impact would be less than significant.

Impact WQ-19j (CP3) would be similar to Impact WQ-19j (CP1). On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months in both average years and in dry and critical years. Moreover, CP3 would not measurably change EC on the Old River at Tracy Road Bridge, as shown in Table 7-89. Table 7-90 shows the number of months simulated EC values exceeded the standards for the Old River near Tracy Road Bridge in the period of simulation. On an annual average basis, the compliance of salinity standards under CP3 would not change from the Existing Conditions by more than 2 percent. Overall, CP3 would not change the baseline compliance levels under both Existing and Future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP3): X2 Position CP3 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the Existing Condition or Future Condition. While several months may be out of compliance under the bases of comparison, the change resulting from CP3 would not increase the amount out of compliance. This impact would be less than significant.

Impact WQ-20 (CP3) would be similar to Impact WQ-20 (CP1). Table 7-91 shows the simulated monthly average X2 position for CP3 compared to the Existing Condition and Future Condition baselines. CalSim-II calculates the X2 position on a 1-month delay; the values shown have been corrected to accurately reflect the X2 position for the specified month.

CP3 would not change average monthly X2 in either average years or in dry or critical years by more than 0.1 km under either the Existing Condition or Future Condition. While several months may be out of compliance under the bases of comparison, the change resulting from CP3 would not increase the amount out of compliance.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

The primary function of CP4 is to address survival of anadromous fish, while still improving water supply reliability. It focuses on increasing the volume of cold water available to the TCD through reservoir reoperations, and on raising Shasta Dam 18.5 feet. As with CP3 and the common features, this raise would increase the full pool elevation by 20.5 feet and enlarge total reservoir storage space by 634 TAF. This additional storage space would expand Shasta Lake's cold-water supply available to the TCD by 378 TAF, a feature that would help improve cooler water temperatures in the upper Sacramento River. CP4 would differ from the No-Action Alternative primarily through a 634 TAF enlargement of Shasta Lake, with 256 TAF operated for water supply reliability and 378 TAF of the storage dedicated to anadromous fish survivability, through an increase in available cold water for release to the Sacramento River. In

addition, CP4 would include riparian, floodplain, and side channel habitat restoration activities at Reading Island.

Shasta Lake and Vicinity

Impact WQ-1 (CP4): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-1 (CP3). The nature of inundation and relocation impacts are consistent with those described for CP3 in Chapter 2, "Alternatives." This impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP4): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-2 (CP3). The nature of inundation and relocation impacts are consistent with those described for CP3 in Chapter 2, "Alternatives." This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP4): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-3 (CP1). There would be no construction activities that would disturb locations known to contain elevated metal concentrations in either sediments or the water column. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP4): Long-Term Sediment Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact would be similar to Impact WQ-4 (CP3). The nature of inundation and relocation impacts are consistent with those described for CP3. This would be a potentially significant impact. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP4): Long-Term Temperature Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, this alternative would increase storage on a monthly basis, although it would vary by water year. Table 7-92 illustrates the monthly change in simulated storage for CP4 as a percent increase above the No-Action Alternative. On average, CP4 represents about a 17-percent increase in the end-of-month storage on an annual basis.

Under CP4, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-92 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Table 7-92. Simulated Average Increased End-of-Month Shasta Lake Storage – CP4

Month	Existing Condition (TAF)	CP4 (TAF)	CP4 % Increase
Oct	2,671	522	19.5%
Nov	2,690	526	19.6%
Dec	2,815	538	19.1%
Jan	3,067	543	17.7%
Feb	3,291	553	16.8%
Mar	3,624	553	15.3%
Apr	3,919	548	14.0%
May	3,950	549	13.9%
Jun	3,642	547	15.0%
Jul	3,187	540	16.9%
Aug	2,879	528	18.3%
Sep	2,782	523	18.8%

Source: Common Assumptions Common Modeling Package Version 8D CalSim-II 2005 and 2030 simulations (Node S4+S44)

Note:
Simulation period: 1922-2003

Key:
TAF = thousand acre-feet

Similar to CP1, the increase in storage provided by CP4 fluctuates greatly throughout a year. A key indicator of water temperature benefits of CP3 to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake prior to the water temperature operation season, about May through October. Similar to CP1, the CWP volume in the lake accumulates during the winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP4 should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52˚F for the No-Action Alternative and the change in CWP volume for CP4 is shown, by SVI, in Table 7-93.

Under CP4, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-92 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Table 7-93. Simulated Average Volume of Water Less than 52˚F in Shasta Lake at the End of April – CP4

SVI Year Type	Existing Condition (TAF)	CP4 (TAF)	CP4 % Increase
Average of All Years	1,577	348	22.1%
Wet	1,807	437	24.2%
Above Normal	1,721	324	18.8%
Below Normal	1,743	341	19.6%
Dry	1,451	310	21.4%
Critical	928	241	26.0%

Note:
Simulation period: 1922-2003
Year types as defined by the Sacramento Valley Index

Key:
SVI = Sacramento Valley Index
TAF = thousand acre-feet

In addition to illustrating the average change in available CWP, Table 7-93 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although there is a meaningful increase in active storage and carryover storage of the CWP, this increase is considered to be a less than significant impact. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-6 (CP4): Long-Term Metals Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to CP1. The nature of inundation and relocation impacts are consistent with those described for CP3. It would be a potentially significant impact. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact WQ-7 (CP4): Temporary Construction-Related Sediment Effects on the Upper Sacramento River That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

Ground-disturbing activities associated with construction could cause soil erosion and sedimentation of local drainages and eventually the Sacramento River. Construction activities could also discharge waste petroleum products or other construction-related substances that could enter these waterways/facilities in runoff. In addition, transportation, handling, and placement of materials used

for gravel augmentation as well as clearing, grubbing, and grading during construction could also adversely affect water quality and temporarily increase turbidity and sedimentation downstream from the gravel augmentation sites. In-water construction work at some gravel augmentation sites could also result in temporary increase in turbidity, downstream sedimentation, and accidental discharge of construction-related substances into the river channel.

In addition, riparian, floodplain, and side channel habitat restoration activities at Reading Island as part of CP4 would involve breaching the levee using an excavator, loader, and compaction equipment and excavation of approximately 15,650 cubic yards of earthen material for off-site disposal, and potential vegetation clearing along 0.8 mile of channel. Invasive aquatic vegetation would be removed as well. Although in-water construction is expected to take place during periods of low flow in the Sacramento River (October to November) to minimize effects on water quality, construction activities related to habitat restoration and vegetation clearing could adversely affect water quality and temporarily increase turbidity and sedimentation downstream, or result in the accidental discharge of construction-related substances into the river channel. In addition, excavated sediments could be contaminated with pesticides and metals. Development and implementation of a SWPPP as part of the environmental commitments described in Chapter 2, "Alternatives," would reduce potential impacts related to pesticides and metals. However, this impact would remain potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP4): Temporary Construction-Related Temperature Effects on the Upper Sacramento River That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

This impact would be similar to Impact WQ-8 (CP1). For the same reasons as described for Impact WQ-8 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP4): Temporary Construction-Related Metal Effects on the Upper Sacramento River That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

This impact would be similar to Impact WQ-9 (CP1). For the same reasons as described for Impact WQ-9 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP4): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment, because modeling results have indicated that CP4 would cause little change in average mean monthly flow, and could cause a decrease in peak flows that are associated with increased sediment transport. This impact would be less than significant.

This impact would be similar to Impact WQ-10 (CP1) because the extent of the effect of CP4 on sediment would be similar to that for CP1. For the same reasons as described for Impact WQ-10 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP4): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP4 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the cold-water pool in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact of CP4 on water quality measured as temperature would be beneficial.

CP4 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critically dry years. Raising Shasta Dam 18.5 feet would increase the cold-water pool and benefit seasonal water temperatures along the upper Sacramento River. This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, “Fisheries and Aquatic Ecosystems.”

Analysis of temperature modeling results indicates that CP4 would have a beneficial effect on temperature within the upper Sacramento River with a measurable decrease in average monthly water temperature during summer months under both existing and future conditions. For instance, at the Balls Ferry compliance station in September, average monthly water temperature would be reduced by 1.2^{o}F. During October at Balls Ferry, the average monthly temperature would decrease by 1.6^{o}F. For more information on modeling results and monthly water temperature, see Chapter 11, “Fisheries and Aquatic Ecosystems.”

Decreased temperatures would improve compliance with the temperature objectives for the upper Sacramento River in the 2004 BO. Analysis of modeling results indicates that CP4 would reduce temperature exceedences at Balls Ferry by 37 percent under existing conditions and 40 percent under future conditions. At the Bend Bridge compliance station, CP4 would reduce temperature exceedences by 13-percent under existing conditions and 15

percent under future conditions. Table 7-6 summarizes the temperature modeling results.

CP4 would have the greatest beneficial effect on water temperature of all alternatives evaluated. Based on this analysis, effects of CP4 on water quality measured as temperature would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP4): Long-Term Metals Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant.

This impact is similar to Impact WQ-12 (CP1) because the extent of the effect of CP4 on metals would be similar to that for CP1. For the same reasons as described for Impact WQ-12 (CP1), this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact WQ-13 (CP4): Temporary Construction-Related Sediment Effects on the Extended Study Area That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

This impact would be similar to Impact WQ-13 (CP1). For the same reasons as described for Impact WQ-13 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP4): Temporary Construction-Related Temperature Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-14 (CP1). For the same reasons as described for Impact WQ-14 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP4): Temporary Construction-Related Metal Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-15 (CP1). For the same reasons as described for Impact WQ-15 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP4): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Project implementation could affect water quality in the extended

study area, but effects would diminish with distance. This impact would be less than significant.

This impact would be similar to Impact WQ-16 (CP1). For the same reasons described for Impact WQ-16 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP4): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-17 (CP1). For the same reasons as described for Impact WQ-17 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP4): Long-Term Metals Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-18 (CP1). For the same reasons described for Impact WQ-18 (CP1), this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-19a (CP4): Delta Salinity on the Sacramento River at Collinsville Operations for CP4 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. Similarly, on a percentage basis, all increases in salinity would be less than 10 percent; this would be within the range of natural variability. This impact would be less than significant.

This impact would be the same as Impact WQ-19a (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP4): Delta Salinity on the Sacramento River at Jersey Point On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months in an average year. Moreover, CP4 would not increase the EC at Jersey Point. This impact would be less than significant.

This impact would be the same as Impact WQ-19b (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP4): Delta Salinity on the Sacramento River at Emmaton On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months on an average annual basis; moreover, CP4 would not increase the EC at Emmaton during this period by more than 0.2 percent. This impact would be less than significant.

This impact would be the same as Impact WQ-19c (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19d (CP4): Delta Salinity on the Old River at Rock Slough On an average annual basis, all months except October through January under both the

Existing Condition and Future Condition would be less than 150 mg/L. In dry and critical years, only October and November would exceed the standard under the Existing Condition, and October through February would exceed the standard in the Future Condition. In average annual years, CP4 would not increase chlorides by more than 1.2 percent, and even in that instance, the standard would be met. For dry and critical years, larger increases in chlorides would occur in November and December under the Existing Condition. However, the change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. This impact would be less than significant.

This impact would be the same as Impact WQ-19d (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19e (CP4): Delta Salinity on the Delta-Mendota Canal at Jones Pumping Plant The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. CP4 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

This impact would be the same as Impact WQ-19e (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19f (CP4): Delta Salinity on the West Canal at Clifton Court Forebay The 250 mg/L chloride concentration at the West Canal would not be exceeded on an average annual or dry and critical year basis. Furthermore, chloride concentrations would typically be lower under CP4 than under the basis of comparisons. CP4 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

This impact would be the same as Impact WQ-19f (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19g (CP4): Delta Salinity on the San Joaquin River near Vernalis On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP4 would not measurably change the EC on the San Joaquin River at Vernalis. This impact would be less than significant.

This impact would be the same as Impact WQ-19g (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19h (CP4): Delta Salinity on the San Joaquin River at Brandt Bridge Impact WQ-19h (CP4) would be the same as Impact WQ-19g (CP4). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years.

Moreover, CP4 would not measurably change EC on the San Joaquin River at Brandt Bridge. This impact would be less than significant.

This impact would be the same as Impact WQ-19h (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19i (CP4): Delta Salinity on the Old River near the Middle River
Impact WQ-19i (CP4) would be similar to Impact WQ-19g (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP4 would not measurably change EC on the Old River near the Middle River. This impact would be less than significant.

This impact would be the same as Impact WQ-19i (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19j (CP4): Delta Salinity on the Old River near Tracy Road Bridge
Impact WQ-19j (CP4) would be similar to Impact WQ-19j (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP4 would not measurably change EC on the Old River at Tracy Road Bridge. This impact would be less than significant.

This impact would be the same as Impact WQ-19j (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP4): X2 Position CP4 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the Existing Condition or Future Condition. While several months may be out of compliance under the bases of comparison, the change resulting from CP4 would not increase the amount out of compliance. This impact would be less than significant.

This impact would be the same as Impact WQ-20 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan
CP5 would address both the primary and secondary planning objectives. This alternative involves enlarging Shasta Dam 18.5 feet, which is consistent with the objectives of the 2000 CALFED ROD, and also includes the common features mentioned in CP1. CP5 also involves (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing either additional or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. CP5 would differ from the No-Action Alternative primarily through a 634-TAF enlargement of Shasta Lake with additional recreation facilities at Shasta Lake and environmental restoration to the lower ends of the Shasta Lake tributaries.

In addition, CP5, like CP4, would include riparian, floodplain, and side channel habitat restoration activities at Reading Island.

Shasta Lake and Vicinity

Impact WQ-1 (CP5): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-1 (CP3). However, CP5 includes several ecosystem restoration projects that would require temporary construction-related activities, as described in Chapter 2, "Alternatives."

Although the environmental protection measures and BMPs described in Chapter 2, "Alternatives," are intended to reduce the potential effects of introducing sediment into Shasta Lake and its tributaries, CP5 would affect water quality by increasing the levels of turbidity and suspended sediment in the receiving waters at levels that could be inconsistent with the Basin Plan. These increased levels of turbidity and suspended sediment could affect the beneficial uses of Shasta Lake and/or its tributaries. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP5): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact would be identical to Impact WQ-2 (CP3). The nature of inundation and relocation impacts are consistent with those described for CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP5): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-3 (CP1). There would be no construction activities that would disturb locations known to contain elevated metal concentrations in either sediments or the water column. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP5): Long-Term Sediment Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to WQ-4 (CP3). Although some ecosystem enhancement measures (i.e., road restoration) are expected to reduce the long-term sediment delivery to Shasta Lake and its tributaries, CP5 would nonetheless result in increased levels of suspended sediment and turbidity that could affect beneficial uses. The amount of sediment that could be delivered is not quantifiable because of the size of the lake and the number of variables that influence sediment transport and delivery. This would be a potentially significant impact. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP5): Long-Term Temperature Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to the discussion in CP3, this alternative would increase storage on a monthly basis although it would vary by water year. Table 7-65 illustrates the monthly change in simulated storage for CP5 as a percent increase above the No-Action Alternative. On average, CP5 represents about a 13 percent increase in the end-of-month storage on an annual basis.

Consistent with the discussion presented under CP3, existing water temperature requirements would typically be met in most years. The simulated end-of-April volume of water with a temperature lower than 52˚F for the No-Action Alternative and the change in CWP volume for CP5 is shown, by SVI, in Table 7-66.

In addition to illustrating the average change in available CWP, this table also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although there is a meaningful increase in active storage and carryover storage of the CWP, this increase is considered to be a less than significant impact. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-6 (CP5): Long-Term Metals Effects That Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to CP1. The nature of inundation and relocation impacts are consistent with those described for CP3. It would be a potentially significant impact. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact WQ-7 (CP5): Temporary Construction-Related Sediment Effects on the Upper Sacramento River That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

Ground-disturbing activities associated with construction could cause soil erosion and sedimentation of local drainages and eventually the Sacramento River. Construction activities could also discharge waste petroleum products or other construction-related substances that could enter these waterways/facilities in runoff. As described for Impact WQ-7 (CP4), gravel augmentation construction activities could also adversely affect water quality and temporarily increase turbidity and sedimentation downstream from the gravel augmentation sites.

In addition, riparian, floodplain, and side channel habitat restoration activities at Reading Island as part of CP5 would involve breaching the levee using an excavator, loader, and compaction equipment and excavation of approximately 15,650 cubic yards of earthen material for off-site disposal, and potential vegetation clearing along 0.8 mile of channel. Invasive aquatic vegetation would be removed as well. As described for Impact WQ-7 (CP4), construction activities related to habitat restoration and vegetation clearing could adversely affect water quality and temporarily increase turbidity and sedimentation downstream, or result in the accidental discharge of construction-related substances into the river channel. In addition, excavated sediments could be contaminated with pesticides and metals. Development and implementation of a SWPPP as part of the environmental commitments described in Chapter 2, "Alternatives," would reduce potential impacts related to pesticides and metals. However, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP5): Temporary Construction-Related Temperature Effects on the Upper Sacramento River That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

This impact would be similar to Impact WQ-8 (CP1). For the same reasons described for Impact WQ-8 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP5): Temporary Construction-Related Metal Effects on the Upper Sacramento River That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

This impact would be similar to Impact WQ-9 (CP1). For the same reasons described for Impact WQ-9 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP5): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment because modeling results have indicated that CP5 would cause little change in average mean monthly flow, and could cause a decrease in peak flows that are associated with increased sediment transport. This impact would be less than significant.

This impact would be similar to Impact WQ-10 (CP1) because the extent of the effect of CP5 on sediment would be similar to that for CP1. For the same reasons as described for Impact WQ-10 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP5): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP5 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the cold-water pool in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact of CP5 on water quality measured as temperature would be beneficial.

CP5 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critically dry years. Raising Shasta Dam 18.5 feet would increase the cold-water pool and benefit seasonal water temperatures along the upper Sacramento River. This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, "Fisheries and Aquatic Resources."

CP5 is the same as CP3 for both flow and temperature characteristics. Therefore, separate temperature modeling was not completed for CP5. See Impact WQ-11 (CP3) for a more complete discussion on temperature modeling analysis. For the same reasons as described for Impact WQ-11 (CP3), this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP5): Long-Term Metals Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant.

This impact would be similar to Impact WQ-12 (CP1) because the extent of the effect of CP5 on metals would be similar to that for CP1. For the same reasons as described for Impact WQ-12 (CP1), this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact WQ-13 (CP5): Temporary Construction-Related Sediment Effects on the Extended Study Area That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

This impact is similar to Impact WQ-13 (CP1). For the same reasons as described for Impact WQ-13 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP5): Temporary Construction-Related Temperature Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to Impact WQ-14 (CP1). For the same reasons as described for Impact WQ-14 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP5): Temporary Construction-Related Metal Effects on the Extended Study Area That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to Impact WQ-15 (CP1). For the same reasons as described for Impact WQ-15 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP5): Long-Term Sediment Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Project implementation could affect water quality in the extended study area, but effects would diminish with distance. This impact would be less than significant.

This impact is similar to Impact WQ-16 (CP1). For the same reasons as described for CP1, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP5): Long-Term Temperature Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact is similar to Impact WQ-17 (CP1). For the same reasons as described for CP1, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP5): Long-Term Metals Effects That Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact is similar to Impact WQ-18 (CP1). For the same reasons as described for CP1, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-19a (CP5): Delta Salinity on the Sacramento River at Collinsville Operations for CP5 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. Similarly, on a percentage basis, all increases in salinity would be less than 10 percent; this would be within the range of natural variability. This impact would be less than significant.

This impact would be the same as Impact WQ-19a (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP5): Delta Salinity on the Sacramento River at Jersey Point On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months in an average year. Moreover, CP5 would not increase the EC at Jersey Point. This impact would be less than significant.

This impact would be the same as Impact WQ-19b (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP5): Delta Salinity on the Sacramento River at Emmaton On an average monthly basis, for the basis of comparison, EC would meet the requirements in all months on an average annual basis; moreover, CP5 would not increase the EC at Emmaton during this period by more than 0.2 percent. This impact would be less than significant.

This impact would be the same as Impact WQ-19c (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19d (CP5): Delta Salinity on the Old River at Rock Slough On an average annual basis, all months except October through January under both the Existing Condition and Future Condition would be less than 150 mg/L. In dry and critical years, only October and November would exceed the standard under the Existing Condition, and October through February would exceed the standard in the Future Condition. In average annual years, CP5 would not increase chlorides by more than 1.2 percent, and even in that instance, the standard would be met. For dry and critical years, larger increases in chlorides would occur in November and December under the Existing Condition. However, the change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. This impact would be less than significant.

This impact would be the same as Impact WQ-19d (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19e (CP5): Delta Salinity on the Delta-Mendota Canal at Jones Pumping Plant The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. CP1 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

This impact would be the same as Impact WQ-19e (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19f (CP5): Delta Salinity on the West Canal at Clifton Court Forebay The 250 mg/L chloride concentration at the West Canal would not be

exceeded on an average annual or dry and critical year basis. Furthermore, chloride concentrations would typically be lower under CP5 than under the basis of comparisons. CP5 would not measurably change EC, and the increases in chloride concentration would be less than 1.0 percent. This impact would be less than significant.

This impact would be the same as Impact WQ-19f (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19g (CP5): Delta Salinity on the San Joaquin River near Vernalis On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP5 would not measurably change the EC on the San Joaquin River at Vernalis. This impact would be less than significant.

This impact would be the same as Impact WQ-19g (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19h (CP5): Delta Salinity on the San Joaquin River at Brandt Bridge Impact WQ-19h (CP5) would be the same as Impact WQ-19g (CP5). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP5 would not measurably change EC on the San Joaquin River at Brandt Bridge. This impact would be less than significant.

This impact would be the same as Impact WQ-19h (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19i (CP5): Delta Salinity on the Old River near the Middle River Impact WQ-19i (CP1) would be similar to Impact WQ-19i (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP1 would not measurably change EC on the Old River near the Middle River. This impact would be less than significant.

This impact would be the same as Impact WQ-19i (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19j (CP5): Delta Salinity on the Old River near Tracy Road Bridge Impact WQ-19j (CP5) would be similar to Impact WQ-19j (CP1). On an average monthly basis, for the basis of comparison, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP5 would not measurably change EC on the Old River at Tracy Road Bridge. This impact would be less than significant.

This impact would be the same as Impact WQ-19j (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP5): X2 Position CP5 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the Existing Condition or Future Condition. While several months may be out of compliance under the bases of comparison, the change resulting from CP5 would not increase the amount out of compliance. This impact would be less than significant.

This impact would be the same as Impact WQ-20 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

7.3.5 Mitigation Measures

Table 7-94 presents a summary of mitigation measures for water quality.

Table 7-94. Summary of Mitigation Measures for Water Quality

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact WQ-1: Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries That Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses	LOS before Mitigation	NI	PS	PS	PS	PS	PS

Key:
B = Beneficial
LTS = less than significant
NI = no impact
PS = potentially significant

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are needed for Impacts WQ-2 (CP1), WQ-3 (CP1), WQ-5 (CP1), WQ-8 (CP1) through WQ-11 (CP1), WQ-13 (CP1) through WQ-17 (CP1), WQ-19a (CP1) through WQ-19j (CP1), and WQ-20 (CP1). Mitigation is provided below for the remaining impacts of CP1 on water quality.

Mitigation Measure WQ-1 (CP1): Prepare and Implement a Stormwater Pollution Prevention Program that Minimizes the Potential Contamination of Surface Waters, and Comply with Applicable Federal Regulations Concerning Construction Activities This project is subject to construction-related stormwater permit requirements of the CWA NPDES program. Reclamation will obtain any required permits through the CVRWQCB before any ground-disturbing construction activity. Reclamation will prepare and implement a SWPPP that identifies BMPs to prevent or minimize the introduction of contaminants into surface waters. BMPs for the project could include but are not limited to silt fencing, straw bale barriers, fiber rolls, storm drain inlet protection, hydraulic mulch, and stabilized construction entrance.

The SWPPP will include development of site-specific structural and operational BMPs to prevent and control impacts on runoff quality, measures to be implemented before each storm event, inspection and maintenance of BMPs, and monitoring of runoff quality by visual and/or analytical means.

Implementation of this mitigation measure would reduce Impact WQ-1 (CP1) to a less than significant level.

Mitigation Measure WQ-4 (CP1): Implement Mitigation Measure WQ-1 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce long-term effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-4 (CP1) to a less than significant level.

Mitigation Measure WQ-6 (CP1): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines Reclamation will prepare and implement a plan to remove or otherwise remediate two sites related to historic mining activities that have the potential to introduce metals into Shasta Lake, a Section 303(d)-listed water body. This plan will include requirements to coordinate with Federal, State, and local agencies and landowners to ensure that measures taken will reduce the potential for a discharge of metals into Shasta

Lake. Reclamation will obtain any required permits, approvals, and authorizations before any ground-disturbing remediation activity occurs.

Implementation of this mitigation measure would reduce Impact WQ-6 (CP1) to a less than significant level.

Mitigation Measure WQ-7 (CP1): Implement Mitigation Measure WQ-1 (CP1) to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce temporary construction-related effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-7 (CP1) to a less than significant level.

Mitigation Measure WQ-12 (CP1): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP1) to a less than significant level.

Mitigation Measure WQ-18 (CP1): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP1) to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are needed for Impacts WQ-2 (CP2), WQ-3 (CP2), WQ-5 (CP2), WQ-8 (CP2) through WQ-11 (CP2), WQ-13 (CP2) through WQ-17 (CP2), WQ-19a (CP2) through WQ-19j (CP2), and WQ-20 (CP2). Mitigation is provided below for the remaining impacts of CP2 on water quality.

Mitigation Measure WQ-1 (CP2): Prepare and Implement a Stormwater Pollution Prevention Plan that Minimizes the Potential Contamination of Surface Waters, and Comply with Applicable Federal Regulations Concerning Construction Activities This mitigation measure is identical to Mitigation Measure WQ-1 (CP1). Implementation of this mitigation measure would reduce Impact WQ-1 (CP2) to a less than significant level.

Mitigation Measure WQ-4 (CP2): Implement Mitigation Measure WQ-1 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce long-term effects related to sediment.

Implementation of this mitigation measure would reduce Impact WQ-4 (CP2) to a less than significant level.

Mitigation Measure WQ-6 (CP2): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines This mitigation measure is identical to Mitigation Measure WQ-6 (CP1). Implementation of this mitigation measure would reduce Impact WQ-6 (CP2) to a less than significant level.

Mitigation Measure WQ-7 (CP2): Implement Mitigation Measure WQ-1 (CP1) to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce temporary construction-related effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-7 (CP2) to a less than significant level.

Mitigation Measure WQ-12 (CP2): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP2) to a less than significant level.

Mitigation Measure WQ-18 (CP2): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation measures are needed for Impacts WQ-2 (CP3), WQ-3 (CP3), WQ-5 (CP3), WQ-8 (CP3) through WQ-11 (CP3), WQ-13 (CP3) through WQ-17 (CP3), WQ-19a (CP3) through WQ-19j (CP3), and WQ-20 (CP3). Mitigation is provided below for the remaining impacts of CP3 on water quality.

Mitigation Measure WQ-1 (CP3): Prepare and Implement a Stormwater Pollution Prevention Plan that Minimizes the Potential Contamination of Surface Waters, and Comply with Applicable Federal Regulations Concerning Construction Activities This mitigation measure is identical to Mitigation Measure WQ-1 (CP1). Implementation of this mitigation measure would reduce Impact WQ-1 (CP3) to a less than significant level.

Mitigation Measure WQ-4 (CP3): Implement Mitigation Measure WQ-1 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-1

(CP1) as described above to reduce long-term effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-4 (CP3) to a less than significant level.

Mitigation Measure WQ-6 (CP3): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines This mitigation measure is identical to Mitigation Measure WQ-6 (CP1). Implementation of this mitigation measure would reduce Impact WQ-6 (CP3) to a less than significant level.

Mitigation Measure WQ-7 (CP3): Implement Mitigation Measure WQ-1 (CP1) to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce temporary construction-related effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-7 (CP3) to a less than significant level.

Mitigation Measure WQ-12 (CP3): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP3) to a less than significant level.

Mitigation Measure WQ-18 (CP3): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area
Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation measures are needed for Impacts WQ-2 (CP4), WQ-3 (CP4), WQ-5 (CP4), WQ-8 (CP4) through WQ-11 (CP4), WQ-13 (CP4) through WQ-17 (CP4), WQ-19a (CP4) through WQ-19j (CP4), and WQ-20 (CP4). Mitigation is provided below for the remaining impacts of CP4 on water quality.

Mitigation Measure WQ-1 (CP4): Prepare and Implement a Stormwater Pollution Prevention Plan that Minimizes the Potential Contamination of Surface Waters, and Comply with Applicable Federal Regulations Concerning Construction Activities This mitigation measure is identical to Mitigation Measure WQ-1 (CP1). Implementation of this mitigation measure would reduce Impact WQ-1 (CP4) to a less than significant level.

Mitigation Measure WQ-4 (CP4): Implement Mitigation Measure WQ-1 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce long-term effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-4 (CP4) to a less than significant level.

Mitigation Measure WQ-6 (CP4): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines This mitigation measure is identical to Mitigation Measure WQ-6 (CP1). Implementation of this mitigation measure would reduce Impact WQ-6 (CP4) to a less than significant level.

Mitigation Measure WQ-7 (CP4): Implement Mitigation Measure WQ-1 (CP1) and Gravel Augmentation BMPs to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment Reclamation will implement (a) Mitigation Measure WQ-1 (CP1) as described above; and (b) specific BMPs for the gravel augmentation program. Gravel augmentation BMPs will include, but will not be limited to:

- **Construction Work Windows** – All gravel augmentation construction activities will be conducted outside of the flood season (e.g., June 15 to September 15).

- **Source and Handle Gravel So As to Minimize Potential Water Quality Impacts** – Gravel will be sorted and transported in a manner that minimizes potential water quality impacts (e.g., management of fine sediments). Gravel will be washed at least once and have a cleanliness value of 85 or higher based on Caltrans Test No. 227. Gravel will also be completely free of oils, clay, debris, and organic material.

- **Minimize Potential Impacts Associated with Equipment Contaminants** – For in-river work, all equipment will be steam cleaned every day to remove hazardous materials before the equipment enters the water.

- **Implement Feasible Spill Prevention and Hazardous Materials Management** – The accidental release of chemicals, fuels, lubricants, and non-storm drainage water into channels will be prevented to the extent feasible. Spill prevention kits will always be in close proximity when using hazardous materials (e.g., crew trucks and other logical locations). Feasible measures will be implemented to ensure that hazardous materials are properly handled and the quality of aquatic resources is protected by all reasonable means. No fueling will be done within the ordinary high-water mark or immediate floodplain, unless equipment stationed in these locations is not readily relocated (i.e.,

pumps, generators). For stationary equipment that must be fueled on site, containments will be provided in such a manner that any accidental spill of fuel will not be able to enter the water or contaminate sediments that may come in contact with water. Any equipment that is readily moved out of the channel will not be fueled in the channel or immediate floodplain. All fueling done at the construction site will provide containment to the degree that any spill shall be unable to enter the channel or damage wetland or riparian vegetation. No equipment servicing will be done within the ordinary high-water mark or immediate floodplain, unless equipment stationed in these locations cannot be readily relocated (i.e., pumps, generators). Additional BMPs designed to avoid spills from construction equipment and subsequent contamination of waterways will also be implemented.

- **Minimize Potential Impacts Associated with Access and Staging** – Existing access roads will be used. Equipment staging areas will be located outside of the ordinary high-water mark and away from sensitive resources.

- **Remove Temporary Fills as Appropriate** – Temporary fill, such as for access, side channel diversions, and/or side channel cofferdams, will be completely removed upon the completion of construction.

Implementation of this mitigation measure would reduce Impact WQ-1 (CP4) to a less than significant level.

Mitigation Measure WQ-12 (CP4): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP4) to a less than significant level.

Mitigation Measure WQ-18 (CP4): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation measures are needed for Impacts WQ-2 (CP5), WQ-3 (CP5), WQ-5 (CP5), WQ-8 (CP5) through WQ-11 (CP5), WQ-13 (CP5) through WQ-17 (CP5), WQ-19a (CP5) through WQ-19j (CP5), and WQ-20 (CP5). Mitigation is provided below for the remaining impacts of CP5 on water quality.

Mitigation Measure WQ-1 (CP5): Prepare and Implement a Stormwater Pollution Prevention Plan That Minimizes the Potential Contamination of Surface Waters, and Comply with Applicable Federal Regulations Concerning Construction Activities This mitigation measure is identical to Mitigation Measure WQ-1 (CP1). Implementation of this mitigation measure would reduce Impact WQ-1 (CP5) to a less than significant level.

Mitigation Measure WQ-4 (CP5): Implement Mitigation Measure WQ-1 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce long-term effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-4 (CP5) to a less than significant level.

Mitigation Measure WQ-6 (CP5): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines This mitigation measure is identical to Mitigation Measure WQ-6 (CP1). Implementation of this mitigation measure would reduce Impact WQ-6 (CP5) to a less than significant level.

Mitigation Measure WQ-7 (CP5): Implement Mitigation Measure WQ-1 (CP1) and Gravel Augmentation BMPs to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment This mitigation measure is identical to Mitigation Measure WQ-7 (CP4). Implementation of this mitigation measure would reduce Impact WQ-7 (CP5) to a less than significant level.

Mitigation Measure WQ-12 (CP5): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP5) to a less than significant level.

Mitigation Measure WQ-18 (CP5): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP5) to a less than significant level.

7.3.6 Cumulative Effects

Chapter 3, “Considerations for Describing the Affected Environment and Environmental Consequences” discusses the overall methodology for cumulative impacts of the project alternatives, including the relationship to the CALFED programmatic cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria.

This section analyzes the overall cumulative impacts of the project alternatives with other past, present, and reasonably foreseeable future projects that would produce related impacts.

The projects listed in the quantitative analysis section of Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences" are included in the 2030 level of development alternatives above. Accordingly, quantitative effects of the projects combined with the SLWRI alternatives are described in the Section 7.3, "Environmental Consequences and Mitigation Measures." The discussion below focuses on the qualitative effect of the SLWRI alternatives and the other past, present, and reasonably foreseeable future projects.

Given the substantial degradation in water quality in the study areas when considering past, present, and reasonably foreseeable projects, and as identified in the existing conditions presented in this chapter, it is concluded that there is a significant cumulative impact on water quality overall under both existing and future conditions. These cumulative impacts are occurring without the proposed action. Several factors could substantially affect water quality in both the primary and extended study areas as an outcome of reasonably foreseeable future actions, but the potential effects are highly uncertain and may result in either a beneficial or adverse impact on water quality in the study areas.

The effect of climate change on operations at Shasta Lake could potentially result in changes to water quality. As described in the Climate Change Projection Appendix, climate change could result in higher inflows to Shasta Lake in the winter and early spring due to a shift from precipitation falling as snow to rain. This change could result in both higher Shasta Lake releases in the winter and spring to manage the increased potential for flood events, and an increase in water temperature for Shasta Lake inflows. A corresponding decrease in Shasta Lake releases in the summer and fall and a decrease in operable cold-water volume could result in warmer flows downstream.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 would not result in adverse changes to sediment, metals, and temperature, and therefore would not make a cumulatively considerable incremental contribution to an overall significant cumulative impact on water quality.

Without mitigation, CP1 could cause potentially significant effects on water quality in the primary study area. These effects could be caused temporarily or for the short term by construction-related activities that cause sediment, petroleum, or other substances to enter waterways in runoff. Mitigation measures would eliminate these effects or reduce them to a less than significant level.

CP1 would also affect water quality by increasing the volume of water in the reservoir and by altering downstream river flows. The effects on water quality resulting from these hydrologic alterations would be long term and much greater than the temporary and short-term effects related to construction.

Hydrologic modeling output predicts that hydrologically, CP1 would result in a small change in reservoir storage and minimal change in river flows relative to the No-Action Alternative. A small increase in the volume of water stored in the reservoir under CP1 could result in additional inputs of metals from shoreline erosion of historical mining deposits and would result in a slight dilution of inputs of sediment and metals relative to existing and future No-Action conditions. The potential for additional inputs of metals would be substantially reduced or eliminated by Mitigation Measure WQ-6 (CP1). Changes in Sacramento River flows can be best characterized as a small decrease in monthly average winter and early spring flows in some years as measured below Keswick Dam, RBDD, Wilkins Slough, and Freeport, and a slight increase in summer flows in most years. This redistribution of flows would have little effect on water quality as measured by metals, sediment, salinity, and temperature.

The small reduction in winter flows caused by CP1 would slightly reduce potential sediment loading and discharge rates, and would also slightly reduce transport of heavy metals. Therefore, the water quality impact of CP1 related to metals and sediment would not be adverse.

Monthly mean water temperatures at all modeling locations (below Shasta Dam, below Keswick Dam, above Bend Bridge, and above Red Bluff) within the upper Sacramento River under CP1 would be essentially equivalent or slightly decreased (i.e., beneficial). Therefore, the effects of CP1 on water quality measured as water temperature would be beneficial, not adverse.

Implementing Mitigation Measure WQ-1 (CP1) would eliminate adverse effects from CP1, and the incremental contribution of CP1 to cumulative effects on water quality would no longer be cumulatively considerable. In summary, effects of CP1 on water quality measured as water temperature, metals, and sediment would be less than significant, and CP1 would not cause an incremental cumulatively considerable contribution to an overall significant cumulative impact on water quality in the primary study area.

In the extended study area, CP1 could also influence water quality in the Delta by altering the quality, volume, or timing of Sacramento River flows. However, because changes in Sacramento River flows relative to the No-Action Alternative would be minimal and effects would diminish with distance from Shasta Dam, the effects would be very minor. (Water quality effects are attenuated by multiple factors, including flow from tributaries, stormwater runoff, and municipal and agricultural discharges.) Furthermore, the Central Valley’s reservoirs and diversions are managed as a single integrated system,

and the guidelines for this system, which are described in the CVP OCAP, have been designed to maintain standards for Delta inflow and water quality. Therefore, water quality impacts of CP1 at the Delta would not make a cumulatively considerable incremental contribution to the overall significant cumulative impact on Delta water quality.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP1 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP1. Therefore, even with the addition of anticipated effects of climate change, CP1 would not have a significant cumulative effect, and could be potentially beneficial.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The cumulative effects of CP2 would be similar to those of CP1, except that the greater increase in reservoir storage and river flow alteration under CP2 would result in greater beneficial effects on water temperature in the upper Sacramento River. Effects on sediments and metals in the Upper Sacramento River, and on Delta water quality would be effectively the same as CP1. Therefore, water quality impacts of CP2 would not make a cumulatively considerable incremental contribution to the overall significant cumulative water quality impact in the primary study area or extended study area, including the Delta.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP2 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP2. Therefore, even with the addition of anticipated effects of climate change, CP2 would not have a significant cumulative effect, and could be potentially beneficial.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

The cumulative effects of CP3 would be similar to those of CP1 and CP2, except that the greater increase in reservoir storage and river flow alteration under CP3 would result in greater beneficial effects on water temperature in the

upper Sacramento River. Effects on sediments and metals in the Upper Sacramento River, and on Delta water quality would be effectively the same as CP1. Therefore, water quality impacts of CP3 would not make a cumulatively considerable incremental contribution to the overall significant cumulative water quality impact in the primary study area or extended study area, including the Delta.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP3 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP3. Therefore, even with the addition of anticipated effects of climate change, CP3 would not have a significant cumulative effect, and could be potentially beneficial.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

With the exception of water quality measured as water temperature, the cumulative effects of CP4 would be the same as those of CP1. Effects of CP4 on water quality measured as water temperature would be beneficial and greater than those of other alternatives.

Therefore, water quality impacts of CP4 would not make a cumulatively considerable incremental contribution to the overall significant cumulative water quality impact in the primary study area or extended study area, including the Delta.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP4 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP4. Therefore, even with the addition of anticipated effects of climate change, CP4 would not have a significant cumulative effect, and could be potentially beneficial.

CP5 – 18.5-Foot Dam Raise, Combination Plan

With the exception of water quality measured as water temperature, the cumulative effects of CP5 would be the same as those of CP1. Effects of CP5 on water quality measured as water temperature would be beneficial and effectively the same as CP3. Therefore, water quality impacts of CP5 would not make a cumulatively considerable incremental contribution to the overall significant cumulative water quality impact in the primary study area or extended study area, including the Delta.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP5 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP5. Therefore, even with the addition of anticipated effects of climate change, CP5 would not have a significant cumulative effect, and could be potentially beneficial.

Chapter 8
Noise and Vibration

8.1 Affected Environment

This section describes the affected environment related to noise and vibration for the dam and reservoir modifications proposed under the Shasta Lake Water Resources Investigation.

8.1.1 Acoustic Fundamentals

Noise is generally defined as sound that is loud, disagreeable, or unexpected. Sound, as described in more detail below, is an audible vibration of an elastic medium.

Sound Properties

A sound wave is introduced into a medium (e.g., air) by a vibrating object. The vibrating object (e.g., vocal cords, the string and sound board of a guitar, or the diaphragm of a radio speaker) is the source of the disturbance that sets the medium to vibrate and then propagates through the medium. Regardless of the type of source creating the sound wave, the particles of the medium through which the sound moves are vibrating in a back-and-forth motion at a given frequency, tone, or pitch. The frequency of a wave refers to how often the particles vibrate when a wave passes through the medium. Wave frequency is measured as the number of complete back-and-forth vibrations of a particle per unit of time. If a particle of air undergoes 1,000 longitudinal vibrations in 2 seconds, then the frequency of the wave would be 500 vibrations per second. A commonly used unit for frequency is Hertz (Hz).

Each particle vibrates as a result of the motion of its nearest neighbor. For example, the first particle of the medium begins vibrating at 500 Hz and sets the second particle of the medium into motion at the same frequency (500 Hz). The second particle begins vibrating at 500 Hz and thus sets the third particle into motion at 500 Hz. The process continues throughout the medium; hence each particle vibrates at the same frequency, which is the frequency of the original source. Subsequently, a guitar string vibrating at 500 Hz will set the air particles in the room vibrating at the same frequency (500 Hz), which carries a sound signal to the ear of a listener that is detected as a 500-Hz sound wave.

The back-and-forth vibration motion of the particles of the medium would not be the only observable phenomenon occurring at a given frequency. Because a sound wave is a pressure wave, a detector could be used to detect oscillations in pressure from high to low and back to high pressure. As the compression (high-

pressure points) and rarefaction (low-pressure points) disturbances move through the medium, they would reach the detector at a given frequency. For example, a compression would reach the detector 500 times per second if the frequency of the wave were 500 Hz. Similarly, a rarefaction would reach the detector 500 times per second if the frequency of the wave were 500 Hz. Thus, the frequency of a sound wave refers not only to the number of back-and-forth vibrations of the particles per unit of time but also to the number of compression or rarefaction disturbances that pass a given point per unit of time. A detector could be used to detect the frequency of these pressure oscillations over a given period of time. The period of the sound wave can be found by measuring the time between successive compressions or the time between successive rarefactions. The frequency is simply the reciprocal of the period; thus an inverse relationship exists so that as frequency increases, the period decreases, and vice versa.

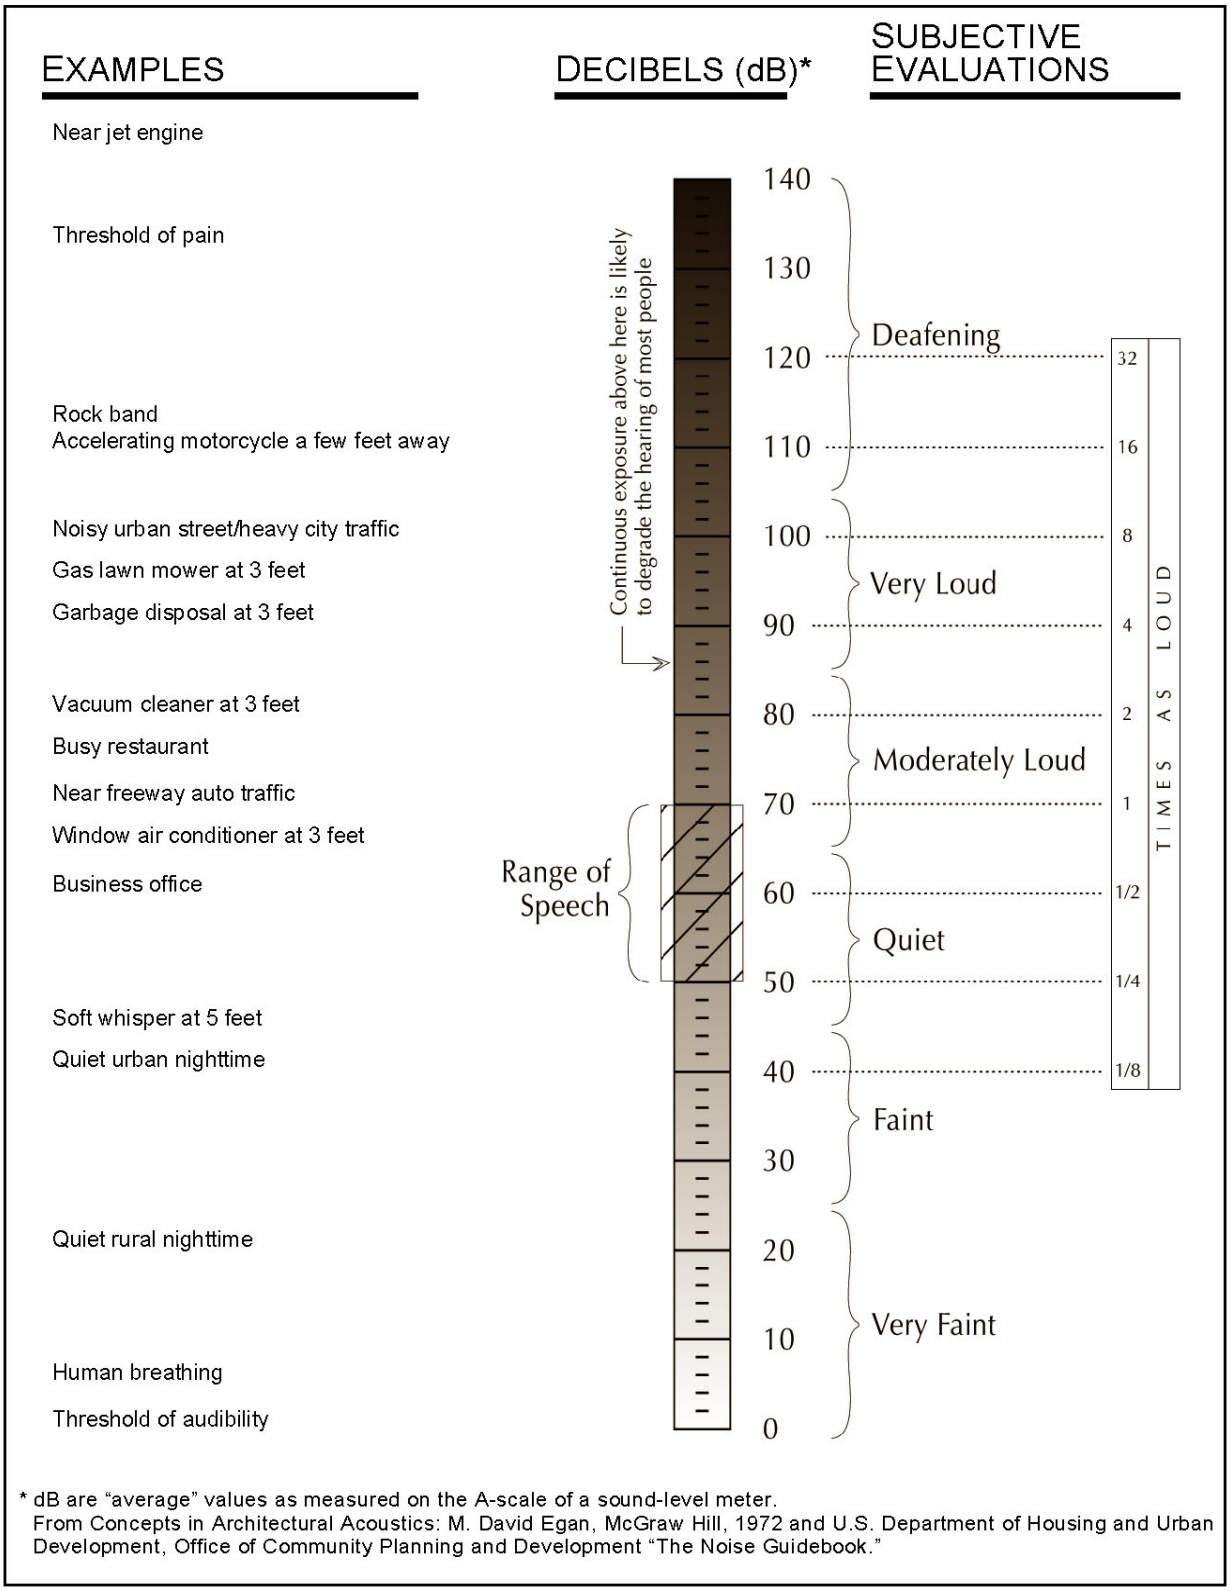
A wave is a disturbance through some medium (e.g., air, water, space) that typically transfers energy. Waves travel and transfer energy from one point to another, often with little or no permanent displacement of the particles of the medium. For example, in an ocean wave, the seawater appears to be move along the path of the wave. However, the water particles themselves are nearly stationary—it is the energy transferred through those particles (the wave) causing displacement that makes it appear that the water itself is moving.

In the case of sound (and noise), the “wave” is a vibration or disturbance moving through air particles and, at a certain range of frequencies, is audible to the human ear. The amount of energy carried by a wave is related to the amplitude (loudness) of the wave. A high-energy wave is characterized by high amplitude; a low-energy wave is characterized by low amplitude. The amplitude of a wave refers to the maximum amount of displacement of a particle from its rest position. The energy transported by a wave is directly proportional to the square of the amplitude of the wave. This means that a doubling of the amplitude of a wave indicates a quadrupling of the energy transported by the wave.

Sound and the Human Ear

Because of the ability of the human ear to detect a wide range of sound-pressure fluctuations, sound-pressure levels are expressed in logarithmic units called decibels (dB). The sound-pressure level in decibels is calculated by taking the log of the ratio between the actual sound pressure and the reference sound pressure squared. The reference sound pressure is considered the absolute hearing threshold (Caltrans 1998). Use of this logarithmic scale reveals that the total sound from two individual sources of 65 A-weighted decibels (dBA) each (see explanation of the A-weighting scale below) is 68 dBA, not 130 dBA; that is, doubling the source strength increases the sound pressure by 3 dBA.

The human ear is sensitive to frequencies from 20 Hz to 20,000 Hz (the audible range) and can detect the vibration amplitudes that are comparable in size to a



hydrogen atom (EPA 1974). When damaged by noise, the ear is typically affected at the 4,000-Hz frequency first; therefore, this can be considered the most noise-sensitive frequency. The averaged frequencies of 500 Hz, 1,000 Hz, and 2,000 Hz have traditionally been employed in hearing conservation criteria because of their importance to the hearing of speech sounds (ASA 1997).

The human ear is not equally sensitive to all sound frequencies, depending on the amplitude of the sound; therefore, a specific frequency-dependent rating scale was devised to relate noise to human sensitivity. This called the weighting scale or function. The A-weighting scale is the most commonly used and is noted as A-weighted dB, dB(A), or dBA. The dBA scale discriminates against frequencies in a manner approximating the sensitivity of the human ear when a source is at 50 dB. The basis for compensation is a comparison of the "loudness" of tones played one at a time with a reference tone producing 50 dB. This dBA scale has been chosen by most authorities for the purpose of regulating environmental noise. Typical indoor and outdoor noise levels are presented on Figure 8-1.

With respect to how humans perceive increases in noise levels, for pure tones or some broadband tones, a 1-dBA increase is imperceptible, a 3-dBA increase is barely perceptible, a 6-dBA increase is clearly perceptible, and a 10-dBA increase is subjectively perceived as approximately twice as loud (Egan 1988). For this reason, an increase of 3 dBA or more is generally considered a degradation of the existing noise environment for this type of source. For more complex sources, that is, where the tones differ substantially between sources, such as for the sound of a heavy truck versus a new car or a kitchen blender, the ear perceives differences much more quickly.

Sound Propagation

As sound (noise) propagates from the source to the receptor, the attenuation, or manner of noise reduction in relation to distance, depends on surface characteristics, atmospheric conditions, and the presence of physical barriers. The inverse-square law describes the attenuation when sound travels from a point source such as an air-conditioning unit to the receptor. Sound travels uniformly outward from a point source in a spherical pattern with an attenuation rate of 6 dBA per doubling of distance (dBA/DD). However, from a line source, such as a long line of traffic on a freeway, sound travels uniformly outward in a cylindrical pattern with an attenuation rate of 3 dBA/DD. The surface characteristics between the source and the receptor may result in additional sound absorption and/or reflection. Atmospheric conditions such as wind speed, temperature, and humidity may affect noise levels. Furthermore, the presence of a barrier between the source and the receptor may also attenuate noise levels. The actual amount of attenuation depends on the size of the barrier and the frequency of the noise. A noise barrier may be any natural or human-made feature such as a hill, building, wall, or berm (Caltrans 1998).

Source: Data compiled by AECOM in 2011

Figure 8-1. Typical Noise Levels

Noise Descriptors

The selection of a proper noise descriptor for a specific source depends on the spatial and temporal distribution, duration, and fluctuation of the noise. The noise descriptors most often encountered when dealing with traffic, community, and environmental noise are defined below (Caltrans 1998; Lipscomb and Taylor 1978):

- **L_{max} (maximum noise level)** – The maximum noise level during a specific period of time. The L_{max} may also be referred to as the "highest (noise) level."

- **L_{min} (minimum noise level)** – The minimum noise level during a specific period of time.

- **L_x (statistical descriptor)** – The noise level exceeded X percent of a specific period of time.

- **L_{eq} (equivalent noise level)** – The energy mean (average) noise level. The instantaneous noise levels during a specific period of time in dBA are converted to relative energy values. From the sum of the relative energy values, an average energy value is calculated, which is then converted back to dBA to determine the L_{eq}.

- **L_{dn} (day-night noise level)** – The 24-hour L_{eq} with a 10-dBA "penalty" for the noise-sensitive hours between 10 p.m. and 7 a.m. The L_{dn} attempts to account for the fact that noise during this specific period of time is a potential source of disturbance with respect to normal sleeping hours.

- **CNEL (community noise equivalent level)** – A noise level similar to the L_{dn} described above, but with an additional 5-dBA "penalty" for the noise-sensitive hours between 7 p.m. and 10 p.m., which are typically reserved for relaxation, conversation, reading, and television. If the same 24-hour noise data are used, the CNEL is typically approximately 0.5 dBA higher than the L_{dn}.

- **SEL (single-event (impulsive) noise level)** – A receiver's cumulative noise exposure from a single impulsive-noise event, which is defined as an acoustical event of short duration and which involves a change in sound pressure above some reference value.

Negative Effects of Noise on Humans

Negative effects of noise exposure include physical damage to the human auditory system, speech interference, sleep interference, activity interference, and disease. Exposure to noise may result in physical damage to the auditory system, which may lead to gradual or traumatic hearing loss. Gradual hearing loss is caused by sustained exposure to moderately high noise levels over a

period of time; traumatic hearing loss is caused by sudden exposure to extremely high noise levels over a short period. However, gradual and traumatic hearing loss both may result in permanent hearing damage. In addition, noise may interfere with or interrupt sleep, relaxation, recreation, and communication. Although most interference may be classified as annoying, the inability to hear a warning signal may be considered dangerous. Noise may also be a contributor to diseases associated with stress, such as hypertension, anxiety, and heart disease. The degree to which noise contributes to such diseases depends on the frequency, bandwidth, and level of the noise, and the exposure time (Caltrans 1998).

Vibration Fundamentals

Vibration is sound radiated through the ground. The rumbling sound caused by the vibration of room surfaces is called groundborne noise. Sources of groundborne vibrations include natural phenomena (e.g., earthquakes, volcanic eruptions, sea waves, and landslides) and human-made causes (e.g., explosions, machinery, traffic, trains, and construction equipment). Vibration sources may be continuous, such as factory machinery, or transient, such as explosions. As is the case with airborne sound, groundborne vibrations may be described by amplitude and frequency.

Vibration amplitudes are usually expressed in peak particle velocity (PPV) or root mean squared (RMS), as in RMS vibration velocity. The PPV and RMS velocity are normally described in inches per second (in/sec). PPV is defined as the maximum instantaneous positive or negative peak of a vibration signal. PPV is often used in monitoring of blasting vibration because it is related to the stresses that are experienced by buildings (FTA 2006; Caltrans 2002a).

Although PPV is appropriate for evaluating the potential for building damage, it is not always suitable for evaluating human response. It takes some time for the human body to respond to vibration signals. In a sense, the human body responds to average vibration amplitude. The RMS of a signal is the average of the squared amplitude of the signal, typically calculated over a 1-second period. As with airborne sound, the RMS velocity is often expressed in decibel notation, expressed as vibration decibels (VdB), which serves to compress the range of numbers required to describe vibration (FTA 2006).

The background vibration-velocity level in residential areas is usually approximately 50 VdB. Groundborne vibration is normally perceptible to humans at approximately 65 VdB. For most people, a vibration-velocity level of 75 VdB is the approximate dividing line between barely perceptible and distinctly perceptible levels (FTA 2006).

Typical outdoor sources of perceptible groundborne vibration are construction equipment, steel-wheeled trains, and traffic on rough roads. If a roadway is smooth, the groundborne vibration is rarely perceptible. The range of interest is from approximately 50 VdB, which is the typical background vibration-velocity

level, to 100 VdB, which is the general threshold where minor damage can occur in fragile buildings. Construction activities can generate groundborne vibrations, which can pose a risk to nearby structures. Constant or transient vibrations can weaken structures, crack facades, and disturb occupants (FTA 2006).

Construction vibrations can be either transient, random, or continuous. Transient construction vibrations are generated by blasting, impact pile driving, and wrecking balls. Continuous vibrations result from vibratory pile drivers, large pumps, and compressors. Random vibration can result from jackhammers, pavement breakers, and heavy construction equipment. Table 8-1 describes the general human response to different levels of groundborne vibration-velocity levels.

Table 8-1. Human Response to Different Levels of Groundborne Noise and Vibration

Vibration-Velocity Level	Human Reaction
65 VdB	Approximate threshold of perception.
75 VdB	Approximate dividing line between barely perceptible and distinctly perceptible. Many people find that transportation-related vibration at this level is unacceptable.
85 VdB	Vibration acceptable only if there are an infrequent number of events per day.

VdB = vibration decibels

8.1.2 Existing Noise Sources and Levels

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Existing sources of noise and vibration in the primary study area associated with roadway traffic and aircraft noise are outlined below. Noise is also generated by watercraft on Shasta Lake and stationary noise sources such as mechanical equipment at the existing dam facility. Additional sites that would be affected by the project are existing bridges, roads, and structures that would be inundated with implementation of the proposed dam rise and would need to be modified, demolished, or reconstructed. Sensitive receptors in these areas consist of residences, transient lodging, and recreational facilities.

Roadway Traffic Interstate 5 (I-5) and State Routes 36, 44, 151, 273, and 299 contribute the majority of roadway noise in the greater Shasta area. The Federal Highway Administration's Highway Traffic Noise Prediction Model was used to predict existing traffic noise levels for these routes. Table 8-2 shows existing average daily traffic volumes for Shasta County's major roadways, modeled

vehicle distribution characteristics, and the modeled distance from the roadway centerline to the various noise-level contours for each affected roadway segment in the study area under existing conditions. The traffic noise levels shown in the table assume no shielding or reflection from structures or topography. Actual noise levels would vary from day to day.

Railway Traffic Shasta County is served by the Union Pacific Railroad single-track main line, which travels north/south through the primary study area, paralleling I-5. (The McCloud Railway Company, a single-track short line, runs from McCloud to Burney, but because its activity is limited, noise measurements were not conducted for this line.) Noise measurements were conducted at two sites near Redding and Cottonwood for the *Shasta County General Plan* Noise Element. Table 8-3 presents noise levels associated with railroad noise in the Shasta Lake area.

Aircraft The three existing airports in the primary study area are described below.

Redding Municipal Airport In 2003, there were approximately 81,000 total aircraft operations at Redding Municipal Airport. As shown in the background report for the *Shasta County General Plan* Noise Element, the 65-dB CNEL contour is confined primarily to the airport property. The 60-dB CNEL contour extends outside of the property, but does not encroach on existing residential uses. According to the *Redding Municipal Airport Master Plan*, aviation growth at the airport will affect the surrounding area. The total number of aircraft operations is estimated to increase to 162,400 by 2015.

Shingletown Airport In 2003, there were zero aircraft operations at Shingletown Airport. Because of trees in the runway protection zone and deterioration of the tarmac, the operating permit was suspended indefinitely by the State in 2002. No future operations are planned for this facility at this time.

Fall River Mills Airport In 2001, there were approximately 6,000 total aircraft operations at Fall River Mills Airport. Based on the *Environmental Assessment for the Fall River Mills Airport Layout Plan* (April 2003), the existing 65-dB CNEL contour is contained within the existing airport boundary. Aviation growth at Fall River Mills Airport can also affect the area surrounding the airport. The number of aircraft operations is expected to increase to 15,000 by 2021. The future (2021) 65-dB CNEL contour is confined to Public Facility and Agriculture lands. The 60-dB CNEL contour also encompasses Urban Residential lands.

Table 8-2. Summary of Modeled Existing Traffic Noise Levels (Year 2006)

Roadway Segment	Modeling Assumptions					Distance (feet) from Roadway Edge to CNEL/L_{dn} (dBA)[1]				CNEL/L_{dn} (dBA) from Roadway Edge
	Average Daily Traffic Volume	Speed (mph)	Grade (%)	Traffic Distribution Percentages (%)		70 CNEL	65 CNEL	60 CNEL	55 CNEL	50 Feet
				Auto/Medium Truck/Heavy Truck	Day/ Evening/ Night					
SR 36, north of Red Bluff	12,000	45	0	79/9/12	79/11/10	64	138	298	641	72
SR 44, junction with I-5	51,000	65	0	81/9/10	79/11/10	235	507	1,093	2354	80
SR 151, Shasta Lake	5,500	45	0	81/9/10	79/11/10	36	77	165	356	68

dB = decibel
L_{dn} = day-night noise level

Benton Airpark In 2009, there were approximately 35,000 total aircraft operations at Benton Airpark. Based on the *Benton Airpark Master Plan* (March 2005), the existing 65-dB CNEL contour is contained within the existing airport boundary. Aviation growth at Benton Airpark can also affect the area surrounding the airport. The number of aircraft operations is expected to increase to 38,000 by 2021. The future (2021) 65-dB CNEL contour is confined to airport property and vacant land.

Other Aircraft Activities In addition to the aircraft facilities listed above, helipads from medical facilities in Redding are also in use. Usage of these helipads would be reserved for emergencies and would be intermittent in comparison to usage by full-time facilities such as the Benton Airpark. In the fire season, aircraft operated by the California Department of Forestry and Fire Protection use Shasta Lake as a source of water for fighting wildfires. Fire helicopters and tankers use the lake as needed during emergencies. Because firefighting is intermittent, no consistent noise levels would result from firefighting operations.

Fixed Noise Sources Industrial, light industrial, commercial, and public service facilities that could produce objectionable noise levels at nearby noise-sensitive uses are dispersed throughout the primary study area. Among these fixed noise sources are lumber mills, auto maintenance shops, car washes, loading docks, recycling centers, electricity generating stations, landfills, and athletic fields.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Noise sources within the extended study area would be similar to the general descriptions provided for the primary study area.

8.1.3 Existing Noise-Sensitive Land Uses

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Noise-sensitive land uses (sensitive receptors) are uses where exposure to noise would result in adverse effects and uses where quiet is essential. Residential dwellings are of primary concern. Other noise-sensitive land uses are schools, hospitals, convalescent facilities, parks, hotels, places of worship, and libraries. No sensitive land uses are immediately adjacent to (within 0.5 mile of) the dam. Sensitive land uses in the proximity of the dam raise site would be the vacant on site residence at the fish hatchery approximately one-half mile downstream. The nearest occupied residence is the horse camp located approximately 7,000 feet downstream; residents on Lake Boulevard are located approximately 4,500 feet east. Other sensitive receptors would include any residences within one-half mile of other construction work being done as a result of the dam raise. Bridge construction would occur at Charlie Creek, Doney Creek, McCloud River, Pit River, and other Union Pacific Railroad bridges. Major road construction would occur on Lakeshore Drive, in the Turntable Bay Area, on Gillman Road, in Jones Valley and the Silverthorne Area, and on Salt Creek Road. The nearest school to construction activities would be the Smithson School in Lakehead (approximately 500 feet); the nearest place of worship would be Canyon Community Church also in Lakehead (approximately 800 feet).

Lower Sacramento River and Delta and CVP/SWP Service Areas

Noise receptors within the extended study area would be similar to those generally described above for the primary study area.

8.2 Regulatory Framework

8.2.1 Federal

No Federal plans, policies, regulations, or laws related to noise are applicable to the project. The environmental review of Federal projects generally defers to State, county, or other local guidelines.

To address the human response to groundborne vibration, the Federal Transit Administration (FTA) of the U.S. Department of Transportation has set forth guidelines for maximum-acceptable vibration criteria for different types of land uses. These criteria include 65 VdB for land uses where low ambient vibration is essential for interior operations (e.g., hospitals, high-tech manufacturing, and laboratory facilities), 80 VdB for residential uses and buildings where people normally sleep, and 83 VdB for institutional land uses with primarily daytime operations (e.g., schools, churches, clinics, and offices) (FTA 2006).

Standards have also been established to address the potential for groundborne vibration to cause structural damage to buildings. These standards were developed by the Committee of Hearing, Bio Acoustics, and Bio Mechanics at

the request of the U.S. Environmental Protection Agency (FTA 2006). For fragile structures, Committee of Hearing, Bio Acoustics, and Bio Mechanics recommends a maximum limit of 0.25 in/sec PPV (FTA 2006).

8.2.2 State

Governor's Office of Planning and Research

The Governor's Office of Planning and Research published the *State of California General Plan Guidelines* (OPR 2003), which provides guidance for the acceptability of projects within specific L_{dn} contours. Table 8-4 summarizes acceptable and unacceptable community noise exposure limits for various land use categories.

Generally, residential uses (e.g., mobile homes) are considered to be acceptable in areas where exterior noise levels do not exceed 60 dBA L_{dn}. Residential uses are normally unacceptable in areas exceeding 70 dBA L_{dn} and conditionally acceptable within 55–70 dBA L_{dn}. Schools are normally acceptable in areas up to 70 dBA L_{dn} and normally unacceptable in areas exceeding 70 dBA L_{dn}. Commercial uses are normally acceptable in areas up to 70 dBA CNEL. Between 67.5 and 77.5 dBA L_{dn}, commercial uses are conditionally acceptable, depending on the noise insulation features and the noise reduction requirements. With respect to water recreation uses, exterior noise levels that do not exceed 75 dBA CNEL/L_{dn} are considered normally acceptable, levels between 70 and 80 dBA CNEL/L_{dn} are normally unacceptable, and levels that exceed 80 dBA CNEL/L_{dn} are clearly unacceptable. The guidelines also present adjustment factors that may be used to arrive at noise-acceptability standards that reflect the noise-control goals of the community, the particular community's sensitivity to noise, and the community's assessment of the relative importance of noise issues.

California Department of Transportation

For the protection of fragile, historic, and residential structures, the California Department of Transportation (Caltrans) recommends a threshold of 0.2 in/sec PPV for normal residential buildings and 0.08 in/sec PPV for old or historically significant structures (Caltrans 2002a). These standards are more stringent than the Federal standard established by Committee of Hearing, Bio Acoustics, and Bio Mechanics, presented above.

Table 8-4. State Noise-Compatibility Guidelines by Land-Use Category

Land-Use Category	Community Noise Exposure (CNEL/L_{dn}, dBA)			
	Normally Acceptable [a]	Conditionally Acceptable [b]	Normally Unacceptable [c]	Clearly Unacceptable [d]
Residential – Low-Density Single-Family, Duplexes, Mobile Homes	< 60	55–70	70–75	75+
Residential – Multifamily	< 65	60–70	70–75	75+
Transient Lodging – Motels, Hotels	< 65	60–70	70–80	80+
Schools, Libraries, Churches, Hospitals, Nursing Homes	< 70	60–70	70–80	80+
Auditoriums, Concert Halls, Amphitheaters		< 70	65+	
Sports Arenas, Outdoor Spectator Sports		< 75	70+	
Playgrounds, Neighborhood Parks	< 70		68–75	72.5+
Golf Courses, Riding Stables, Water Recreation, Cemeteries	< 75		70–80	80+
Office Buildings, Businesses, Commercial and Professional	< 70	68–78	75+	
Industrial, Manufacturing, Utilities, Agriculture	< 75	70–80	75+	

Source: OPR 2003

Notes:

[a] Specified land use is satisfactory, based on the assumption that any buildings involved are of normal conventional construction, without any special noise-insulation requirements.

[b] New construction or development should be undertaken only after a detailed analysis of the noise-reduction requirements is made and needed noise-insulation features are included in the design. Conventional construction, but with closed windows and fresh-air supply systems or air conditioning, will normally suffice.

[c] New construction or development should generally be discouraged. If new construction or development does proceed, a detailed analysis of the noise-reduction requirements must be made and needed noise-insulation features included in the design. Outdoor areas must be shielded.

[d] New construction or development should generally not be undertaken.

Key:

CNEL = community noise equivalent level

dBA = A-weighted decibels

L_{dn} = day-night noise level

8.2.3 Regional and Local

Shasta County

Shasta County General Plan Noise Element The Noise Element of the *Shasta County General Plan* includes goals, standards, and policies designed to ensure that county residents are not subjected to noise beyond acceptable levels (Shasta County 2004). Policies that may be applicable to the project include the following:

- **Policy N-b** – Noise likely to be created by a proposed non-transportation land use shall be mitigated so as not to exceed the noise level standards of Table 8-5 as measured immediately within the property line of adjacent lands designated as noise-sensitive.

- **Policy N-c** – Where proposed non-residential land uses are likely to produce noise levels exceeding the performance standards of Table 8-5 upon existing or planned noise-sensitive uses, an acoustical analysis shall be required as part of the environmental review process so that appropriate noise mitigation may be included in the project design. The requirements for the content of an acoustical analysis are given by Table 8-5.

- **Policy N-d** – The feasibility of proposed projects with respect to existing and future transportation noise levels shall be evaluated by comparison to Tables 8-5 and 8-6.

- **Policy N-f** – Noise created by new transportation sources shall be mitigated to satisfy the levels specified in Table 8-5 at outdoor activity areas and/or interior spaces of existing noise-sensitive land uses. Transportation noise shall be compared with existing and projected noise levels.

- **Policy N-g** – Existing noise-sensitive uses may be exposed to increased noise levels due to future roadway improvement projects as a result of increased traffic capacity and volumes and increases in travel speeds. In these instances, it may not be practical to reduce increased traffic noise levels consistent with those contained in Table 8-5. Therefore, as an alternative, the following criteria may be used as a test of significance for increases in the ambient outdoor activity areas of the noise level of noise-sensitive uses created as a result of a new roadway improvement project:

Table 8-5. Noise Level Performance Standards for New Projects Affected by or Including Nontransportation Sources

Noise Level Descriptor	Daytime (7 a.m. to 10 p.m.)	Nighttime (10 p.m. to 7 a.m.)
Hourly L_{eq}, dB	55	50
The noise levels specified above shall be lowered by 5 dB for simple tone noises, noises consisting primarily of speech or music, or for recurring impulsive noises. These noise level standards do not apply to residential units established in conjunction with industrial or commercial uses (e.g., caretaker dwellings). The County can impose noise level standards which are more restrictive than those specified above based upon determination of existing low ambient noise levels. In rural areas where large lots exist, the exterior noise level standard shall be applied at a point 100 feet away from the residence. Industrial, light industrial, commercial, and public service facilities which have the potential for producing objectionable noise levels at nearby noise-sensitive uses are dispersed throughout the County. Fixed-noise sources which are typically of concern include, but are not limited to, the following:		
HVAC Systems Cooling Towers/Evaporative Condensers Pump Stations Lift Stations Emergency Generators Boilers Steam Valves Steam Turbines Generators Fans Air Compressors	Heavy Equipment Conveyor Systems Transformers Pile Drivers Grinders Drill Rigs Gas or Diesel Motors Welders Cutting Equipment Outdoor Speakers Blowers	

Source: Shasta County 2004

Notes:

The types of uses which may typically produce the noise sources described above include, but are not limited to: industrial facilities including lumber mills, trucking operations, tire shops, auto maintenance shops, metal fabricating shops, shopping centers, drive-up windows, car washes, loading docks, public works projects, batch plants, bottling and canning plants, recycling centers, electric generating stations, race tracks, landfills, sand and gravel operations, and athletic fields.

For the purposes of the Noise Element, transportation noise sources are defined as traffic on public roadways, railroad line operations, and aircraft in flight. Control of noise from these sources is preempted by Federal and State regulations. Other noise sources are presumed to be subject to local regulations, such as a noise control ordinance. Non-transportation noise sources may include industrial operations, outdoor recreation facilities, heating, ventilation, and air conditioning units, loading docks, etc.

Key:

County = Shasta County

dB = decibels

HVAC = heating, ventilation, and air conditioning

L_{eq} = equivalent noise level

Table 8-6. Requirements for an Acoustical Analysis

An acoustical analysis prepared pursuant to the Noise Element shall:	
A.	Be the financial responsibility of the applicant.
B.	Be prepared by a qualified person experienced in the fields of environmental noise assessment and architectural acoustics.
C.	Include representative noise level measurements with sufficient sampling periods and locations to adequately describe local conditions and the predominant noise sources.
D.	Estimate existing and projected cumulative (20 years) noise levels in terms of L_{dn} or CNEL and/or the standards of Table [8-5], and compare those levels to the adopted policies of the Noise Element.
E.	Recommend appropriate mitigation to achieve compliance with the adopted policies and standards of the Noise Element, giving preference to proper site planning and design over mitigation measures which require the construction of noise barriers or structural modifications to buildings which contain noise-sensitive land uses.
F.	Estimate noise exposure after the prescribed mitigation measures have been implemented.
G.	Describe a post-project assessment program which could be used to evaluate the effectiveness of the proposed mitigation measures.

Source: Shasta County 2004

Key:
CNEL = community noise equivalent level
L_{dn} = day-night noise level

  - Where existing traffic noise levels are less than 60 dB Ldn, a +5 dB Ldn increase will be considered significant,

  - Where existing traffic noise levels range between 60 and 65 dB Ldn, a +3 dB Ldn increase will be considered significant, and

  - Where existing traffic noise levels are greater than 65 dB Ldn, a + 1.5 dB Ldn increase will be considered significant.

- **Policy N-i** – Where noise mitigation measures are required to achieve the standards of Tables 8-5 and 8-6, the emphasis of such measures shall be placed upon site planning and project design. The use of noise barriers shall be considered a means of achieving compliance with the noise standards only after all other practical design-related noise mitigation measures have been integrated into the project.

- **Policy N-j** – Encourage railroad officials to install noise-mitigation features on trains, equipment, and at fixed-based facilities whenever possible, and instruct railroad engineers to limit their use of air horns to reduce rail-related noise impacts on cities, towns, and rural community centers.

- **Policy N-k** – All County airports lacking adopted noise level contours consistent with the General Plan forecast year of 2025 should update their respective Master Plans or Comprehensive Land Use Plans to reflect aircraft operation noise levels for existing and future operations.

- **Policy N-l** – The use of site planning and building materials/design as primary methods of noise attenuation is encouraged.

- **Policy N-m** – The County should adopt noise control guidelines to assist staff and project applicants in determining the appropriate methods for reducing transportation and non-transportation generated noise.

- **Policy N-n** – The State Noise Insulation Standards (California Code of Regulations, Title 24) and Chapter 35 of the Uniform Building Code shall be enforced.

- **Policy N-o** – As the County updates the GIS mapping data base, the traffic, airport, and railroad noise contour information contained within the Background Report for the Noise Element shall be included as a part of the mapping data base. Noise contours for transportation and fixed noise sources should be periodically updated and any subsequent revisions of the data shall be incorporated into the General Plan and adopted for noise control planning purposes, as appropriate (see Tables 8-7 and 8-8).

Table 8-7. Maximum Allowable Noise Exposure Transportation Noise Sources

Land Use	Outdoor Activity Areas[a] L_{dn}/CNEL, dB	Interior Spaces	
		L_{dn}/CNEL, dB	L_{eq}, dB[b]
Residential	60 [c]	45	–

Notes:

[a] Where the location of outdoor activity areas is unknown, the exterior noise level standard shall be applied to the property line of the receiving land use. Where it is not practical to mitigate exterior noise levels at patio or balconies of apartment complexes, a common area such as a pool or recreation area may be designated as the outdoor activity area.

[b] As determined for a typical worst-case hour during periods of use.

[c] Where it is not possible to reduce noise in outdoor activity areas to 60 dB Ldn/CNEL or less using a practical application of the best-available noise reduction measures, exterior noise levels of up to 65 dB Ldn/CNEL may be allowed provided that available exterior noise level reduction measures have been implemented and interior noise levels are in compliance with this table.

[d] In the case of hotel/motel facilities or other transient lodging, outdoor activity areas such as pool areas may not be included in the project design. In these cases, only the interior noise level criterion will apply.

Notes:

G.A. = Generally Acceptable. Specified land use is satisfactory. No noise mitigation measures are required.

C.A. = Conditionally Acceptable. Use should be permitted only after careful study and inclusion of protective measures as needed to satisfy the policies of the Noise Element.

G.U. = Generally Unacceptable. Development is usually not feasible in accordance with the goals of the Noise Element.

Key:

CNEL = community noise equivalent level

dB = decibels

L_{dn} = day-night noise level

Shasta County Code The Shasta County Code has one provision related to noise:

> 13.04.170: Unnecessary Noise Prohibited. No person shall operate any aircraft in flight or on the ground in such a manner as to cause unnecessary noise as determined by applicable Federal or State or local laws and regulations. (Prior code Section 2112.)

Tehama County

Tehama County General Plan The Noise Element of the *Tehama County General Plan* provides a basis for comprehensive local policies to control and abate environmental noise and to protect the citizens of the county from excessive noise exposure (Tehama County 2009). The fundamental goals of the Noise Element are as follows:

- **Goal N-1** – Provide sufficient information concerning the community noise environment so that noise may be effectively considered in the land use planning process.
  - **Policy N-1.1** – The County shall require an acoustical analysis for new projects anticipated to generate excessive noise located adjacent, or near, to noise-sensitive land uses. The acoustical analysis shall be prepared in accordance with Table 8-9, Requirements for Acoustical Analysis Prepared in Tehama County.

Table 8-9. Requirements for an Acoustical Analysis Prepared In Tehama County

An acoustical analysis prepared pursuant to the Noise Element shall:
(1) Be the responsibility of the applicant.
(2) Be prepared by qualified persons experienced in the fields of environmental noise assessment and architectural acoustics.
(3) Include representative noise level measurements with sufficient sampling periods and locations to adequately describe local conditions.
(4) Estimate existing and projected cumulative noise levels in terms of the standards of Tables 9-6 and 9-7 of this General Plan and compare those levels to the adopted policies of the Noise Element.
(5) Recommend appropriate mitigation to achieve compliance with the adopted policies and standards of the Noise Element. Where the noise source in question consists of intermittent single events, the report must address the effects of maximum noise levels in sleeping rooms evaluating possible sleep disturbance.
(6) Estimate interior and exterior noise exposure after the prescribed mitigation measures have been implemented.
(7) Describe the post-project assessment program that could be used to evaluate the effectiveness of the proposed mitigation measures.

Source: Tehama County 2009

- **Goal N-2** – Develop strategies for abating excessive noise exposure through cost-effective mitigation measures in combination with appropriate zoning to avoid incompatible land uses.
  - **Policy N-2.4** – The County shall restrict construction activities to the hours as determined in the Countywide Noise Control Ordinance, if such an Ordinance is adopted.
    - **Implementation Measure N-2.4a** – Restrict construction activities to the hours as determined by the County's Noise Control Ordinance unless an exemption is received from the County to cover special circumstances. Special circumstances

may include emergency operations, short-duration construction, etc.

- **Implementation Measure N-2.4b** – Require all internal combustion engines that are used in conjunction with construction activities be muffled according to the equipment manufacturer's requirements.

- **Goal N-3** – Protect those existing regions of the planning area whose noise environments are deemed acceptable, and also those locations throughout the community deemed "noise sensitive."

- **Goal N-4** – Protect existing noise-producing commercial and industrial uses in Tehama County from encroachment by noise-sensitive land uses.

  – **Policy N-4.1** – The County shall require review for discretionary industrial, commercial, or other noise-generating land uses for compatibility with adjacent and nearby noise-sensitive land uses.

  – **Policy N-4.2** – The interior and exterior noise level standards for noise-sensitive areas of new uses affected by non-transportation noise sources within Tehama County are depicted in Table 8-10.

Lower Sacramento River and Delta

General plan noise elements and noise ordinances from all counties in the lower Sacramento River and Delta and communities in Tehama, Butte, Glenn, Colusa, Sutter, Yolo, Sacramento, Solano, and Contra Costa counties would be applicable to affected areas within their jurisdictions. The general plans and codes in these jurisdictions would be similar to the Shasta and Tehama county regulations outlined above. Construction, land use, and acceptable levels for various land uses would be defined and outlined.

CVP/SWP Service Areas

All community and county plans and ordinances in the CVP and SWP service areas would be applicable to affected areas within their jurisdictions. The general plans and codes in these jurisdictions would be similar to the Shasta and Tehama county regulations outlined above. Construction, land use, and acceptable levels for various land uses would be defined and outlined.

Table 8-10. Noise Standards for New Uses Affected By Nontransportation Noise in Tehama County

New Land Use	Outdoor Activity Area—L_{eq}, dB		Interior—L_{eq}, dB	
	Daytime	Nighttime	Day and Night	Notes

Playgrounds, Parks, etc.	65	–	–	6
Industry	65	65	50	5

Source: Tehama County 2009

Notes:

[1] Outdoor activity areas for single-family residential uses are defined as back yards. For large parcels or residences with no clearly defined outdoor activity area, the standard shall be applicable within a 100-foot radius of the residence.

[2] For multi-family residential uses, the exterior noise level standard shall be applied at the common outdoor recreation area, such as at pools, play areas or tennis courts. Where such areas are not provided, the standards shall be applied at individual patios and balconies of the development.

[3] Outdoor activity areas of transient lodging facilities include swimming pool and picnic areas, and are not commonly used during nighttime hours.

[4] Hospitals are often noise generating uses. The exterior noise level standards for hospitals are applicable only at clearly identified areas designated for outdoor relaxation by either hospital staff or patients.

[5] Only the exterior spaces of these uses designated for employee or customer relaxation have any degree of sensitivity to noise.

[6] The outdoor activity areas of office, commercial and park uses are not typically utilized during nighttime hours.

[7] It may not be possible to achieve compliance with this standard at residential uses located immediately adjacent to loading dock areas of commercial uses while trucks are unloading. The daytime and nighttime noise level standards applicable to loading docks shall be 55 and 50 dB Leq, respectively.

General: The Table 9-7 standards shall be reduced by 5 dB for sounds consisting primarily of speech or music, and for recurring impulsive sounds. If the existing ambient noise level exceeds the standards of Table 9-7, then the noise level standards shall be increased at 5 dB increments to encompass the ambient.

Key:
dB = decibels
L_{eq} = equivalent noise level

8.3 Environmental Consequences and Mitigation Measures

8.3.1 Methods and Assumptions

Land use types and major noise sources in the project vicinity were identified based on existing documentation (e.g., the Shasta County Zoning Code) and site reconnaissance data. To assess potential short-term construction noise impacts,

sensitive receptors and their relative exposure (considering topographic barriers and distance) were identified. Noise levels of specific construction equipment were determined and resultant noise levels at those receptors were calculated.

Potential long-term (operational) traffic, area-source, and stationary-source noise impacts were qualitatively assessed based on the number of vehicle trips and other potential operational noise sources introduced to the project area.

Groundborne vibration impacts were qualitatively assessed based on existing documentation (e.g., vibration levels produced by specific construction equipment) and the distance of sensitive receptors from the given source.

Predicted noise levels were compared with applicable standards for determination of significance. Mitigation measures were developed for significant and potentially significant noise impacts.

8.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an environmental impact statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, other Federal, State, and local guidance, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on noise would be significant if project implementation would do any of the following:

- Expose persons to or generate noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.
- Expose persons to or generate excessive groundborne vibration or groundborne noise levels.
- Permanently increase ambient noise levels in the project vicinity substantially above levels existing without the project.

- Temporarily or periodically increase ambient noise levels in the project vicinity substantially above levels existing without the project.

- Expose people residing or working in the project area to excessive aircraft-generated noise levels.

8.3.3 Topics Eliminated from Further Consideration

None of the project alternatives would expose people residing or working in the project area to excessive aircraft-generated noise levels because of the distance of existing airports to the project area. There would also be no change in railway traffic as a result of any of the alternatives. Therefore, potential effects on the primary and extended study areas related to these issues are not discussed further in this PDEIS.

This analysis assumes that the operation of any of the project alternatives would not generate any new significant long-term noise sources because operation and maintenance of Shasta Dam and current or relocated recreational facilities would be relatively unchanged compared to existing conditions. Relocated recreational facilities would presumably generate the same levels and types of noise, but in a slightly different location than currently exists. After completion of the dam raise, bridge and levee construction, and relocation of recreational facilities, the number of personnel serving at all sites during construction would be reduced to approximately the number currently serving to operate and maintain the facilities. Therefore, no further analysis is needed and no mitigation would be needed.

No effects on the current ambient noise environment would occur in the lower Sacramento River and Delta and the CVP and SWP service areas; no construction activities would occur in these geographic regions, and there would be no long-term noise sources from dam operation, modified flows in the Sacramento River and other tributaries, or water storage and conveyance throughout the CVP and SWP service areas. Therefore, potential effects related to project noise in those geographic regions are not discussed further in this PDEIS.

8.3.4 Direct and Indirect Effects

No-Action Alternative

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (No-Action): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise No construction activities would occur and current operations would continue. Recreational use, population, and traffic would all increase but these increases and the effect on the noise environment would not be substantial. This impact would be less than significant.

No construction activities would occur and the dam would continue to function as it currently functions. Because no construction activities would occur under this alternative, implementing the No-Action Alternative could not contribute toward a temporary change in the ambient noise environment. Generally, ambient noise levels would likely increase under the No-Action Alternative because greater recreational use, population growth, and traffic would occur; however, these increases would not be substantial. As a result, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Noise-2 (No-Action): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction No construction activities would occur and current operations would continue. Recreational use, population, and traffic would all increase, but these increases and the effect on the noise environment would not be substantial. This impact would be less than significant.

This impact is similar to Impact Noise-1 (No-Action) for the primary study area. For the same reasons as described under Impact Noise-1 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Noise-3 (CP1): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations No construction activities would occur and current operations would continue. Recreational use, population, and traffic would all increase, but these increases and the effect on the noise environment would not be substantial. This impact would be less than significant.

This impact is similar to Impact Noise-1 (No-Action) for the primary study area. For the same reasons as described under Impact Noise-1 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (CP1): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise would not exceed applicable noise-level standards at nearby noise-sensitive

receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree removal, material handling, demolition, and site restoration and cleanup. Increases in truck traffic from construction would not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. This temporary impact would be significant.

Construction activities at the Shasta Dam site under CP1 would include site preparation (e.g., excavation, grading, and clearing), the proposed dam raise, blasting, tree removal, material handling, site restoration and clean-up, and other miscellaneous activities. Temporary noise effects of the operation of heavy-duty construction equipment at the dam, blasting activities, operation of heavy-duty construction equipment at other project sites, and off-site construction traffic are addressed separately below.

Operation of Heavy-Duty Construction Equipment at the Dam The construction activities mentioned above would require the use of scrapers, excavators, bulldozers, compactors, loaders, trucks, crushers, pumps, pavers, concrete mixers, cranes, generators, and other miscellaneous pieces of equipment based on similar projects. According to the U.S. Environmental Protection Agency, noise levels generated by individual pieces of these types of equipment can range from 76 to 94 dBA at 50 feet without feasible noise control (Table 8-11). Simultaneous operation of the heavy-duty construction equipment could result in combined intermittent noise levels of approximately 94 dBA at 50 feet from the project site. Based on these noise levels and a typical noise-attenuation rate of 6.0 dBA/DD, exterior noise levels at noise-sensitive receptors located within 4,000 feet of construction activity could exceed 55 dBA L_{eq} (the Shasta County standard for daytime hours) without noise control. However, there is a 450-foot elevation increase spanning 4,500 feet of intervening topography between the nearest receptors (residences on Lake Boulevard) and Shasta Dam. Accounting for the intervening topography attenuation, the vegetation, and the distance between the dam and receptors, an attenuation rate of approximately -100 dBA can be applied (-40 dBA for distance, -10 dBA for trees and vegetation, and -50 dBA for topographic elevation change). Thus, noise levels at the nearest sensitive receptor would be less than 50 dBA L_{dn}.

Additional residential receptors are approximately 7,000 feet down the Sacramento River from Shasta Dam. The construction-related noise level at this location would be approximately 45 dBA (95 dBA at 50 feet from construction site minus 45 dBA attenuation for distance, and minus 5 dBA attenuation from vegetation and topography). Thus, project construction noise generated by on-site construction equipment at Shasta Dam under CP1 would not expose sensitive receptors to or generate noise levels in excess of applicable standards (55 dBA daytime, 50 dBA nighttime), or to a substantial temporary increase in noise levels above existing conditions. This temporary impact would be less than significant.

Blasting Activities at the Dam Construction of the Shasta Dam height increase would require blasting during excavation of rock for the concrete tie-in to adjacent rock. Specific blast design parameters such as explosive type and amount (charge weight), drill pattern, and time scheme are not known at this time. However, it is anticipated that few blasts would occur each day. Blasting operations would result in airborne noise caused by the energy released in the explosion, which creates an air overpressure (airblast) in the form of a propagating wave. Still, as currently planned, single-event noise levels could exceed 110 dBA (FTA 2006). Based on the above attenuation rates, construction noise from project-related blasting activities could result in noise levels of 60 dBA at sensitive receptors downstream along the Sacramento River (7,000 feet away). As a result, the temporary impact of single-event increases in noise levels would be significant.

Operation of Heavy-Duty Construction Equipment at Other Project Sites Multiple construction activities would occur at the other project-related sites (Pit River Bridge, the lakeshore area, and other areas where bridges and roads would require relocation; recreation facilities that would require removal and reconstruction; and inundation areas that would require clearing). Among the anticipated construction activities are site preparation (e.g., excavation, grading, demolition, and clearing), paving, pile driving, laying of railroad tracks, bridge relocation, removal of trees and vegetation, material handling, and site restoration and cleanup.

Based on similar projects, the on-site construction equipment required for the activities would likely include but not be limited to an excavator, bulldozer, front-end loader, grader, compactor, cranes, pile drivers, trucks, and other large pieces of equipment as necessary. According to the U.S. Environmental Protection Agency, noise levels from individual pieces of these types of equipment, when operated without feasible noise control, can range from 79 to 96 dBA at 50 feet (Table 8-11). Simultaneous operation of the three noisiest pieces of heavy-duty construction equipment, including pile driving, could result in combined intermittent noise levels of approximately 97 dBA at 50 feet from the project site. Based on these noise levels and a typical noise-attenuation rate of 6.0 dBA/DD, exterior noise levels at noise-sensitive receptors located within 75 feet of construction activity (i.e., sensitive receptors along Lakeshore Drive) could exceed 94 dBA L_{eq} without noise control. Such noise levels would exceed Shasta County standards (55 dBA daytime, 50 dBA nighttime).

Table 8-11. Typical Construction Equipment Noise Levels

Type of Equipment	Noise Level at 50 feet (dBA)
Scraper	89
Excavator	89
Bulldozer	85
Compactor	82
Loader	85
Truck	88
Crusher	94
Pump	76
Paver	89
Concrete Pump	82
Concrete Mixer	85
Derrick Crane	88
Pile Driving (sonic)	96
Generator	81

Source: FTA 2006

Key:
dBA = A-weighted decibels

Helicopters would be used for vegetation removal during the spring and fall, when helicopters are not in use for firefighting. Helicopter noise levels range from 80 to 90 dBA at 250 feet (Caltrans 2002b). Noise levels from helicopters would be similar to those of other construction equipment described above.

Construction in areas away from the dam site would occur primarily during the daytime; however, the exact hours of construction are not specified at this time, nor has Shasta County adopted a noise ordinance that exempts construction noise from the provisions of the standard. If construction activities were to occur during the more noise-sensitive hours (evening, nighttime, and early morning), or if equipment were not properly equipped with noise-control devices, construction noise could exceed applicable noise-level standards (i.e., Shasta County's nighttime standard of 50 dBA L_{eq}) at existing noise-sensitive receptors located within 7,000 feet. In addition, any project-related construction noise generated during these more noise-sensitive hours may annoy and/or disrupt the sleep of occupants of the nearby existing noise-sensitive land uses, and temporarily but substantially increase ambient noise levels in the project vicinity. As a result, this impact would be significant.

Off-Site Construction Traffic Project construction would require approximately 350 on-site employees at any given time. Assuming two total trips per day per employee and 81 round trips per day for the transport of equipment and materials, project construction would result in a maximum of

approximately 862 one-way daily trips at the dam site. Typically, traffic volumes must double before the associated increase in noise levels is noticeable (3 dBA CNEL/L_{dn}) along roadways. Given that the average daily traffic volumes are 5,500 for State Route 151, 37,000 for I-5, and 2,000 for the Lakeshore Community, traffic would not double. Therefore, adding these daily trips on the local roadway system to existing volumes would be a minor change. Consequently, project construction under CP1 would not noticeably change the traffic-noise contours of area roadways. This impact would be less than significant.

Summary Implementing CP1 would result in less than significant noise impacts related to operation of heavy-duty construction equipment at Shasta Dam and off-site construction traffic. However, the impact of this alternative related to blasting activities at Shasta Dam and operation of heavy-duty construction equipment at other project sites would be significant. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-2 (CP1): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. As a result, this temporary impact would be less than significant.

According to FTA, vibration levels associated with the use of trucks, dozers, and other heavy-duty construction equipment such as the equipment types used at project construction sites are 0.076 to 0.089 in/sec PPV and 86–87 VdB at 25 feet, and vibration levels from pile driving can reach 0.73 in/sec PPV (Table 8-10). Vibration levels generated during project construction under CP1 could exceed Caltrans's recommended standard with respect to the prevention of structural damage (0.2 in/sec PPV for buildings) and FTA's maximum-acceptable constant vibration standard of 80 VdB with respect to human annoyance for residential uses within 65 feet of the impact zone. Because there are no sensitive receptors within these distances from any of the construction sites (the nearest residences would be along Lakeshore Drive and approximately 75 feet from road and bridge construction activities taking place in the area), implementing CP1 would not generate excessive groundborne vibration or groundborne noise levels, nor would it expose persons or buildings to such groundborne vibration or noise. As a result, this temporary impact would be less than significant.

Blasting at the Shasta Dam site would result in ground vibration from the creation of seismic waves that radiate along the earth's surface. As discussed previously, no noise-sensitive receptors are located near the dam site. Receptors would need to be within 250 feet of the blasts to be affected (greater than 80 VdB) by groundborne vibration. No sensitive receptors are within this range of the dam. Therefore, this temporary impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP1): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic noise create a substantial increase in ambient noise levels in the project vicinity. As a result, this impact would be less than significant.

Relocating Lakeshore Drive would move traffic noise closer to sensitive receptors in the Lakeshore Community. Based on roads of this size and service, it is estimated that the maximum average daily traffic in this area would be approximately 2,000 vehicles per day. Modeling by the Federal Highway Administration for a 2,000-average daily traffic two-lane roadway places the 60-dBA L_{dn} contour (Shasta County's transportation standard) at 70 feet from the roadway centerline. With the additional noise emanating from the adjacent railroad line (Shasta County 2004) and the nearest receptors farther than 75 feet from the new roadway centerline, the ambient noise level would not increase by more than 3 dBA or exceed 60 dBA (Shasta County 2004). Thus, project-generated long-term traffic noise would not result in an exceedence of the Shasta County standards. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Implementing CP1 would not generate any new long-term noise outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP1 in those geographic regions are not discussed further in this PDEIS.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The direct and indirect impacts of CP2 related to noise and vibration would be essentially the same as those described for CP1 because construction activities, and equipment and workforce needs, would be similar under both alternatives. Also, the long-term impact of CP2 on traffic levels associated with relocating Lakeshore Drive would be expected to be similar to the corresponding impact of CP1. Thus, as described below, the impacts described for CP1 would generally also apply to CP2.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Noise-1 (CP2): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree

removal, material handling, demolition, and site restoration and cleanup. Increases in truck traffic from construction would not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. This temporary impact would be significant.

This impact would be the same as Impact Noise-1 (CP1) and would be significant. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-2 (CP2): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-2 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP2): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic create a substantial increase in ambient noise levels in the project vicinity. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas Similar to CP1, implementing CP2 would not generate any new long-term noise outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP2 in those geographic regions are not discussed further in this PDEIS.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

The direct and indirect impacts of CP3 related to noise and vibration would be essentially the same as those described for CP1 and CP2 because construction activities, and equipment and workforce needs, would be similar under these alternatives. Also, the long-term impact of CP3 on traffic levels associated with relocating Lakeshore Drive would be expected to be similar to the corresponding impact of CP1 and CP2. Thus, as described below, the impacts described for CP1 and CP2 would generally also apply to CP3.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (CP3): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree removal, material handling, demolition, and site restoration and cleanup. Increases in truck traffic from construction would not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. This temporary impact would be significant.

This impact would be the same as Impact Noise-1 (CP1) and would be significant.

Impact Noise-2 (CP3): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-2 (CP1) and would be less than significant. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-3 (CP3): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic create a substantial increase in ambient noise levels in the project vicinity. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas Similar to CP1 and CP2, implementing CP3 would not generate any new long-term noise outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP3 in those geographic regions are not discussed further in this PDEIS.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

The direct and indirect impacts of CP4 related to noise and vibration would be essentially the same as those described for CP1 through CP3 because

construction activities, and equipment and workforce needs, would be similar under these alternatives. Also, the long-term impact of CP4 on traffic levels associated with relocating Lakeshore Drive would be expected to be similar to the corresponding impact of CP1 and CP2. Thus, as described below, the impacts described for CP1 and CP2 would generally also apply to CP4.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (CP4): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise levels would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree removal, material handling, demolition, and site restoration and cleanup. Increases in truck traffic from construction would not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. Gravel augmentation under CP4 would increase the total number of construction-related truck trips, but not enough to result in a violation of traffic noise standards or a substantial increase in traffic noise. This temporary impact would be significant.

This impact would be similar to Impact Noise-1 (CP1), but slightly greater because of the addition of gravel augmentation along the upper Sacramento River that is proposed under CP4. The proposed gravel augmentation would result in approximately 800 truck trips per year. Assuming 44 work days, approximately 18 truck trips per day would be added to the local roadway network. In addition, the Reading Island restoration project component would also be included under CP4. Reading Island restoration construction would include an excavator, loader, and compaction equipment. Noise levels would be similar to those described under CP1 and CP2 (see Table 8-11). Approximately 350 haul trips would be needed to remove material from the site, resulting in approximately eight trips per day over a 2-month period. As discussed above under Impact Noise-1 (CP1), to generate a substantial increase in traffic noise, the traffic volume must double. Because adding 26 truck trips would not double roadway traffic volumes, no violation of traffic noise standards or substantial increase in traffic noise would occur. For the same reasons as described for Impact Noise-1 (CP1), this impact would be significant. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-2 (CP4): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-2 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP4): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic create a substantial increase in ambient noise levels in the project vicinity. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas Similar to CP1, implementing CP4 would not generate any new long-term noise sources outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP4 in those geographic regions are not discussed further in this PDEIS.

CP5 – 18.5-Foot Dam Raise, Combination Plan

The direct and indirect impacts of CP5 related to noise and vibration would be essentially the same as those described for CP1 through CP4 because construction activities, and equipment and workforce needs, would be similar under these alternatives. Also, the long-term impact of CP5 on traffic levels associated with relocating Lakeshore Drive would be expected to be similar to the corresponding impact under CP1 and CP2. Thus, as described below, the impacts described for CP1 and CP2 would generally also apply to CP5.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (CP5): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise levels would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree removal, material handling, demolition, and site restoration and cleanup. Increases in truck traffic from construction would not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. Gravel augmentation under CP5 would increase the total number of construction-related truck trips, but not enough to result in a violation of traffic noise standards or a substantial increase in traffic noise. This temporary impact would be significant.

Like CP4, CP5 would involve gravel augmentation along the upper Sacramento River and restoration at Reading Island, neither of which would occur under CP1, CP2, or CP3. Reading Island restoration construction would include an excavator, loader, and compaction equipment. Noise levels would be similar to

those described under CP1 and CP2 (see Table 8-11). Approximately 350 haul trips would be needed to remove material from the site, resulting in approximately eight trips per day over a 2-month period. As discussed above under Impact Noise-1(CP1), to generate a substantial increase in traffic noise, a doubling of traffic volume would be required. Because adding 26 truck trips would not double roadway traffic volumes, no violation of traffic noise standards or substantial increase in traffic noise would occur. Noise levels from construction equipment, however, would still likely exceed noise standards. Therefore, temporary, construction-related impacts would be significant.

Thus, this impact would be the same as Impact Noise-1 (CP4) and would be significant. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-2 (CP5): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. The additional habitat development included in CP5 would occur in uninhabited areas of Shasta-Trinity National Forest, would not affect sensitive receptors, and would be temporary. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-2 (CP1). CP5 would also involve development of additional habitat; however, habitat development would occur in an uninhabited area managed by the U.S. Bureau of Land Management, would not be expected to affect any sensitive receptors, and would be temporary. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP5): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic create a substantial increase in ambient noise levels in the project vicinity. The additional habitat development included in CP5 would occur in uninhabited areas of Shasta-Trinity National Forest, would not create new operational traffic, and would not affect sensitive receptors. This impact would be less than significant.

This impact would be the same as Impact Noise-3 (CP1). CP5 would also involve development of additional habitat; however, habitat development would occur in an uninhabited area managed by the U.S. Bureau of Land Management, would not create any new operational traffic, and is not expected to affect any sensitive receptors. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas Similar to CP1 and CP2, implementing CP5 would not generate any new long-term

noise outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP5 in those geographic regions are not discussed further in this **P**DEIS.

8.3.5 Mitigation Measures

Table 8-12 presents a summary of mitigation measures for noise and vibration.

Table 8-12. Summary of Mitigation Measures for Noise and Vibration

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Noise-1: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise	LOS before Mitigation	LTS	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure Noise-1: Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites.				
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS
Impact Noise-2: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction	LOS before Mitigation	LTS	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed				
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS
Impact Noise-3: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations	LOS before Mitigation	LTS	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS

Key:
LOS = level of significance
LTS = less than significant
S = significant

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Noise-2 (CP1) and Noise-3 (CP1). Mitigation is provided below for the remaining noise impact of CP1.

Mitigation Measure Noise-1 (CP1): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites Reclamation and its primary construction contractors will implement the measures listed below during construction:

- Construction activities at non-dam sites will be limited to the less noise-sensitive daytime hours (7 a.m. to 10 p.m., Monday through Friday).
- All construction equipment and staging areas will be located at the farthest distance possible from nearby noise-sensitive land uses.
- All construction equipment will be properly maintained and equipped with noise-reduction intake and exhaust mufflers and engine shrouds, in accordance with manufacturers' recommendations. Equipment engine shrouds will be closed during equipment operation.
- All motorized construction equipment will be shut down when not in use to prevent idling.
- A temporary barrier will be placed as close to the noise source or receptor as possible and will break the line of sight between the source and receptor.
- A disturbance coordinator will be designated and the person's telephone number conspicuously posted around the project sites and supplied to nearby residences. The disturbance coordinator will receive all public complaints and be responsible for determining the cause of the complaint and implementing any feasible measures to alleviate the problem.

Implementation of this mitigation measure would reduce temporary project-generated construction source noise levels and limit them to the less sensitive daytime hours, thus preventing exposure of sensitive receptors to temporary construction noise at dam and non-dam sites. As a result, Impact Noise-1 (CP1) would be reduced to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Noise-2 (CP2) and Noise-3 (CP2). Mitigation is provided below for the remaining noise impact of CP2.

Mitigation Measure Noise-1 (CP2): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites This mitigation measure is identical to Mitigation Measure Noise-1 (CP1). Implementation of this mitigation measure would reduce Impact Noise-1 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impacts Noise-2 (CP3) and Noise-3 (CP3). Mitigation is provided below for the remaining noise impact of CP3.

Mitigation Measure Noise-1 (CP3): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites This mitigation measure is identical to Mitigation Measure Noise-1 (CP1). Implementation of this mitigation measure would reduce Impact Noise-1 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

No mitigation is needed for Impacts Noise-2 (CP4) and Noise-3 (CP4). Mitigation is provided below for the remaining noise impact of CP4.

Mitigation Measure Noise-1 (CP4): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites This mitigation measure is identical to Mitigation Measure Noise-1 (CP1). Implementation of this mitigation measure would reduce Impact Noise-1 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts Noise-2 (CP5) and Noise-3 (CP5). Mitigation is provided below for the remaining noise impact of CP5.

Mitigation Measure Noise-1 (CP5): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites This mitigation measure is identical to Mitigation Measure Noise-1 (CP1). Implementation of this mitigation measure would reduce Impact Noise-1 (CP5) to a less than significant level.

8.3.6 Cumulative Effects

Past and present projects from areas within Shasta and Tehama counties affect noise conditions in the primary study area through the use of heavy construction equipment and the increase in traffic resulting from construction activities. Other stationary sources (e.g., railroads, traffic on existing highways) also contribute to ambient noise in the primary study area. In many cases, other related projects could create substantially more noise than the project, and would result in a cumulatively significant noise impact.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Projects that could influence ambient noise levels in areas where the SLWRI could contribute noise include the *Shasta-Trinity National Forest Land and Resource Management Plan, Iron Mountain Mine Restoration Plan, and Mendocino National Forest Land and Resource Management Plan; development of the Turntable Bay Master Development Plan*; and construction of the Antlers Bridge replacement. If the listed projects were to occur

concurrently with any of the project alternatives under the SLWRI (CP1–CP5), combined noise generation during construction would be unlikely to be substantial because noise is generally a local phenomenon and is minimal beyond 0.5 mile. Noise from the SLWRI would not combine with other noise sources, such as construction from the projects listed above. After project construction is completed, the ambient noise environment relative to Shasta Dam would return to existing conditions. Therefore, none of the project alternatives would make a cumulatively considerable incremental contribution to cumulative noise effects.

Lower Sacramento and Delta and CVP/SWP Service Areas

Raising Shasta Dam would not result in any short-term or long-term effects on the ambient noise environment in the extended study area under any of the project alternatives. Therefore, there would be no cumulatively considerable incremental contribution to cumulative noise effects under any of the project alternatives.

Chapter 9
Hazards and Hazardous Materials and Waste

9.1 Affected Environment

This chapter describes the affected environment related to hazards and hazardous materials for the dam and reservoir modifications proposed under SLWRI.

Because of the potential influence of the proposed modification of Shasta Dam and water deliveries over a rather large geographic area, the SLWRI includes both a primary study area and an extended study area. The primary study area has been further divided into Shasta Lake and vicinity and upper Sacramento River (Shasta Dam to Red Bluff). The extended study area has been further divided into the lower Sacramento River and Delta and CVP/SWP service areas.

This section describes hazards and hazardous materials, defined as hazardous waste and hazardous substances, in the primary and extended study areas. The discussion of hazards focuses primarily on wildland fire and its related effects on the human environment and natural resources, and water safety hazards, particularly those related to Shasta Lake. Other relevant hazards, such as flooding, dam failure, and issues related to hydropower generation, public services (e.g., fire protection, law enforcement, emergency services), roadways and bridges, and recreation, are addressed in separate chapters. The effects of proposed fuels treatments, such as pile burning, on air quality are addressed in Chapter 5, “Air Quality.”

The hazards and hazardous waste setting for the primary study area consists of the portion of Shasta County above Shasta Dam and the upper Sacramento River from the dam downstream to the Red Bluff Diversion Dam, including the lands within the boundary of the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). This area encompasses parts of the Pit River, Squaw Creek, McCloud River, and Sacramento River watersheds. The hazards and hazardous waste setting for the upper Sacramento River portion of the primary study area consists of lands draining to the Sacramento River between Shasta Dam and Red Bluff.

The hazards and hazardous waste setting for the extended study area includes the Sacramento River basin downstream from the Red Bluff Diversion Dam to the Delta, the Delta itself, the San Joaquin River basin to the Delta, portions of the American River basin, and the CVP/SWP service areas.

9.1.1 Hazards

Shasta Lake and Vicinity

Water Safety Hazards The surface waters of Shasta Lake and, to a lesser extent, Keswick Reservoir and other surface waters in the vicinity pose hazards to persons engaging in boating and other water-based activities (see Chapter 18, "Recreation," for a detailed discussion of water safety hazards related to recreational activities). Water safety hazards are related to equipment operations, flow velocity, morphology, instream or submerged material, accessibility, and water temperature. Working in and adjacent to water bodies also poses risks to workers.

Fluctuations in the reservoir's pool level affect the pattern of submerged obstacles, which poses a risk to boaters, water skiers, operators of personal watercraft, and workers. Reservoir drawdowns can leave rocks, shoals, and islands submerged below the water surface, where watercraft or skiers can strike them. Conversely, increases in the reservoir's pool level conceal obstacles beneath the water surface that may be visible one day and submerged the next. Most of these hazards are not marked; however, the USFS public information program warns water-based recreationists via signage and various media to use caution when operating watercraft on the lake.

Although the USFS manages Shasta Lake and adjacent Federal lands comprising the NRA's Shasta Unit, law enforcement and emergency services are provided through a partnership between the Shasta-Trinity National Forest (STNF) and the Shasta County Sheriff's Office (SCSO) (see Chapter 22, "Public Services," for a detailed discussion of fire, law enforcement, and emergency services in Shasta Lake and vicinity). SCSO provides safety patrols and emergency response on Shasta Lake and its associated recreational areas and manages a Boating Safety Unit at the Bridge Bay Resort. SCSO staff consists of four full-time personnel and 22 seasonal deputies. An organized citizen volunteer patrol also assists with boater safety on Shasta Lake.

Fire Hazards Wildland fires pose a hazard to rural development, infrastructure, and natural resources. Climate, topography, vegetation characteristics, and ignition sources in a given area influence the degree of fire hazard. The California Department of Forestry and Fire Protection (CDF) and STNF have delineated most of the primary study area as being at very high risk for wildland fire; some areas, such as Lakehead, are at extreme risk for fire (Figure 9-1) (CDF 2005, CDF 2008, USFS 1995, WSRCD 2010).

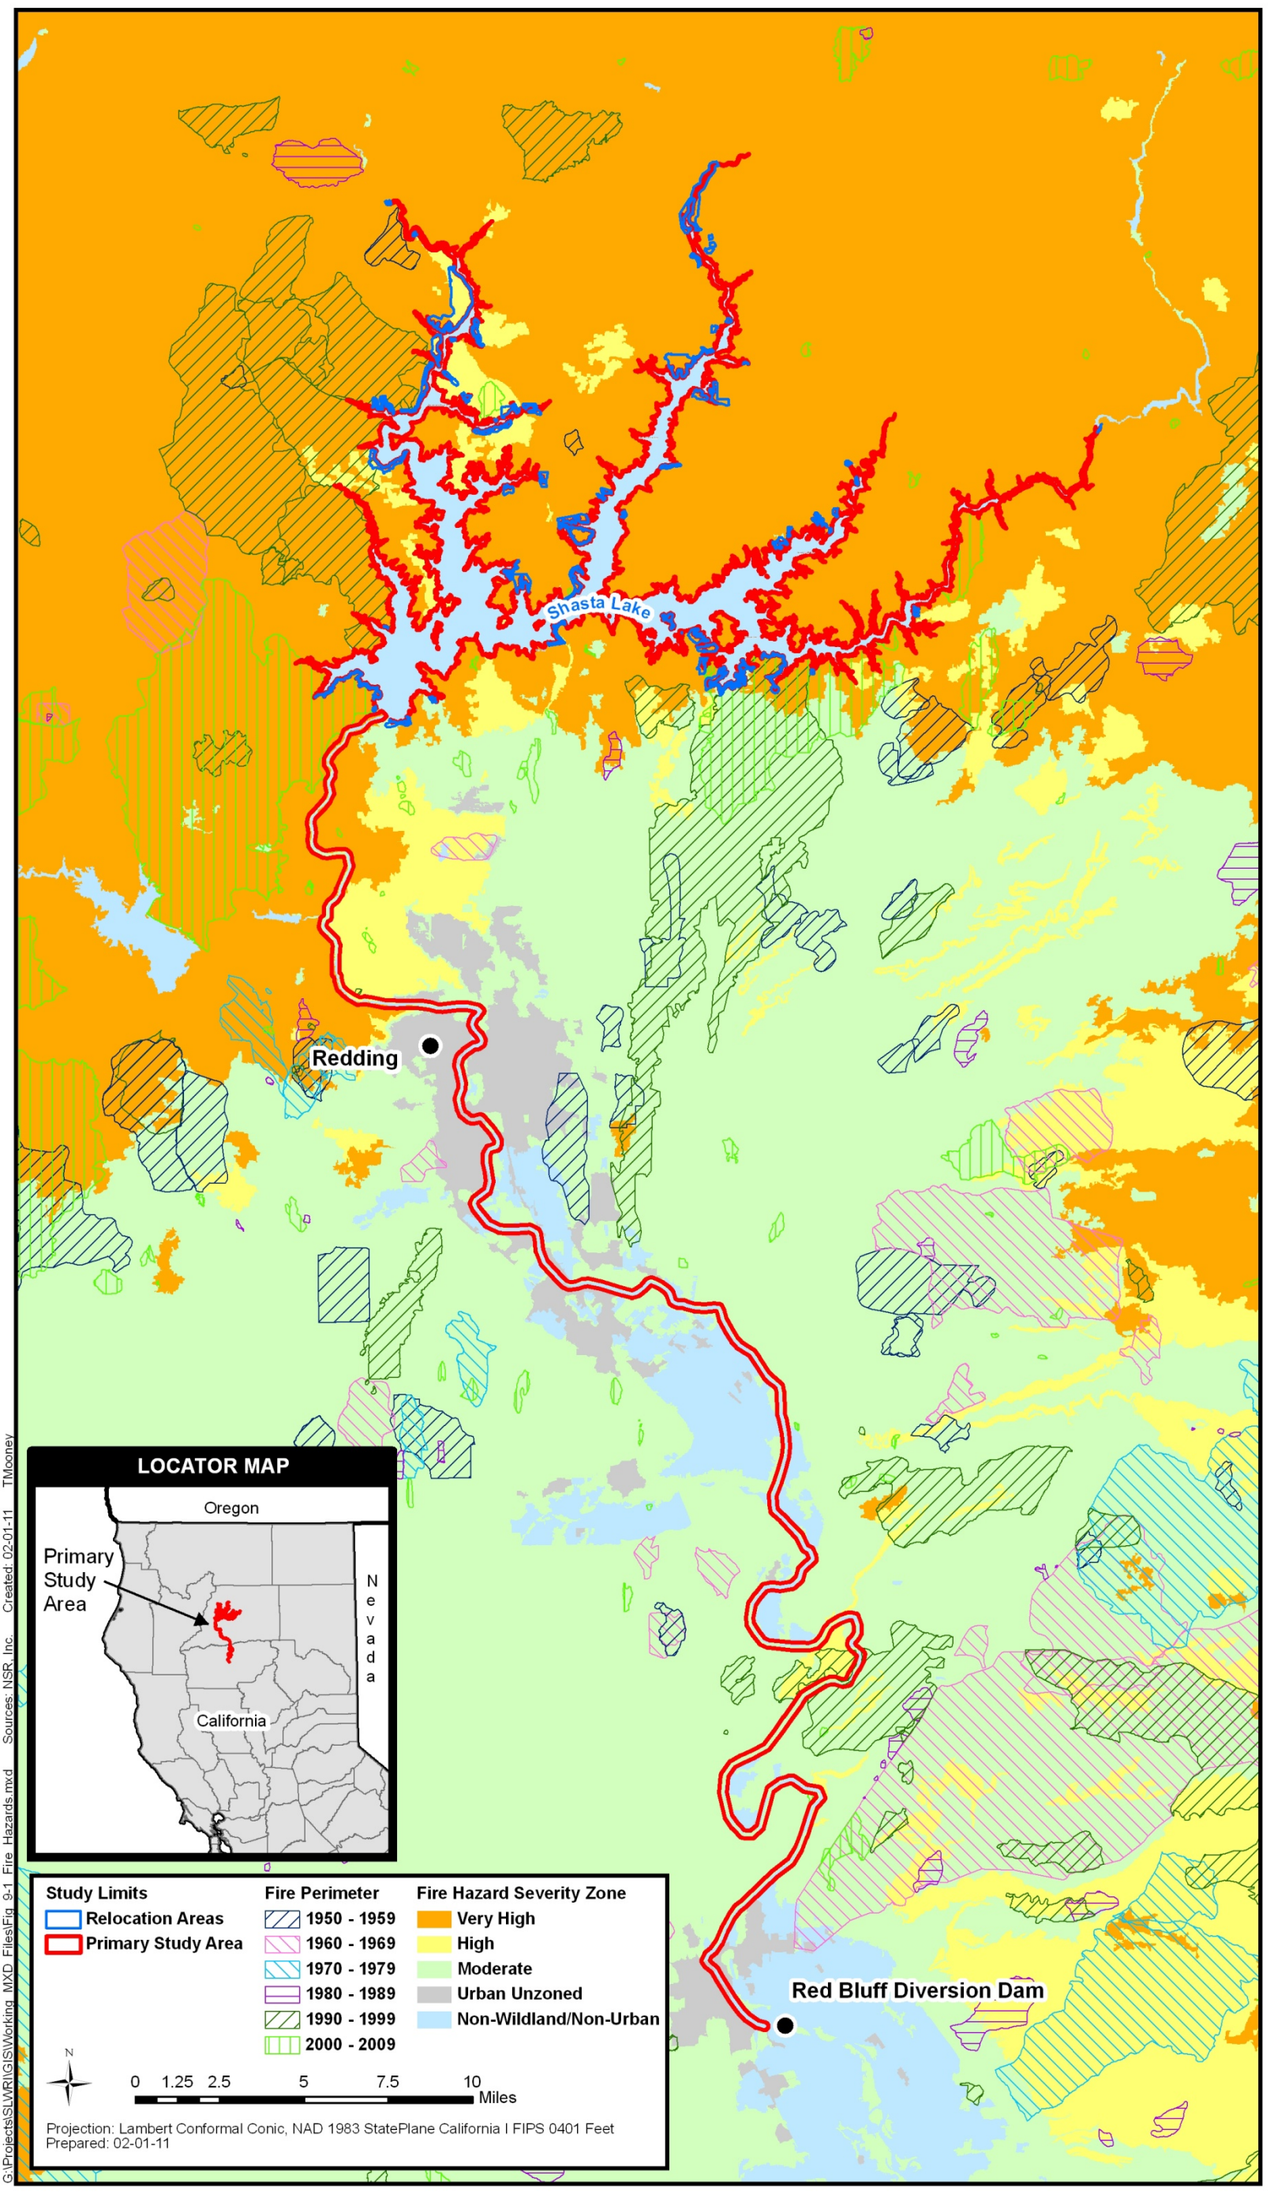

Figure 9-1. Fire Hazard Severity and Historic Fires

This page left blank intentionally.

Historic fire data show that high-intensity, stand-replacing fires commonly occur at the lower elevations surrounding Shasta Lake. Major transportation corridors cross the NRA and the area receives high recreational use, resulting in numerous human-caused fires each year (USFS 1996). During the 5-year period from 2000 through 2004, the Shasta and Trinity units of the NRA experienced 1,545 vegetation fires affecting 40,352 acres (CDF 2005). Roadside fires, abandoned campfires, and fireworks are common causes of these fires. Lightning from summer thunderstorms also causes a significant number of wildfires in and adjacent to the NRA. Large fires (more than 300 acres) that have occurred in the primary study area since 1950 are shown in Figure 9-1.

Rural and urban development has increasingly influenced the wildland fire hazard potential. Development in grasslands, oak woodlands, and forests (generally referred to as the wildland-urban interface (WUI)) and population growth have increased the risk to humans of wildland fire hazards. CDF and other fire protection agencies expect this trend to continue.

Fire suppression has had a significant effect on the volume and types of fuels across the Shasta Lake region. Extreme fire weather conditions are perpetuated by high summer temperatures and dry lightning storms; particularly along the Sacramento and McCloud arms of Shasta Lake, frequent strong zonal north winds occur during the late summer and fall months. In the past 30 years, the Lakehead area, which is along the Sacramento Arm, has experienced several major fires, including the 1999 High Complex Fire, which was eventually contained at 39,000 acres, and numerous smaller fires that were suppressed in their initial stages (WSRCD 2010).

The concentration of human activity along the McCloud Arm of Shasta Lake prompted the STNF to prepare a fire analysis as part of the McCloud Arm Watershed Analysis (USFS 1998). The fire analysis concludes that, at the time it was prepared (1998), more than 17,500 acres of forest surrounding the McCloud Arm was considered at high risk for a catastrophic fire. The fire hazard severity potential in the McCloud Arm has been designated as very high by CDF (CDF 2008).

The Jones Valley/Silverthorn area adjacent to the Pit Arm of Shasta Lake is another interface area with recognized fire hazards. In the last 12 years, two large fires have greatly affected residential and commercial developments in this area. The Bear Fire in 2004 burned 10,484 acres and destroyed 80 homes in the Jones Valley community, and the 1999 Jones Fire burned 26,020 acres and consumed 900 structures.

CDF has devised a fire hazard severity scale that considers fuel load (vegetation is the major source of fuel), climate, and topography (fire hazards increase with slope) to evaluate the level of wildfire hazard in areas where the State is primarily responsible for fire suppression (these are known as State Responsibility Areas). CDF designates three levels of fire hazard severity zones

– moderate, high, and very high – to indicate the severity of fire hazard in a particular geographical area. Based on a review of CDF's statewide map of fire hazard severity zones, the primary study area includes lands designated as high and very high (Figure 9-1) (CDF 2007).

Fuels management actions are conducted with some frequency on Federal lands in the Shasta Lake and vicinity portion of the study area. Since 2009, USFS has completed, or is currently proposing, several fuels management projects along the various arms of Shasta Lake, including the Bear Hazardous Fuels Project (Pit Arm), the Green-Horse Habitat Restoration and Maintenance Project (between the Pit and McCloud arms), the Interstate-5 Corridor Fuels Reduction Project (upper Sacramento Arm), and the Packers Bay Invasive Plant Species Removal Project (Sacramento Arm) (USFS 2009, 2011).

Upper Sacramento River (Shasta Dam to Red Bluff)

Water Safety Hazards Water safety hazards in the upper Sacramento River are similar to those in Shasta Lake and vicinity. Surface waters (i.e., Keswick Reservoir and the Sacramento River) pose hazards to persons engaging in boating and other water-based activities on these water bodies. Water hazards are posed by equipment operations, flow velocity, morphology, instream or submerged material, accessibility, and water temperature. Working in and adjacent to water bodies also poses risks to workers.

Fire Hazards Wildland and nonwildland fires present hazard risks to rural and urban development in the upper Sacramento River area. Based on a review of CDF's statewide map of fire hazard severity zones, the upper Sacramento River area includes lands designated as high and very high risk (Figure 9-1) (CDF 2007).

Human activities such as smoking, debris burning, and equipment operation cause 90 percent of the wildland fires in Shasta County, and lightning causes the remaining 10 percent. Wildland fires present a major safety hazard to rural development located in forest, brush, and grass-covered areas. Between 1992 and 2003, an average of 333 wildland fires per year occurred in Shasta County; the majority of these fires were in upland areas, where fire hazards are extreme because of an abundance of highly flammable vegetation and long, dry summers (Shasta County 2004). Large fires (more than 300 acres) that have occurred in the primary study area since 1950, including the upper Sacramento River near Shasta Dam, are shown in Figure 9-1.

Much of Tehama County, outside of the valley floor, is classified as wildland and contains substantial forest fire risks and hazards (PMC 2009). Outside of urbanized areas, fire hazard is considered to be moderate (CDF 2007). Encroachment by development into previously uninhabited areas has expanded the WUI, compounding the challenges of wildland fire management. In the portion of the project area that is in Tehama County, no large fires (greater than 300 acres) have occurred in the last 60 years (Figure 9-1) (CDF 2009), because

vegetation adjacent to the Sacramento River is not conducive to carrying wildland fire.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Water safety hazards are similar to those described for the primary study area. Fire hazard in the extended study area varies, with risk increasing proportionally with the degree of WUI. As noted previously, CDF maintains a map-based program that identifies fire hazard severity zones throughout the state. The program differentiates between State Responsibility Areas and Local Responsibility Areas. Most of the extended study area is mapped as local (or Federal) responsibility areas with moderate or unzoned fire hazard severity classifications (CDF 2008).

9.1.2 Hazardous Materials and Waste

For purposes of this section, the term "hazardous materials" refers to both hazardous substances and hazardous wastes. A hazardous material is defined in the Code of Federal Regulations (CFR) as "a substance or material that … is capable of posing an unreasonable risk to health, safety, and property when transported in commerce" (49 CFR 171.8). California Health and Safety Code Section 25501 defines a hazardous material as follows:

> *Hazardous material" means any material that, because of its quantity, concentration, or physical or chemical characteristics, poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment. "Hazardous materials" include, but are not limited to, hazardous substances, hazardous waste, and any material which a handler or the administering agency has a reasonable basis for believing that it would be injurious to the health and safety of persons or harmful to the environment if released into the workplace or the environment.*

Hazardous wastes are defined in California Health and Safety Code Section 25141(b) as wastes that

> *…because of their quantity, concentration, or physical, chemical, or infectious characteristics, [may either] cause, or significantly contribute to an increase in mortality or an increase in serious illness [or] pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed.*

Potential sources of hazardous material and waste may exist in the urbanized, rural, industrial, and agricultural portions of the study areas. Hazardous materials may be present in a variety of common contexts, including the following:

- Construction and demolition debris
- Drums
- Landfills or solid waste disposal sites
- Pits, ponds, or lagoons
- Wastewater and wastewater treatment plants
- Fill, dirt, depressions, and mounds
- Herbicides, pesticides, and fungicides
- Contaminated aggregate (mercury, dioxin)
- Explosives
- Fish hatcheries (e.g., Livingston Stone, Coleman)
- Underground storage tanks
- Stormwater runoff structures
- Transformers that may contain polychlorinated biphenyls (PCB)
- Utility poles
- Abandoned mines

Shasta Lake and Vicinity

Facilities used to store, generate, and transport hazardous materials and hazardous waste are present upstream from Shasta Dam. In addition, several inactive or abandoned mines contribute hazardous materials to Shasta Lake or its tributaries. The following discussion describes these features and facilities.

Reclamation operates the Shasta Dam facility and controls the use and movement of hazardous materials and associated hazardous waste in and out of the Shasta Dam administrative compound. Operation and maintenance of the dam and the water project facility require the use of many of the hazardous materials listed in the previous section. In addition, utility poles, transformers, and associated power transmission facilities typically contain hazardous materials.

A number of recreational facilities are located on or adjacent to Shasta Lake. These facilities include marinas, campgrounds, day use facilities, and residences for recreational use. Although several of these are privately owned, most are operated under special use permits issued by USFS. Operation and maintenance of recreational facilities involve the use of a number of substances that are considered hazardous under Federal or State statutes. Additionally, facilities that service and/or repair watercraft (e.g., marinas) generate wastes that are considered hazardous (e.g., oil, grease, solvents).

Currently, there are three underground fuel storage tanks permitted by the State Water Resources Control Board in the primary study area, all of which are in the Shasta Lake and vicinity portion of the primary study area: Holiday Harbor, Sugarloaf Marina, and Digger Bay Marina (SWRCB 2011). Also in the Shasta Lake and vicinity portion are four underground fuel storage tanks that are no longer in use due to regulatory actions resulting from documented occurrences of fuel leaks (SWRCB 2011).

The project would include the decommissioning/abandonment and/or relocation of a number of features and facilities on or adjacent to Shasta Lake. Underground and aboveground fuel storage tanks – including tanks in use and tanks no longer used – would be permanently removed from areas that would be inundated by the project. Above- and belowground fuel pipelines within the inundation area would be relocated/removed. Relocated fuel storage tanks would be designed and constructed in accordance with Title 23 of the California Code of Regulations (Division 3, Chapter 15, Underground Tank Regulations); the Uniform Fire Code; California Air Resources Board; Shasta County Development Standards, Section 6.7; and Shasta County Environmental Health Division requirements. Additionally, the age of some buildings suggests that substances such as asbestos or lead paint may be included in demolition debris.

A records search of the Federal Superfund National Priorities List (NPL) identified no sites in the Shasta Lake and vicinity portion of the study area. In its scoping comments, the Central Valley Regional Water Quality Control Board identified three sites that are currently subject to some degree of remediation. These sites are associated with the Bully Hill/Rising Star Mine and the Digger Bay and Sugarloaf marinas. All three sites may be influenced by fluctuating water levels in Shasta Lake. An additional site near the Bully Hill Mine complex contains depositional features with elevated metal concentrations that are exposed to surficial and wave erosion processes. Central Valley Regional Water Quality Control Board has also identified an abandoned mine complex west of Shasta Dam (Golinsky Mine) as a source of heavy metals and acid mine discharge that enters Shasta Lake via Dry Creek.

Interstate 5 (I-5) and Union Pacific Railroad transportation corridors are near to Shasta Lake and its tributaries. The potential exists for the accidental spill of chemicals and hazardous materials transported through these travel corridors. Transport through mountainous terrain and over water bodies, equipment failure, and improper storage and handling of hazardous materials contribute to the risk of accidental chemical spills.

The Cantara Spill is a prime example of the hazards associated with the transport of hazardous materials through the region. On July 14, 1991, a Southern Pacific train derailed upstream from Dunsmuir, sending several cars into the Sacramento River, including a tank car containing the herbicide/pesticide metam sodium (a potent chemical used principally to sterilize soil for agricultural purposes). A rupture in one of the tank cars resulted

in the catastrophic spill of approximately 19,000 gallons of the soil fumigant into the river. When mixed with water, metam sodium breaks down into several highly toxic compounds. Although the toxins formed by the mixing of metam sodium with water dissipated in a matter of hours or weeks, the immediate effects of the spill were staggering. In the upper Sacramento River, every living aquatic creature downstream from the spill died over the 20-mile stretch of river between the spill and Shasta Lake (Cantara Trustee Council 2007). On July 17, 1991, the plume, estimated to have traveled at just under 1 mile per hour, entered Shasta Lake, where the chemical was reduced to undetectable levels approximately 2 weeks later. As a result of the Cantara Spill, more than $14 million in settlement funds – administered by the Cantara Trust Council – have been available for ecosystem restoration.

Historic mining activities in the Shasta Lake and vicinity portion of the primary study area have left mine tailings piles scattered throughout the uplands surrounding the lake. These tailings piles often contain high concentrations of various metals, including iron, copper, zinc, and mercury. The discharge of these dissolved metals into waterways can have an adverse effect on water quality, aquatic ecosystems, and human health. The historic Bully Hill Mine, located along the Squaw Arm, is the only mine site that would be inundated by the project. The effects on water quality that could result from the inundation of mine tailings are discussed in detail in Chapter 7, “Water Quality.”

Upper Sacramento River (Shasta Dam to Red Bluff)

A number of business and industrial land uses in the upper Sacramento River area use and transport hazardous materials as part of their operations. Existing land uses that may have a hazardous material component include mining operations, heavy and light industrial uses, propane/petroleum fueling and/or storage facilities, and commercial and retail operations. Businesses that require storage of hazardous materials must submit a Hazardous Material Business Plan (HMBP) to the County Environmental Health Department. I-5, Union Pacific Railroad lines, and several major surface routes are used for the transportation of hazardous materials throughout the region.

Hazardous waste sites associated with agricultural activities include storage facilities and agricultural ponds or pits contaminated with fertilizers, pesticides, herbicides, or insecticides. Petroleum products and other materials may also be present in the soil and groundwater near leaking underground tanks used to store these materials. However, there are no permitted underground fuel storage tanks – Including tanks currently in use or tanks that have been subject to regulatory actions – within the project boundaries for the upper Sacramento River portion of the primary study area (SWRCB 2011).

Metals such as cadmium, copper, mercury, and zinc are present in inactive and abandoned mines in the upper Sacramento River area. Landfills and commercial activities, such as dry cleaning, could also be sources of contamination in this

region. The project would not result in the inundation of any of these potentially hazardous locations.

A records search of the U.S. Environmental Protection Agency's (EPA) NPL identified one site in the upper Sacramento River area: Iron Mountain Mine. The mine is a privately owned site southwest of Shasta Dam and 9 miles northwest of Redding. The entire mine area, which encompasses about 2,000 acres, is drained by Boulder Creek and Slickrock Creek, tributaries to Spring Creek. Spring Creek enters Keswick Reservoir several miles downstream from Shasta Dam.

From the 1860s through 1963, the 4,400-acre Iron Mountain Mine was periodically mined for iron, silver, gold, copper, zinc, and pyrite. Although mining operations were discontinued in 1963, underground mine workings, waste rock dumps, piles of mine tailings, and an open mine pit remain at the site. Historic mining activity at Iron Mountain Mine has fractured the rock units, exposing minerals to surface water, rainwater, and oxygen. Acidic mine drainage typically contains high concentrations of copper, cadmium, zinc, and other heavy metals. Much of the acidic mine drainage ultimately is channeled into Spring Creek Reservoir via adjacent creeks and constructed diversion facilities. The low pH level and the heavy metal contamination from the mine have virtually extirpated aquatic life in sections of Slickrock Creek, Boulder Creek, and Spring Creek. (Project effects on potentially contaminated historic mine waste are discussed in Chapter 7, "Water Quality".)

Reclamation periodically releases water from Spring Creek Reservoir into Keswick Reservoir. Planned releases are timed to coincide with the presence of diluting releases of water from Shasta Dam. On occasion, uncontrolled spills and excessive waste releases have occurred when Spring Creek Reservoir reaches capacity. Without sufficient dilution, these events have resulted in the release of harmful quantities of heavy metals into the Sacramento River downstream from Keswick Dam. Acid mine drainage and associated heavy-metal contamination from the Spring Creek drainage and other abandoned mine sites are among the principal water quality issues in the upper Sacramento River portion of the primary study area. In recent years, Reclamation has implemented a dredging program to restore active storage space in Keswick Reservoir, which has been reduced by the influx of sediment from the Spring Creek watershed.

In 2009, EPA began the removal of approximately 200,000 cubic yards of contaminated sediment from the Spring Creek Arm of Keswick Reservoir for disposal in an engineered disposal cell. The project was near completion at the end of 2010. EPA plans to use a hydraulic dredge to fully remove contaminated sediments located in two areas that have high erosion potential and to partially remove sediments located in a deep-water area of the Spring Creek Arm (EPA 2008).

The Livingston Stone National Fish Hatchery facility, located at the foot of Shasta Dam, is used to propagate adult winter-run Chinook salmon collected from the mainstem Sacramento River. Water from Shasta Dam is used to supply the hatchery and waste is discharged to the Sacramento River downstream from the dam. The facility's discharge is regulated under the Central Valley Water Board General Order R5-2010-0018 (National Pollutant Discharge Elimination System No. GAG135001) Waste Discharge Requirements for Cold-Water Concentrated Aquatic Animal Production Facility Discharges to Surface Waters (California RWQCB 2010).

Lower Sacramento River and Delta and CVP/SWP Study Areas

Many of the land uses in the extended study area are similar to those in the primary study area. Thus, contamination is possible from agricultural, urban, industrial, commercial, landfill, and military land uses in the region. Because the extended study area covers many counties and regions, a records search of the NPL and the California Department of Toxic Substances Control list was not conducted. Although many sites in the extended study area undoubtedly are on these lists, it is not expected that these sites would be affected by project implementation.

Facilities created by CVP/SWP for the purposes of water conservation and management include dams, powerplants, and an extensive canal system. Operation of these facilities involves the use of a variety of hazardous materials such as lubricants.

The Sacramento National Wildlife Refuge Complex consists of five national wildlife refuges and three wildlife management areas covering over 35,000 acres of wetlands and uplands, in addition to more than 30,000 acres of conservation easements. Many of the wetlands in the Sacramento Valley receive water not only from the Sacramento River, but also from agricultural runoff. Urban, industrial, agricultural, and natural sources of toxins contribute to water quality problems in the lower Sacramento River and Delta and can pose a hazard to fish and wildlife through processes such as bioaccumulation in the food chain.

A discussion of the current water quality and potential hazards to water quality associated with the project is presented in Chapter 7, "Water Quality."

9.2 Regulatory Framework

9.2.1 Federal

Federal Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (RCRA) is a Federal statute designed to provide "cradle to grave" control of hazardous waste by imposing management requirements on generators and transporters of hazardous wastes,

and on owners and operators of treatment, storage, and disposal facilities. The EPA is responsible for administering the RCRA.

Federal Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), also known as the Superfund Act, provides for the liability, compensation, cleanup, and emergency response for hazardous substances released into the environment and the cleanup of inactive hazardous waste disposal sites. CERCLA authorized the NPL, which identifies contaminated sites that are eligible for remedial action. The scope of CERCLA is broad; it holds current and prior owners and operators of contaminated sites responsible, and its definition of a hazardous substance incorporates definitions from the Clean Air Act, the Clean Water Act, the Toxic Substances Control Act, and the RCRA (CERCLA Section 101(14)). EPA is the agency responsible for administering CERCLA.

Occupational Safety and Health Act

The Occupational Safety and Health Act defines occupational health and safety standards with the goal of providing employees with a safe working environment. The California Occupational Safety and Health Administration (Cal/OSHA) is the agency responsible for administering this Federal act. The Occupational Safety and Health Administration (OSHA) regulations apply to the workplace and cover activities ranging from confined space entry to toxic chemical exposure. Employers are required to provide a workplace free of recognized hazards that could cause serious physical harm. OSHA regulates workplace exposure to hazardous chemicals and activities through workplace procedures and equipment requirements (29 U.S.C. 651-678).

Hazardous Materials Transportation Act

The Hazardous Materials Transportation Act regulates interstate transport of hazardous materials and wastes. This act specifies driver training requirements, load labeling procedures, and container design and safety requirements. Transporters of hazardous wastes must also meet the requirements of other statutes, such as the RCRA. The Hazardous Materials Transportation Act requires that carriers report accidental releases of hazardous materials to the U.S. Department of Transportation at soon as is practical (49 CFR Subchapter C). Incidents that must be reported include deaths, injuries requiring hospitalization, and property damage exceeding $50,000. U.S. Department of Transportation, the Federal Highway Administration, and the Federal Railroad Administration are the agencies responsible for administering the Hazardous Materials Transportation Act.

Code of Federal Regulations, Title 36

Title 36 of the CFR governs parks, forests, and public property in the United States. Chapter 2, Section 260, pertains to prohibited activities within the

boundaries of Federally owned lands and waters administered by the USFS. The USFS is responsible for administering the regulations described as follows.

Sec. 261.5 Fire (General Prohibitions) The following are prohibited:

- Carelessly or negligently throwing or placing any ignited substance or other substance that may cause a fire
- Firing any tracer bullet or incendiary ammunition
- Causing timber, trees, slash, brush, or grass to burn except as authorized by permit
- Leaving a fire without completely extinguishing it
- Allowing a fire to escape from control
- Building, attending, maintaining, or using a campfire without removing all flammable material from around the campfire adequate to prevent its escape

Sec. 261.52 Fire (Prohibitions in Areas Designated by Order) When provided by an order, the following are prohibited:

- Building, maintaining, attending or using a fire, campfire, or stove fire
- Using an explosive
- Smoking, except within an enclosed vehicle or building, a developed recreation site, or while stopped in an area at least 3 feet in diameter that is barren or cleared of all flammable material
- Possessing, discharging, or using any kind of firework or other pyrotechnic device

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF Land and Resource Management Plan (LRMP) contains goals, standards, and guidelines designed to guide the management of STNF. The following goals, standards, and guidelines relative to hazards and/or hazardous materials issues associated with the project area were excerpted from the LRMP (USFS 1995).

Facilities Goals (LRMP, p. 4-17)

- Provide and maintain those administrative facilities that effectively and safely serve the public and USFS work force.

Facilities Standards and Guidelines (LRMP, p. 4-17)

- Upgrade the surfacing on the forest's road system as necessary to protect the road and other resource values.

- Trails will be maintained as needed for specific management objectives. Erosion control and primary access will receive priority.

- Trails and trail bridges will be located, designed, constructed, and maintained so that they are suitable for the type of travel being served.

- Consider volcanic, seismic, flood, and slope stability hazards in the location and design of administrative and recreation facilities.

- Manage, construct, and maintain buildings and administrative sites to meet applicable codes and to provide the necessary facilities to support resource management.

- Monitor potable water sources and designated swimming areas according to the Safe Drinking Water Act and other regulatory health requirements.

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The STNF Management Guide contains management strategies intended to achieve or maintain a desired condition. These strategies take into account opportunities, management recommendations for specific projects, and mitigation measures needed to achieve specific goals. STNF is responsible for administering the following strategies related to hazards and/or hazardous materials issues associated with the project area.

Fire and Fuels (Management Guide, p. IV-1)

- Treatment of fuels created by project activities will be determined during project planning.

- Treatment of natural fuels for hazard reduction will be high priority in and around urban interface areas. Treatment of natural fuels near developed recreation sites will be a secondary priority, unless hazard and risk analysis shows a specific need.

Health and Safety (Management Guide, pp. IV-15 Through IV-16)

- Resorts/marinas are responsible for inspecting their own facilities to ensure that they comply with applicable laws, ordinances, and codes and standards for health and safety and are safe for public use. Copies of all health and safety inspections must be incorporated in the operation and maintenance plan annually and be available to the STNF.

- Marinas are required to anchor docks using underwater cables and anchor systems. Minor exceptions may be made, with STNF approval, in areas where low-speed boating is required, such as behind a marina in a semi-enclosed, restricted waterway. If cables and anchors are positioned in main travel-ways where they can come in contact with boats or people, the cables must be flagged and have warning lights so that they are visible day and night.

- Buoys and floats placed and maintained by marinas must meet the following criteria:

  – If the float or buoy is constructed of a material that will not damage a boat or cause personal injury on contact, the float or buoy must be of a contrasting color that can be easily seen. Examples are floats and buoys made of lightweight Styrofoam and plastic.

  – If the float or buoy is made of a material that could damage a boat or cause personal injury on contact, it must be of a contrasting color that can be easily seen, and must have a blinking yellow light visible from 360 degrees for night boating safety. Examples are floats and buoys made of steel or aluminum.

  – Log booms may be installed around marinas to suppress wave action at the docks. Log booms must not infringe on the main boating channels. Log booms must have yellow blinking lights installed every 100 feet on or immediately adjacent to the boom so that the boom's location is visible at night. Boating entrances through log booms or other breakwaters will display red and green navigation lights on either side of the log boom or breakwater for nighttime navigation.

  – All docks that are approved to extend out into a main boating travel-way, and are not protected by a lighted breakwater or other lighting system, must have at least one blinking yellow light for nighttime boating safety every 100 feet.

- No work that would leave pollutants in the lake when the area is inundated is permitted below the lake high-water line. Examples of this are water blasting and sand blasting pontoons and mechanical repairs that would allow oil and grease to drain on the ground.

- Resorts/marinas may restrict vehicle nighttime land access to their facilities if they can display to STNF that such action is needed to protect people and property.

Vegetation (Management Guide, p. IV-18)

- Prescribed burning, fuel break construction, and other forms of vegetation manipulation will be used to reduce fire hazards and improve forest health.

- Hazard trees in traditionally high-use recreation areas that pose safety hazards to people or property will be identified and removed.

U.S. Bureau of Land Management Resource Management Plan

The U.S. Bureau of Land Management (BLM) manages a number of public lands adjacent to the Sacramento River corridor downstream from Shasta Dam. The study area falls under two BLM districts (Northern California and Central California) and the resource management plans of three BLM field offices: Redding, Ukiah, and Mother Lode (BLM 2006a). The purpose of BLM's resource management plans is to provide an overall direction for managing and allocating public resources in each planning area. BLM is responsible for administering the following strategies related to hazards and/or hazardous materials issues common to the districts in the study area (BLM 1992, 2006b, 2008).

Wildfire Suppression Goal

- Provide an appropriate management response for all wildland fires, emphasizing firefighter and public safety.

Fuels Management Goals

- Reduce fire risk to the wildland-urban interface communities.
- Protect riparian and wetland areas.
- Improve ecological conditions and reduce the risk of catastrophic wildfire through the use of prescribed burning.
- Improve ecological conditions and reduce the risk of catastrophic wildfire through mechanical treatments.
- Increase the public's knowledge of the natural role of fire in the ecosystem, and hazards and risks associated with living in the wildland-urban interface.

Hazardous Materials

- Land use authorizations will not be issued for uses that would involve the disposal or storage of materials that could contaminate the land (e.g., hazardous waste disposal sites, landfills, rifle ranges).
- Minimize hazardous conditions on BLM lands to reduce risks to the public and ensure environmental health and safety.

9.2.2 State

Hazardous Waste Control Act

The California Hazardous Waste Control Act governs hazardous waste management and cleanup in the State (Health and Safety Code, Ch. 6.5–6.98).

The act mirrors the RCRA and imposes a "cradle to grave" regulatory system for handling hazardous waste in a manner that protects human health and the environment. It requires all businesses to report the quantity and locations of hazardous materials on an annual basis if the business stores (a) more than 55 gallons of a liquid or 500 pounds of a solid hazardous material, (b)more than 200 cubic feet of a compressed gas, or (c) a radioactive material that is handled in quantities for which an emergency plan is required. Businesses falling within these limits must prepare a HMBP, which includes spill prevention, containment and emergency response measures and a contingency plan.

County Environmental Health Departments and the California Environmental Protection Agency's (Cal/EPA) Certified Unified Program Agencies assume responsibility for enforcing local hazardous waste reporting requirements. Sites that store, handle, or transport specified quantities of hazardous materials are inspected annually. Cal/EPA, Department of Toxic Substances Control, regulates the generation, transportation, treatment, storage, and disposal of hazardous waste under the RCRA and the State Hazardous Waste Control Act.

Hazardous Substances Account Act

California enacted the Hazardous Substances Account Act (1981) to establish State authority to clean up hazardous substances releases, compensate persons injured from exposure to hazardous substances, and provide funds for payment of the State's mandatory 10 percent share of cleanup costs under the Federal Superfund law. Cal/EPA administers the State Superfund program and receives assistance from the California Department of Public Health.

Emergency Response Plan

California developed an Emergency Response Plan to facilitate and coordinate responses to emergencies. Emergency prevention and response to hazardous materials incidents are part of the State plan that is administered by the California Office of Emergency Services (OES). Coordinating agencies include Cal/EPA, California Highway Patrol (CHP), CDF, local fire departments, the California National Guard, the California Department of Transportation (Caltrans), DFG, regional water quality control boards, and other emergency service providers.

California Code of Regulations, Title 13, Vehicle Code

In addition to the RCRA hazardous waste transportation standards, California regulates the transportation of hazardous waste originating or passing through the state. State regulations are contained in the California Code of Regulations (CCR), Title 13, Vehicle Code. Hazardous waste must be regularly removed from generating sites by licensed hazardous waste transporters. Transported materials must be accompanied by hazardous waste manifests.

CHP and Caltrans are responsible for enforcing Federal and State regulations pertaining to the transport of hazardous materials through California. CHP enforces materials and hazardous waste labeling and packaging regulations that

prevent leakage and spills of material in transit and provides information to cleanup crews in the event of an incident. Vehicle and equipment inspection, shipment preparation, container identification, and shipping documentation are all part of the responsibility of CHP. CHP conducts regular inspections of licensed transporters to assure regulatory compliance. CHP and Caltrans also respond to hazardous materials transportation emergencies. Caltrans has emergency chemical spill identification teams at locations throughout the state.

Worker Safety Requirements

Regulations pertaining to the use of hazardous materials in California workplaces are provided in CCR Title 8 and include requirements for safety training, availability of safety equipment, accident and illness prevention programs, hazardous substance exposure warnings, and emergency action and fire prevention plan preparation. Cal/OSHA standards are more stringent than Federal OSHA regulations.

As described above, Cal/OSHA assumes primary responsibility for developing and enforcing workplace safety regulations in the state. Cal/OSHA enforces hazard communication program regulations that contain training and information requirements, including procedures for identifying and labeling hazardous substances, communicating information related to hazardous substances and their handling, and preparing health and safety plans to protect workers and employees at hazardous waste sites. The hazard communication program requires that material safety data sheets be available to employees and that employee information and training programs be documented.

Government Planning

California law requires that each county and city in the state adopt a general plan (Government Code Sec. 65300). The State-mandated general plans consist of development policies and objectives for the long-term physical development of counties and cities. Each general plan must include a safety element that addresses a variety of natural and human-caused hazards. At a minimum, the safety element must adopt policies related to fire safety, flooding, and geologic and seismic hazards (Government Code Sec.65302(g)).

California Building Code

In 2007, the California Building Code was amended to include regulations pertaining to fire safety. The amendments provide safety standards for new construction located in WUI areas. The building code requires landowners to maintain an area of defensible space around structures and requires the use of fire-resistant building materials. County building inspectors, CDF, and local fire agencies are responsible for enforcing the requirements (CCR Title 24, Part 2). On Federal lands, the Federal agency is responsible for ensuring that buildings and facilities meet public health and safety standards.

9.2.3 Regional and Local

County General Plans

The general plans for the counties in the primary and extended study areas contain general policies aimed at reducing the use of hazardous substances and the generation of hazardous waste and ensuring safe use and storage of hazardous materials and management of hazardous waste.

County Fire Management Plans

Fire Management Plans have been prepared for Tehama County and Shasta County (CDF and Tehama Fire-Safe Council 2005; SCFD 2007; CDF 2005). The plans tier from the California Fire Plan and are intended to be used for prefire planning, prioritization, and implementation. The plans outline cooperative efforts of local fire agencies, CDF, and fire safe councils.

9.3 Environmental Consequences and Mitigation Measures

9.3.1 Methods and Assumptions

This analysis addresses potential impacts associated with implementation of the project with respect to hazards and hazardous materials. This analysis is based on a review of planning documents applicable to the project area, consultation with appropriate agencies, and field reconnaissance.

9.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the projects. Under NEPA, the significance of an effect is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions in the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria are based on guidance provided by CEQA Guidelines (AEP 2010) and consider the context and intensity of the environmental effects as required under NEPA. Impacts concerning hazards and hazardous materials would be significant if they:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials

- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment

- Emit hazardous emissions or involve the handling of hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school

- Are located on a site that is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment

- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan

- Expose people or structures to a significant risk of loss, injury, or death involving wildland fires

9.3.3 Topics Eliminated from Further Consideration

Water safety hazards posed by the project alternatives to water-based recreationists are assessed in Chapter 18, "Recreation"; therefore, this topic has been eliminated from further analysis in this chapter. Similarly, the effects of hazardous materials on water quality are assessed in Chapter 7, "Water Quality."

9.3.4 Direct and Indirect Effects

Information on fire risk and severity was obtained from USFS and CDF. This information was used to identify specific types and locations of activities that could present a threat to the human environment as a result of wildland fires.

A regulatory database search was conducted for portions of the primary study area. The purpose of such a search was to identify sites that are associated with the documented use, generation, storage, or release of hazardous materials or petroleum products. The results also include regulatory lists of known or potential hazardous waste sites, landfills, hazardous waste generators, and disposal facilities, in addition to sites under investigation. Information provided in the database search was obtained from publicly available sources, including the following:

- Cortese List (California Department of Toxic Substances Control 2011)

- Leaking Tanks (SWRCB 2011)

- Comprehensive Environmental Response, Compensation and Liability Information System: EPA Superfund Sites (EPA 2011)

- Annual Work Plan (SWRCB et al. 2008)

No-Action Alternative

Shasta Lake and Vicinity, Upper Sacramento River (Shasta Dam to Red Bluff), Lower Sacramento and Delta, and CVP/SWP Service Areas

Impact Haz-1 (No-Action): Wildland Fire Risk Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increase in the risk of wildland fire in the project area. Therefore, the No-Action Alternative would not have an impact on wildland fire hazards in the project area. Mitigation is not required for the No-Action Alternative.

Impact Haz-2 (No-Action): Release Potentially Hazardous Materials or Hazardous Waste Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increase in hazards, hazardous materials, or hazardous waste in the project area. Therefore, the No-Action Alternative would not have an impact related to the release of hazardous materials or hazardous waste in the project area. Mitigation is not required for the No-Action Alternative.

Impact Haz-3 (No-Action): Expose Workers to Hazardous Materials Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increase in exposure of workers to hazards, hazardous materials, or hazardous waste in the project area. Therefore, the No-Action Alternative would not have an impact involving exposure of workers in the project area to hazardous materials. Mitigation is not required for the No-Action Alternative.

Impact Haz-4 (No-Action): Expose Sensitive Receptors to Hazardous Materials Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increase in hazards, hazardous materials, or hazardous waste in the project area. Therefore, the No-Action Alternative would have no impact on sensitive receptors in the project area. Mitigation is not required for the No-Action Alternative..

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP1): Wildland Fire Risk Project implementation could contribute to wildland fire risk. Project construction and operation, and the anticipated post-construction human activity in the primary study area would

increase the potential for fire ignition. Therefore, this impact is considered potentially significant.

Wildland fire in the primary study area would expose people, structures, infrastructure, and other resources to a significant risk of loss, injury, or death. Project design, implementation, and operation incorporate safety measures that prevent fire hazards. Although the construction details have not been finalized, this conclusion is based on the scope of activities involved and the fire hazard ratings (i.e., very high risk and extreme risk) in the primary study area and the relocation sites where project construction activities would occur. Construction activities would likely occur during the summer and fall months, which are generally considered a time of high fire hazard in northern California. Reclamation and its contractors would follow fire safety regulations and procedures to prevent accidental fires.

Project activities associated with the removal and relocation of utilities could pose a wildland fire hazard in the primary study area, although it is anticipated that 100 percent vegetation clearance beneath high-voltage power transmission lines (typically 60 to 230 kilovolts) will be maintained. Under CP1, approximately 31,000 feet (5.8 miles) of power transmission lines and 35,000 feet (6 miles) of telecommunications lines would require demolition and relocation to prevent inundation by the new reservoir elevation resulting from project implementation. In addition, six power towers would be demolished, and six new towers would be constructed in new locations. CP1 also involves several miles of road construction and demolition of several vehicle and railroad bridges.

Other utility relocations and/or construction proposed under CP1 include potable water facilities, gas/petroleum facilities, and wastewater facilities. Vegetation clearing would be required to varying degrees for most utility relocation/construction, some of which would be located in densely vegetated areas. During construction/relocation, the potential would exist for the ignition of fire by construction equipment operating in the area. Although the increased risk of ignition would be short term (i.e., during implementation), it would be significant. CP1 would also include demolition and construction of recreational and public service facilities.

Relevant safety codes/procedures related to fire prevention would be incorporated into the project design, and would be used during construction activities and project operation and maintenance. Safety codes and procedures would include the California Building Code; the Shasta County Fire Plan; USFS safety requirements regarding fire hazards; California Public Utilities Code General Order 95, which provides procedures for proper removal, disposal, and placement of poles, wires, and associated infrastructure; and the National Electric Safety Code (a voluntary code that provides safety procedures for electric utility installation and operation). Precautionary measures to prevent construction-related fires include locating utilities a safe distance from

vegetation and structures, proper construction of power lines, and construction worker safety training. Post-construction infrastructure operation and maintenance would follow current safety practices associated with fire prevention and would include clearing vegetation from power utility facilities and other sources using combustion engines (e.g., water pumps) on a regular basis.

Right-of-way easements obtained for transmission lines would be cleared of vegetation to provide for public and worker safety, and to provide reliable operations. The California Building Code, the National Electric Safety Code, and the Shasta County Fire Plan clearance requirements for power distribution facilities would be incorporated into the project design.

No new facilities or project construction would occur in the upper Sacramento River area, however, some aggregate material for the project might be extracted could occur downstream from Shasta Dam. In addition, flammable vegetation below Shasta Dam would readily carry a fire started elsewhere in the primary study area.

Project materials and workers traveling to the construction sites from the upper Sacramento River area could also increase the risk of fire hazard over their route. Operation of motor vehicles throughout the region, particularly when vegetation adjacent to roadways is dry, imparts a certain level of fire potential from accidental combustion (e.g., sparks), hot metal (e.g., tail pipes, motors), or traffic accidents which could result in fire.

Project activities, including those intended to mitigate impacts on vegetation, are expected to reduce the overall fuel loading around the Shasta Lake and vicinity portion of the primary study area, thereby reducing the long-term fire hazard. In addition, the project could result in additional water supplies in the primary study area, which could assist future fire responses in the primary study area.

Project activities would increase the risk of wildland fires. Therefore, this impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP1): Release Potentially Hazardous Materials or Hazardous Waste Project construction and operation would involve the transportation, use, or storage of hazardous materials. Local, State, and Federal safety codes and procedures related to hazardous material transport, handling, and disposal would be followed for project construction and operation to minimize the risk of a hazardous materials release. However, an accidental release resulting from project activities could expose the public and the environment to a significant safety hazard. Therefore, this impact is considered potentially significant.

Project facilities proposed for construction under CP1 would be located in the Shasta Lake and vicinity portion of the primary study area. Certain hazardous materials needed for construction and operation would need to be stored at the Shasta Dam facility and at other utility and infrastructure relocation sites around the primary study area. Certain hazardous materials would be used to operate equipment both during and after construction, and the construction, and operation, and maintenance of project facilities and infrastructure would require the use of potentially hazardous materials such as paint, concrete, and wood preservatives. In addition, industrial uses associated with the operation and maintenance of the modified Shasta Dam compound would require the use, storage, and routine transport of small quantities of hydraulic fluids, solvents, and other standard mechanical maintenance fluids.

Construction staging and equipment and materials storage, including storage of possible contaminants, and equipment maintenance in the primary study area would occur in areas specified by Reclamation. Staging areas would likely be located in disturbed areas or existing facilities that would be inundated after the dam is raised, such as campgrounds, recreation parking facilities, the top of Shasta Dam, and the parking area along the left wing dam. All staging areas would be located at least 100 feet from bodies of water, wherever possible. Equipment refueling and maintenance would not occur within 100 feet of water bodies, wherever possible.

Seven existing gas/petroleum facilities would be subject to inundation under CP1 and would be relocated subsequent to demolition. The existing fuel tanks would be excavated and all associated piping would be removed. Hazardous material tests and removal would be performed, as required, in accordance with Title 23 CFR, Division 3, Chapter 16: Underground Tank Regulations, and in accordance with Shasta County Environmental Health Division requirements. In addition to adherence to the directives of Title 23, relocated tanks would be designed and constructed in accordance with the Uniform Fire Code; California Air Resources Board; Shasta County Development Standards, Section 6.7 (December 1997); and Shasta County Environmental Health Division requirements. Relocated tanks would be located in cleared areas with code-mandated clearances from other facilities.

Aggregate material for the project could originate from the drawdown portion of Shasta Lake and from areas downstream from Shasta Dam (e.g., Churn Creek bottom, Clear Creek confluence, Keswick Reservoir). These materials could contain hazardous substances such as mercury or selenium. Hazardous materials released into area waterways, including Shasta Lake and many of upper Sacramento River tributaries, come from past land use activities (e.g., mining) or natural sources (e.g., asbestos, selenium) and are likely to be trapped in lake-bottom, river, or floodplain sediments.

Aggregate extraction could also require operation of heavy equipment next to and in Shasta Lake or the upper Sacramento River. Reclamation may use

aggregate supplies from Shasta Lake or the upper Sacramento River floodplain for dam construction materials in the general vicinity of Bridge Bay Marina and Lakeshore Drive. Several additional aggregate sources near the existing shoreline of Shasta Lake are also being considered (e.g., Bass Mountain, Stillwater Creek valley, Gray Rocks). Excavation and extraction of aggregate from these sources, or the augmentation of gravel in the Sacramento River, would require the use of construction equipment, which would involve the use of various hazardous materials such as fuel, oils, grease, and other petroleum products. These contaminants could be introduced into water systems, either directly or through surface runoff.

Project implementation could result in dam operations that would inundate abandoned or inoperative mines located next to Shasta Lake. Areas adjacent to the Bully Hill/Rising Star property contain hazardous materials that would affect Shasta Lake. The effects of CP1 on mines in the primary study area and the upper Sacramento River are discussed in Chapter 7, "Water Quality."

Four vehicle bridges would be removed under CP1: Charlie Creek Bridge, Doney Creek Bridge, McCloud River Bridge, and Didallas Creek Bridge. Bridge demolition, as well as the demolition of other structures and facilities that would be inundated under CP1, could require handling of hazardous waste including asbestos, lead paint, and wood preservatives. This hazardous waste, along with any additional forms of hazardous waste materials generated by project construction, would be removed to an approved landfill for disposal per permit requirements. Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code, Section 32000, which requires proper packaging and licensing by hazardous materials haulers.

Although the environmental commitments for all action alternatives include the development and implementation of a Construction Management Plan, Erosion and Sediment Control Plan, Stormwater Pollution Prevention Plan, and Revegetation Plan as well as water quality and fisheries conservation measures and compliance with all required permit terms and conditions, the accidental release of hazardous materials or waste could expose the public and the environment to a significant safety hazard. Therefore, this impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP1): Expose Workers to Hazardous Materials Project implementation could result in the exposure of workers to hazardous materials. The project would require the use of potentially hazardous materials to operate construction equipment and to construct various facilities. Reclamation and project contractors would follow local, State, and Federal regulations and procedures for properly transporting, handling, and storing hazardous materials and hazardous waste to decrease the risk of exposure; however, there is a possibility of accidents that could expose project workers to hazardous materials. Structures proposed for demolition, such as bridges, may contain

asbestos, lead paint, toxic wood preservatives, or other hazardous substances. Fuel tanks and utility infrastructure (e.g., transformers containing PCBs) proposed for relocation also would involve some risk of exposure to hazardous substances. However, at this time it appears that the quantities and types of hazardous materials and possible exposure levels to these materials in the workplace would not pose a significant risk to worker health and safety. Furthermore, there are no known hazardous waste sites in the primary study area. Therefore, this impact would be less than significant.

Project workers would be required to transport hazardous materials at various times, in various quantities, and for various stages of project development. I-5 and local roadways would be used to transport hazardous materials and hazardous waste to and from Shasta Lake and vicinity during construction and dam operations. Traffic accidents or equipment failure could expose project workers to hazardous materials. Reclamation and contractors would follow appropriate safety procedures to minimize these risks.

Project construction activities associated with utility line removal and relocation could expose workers to health risks associated with wood preservatives used on wooden utility poles and PCBs, which are commonly found in transformers. Approximately 66,000 feet of power and telecommunication lines and six power towers would be demolished and relocated to avoid inundation resulting from the proposed change in Shasta Lake's elevation. A large number of wooden utility poles would be demolished and relocated outside of the inundation area. Construction activities associated with utility demolition and relocation are estimated to take 3 to 4 years. During that time, workers handling utility poles and transformers would follow protocols to minimize exposure to hazardous material and hazardous waste.

Aggregate extraction from sites in the primary study area that may contain hazardous materials entrained in sediments, such as mercury, could result in the exposure of workers to toxic substances. During construction, workers involved in gravel extraction activities would follow protocols to minimize exposure to hazardous materials.

Shasta Dam operations could expose workers at the facility to hazardous materials. Dam operations require the use of fuels, oils, greases, and solvents. Additional amounts of hazardous materials, beyond the volumes required for operation of the existing structure, may be needed to operate the expanded raised dam structure. Reclamation would update its HMBP and would ensure that its employees follow Cal/EPA and OSHA standards for handling hazardous waste.

In summary, the quantities and types of hazardous materials and possible exposure levels to these materials in the workplace would not pose a significant risk to worker health and safety. Furthermore, there are no known hazardous

waste sites in the primary study area. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP1): Expose Sensitive Receptors to Hazardous Materials Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. Travel routes to and from the primary study area are limited (i.e., there are few roads); thus, construction traffic would have to use I-5 and local roads, such as Shasta Dam Boulevard and/or Lake Boulevard. A school and park, as well as numerous homes, are located in Shasta Lake City at the intersection of Shasta Dam Boulevard and Lake Boulevard, about 4 miles from Shasta Dam. Project activity would occur while school is in session. The park is open to the public year around. This park is the primary venue for a number of youth and adult sport programs. Although Reclamation would implement measures to lessen the risk of hazardous materials exposure to sensitive receptors, this impact is considered potentially significant.

Aside from scattered residential and recreation areas throughout the primary study area, it does not appear that any other sensitive receptors (e.g., hospitals, schools) in the primary study area would be placed at risk of exposure to hazardous materials as a result of the project. Project implementation would follow local, State, and Federal regulations and procedures regarding the transport of hazardous materials. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Haz-5 (CP1): Wildland Fire Risk No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. Construction materials would be transported and workers would travel to the extended study area from outlying areas via I-5. The potential would exist for truck and vehicular traffic associated with the project to ignite a fire as the result of an accident, a spark, or overheating. However, traffic accidents and fires ignited along roadways typically receive quick local emergency assistance, which includes fire protection. This typical response significantly decreases the potential for a wildland fire being accidentally ignited by project-related traffic. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP1): Release Potentially Hazardous Materials or Hazardous Waste No new facilities or project construction would occur in the extended study area that would directly or indirectly result in the release of hazardous material or waste. Although hazardous materials used for or generated by the project in the primary study area may be transported through the extended study area, the potential for their release into the environment is less than significant. Hazardous waste generated by the project in the primary study area would likely be disposed of in landfills in the extended study area, and would likely include

utility poles, transformers, asbestos, or lead-based paint. Construction equipment would also generate petroleum product waste. Petroleum products would likely be reclaimed in the primary study area. Other hazardous waste would go to one of three EPA-certified commercial hazardous waste landfills in the state. They are all located in Kings, Kern, and Imperial counties.

Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code, Section 32000, which requires proper packaging and licensing by hazardous materials haulers and approved by Caltrans. Highly explosive hazardous waste and large amounts of liquid hazardous waste or are not anticipated to be transported out of the primary study area for disposal. This impacts is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP1): Expose Workers to Hazardous Materials Project implementation would not result in new facilities or construction in the extended study area. Workers may be required to transport hazardous materials through the extended study area for project purposes and could be exposed to the materials in the case of an accidental spill. However, hazardous material transport and safety procedures for hazardous material transported through the extended study area would be sufficient to minimize risks to workers. Workers involved in hazardous waste disposal activities would follow Cal/EPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-8 (CP1): Expose Sensitive Receptors to Hazardous Materials or Hazardous Waste No new facilities or project construction would occur in the extended study area that would directly or indirectly result in the exposure of sensitive receptors to hazardous materials or hazardous waste. Therefore, this impact is considered less than significant.

Hazardous materials needed for construction or operation of the project and hazardous waste generated in the primary study area would be transported through the extended study area. Accidental spills of hazardous materials or waste during transport is possible; however, hazardous waste haulers and hazardous materials suppliers would adhere to all safety precautions and regulations pertaining to hazardous material and hazardous waste transport. These actions would minimize the risk of exposure to hazardous materials or hazardous waste by sensitive receptors in the extended study area. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP2): Wildland Fire Risk This impact would be similar to Impact Haz-1 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Activities that could result in wildland fire risks would be the same as those discussed for Impact Haz-1 (CP1). However, the larger inundation area proposed under CP2 would require that more utilities, public service, and recreational facilities to be demolished and relocated than under CP1, and would require more vegetation to be cleared within inundation area. The additional construction and mechanized vegetation clearing associated with CP2 would require prolonged operation of construction equipment in vegetated areas and increase the potential for fire ignition from motor vehicle operation and the presence of charged utility lines in areas with a high fire hazard potential. A proposed increase in the number of campground/day use recreation areas (216 versus 178 for CP1) would increase the potential for wildfire ignition. Therefore, this impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP2): Release Potentially Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-2 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). However, the amount of potentially hazardous materials required for construction and operation of the project, and the volume of hazardous waste generated by project construction, could be greater for CP2 than for CP1. The number of bridge relocations, aggregate extraction or augmentation actions, and operations and maintenance of CP2 would be similar to those of CP1. Infrastructure relocation actions would require that land- and water- based construction and maintenance equipment operate in and adjacent to Shasta Lake and other potentially sensitive areas. Hazardous materials from leaking equipment, improper handling, or accidental spills could enter the lake, waterways, or adjacent land. Also under CP2, nine gas/petroleum tanks would be excavated and relocated to avoid inundation. Therefore, this impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP2): Expose Workers to Hazardous Materials This impact would be similar to Impact Haz-3 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). CP2 would require the use of potentially hazardous materials during construction, operation, and maintenance of the project. The larger scale of CP2 compared to CP1 would also generate a larger volume of hazardous waste resulting from utility line and infrastructure demolition. However, workers involved in hazardous waste disposal activities would follow Cal/EPA and OSHA hazardous material and waste handling rules and regulations. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP2): Expose Sensitive Receptors to Hazardous Materials This impact would be similar to Impact Haz-4 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. Travel routes to and from the primary study area are limited (i.e., there are few roads); thus, construction traffic would have to use I-5 and local roads, such as Shasta Dam Boulevard and/or Lake Boulevard. A school and park, as well as numerous homes are located in Shasta Lake City at the intersection of Shasta Dam Boulevard and Lake Boulevard, about 4 miles from Shasta Dam. Although the scale of project actions proposed under CP2 would be larger than that of CP1, the primary study area would remain the same. Therefore, this impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Haz-5 (CP2): Wildland Fire Risk This impact would be similar to Haz-5 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. The potential for an increased risk of fire resulting from haul trucks associated with the project would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP2): Release Potentially Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-6 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would result in the direct or indirect release of hazardous material or waste. The potential for an increased risk of hazardous materials spills resulting from haul trucks associated with the project would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP2): Expose Workers to Hazardous Materials This impact would be similar to Impact Haz-7 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. Project implementation would not result in new facilities or construction in the extended study area. Workers involved in hazardous waste disposal activities would follow Cal/EPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-8 (CP2): Expose Sensitive Receptors to Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-8 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that

would result in the direct or indirect exposure of sensitive receptors to hazardous materials or hazardous waste. The potential for the exposure of sensitive receptors to hazard materials or waste associated with the project would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP3): Wildland Fire Risk This impact would be similar to Impact Haz-1 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). However, the larger inundation area proposed under CP2 would require that more utilities, public service, and recreational facilities to be demolished and relocated than under CP1, and would require more vegetation to be cleared within inundation area. The larger scale of utility line and road construction, and the vegetation clearing and grubbing associated with CP3, would require prolonged operation of construction equipment in vegetated areas and increase the potential for fire ignition that comes from motor vehicle operation and the presence of charged utility lines in areas with a high fire hazard potential. A proposed increase in the number of campground/day use recreation areas (254 versus 178 (CP1) or 216 (CP2)) would also increase the potential for wildfire ignition. This impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP3): Release Potentially Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-2 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). However, the amount of potentially hazardous materials required for construction and operation of the project and the volume of hazardous waste generated by project construction could be greater for CP3 than either CP1 or CP2. The number of bridge relocations, aggregate extraction or augmentation actions, and operations and maintenance of CP3 would be similar to those of CP1 and CP2. However, infrastructure relocation actions would require that land- and water-based construction and maintenance equipment operate in and adjacent to Shasta Lake and other potentially sensitive areas. Hazardous materials from leaking equipment, improper handling, or accidental spills could enter the lake, waterways, or adjacent land. Under CP3, nine gas/petroleum tanks would be excavated and relocated to avoid inundation. This impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP3): Expose Workers to Hazardous Materials This impact would be similar to Impact Haz-3 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). CP3 would require the use of potentially hazardous materials during construction, operation, and maintenance of the project. The larger scale of CP3 compared to CP1 or CP2

would also generate a larger volume of hazardous waste resulting from utility line demolition. However, workers involved in hazardous waste disposal activities would follow Cal/EPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP3): Expose Sensitive Receptors to Hazardous Materials This impact would be similar to Impact Haz-4 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. Travel routes to and from the primary study area are limited (i.e., there are few roads); thus, construction traffic would have to use I-5 and local roads, such as Shasta Dam Boulevard and/or Lake Street. A school and park, as well as numerous homes, are located in Shasta Lake City at the intersection of Shasta Dam Boulevard and Lake Boulevard, about 4 miles from Shasta Dam. Although the scale of project actions proposed under CP3 would be larger than that of CP1 or CP2, the primary study area would remain the same. Therefore, this impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Haz-5 (CP3): Wildland Fire Risk This impact would be similar to Haz-5 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. The potential for an increased risk of fire resulting from haul trucks and construction traffic associated with the project would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP3): Release Potentially Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-6 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would result in the direct or indirect release of hazardous material or waste. The potential for an increased risk of hazardous materials spills resulting from haul trucks associated with the project would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP3): Expose Workers to Hazardous Materials This impact would be similar to Impact Haz-7 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. Project implementation would not result in new facilities or construction in the extended study area. Workers involved in hazardous waste disposal activities would follow Cal/EPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact is considered less than significant.

Impact Haz-8 (CP3): Expose Sensitive Receptors to Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-8 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would result in the direct or indirect exposure of sensitive receptors to hazardous materials or hazardous waste. The potential for the exposure of sensitive receptors to hazardous materials or waste associated with the project would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP4): Wildland Fire Risk This impact would be similar to Impact Haz-1 (CP3), except that vehicles and equipment involved in the gravel augmentation activities and Reading Island habitat restoration project along the upper Sacramento River would slightly increase the potential for wildland fires. This impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP4): Release Potentially Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-2 (CP3), except that vehicles and equipment involved in the gravel augmentation activities and Reading Island habitat restoration project along the upper Sacramento River would slightly increase the potential for release of hazardous materials or waste.

Under CP4, the major components described for CP3 would be implemented, but the project focus would be on increasing habitat for anadromous fish. Gravel may be augmented at points along the Sacramento River downstream from Shasta Dam to create fish habitat. Aggregate extraction and/or augmentation activities under CP4 could release hazardous substances (e.g., mercury) entrained in these gravels into the water. Also, gravel augmentation and the Reading Island habitat restoration project could cause hazardous materials from leaking equipment, improper handling, or accidental spills could enter nearby waterways or adjacent land. This impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP4): Expose Workers to Hazardous Materials This impact would be similar to Impact Haz-3 (CP3), except that gravel augmentation activities and the Reading Island habitat restoration project along the upper Sacramento River would slightly increase the potential for the exposure of workers to hazardous materials or hazardous waste. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP4): Expose Sensitive Receptors to Hazardous Materials This impact would be similar to Impact Haz-4 (CP1) and similar to Impact Haz-4 (CP3) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Under CP4, the major components described for CP3 would be implemented, but the project focus would be on increasing habitat for anadromous fish. No additional actions are proposed that would affect the potential for the exposure of sensitive receptors to hazardous materials or hazardous waste. This impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Haz-5 (CP4): Wildland Fire Risk This impact would be similar to Haz-5 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. The potential for an increased risk of fire resulting from haul trucks or construction traffic associated with the project would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP4): Release Potentially Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-6 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would result in the direct or indirect release of hazardous material or waste. The potential for an increased risk of hazardous materials spills resulting from haul trucks associated with the project would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP4): Expose Workers to Hazardous Materials This impact would be similar to Impact Haz-7 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. Project implementation would not result in new facilities or construction in the extended study area. Workers involved in hazardous waste disposal activities would follow Cal/EPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-8 (CP4): Expose Sensitive Receptors to Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-8 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would result in the direct or indirect exposure of sensitive receptors to hazardous materials or hazardous waste. The potential for the exposure of sensitive receptors to hazard materials or waste associated with the project

would be negligible. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP5): Wildland Fire Risk This impact would be similar to Impact Haz-1 (CP4) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). This impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP5): Release Potentially Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-2 (CP4) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Under CP5, the major components described for CP3 would be implemented, but as described under CP4, the project focus would be a combination of increasing water supply availability, enhancing environmental resources in the primary study area, and maintaining the existing level of recreational opportunities. No additional actions are proposed that would affect the potential for the release of hazardous materials or hazardous waste. This impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP5): Expose Workers to Hazardous Materials This impact would be similar to Impact Haz-3 (CP3) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Under CP5, the major components described for CP3 would be implemented, but the project focus would be a combination of increasing water supply availability, enhancing environmental resources in the primary study area, and maintaining the existing level of recreational opportunities. No additional actions are proposed that would affect the potential for the exposure of workers to hazardous materials or hazardous waste. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP5): Expose Sensitive Receptors to Hazardous Materials This impact would be similar to Impact Haz-4 (CP3) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Under CP5, the major components described for CP3 would be implemented, but the project focus would be a combination of increasing water supply availability, enhancing environmental resources in the primary study area, and maintaining the existing level of recreational opportunities. No additional actions are proposed that would affect the potential for the exposure of sensitive receptors to hazardous materials or hazardous waste. This impact is considered potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Haz-5 (CP5): Wildland Fire Risk This impact would be similar to Haz-5 (CP1) for the lower Sacramento River and Delta and the CVP/SWP

service areas. No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP5): Release Potentially Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-6 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would result in the direct or indirect release of hazardous material or waste. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP5): Expose Workers to Hazardous Materials This impact would be similar to Impact Haz-7 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. Project implementation would not result in new facilities or construction in the extended study area. Therefore, this impact is considered less than significant.

Impact Haz-8 (CP5): Expose Sensitive Receptors to Hazardous Materials or Hazardous Waste This impact would be similar to Impact Haz-8 (CP1) for the lower Sacramento River and Delta and the CVP/SWP service areas. No new facilities or project construction would occur in the extended study area that would result in the direct or indirect exposure of sensitive receptors to hazardous materials or hazardous waste. Therefore, this impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

9.3.5 Mitigation Measures

Table 9-1 presents a summary of mitigation measures for hazards and hazardous materials and waste.

Table 9-1. Summary of Mitigation Measures for Hazards and Hazardous Materials and Waste

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Haz-1: Wildland Fire Risk (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Haz-2: Release Potentially Hazardous Materials or Hazardous Waste (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS

Notes:
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts Haz-3, or Impacts Haz-5 through Haz-8. Mitigation is provided below for other impacts of CP1 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP1): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards Reclamation will coordinate all proposed road closures, detours, and traffic control measures with SCSO and Tehama County Sheriff's Office, which are the designated OES for the primary study area.

Reclamation will also coordinate all proposed road closures, detours, and traffic control measures with USFS, Caltrans, CHP, the City of Shasta Lake, and the surrounding Shasta Lake communities.

Reclamation will appoint a public liaison to communicate construction schedules, road closures, and project activities with the public. The liaison will organize and conduct public meetings for communicating project information. The liaison will meet with all affected public services agencies to coordinate public meetings and information exchanges.

Reclamation will meet with public services agencies to determine that traffic controls for infrastructure, utility, and structure relocation do not impede emergency access for wildland fire response capabilities.

Reclamation will require that all project workers receive fire prevention safety training, which identifies local wildland fire hazards and informs workers of the relevant fire prevention procedures, rules, and regulations.

Implementation of this mitigation measure will reduce Impact Haz-1 (CP1) to less than significant.

Mitigation Measure Haz-2 (CP1): Reduce Potential for Release of Hazardous Materials and Waste Reclamation will update the Shasta Dam facilities HMBP (or like document). The update will provide information regarding the hazardous materials used for project implementation and hazardous waste that would be generated.

Reclamation will coordinate hazardous materials and waste information with SCSO and the Tehama County Sheriff's Office (the designated OES for the primary study area), USFS, the City of Shasta Lake, and the surrounding Shasta Lake communities. Transportation coordination efforts will also include CHP

and Caltrans, and will include disclosing and planning proposed hazardous material transportation routes to ensure use of the route(s) having the least impact.

Reclamation will appoint a public liaison to communicate hazardous material transportation routes related to project activities with the public. The liaison will organize and conduct public meetings, which will include discussions of hazardous waste transport in the primary and extended study areas. The liaison will meet with all affected public services agencies to coordinate public meetings and information exchanges.

Project workers who may come into contact with hazardous materials or waste will be required to receive hazardous material safety training, which identifies hazardous materials on the project site and informs workers of the relevant safety procedures, rules, and regulations that address hazardous waste handling, storage, and transportation.

Reclamation will ensure that project construction sites have staging areas that minimize potential hazardous waste releases and that meet best management practices for short-term construction site hazardous material storage.

Implementation of this mitigation measure will reduce Impact Haz-2 (CP1) to less than significant.

Mitigation Measure Haz-4 (CP1): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste Reclamation will coordinate hazardous materials transportation routes with the SCSO and the Tehama County Sheriff's Office, which are the designated OES for the primary study area, USFS, Caltrans, CHP, the City of Shasta Lake, a representative from the Shasta Lake elementary school, and each county OES office that would be affected in the primary and extended study areas. Coordination efforts will include disclosing and planning proposed hazardous material transportation routes and schedules to allow for site-specific modifications that would lessen the potential impact on sensitive receptors.

Reclamation will appoint a public liaison to communicate hazardous material transportation routes related to project activities with the public. The liaison will organize and conduct public meetings, which will include a discussion of hazardous waste transport near local sensitive receptors. The liaison will meet with all affected public services agencies to coordinate public meetings and information exchanges.

Reclamation will identify sensitive receptor sites for all project workers who would use, handle, or transport hazardous materials, and require workers transporting hazardous materials past the sensitive receptors to proceed with extreme caution.

Reclamation will place road signs identifying sensitive receptor sites for hazardous material haulers and post reduced speed limits if local jurisdictions find it necessary to prevent potential impacts.

Implementation of this mitigation measure will reduce Impact Haz-4 (CP1) to less than significant.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts Haz-3, or Impacts Haz-5 through Haz-8. Mitigation is provided below for other impacts of CP2 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP2): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards This mitigation measure is identical to Mitigation Measure Haz-1 (CP1). Implementation of this mitigation measure will reduce Impact Haz-1 (CP2) to less than significant.

Mitigation Measure Haz-2 (CP2): Reduce Potential for Release of Hazardous Materials and Waste This mitigation measure is identical to Mitigation Measure Haz-2 (CP1). Implementation of this mitigation measure will reduce Impact Haz-2 (CP2) to less than significant.

Mitigation Measure Haz-4 (CP2): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste This mitigation measure is identical to Mitigation Measure Haz-4 (CP1). Implementation of this mitigation measure will reduce Impact Haz-4 (CP2) to less than significant.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts Haz-3, or Impacts Haz-5 through Haz-8. Mitigation is provided below for other impacts of CP3 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP3): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards This mitigation measure is identical to Mitigation Measure Haz-1 (CP1). Implementation of this mitigation measure will reduce Impact Haz-1 (CP3) to less than significant.

Mitigation Measure Haz-2 (CP3): Reduce Potential for Release of Hazardous Materials and Waste This mitigation measure is identical to Mitigation Measure Haz-2 (CP1). Implementation of this mitigation measure will reduce Impact Haz-2 (CP3) to less than significant.

Mitigation Measure Haz-4 (CP3): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste This mitigation measure is identical to Mitigation Measure Haz-4 (CP1). Implementation of this mitigation measure will reduce Impact Haz-4 (CP3) to less than significant.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is required for Impacts Haz-3, or Impacts Haz-5 through Haz-8. Mitigation is provided below for other impacts of CP2 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP4): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards This mitigation measure is identical to Mitigation Measure Haz-1 (CP1). Implementation of this mitigation measure will reduce Impact Haz-1 (CP4) to less than significant.

Mitigation Measure Haz-2 (CP4): Reduce Potential for Release of Hazardous Materials and Waste This mitigation measure is identical to Mitigation Measure Haz-2 (CP1). Implementation of this mitigation measure will reduce Impact Haz-2 (CP4) to less than significant.

Mitigation Measure Haz-4 (CP4): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste This mitigation measure is identical to Mitigation Measure Haz-4 (CP1). Implementation of this mitigation measure will reduce Impact Haz-4 (CP4) to less than significant.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impacts Haz-3, or Impacts Haz-5 through Haz-8. Mitigation is provided below for other impacts of CP2 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP5): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards This mitigation measure is identical to Mitigation Measure Haz-1 (CP1). Implementation of this mitigation measure will reduce Impact Haz-1 (CP5) to less than significant.

Mitigation Measure Haz-2 (CP5): Reduce Potential for Release of Hazardous Materials and Waste This mitigation measure is identical to Mitigation Measure Haz-2 (CP1). Implementation of this mitigation measure will reduce Impact Haz-2 (CP5) to less than significant.

Mitigation Measure Haz-4 (CP5): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste This mitigation

measure is identical to Mitigation Measure Haz-4 (CP1). Implementation of this mitigation measure will reduce Impact Haz-4 (CP5) to less than significant.

9.3.6 Cumulative Effects

Potentially significant effects were identified in the areas of increased wildland fire risk, accidental releases of hazardous materials or hazardous waste; and potential exposure of sensitive receptors to hazardous materials or hazardous waste. The potential effects would be of greater magnitude and duration with the larger dam raises (i.e., CP3 through CP5 would have greater potential effects than CP1 and CP2).

Reasonably foreseeable actions in the Shasta Lake and vicinity area, such as the construction of Antlers Bridge or the Iron Mountain Mine Restoration Plan, may result in increased potential for wildland fire hazards or accidental releases of hazardous materials or hazardous waste within the primary study area. In addition, as described in the Climate Change Projection Appendix, climate change could result in less precipitation through the 2050s and warmer air temperature, thereby increasing the risk of wildland fire hazard in the vicinity of Shasta Lake.

Implementation of the proposed SLWRI alternatives would result in potentially significant impacts to wildland fire hazards, accidental releases of hazardous materials or hazardous waste, and exposure of sensitive receptors to hazardous materials or hazardous waste. Additive and interactive/multiplicative effects of implementing the proposed SLWRI alternatives with past, present, and reasonably foreseeable probable future projects could result in cumulatively considerable impacts. However, mitigation would be used to reduce impacts associated with the project to a less than significant level. Therefore, the potential for project-related impacts to be cumulatively considerable after mitigation would be less than significant.

The exposure of workers to hazards, hazardous materials, or hazardous waste would not be a cumulatively considerable effect. Implementation of the proposed SLWRI alternatives would not be likely to involve the same workers or occur in the same place or time. Therefore, project implementation would not likely be associated with significant cumulative effects in terms of exposing workers and other sensitive receptors to hazards, hazardous materials, or hazardous waste.

Chapter 10
Agriculture and Important Farmland

10.1 Affected Environment

This section describes the affected environment related to existing agricultural land uses, Important Farmland, Williamson Act contract lands, and forest resources in the primary and extended study areas. See Chapter 12, "Botanical Resources and Wetlands," for detailed definitions of forest land habitats and Chapter 13, "Wildlife Resources," for a discussion of the relationship between agricultural land uses and wildlife uses. See Chapter 17, "Land Use and Planning," for a discussion of existing land uses within the primary and extended study area and the project's consistency with existing land uses.

10.1.1 Agriculture

Shasta Lake and Vicinity

The setting for agricultural resources in the Shasta Lake and vicinity portion of the primary study area consists of areas in Shasta County north of Shasta Dam, including lands surrounding the lake, that would be subject to inundation and areas where infrastructure would be removed, modified, or relocated under the five action alternatives.

Shasta Lake is surrounded by mountainous and rugged terrain. There are no known agricultural uses adjacent to the lake or in its immediate vicinity above Shasta Dam.

Upper Sacramento River (Shasta Dam to Red Bluff)

The upper Sacramento River portion of the primary study area consists of the portion of Shasta County south of Shasta Dam and downstream to Red Bluff in Tehama County. The valleys of the Sacramento River and its tributaries (Churn, Cottonwood, Anderson, Stillwater, Cow, Bear, Battle, and Clover creeks) contain some of the most productive agricultural land in Shasta and Tehama counties. In addition to the high quality of their soils, agricultural lands in this area enjoy a long growing season of 172-205 days. Water from the Anderson-Cottonwood Irrigation District (ACID), surface diversions of streams, or groundwater is available and good transportation access exists (Shasta County 2004). As of 2002, Shasta County's 1,126 farms encompassed a total of almost 333,828 acres and Tehama County's 1,573 farms were located on 862,440 acres. About 20,000 acres of Important Farmland are located in the Sacramento River corridor between Shasta Dam and the Red Bluff Diversion Dam. Please see Section 10.1.2, "Important Farmland," below for further discussion.

The majority of agricultural activity is located on the Sacramento Valley floor in the south-central portion of Shasta County and across central Tehama County. Small pockets of pastureland exist throughout Shasta County, including mountainous regions. Based on production value, the largest use of agricultural land in Shasta County is field crops, followed by livestock. Nursery stock is the third largest use. Approximately 13 percent of Shasta County land is devoted to some type of agricultural use.
