Agricultural uses in the Tehama County portion of the Sacramento Valley consist mostly of orchard and nursery plant operations. The primary crops of Tehama County orchards are walnuts, prunes, almonds, or olives. These crops are largely concentrated in the floodplain alongside the Sacramento River (within and below the upper Sacramento River portion of the primary study area) and are irrigated with groundwater, as well as surface water from local creek diversions and the Sacramento River.

A drastic increase in orchard acreage has occurred since orchard production was initially reported by the National Agricultural Statistics Service in 1930. A combination of factors is responsible for this increase: the availability of irrigation water, advances in irrigation technologies, relatively good commodity prices for orchard crops, and the availability of processing facilities.

The upper Sacramento River portion of the primary study area (areas below Shasta Dam) is largely serviced by ACID. ACID's service area of approximately 32,000 acres extends south from the city of Redding in Shasta County into northern Tehama County. ACID does not provide water for municipal and industrial uses in these areas. Approximately 90 percent of ACID's customers irrigate pasture for haying or livestock; however, in most of the river corridor the water is used to irrigate orchard and other food crops. In total, ACID's service area accounts for about two-thirds of all irrigated pasture in the Redding basin.

ACID uses a rotation schedule to deliver irrigation water to its customers. Very little groundwater is used within the district for agricultural purposes, except occasionally during drought years. Water requirements are typically highest during summer (June, July, and August) because of the area's hot, dry climate. A groundwater management program is being developed; by 2005, 12 dual-completion groundwater monitoring wells had been installed within ACID boundaries. The small portion of groundwater used is limited primarily to deciduous crops and is pumped by privately owned wells. ACID's facilities and irrigation are important contributors to groundwater recharge in the Redding basin. Annual seepage associated with the ACID Main Canal is estimated to be approximately 44 thousand acre-feet (TAF).

Agricultural use within ACID's service area is primarily pasture, in addition to alfalfa and some deciduous orchard crops. Pasture use is typically in the range of 75 percent of the total crop mix served by ACID. Annual cropping patterns

have not varied substantially since the mid-1970s. Therefore, associated on-field water requirements and diversions for crops have been more a function of water-year type and climate than changes in cropping.

Agriculture thus accounts for an important segment of the economic base of Shasta and Tehama counties. In 2002, for example, the total market value of farm products in Shasta County was $52,197,800, a slight increase from the $51,691,000 produced in 2001. Minor increases in the annual production value of orchard crops and apiary products accounted for this increase. Field crops accounted for nearly 40 percent of this total, with livestock sales providing nearly one-third (32.1 percent) of the county's total agricultural production value. Shasta County ranked only 42nd among the 58 California counties in 2002 in the value of total agricultural production – $44,477,000, as reported by the California Department of Food and Agriculture (Shasta County 2004).

In addition to its economic contribution, the agriculture industry is in large part responsible for the rural character of Shasta and Tehama counties. Farmland can also play an important role in the support of wildlife values through the effects it has on conservation of wildlife habitats. As more farmland is developed for urban and suburban uses, the available habitat for most field and woodland edge species decreases, resulting in a subsequent decline or potential elimination of their populations. Agricultural lands also provide productive, privately maintained open space that contributes to the open, natural landscape of much of Shasta and Tehama counties.

Lower Sacramento River and Delta

The Sacramento River below Red Bluff Diversion Dam and its tributaries continue to provide water to crops grown in the river's floodplain and the valley floor, which broadens as it expands into the Central Valley. The river crosses Tehama, Butte, Glenn, Colusa, Sutter, Yolo, and Sacramento counties and is an important source of water for the irrigation and agricultural districts in those counties.

California's Central Valley is home to more than 4 million people; agriculture is the most important segment of the region's robust economy. The Sacramento and San Joaquin river basins provide drinking water for more than two-thirds of Californians and irrigation water for California's crops. The availability of irrigation water makes the Central Valley a major source of reliable, high-quality crops, such as almonds, walnuts, grapes, tomatoes, rice, and other orchard, vineyard, and field crops, marketed to the nation and the world (Reclamation and DWR 2005; DWR and Reclamation 2006).

As of 2002, California's 79,631 farms included a total of 27.6 million acres (NASS 2004). Of that acreage, the Sacramento Valley had more than 11,000 farms with about 4.3 million acres. Sacramento Valley portions of the Central Valley's watersheds support a wide variety of agricultural uses, including livestock grazing, irrigated grain and vegetable crops, and orchards (DWR and

Reclamation 2006). Most agricultural water demands in the Sacramento Valley are met in average water years. Farmers have been growing more crops per acre-foot of applied water by improving productivity and efficiency. However, in some areas, water sources once used for agriculture are now used for urban needs, environmental restoration, and groundwater replenishment. During droughts, water supplies are less reliable, heightening competition and at times leading to conflicts among water users. Water quality is degraded, making it difficult and costly to make the water drinkable. Irrigated agriculture and related businesses are adversely affected, in turn affecting California's economy. During droughts, groundwater levels decline, pumping costs increase, and many rural residents who depend on small water systems or wells run short of water (DWR and Reclamation 2006).

Table 10-1 provides examples of water supply distribution among uses in recent wet, above-normal, and dry years.

Delta agricultural lands were "reclaimed" when levees were constructed and marshy areas were drained. In less than 100 years, from 1850 to 1930, hundreds of thousands of acres of land went into agricultural production. Historically, asparagus, corn, alfalfa, and sugar beets were the Delta's dominant crops. However, a wide variety of crops have been grown in the Delta. In 2008, the Delta's main crops were corn, alfalfa, tomatoes, and wine grapes (DWR 2009).

CVP/SWP Service Areas

The CVP is the largest water storage and delivery system in California, covering 29 of the state's 58 counties. Operated by Reclamation, the CVP consists of 21 reservoirs capable of storing 12 million acre-feet of water, 11 powerplants, 500 miles of major canals and aqueducts, and many tunnels, conduits, and power transmission lines. The CVP irrigates about 3.25 million acres of farmland and supplies water to more than 2 million people through more than 250 water districts, individuals, and companies through water service contracts, Sacramento River water rights, and San Joaquin River exchange contracts. Most of the CVP service area is inside the Central Valley. About 90 percent of the south-of-Delta contractual delivery is for agricultural uses (Reclamation 2007).

The CVP plays a key role in California's economy, providing water for six of the top 10 agricultural counties in the nation's leading farm state. The CVP provides about 5 million acre-feet of water for farms, which is enough to irrigate about 3 million acres, or approximately one-third of the agricultural land in California (Reclamation 2009).

Most of the population of the CVP service area is concentrated within urban areas. The CVP service area includes various municipal and industrial water contractors and water districts that serve portions of the Sacramento and Stockton metropolitan areas and the San Francisco Bay Area (Reclamation 2007).

Table 10-1. California Water Balance Summary

Category	State Summary (MAF)			Sacramento River (TAF)			San Joaquin River (TAF)		
	1998 (171%)[a]	**2000 (97%)[a]**	**2001 (72%)[a]**	**1998 (168%)[a]**	**2000 (105%)[a]**	**2001 (67%)[a]**	**1998 (171%)[a]**	**2000 (97%)[a]**	**2001 (72%)[a]**

Source: DWR and Reclamation 2006

Notes:

[a] Percentage of normal precipitation. Water year 1998 was classified as a wet water year; 2000 was an above-normal water year; 2001 was a dry water year.

[b] Environmental water includes instream flows, wild and scenic flows, required Delta outflow, and managed wetlands water use. Some environmental water is reused by agricultural and urban water users.

Key:

MAF = million acre-feet

TAF = thousand acre-feet

Outside of the fast-growing population centers, most of the CVP service area is rural, with irrigated agriculture being the predominant land use and driver of the local and regional economies (Reclamation 2007). As California's population continues to grow at a notable pace, water and power supplies have become more scarce and expensive; as a result, existing supplies have become more valuable.

Through contracts with 29 water agencies, the SWP provides water in the Central Valley to Butte, Solano, Kings, and Kern counties; to several Southern California counties; to Alameda and Santa Clara counties in the south San Francisco Bay Area; and to Napa and Solano counties in the north San Francisco Bay Area. In addition, the SWP provides water rights deliveries to water rights holders along the Feather River (Butte and Plumas counties). Of the total water delivered throughout California, the SWP provides water to about 600,000 acres of farmland. Within the extended study area, the SWP supplies about 10 percent of the total agricultural water used (DWR 2011).

Local surface water supplies (those not delivered by either the CVP or SWP) provide about 40 percent of all agricultural water in the extended study area. More local surface water supplies are available on the east side of the valley because of the larger amount of precipitation in the Sierra Nevada. Locally owned water projects are especially important on the Yuba, Stanislaus, Tuolumne, Kings, and Merced rivers; but local sources on the west side, such as the Federal Solano Project, also are important.

As surface water flows through the San Joaquin Valley, numerous turnouts convey the water to farmland within the service areas of the SWP and CVP. The remaining water conveyed by the California Aqueduct is delivered to Southern California, home to about two-thirds of California's population (DWR 2011).

Groundwater provides an important supply of water for agriculture in normal years and often is used to reduce or eliminate shortages of surface water supplies during drought years. On average, groundwater provides about 20 percent of the total agricultural water use in the extended study area. Declining groundwater tables, subsidence, and loss of aquifer storage continue to be costly problems, particularly in the western and southern parts of the San Joaquin River region and the San Francisco Bay region, where less surface water is available.

10.1.2 Important Farmland

Important Farmland is classified by California Department of Conservation (DOC) as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance (see Section 10.2, "Regulatory Framework," for further discussion). In 2006, DOC estimated that California had approximately 30.8 million acres of agricultural land, of which approximately 12.4 million acres were identified as Important Farmland (DOC 2008a). Prime Farmland, and Important Farmland as a whole, decreased by

record amounts during the 2004 to 2006 period. Fewer new acres were brought into production to offset losses, resulting in a net decrease of 156,650 acres in irrigated farmland. The decrease in Prime Farmland (125,495 acres) was the largest documented in a 2-year update since the inception of DOC's Farmland Mapping and Monitoring Program. Figure 10-1 provides an overview of the distribution of Important Farmland in California, including the extended study area, as classified by DOC's Division of Land Resource Protection in 2008. The vast majority of the Important Farmland is located in the Central Valley, fed by the Sacramento and San Joaquin rivers and their tributaries (DOC 2008a).

Shasta Lake and Vicinity

According to the Shasta County Important Farmland map, published by DOC's Division of Land Resource Protection, there are no lands designated as Important Farmland adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam (Figure 10-1).

Upper Sacramento River (Shasta Dam to Red Bluff)

The majority of Important Farmland in the primary study area is clustered in the former floodplain of the Sacramento River. As of 2006, Shasta County had 25,727 acres and Tehama County had 231,513 acres of Important Farmland (Table 10-2). Reading Island and the potential gravel augmentation sites are not located in Important Farmland.

Table 10-2. Acreage of Important Farmland in Shasta and Tehama Counties

Important Farmland Category	Shasta County	Tehama County	Total
Prime Farmland	13,282	63,707	76,989
Farmland of Statewide Importance	3,444	17,284	20,728
Unique Farmland	488	18,085	18,573
Farmland of Local Importance	8,513	132,437	140,950
Total	**25,727**	**231,513**	**257,240**

Sources: DOC 2008a, 2008b

Most of the Important Farmland in the primary study area is clustered in the former Sacramento River floodplain. According to the Important Farmland maps for Shasta and Tehama counties, the primary study area includes 459 acres of Important Farmland. Of this total, 115 acres are located in Shasta County and 344 acres are located in Tehama County (Table 10-3).

Table 10-3. Acreage of Important Farmland in Portions of Shasta and Tehama Counties Within the Primary Study Area

Important Farmland Category	Shasta County	Tehama County	Total
Prime Farmland	81	44	125
Farmland of Statewide Importance	9	–	9
Unique Farmland	17	41	58
Farmland of Local Importance	8	259	267
Total	**115**	**344**	**459**

Source: DOC 2008a

Lower Sacramento River and Delta

During the 2006 mapping cycle, urban land uses statewide increased by 102,010 acres. Housing was the largest component of new urban acreage in the lower Sacramento River portion of the extended study area; most of the increase was associated with single-family homes located at the periphery of existing cities. Retail and commercial developments and community infrastructure supporting new residential development also contributed substantially to urbanization. Overall, the Sacramento Valley accounted for 18 percent of the net decrease in irrigated farmland.

Other factors besides conversion to urban or other land uses (e.g., habitat restoration) also affect the acreage of irrigated farmland. Regionally, complex factors related to availability of surface and groundwater supplies, crop markets, and anticipation of urban development affect the acreage of irrigated farmland. More locally, changes in annual water supplies, drainage, access, and compatibility with adjacent land uses also affect the productivity and value, and thus use, of agricultural land. Potential conflicts of adjacent land uses with agricultural production include traffic, vandalism, dumping, and provision of habitat for pest organisms (EDAW 2006; Sokolow et al. 2010).

The periphery of the Delta is undergoing rapid urbanization associated with substantial population growth. Current and future population growth will increase the demand for developable land, particularly near the Bay Area, Stockton, and Sacramento. This demand results in the conversion of open space, primarily agricultural land, to residential and commercial uses. In the recent past, thousands of acres of agricultural lands were developed for residential and other urban uses. Between 2000 and 2006, about 75,000 acres of agricultural land were converted to urban and conservation uses in the Delta. Approximately 505,300 acres of Important Farmland were located in the Delta as of 2006 (CVFMPP and FloodSAFE 2010; DOC 2008a).

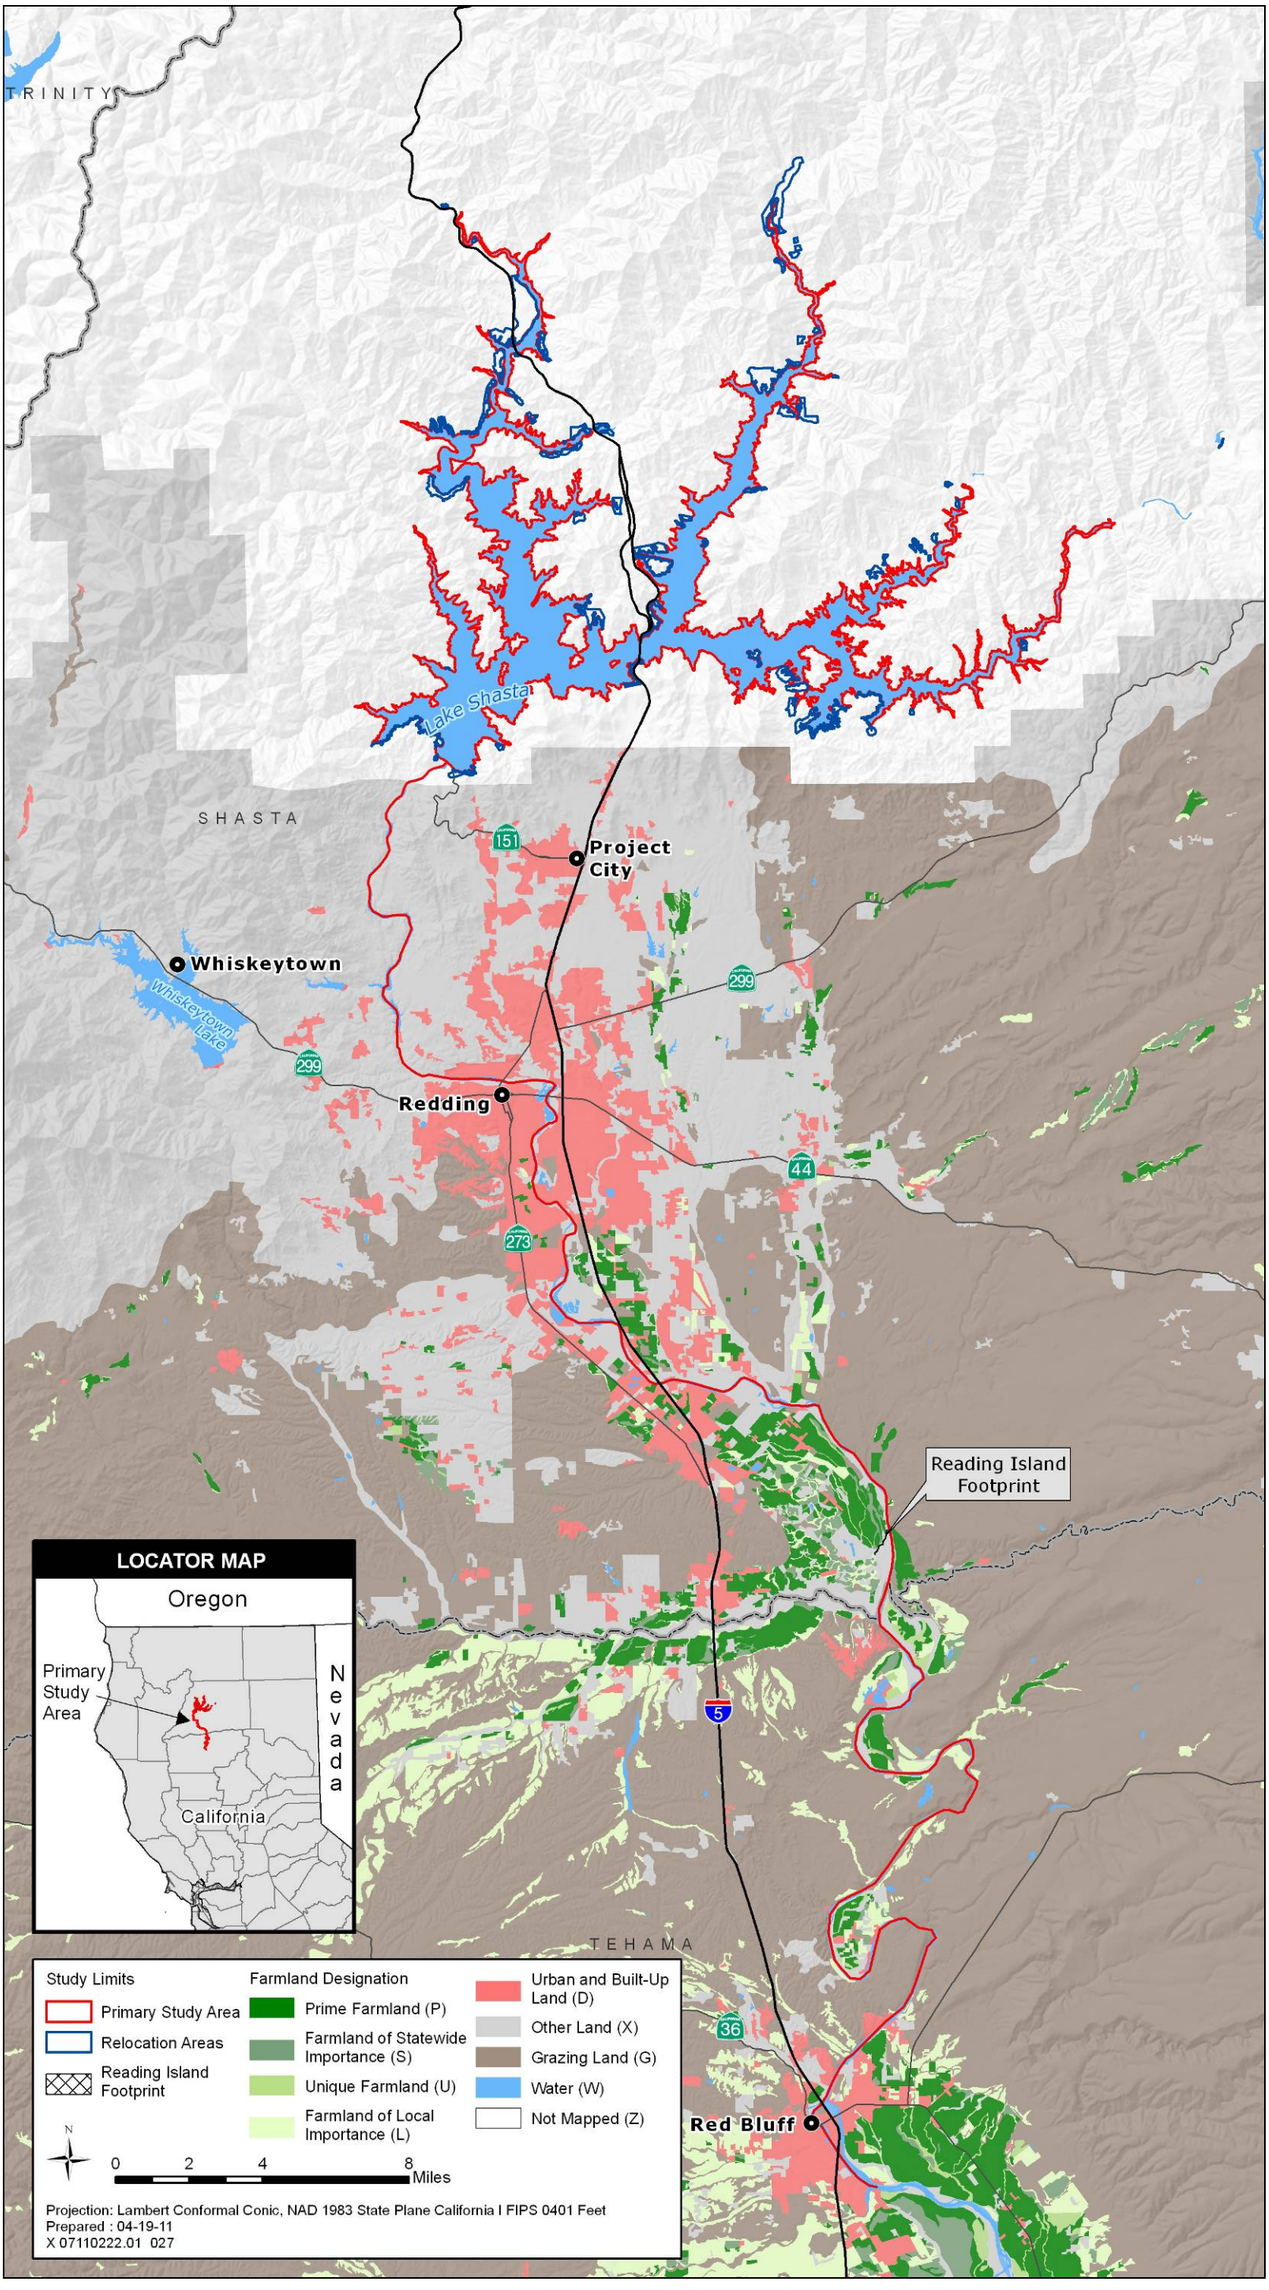

Figure 10-1. Important Farmland in the Primary Study Area

This page left blank intentionally.

CVP/SWP Service Areas

Declines in Important Farmland in the CVP/SWP service areas are similar to those discussed above for the lower Sacramento River and Delta. Urbanization has been responsible for 74 percent of Important Farmland and grazing land losses in the CVP/SWP service areas as a whole. As stated previously, urban land expanded by 102,010 acres during the 2006 mapping cycle. Riverside County alone accounted for 23 percent of the newly developed land. Southern California led all regions with 47 percent of the developed acres, while the San Joaquin Valley ranked second at 23 percent of the total. The Sacramento metropolitan area was third most active with 16 percent of new urban acres; Sacramento County's expansion of nearly 10,000 acres was a record high (DOC 2008a).

10.1.3 Williamson Act

As of January 1, 2007, 16.6 million acres were enrolled under the Williamson Act statewide. (Figure 10-2 shows Williamson Act lands in the primary study area.) This represents approximately half of California's farmland and nearly one-third of its privately owned land. The nonrenewal process is the most common mechanism for terminating Williamson Act contracts. Nonrenewal trends may be seen as an indicator of likely farmland conversion in particular locations. Statewide, nonrenewal initiations have increased each year since 2001 and reached a new high in 2007, with the San Joaquin Valley accounting for the largest increase in nonrenewal initiations. Overall, a total of 535,400 acres of contracted land was at some stage of the nonrenewal process in 2007 (DOC 2009a, 2009b).

10.1.4 Forest Land

Forest land is defined as native tree cover greater than 10 percent that allows for management of timber, aesthetics, fish and wildlife, recreation, and other public benefits (Public Resources Code (PRC) Section 12220(g)). Natural forest and woodland vegetation types in the study area typically have greater than 10 percent cover by native trees. (Figures 12-2a through 12-2f in Chapter 12, "Botanical Resources and Wetlands," display the distribution of natural forest and woodland vegetation.)

Forests serve as high-quality habitat for fish and wildlife species, sequester carbon to mitigate climate change, capture vital runoff for agricultural and domestic water supply, and provide a variety of outdoor recreation and education opportunities. Many rural communities depend on income and employment opportunities that result from working timber industries or on amenity values to attract new residents seeking a better lifestyle. In metropolitan areas, urban forests contribute to improved air quality, cooling of heat islands for energy conservation, and local employment (CDF 2010).

Shasta Lake and Vicinity

The study area for forest resources in the Shasta Lake and vicinity portion of the primary study area corresponds to the area that would be subject to inundation under the five action alternatives and areas where infrastructure would be removed, modified, or relocated.

The Shasta Lake and vicinity area is characterized by a variety of forest lands typical of transitional mixed woodland and low-elevation forests. Forest land within the Shasta Lake and vicinity portion of the primary study area includes blue oak woodland, Brewer's oak, California black oak forest, canyon live oak forest, Fremont cottonwood forest, ghost pine woodland, interior live oak woodland, knobcone pine forest, Oregon white oak woodland, ponderosa pine–Douglas fir forest, ponderosa pine forest, and valley oak woodland (see Figures 12-2a through 12-2f and Table 12-1 in Chapter 12, "Botanical Resources and Wetlands"). The inundation area and relocation areas (which could potentially be affected by the alternatives) contain approximately 4,669 acres of forest land and acres of forest land (Tables 10-1 and 10-2).

Table 10-4. Summary of Forest Land in the Impoundment and Relocation Areas

Forest Land	Area (Acres)
Blue oak woodland	12
Brewer oak scrub	79
California black oak forest	662
Canyon live oak forest	420
Fremont cottonwood forest	<1
Ghost pine woodland	463
Interior live oak woodland	9
Knobcone pine forest	313
Oregon white oak woodland	8
Ponderosa pine–Douglas fir forest	507
Ponderosa pine forest	2,194
Valley oak woodland	1
Total	4,669

Source: Data compiled by AECOM in 2011

The exact combination of vegetation varies, with dramatic changes often occurring in relation to aspect, slope, geologic substrate, or juxtaposition with other habitats.

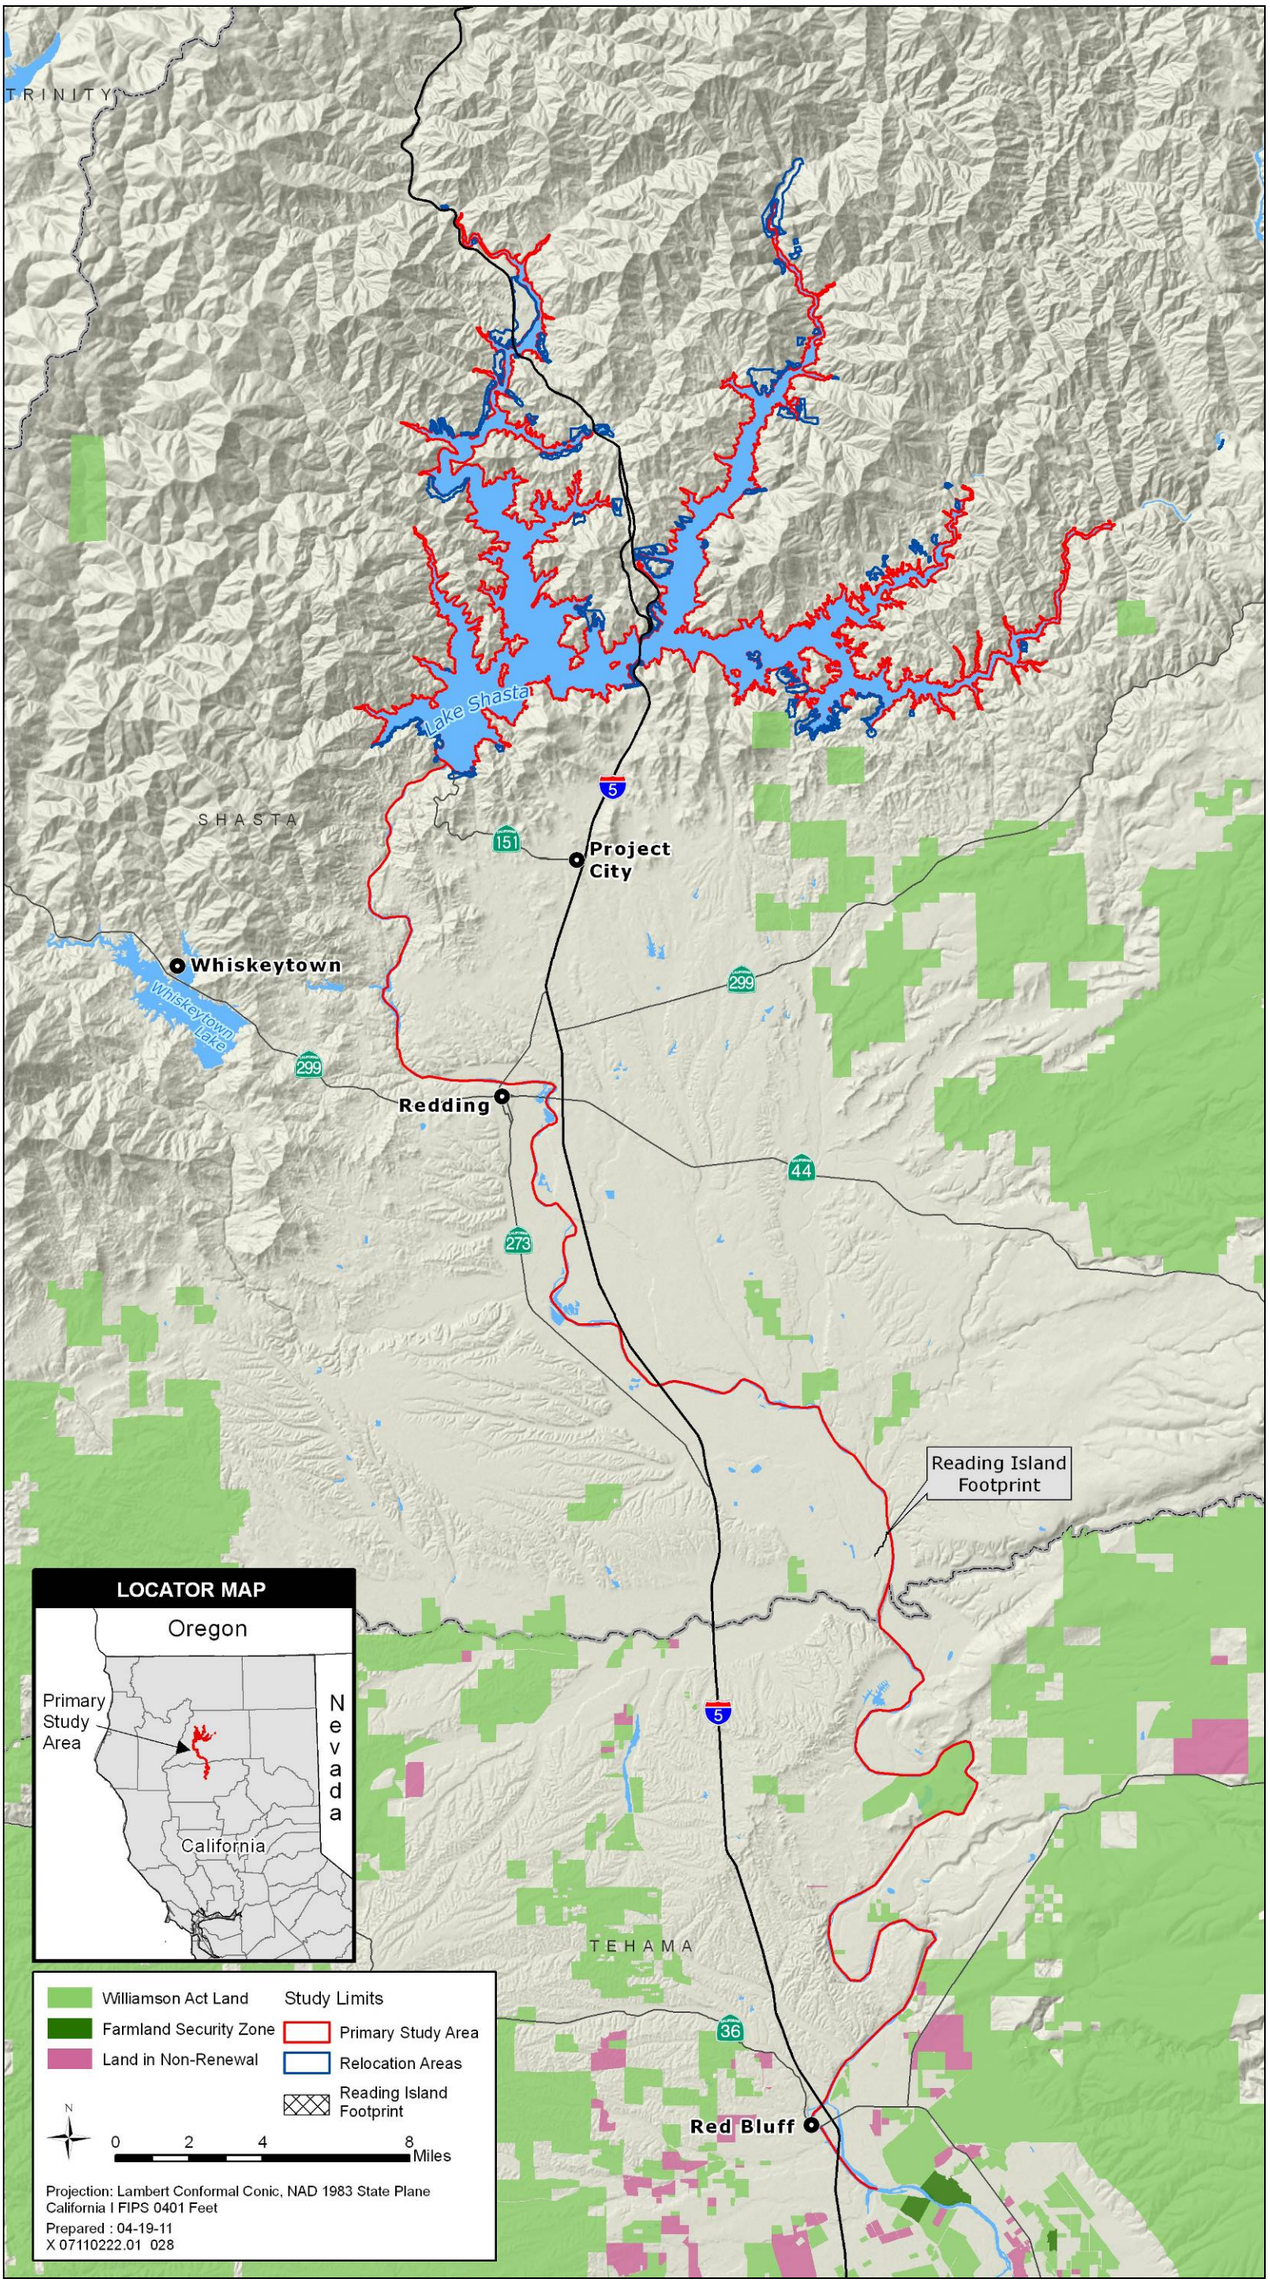

Figure 10-2. Williamson Act Lands in the Primary Study Area

This page left blank intentionally.

Upper Sacramento River (Shasta Dam to Red Bluff)

Forest land in the upper Sacramento River area from Shasta Dam to Red Bluff consists of riparian forest and oak woodland and savanna. Oak woodlands present in the primary study area include blue oak woodland, blue oak savanna, foothill pine-oak woodland, and valley oak woodland. Much of the Sacramento River from Shasta Dam to Redding is deeply entrenched in bedrock, which precludes development of extensive areas of riparian vegetation. The river corridor between Redding and Red Bluff, however, still maintains extensive areas of riparian forest communities.

Riparian plant communities present within the primary study area are located within the floodplain of the Sacramento River. These communities include Great Valley cottonwood riparian forest, Great Valley mixed riparian forest, and Great Valley valley oak riparian forest. Cottonwood- and willow-dominated riparian forest and woodland are present along active channels and on the lower flood terraces, whereas valley oak–dominated communities occur on higher flood terraces. In general, only narrow remnants of these riparian forests remain, often because levees are located close to river channels and the remaining riparian forest habitat is confined primarily to levee slopes. Riparian vegetation exists at Reading Island and some of the potential gravel augmentation sites.

Lower Sacramento River and Delta

Almost all of this forest land in the lower Sacramento River and Delta consists of riparian forests, including cottonwood-willow woodland and Valley oak riparian woodland. These areas are typically found in the lower Sacramento River and Delta as long, linear patches bordering waterways and agricultural or urban land. Riparian vegetation is most extensive on the water side of levees, but patches of riparian vegetation are also found on the interior of Delta islands along levee toes; along drainage channels; along pond margins; and in abandoned, low-lying fields. Forest land in riparian areas is managed primarily for habitat and water quality values, and to a lesser extent for recreation and other public benefits.

CVP/SWP Service Areas

Forest resources in the CVP and SWP service areas are similar to those discussed above for the upper Sacramento River (Shasta Dam to Red Bluff) and the lower Sacramento River and Delta. Agricultural and urban land uses have substantially reduced the area and connectivity of forest land in the CVP and SWP service areas. Substantial changes to the natural landscape in the region occurred in the late 1800s and early 1900s with land conversions to agriculture. In southern California, however, that pattern shifted dramatically compared to the pattern in the Central Valley, as urban growth in the region that started in the 1900s began to convert large areas of forest land to developed land uses.

10.2 Regulatory Framework

10.2.1 Federal

Farmland Protection Policy Act

The Farmland Protection Policy Act is intended to minimize the effect of Federal programs with respect to the conversion of farmland to nonagricultural uses. It ensures that, to the extent possible, Federal programs are administered to be compatible with State, local, and private programs and policies to protect farmland. The U.S. Department of Agriculture Natural Resources Conservation Service (NRCS) is the agency primarily responsible for implementing the Farmland Protection Policy Act.

The Farmland Protection Policy Act established the Farmland Protection Program and the Land Evaluation and Site Assessment system. NRCS administers the Farmland Protection Program, which is a voluntary program that provides funds to help purchase development rights to keep productive farmland in agricultural uses. The program provides matching funds to State, local, and tribal entities and nongovernmental organizations with existing farmland protection programs to purchase conservation easements. Participating landowners agree not to convert the land to nonagricultural uses and retain all rights to the property for future agriculture. A minimum 30-year term is required for conservation easements, and priority is given to applications with perpetual easements. NRCS provides up to 50 percent of the fair market value of the easement (NRCS 2006).

The Land Evaluation and Site Assessment system is a tool used to rank lands for suitability and inclusion in the Farmland Protection Program. The Land Evaluation and Site Assessment evaluates several factors: soil potential for agriculture, climate, location, market access, and adjacent land use. These factors are used to numerically rank land parcels based on local resource evaluation and site considerations (NRCS 2006).

10.2.2 State

California Important Farmland Inventory System and Farmland Mapping and Monitoring Program

The DOC Office of Land Conservation maintains a statewide inventory of farmlands. These lands are mapped by the Division of Land Resource Protection as part of the Farmland Mapping and Monitoring Program. The Farmland Mapping and Monitoring Program was established by the State of California in 1982 to continue the Important Farmland mapping efforts begun in 1975 by the U.S. Soil Conservation Service (now called NRCS). The intent of the U.S. Soil Conservation Service was to produce agricultural-resource maps based on soil quality and land use across the nation. DOC sponsors the Farmland Mapping and Monitoring Program and is also responsible for establishing agricultural easements in accordance with PRC Sections 10250-

10255. The maps are updated every 2 years with the use of aerial photographs, a computer mapping system, public review, and field reconnaissance.

As part of the nationwide agricultural-land-use mapping effort, U.S. Soil Conservation Service/NRCS developed a series of definitions known as Land Inventory and Monitoring criteria. The Land Inventory and Monitoring criteria classify the land's suitability for agricultural production. Suitability includes both the physical and chemical characteristics of soils and the actual land use. Important Farmland maps are derived from NRCS soil survey maps using the Land Inventory and Monitoring criteria and are available by county. The maps prepared by NRCS classify land into one of eight categories, which are defined as follows (DOC 2008a):

- **Prime Farmland** – land that has the best combination of physical and chemical characteristics for crop production. It has the soil quality, growing season, and moisture supply needed to produce sustained high yields of crops when treated and managed.

- **Farmland of Statewide Importance** – land of importance to the local economy, as defined by each county's local advisory committee and adopted by its board of supervisors. Farmland of Local Importance is land other than Prime Farmland that has a good combination of physical and chemical characteristics for crop production. This land has minor shortcomings, such as greater slopes or less ability to store soil moisture than Prime Farmland.

- **Unique Farmland** – land that does not meet the criteria for Prime Farmland or Farmland of Statewide Importance, but that has been used for the production of specific crops with high economic value. This land is usually irrigated, but may include nonirrigated orchards or vineyards as found in some climatic zones in California.

- **Farmland of Local Importance** – land that is either currently producing crops or has the capability of production, but does not meet the criteria of the categories above.

- **Grazing Land** – land on which the vegetation is suited to the grazing of livestock. The minimum mapping unit for Grazing Land is 40 acres.

- **Urban and Built-up Lands** – land occupied by structures with a density of at least one dwelling unit per 1.5 acres.

- **Land Committed to Nonagricultural Use** – vacant areas; existing lands that have a permanent commitment to development but have an existing land use of agricultural or grazing lands.

- **Other Lands** – Land that does not meet the criteria of the remaining categories. This optional designation allows local governments to provide detail on the nature of changes expected to occur in the future.

Important Farmland is classified by DOC as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance. The total acreages of Urban and Built-up Lands and Other Lands are calculated by DOC and are defined by DOC as agricultural land.

The designations for Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance are defined together under the terms "Agricultural Land" and "Important Farmland" in CEQA (PRC Sections 21060.1 and 21095 and State CEQA Guidelines Appendix G). The conversion of these types of farmland could be considered an environmental impact.

Williamson Act Contracts

The California Land Conservation Act of 1965, commonly known as the Williamson Act, is the principal method for encouraging the preservation of agricultural lands in California. The Williamson Act enables local governments to enter into contracts with private landowners for the purpose of restricting specific parcels of land to agricultural or related open-space use for 10 years. In return, landowners receive property tax assessments that are based on farming and open-space uses as opposed to full market value. Local governments receive an annual subvention (subsidy) of forgone property tax revenues from the State via the Open Space Subvention Act of 1971.

The Williamson Act empowers local governments to establish "agricultural preserves" consisting of lands devoted to agricultural uses and other uses that are compatible with agriculture. Upon establishment of such preserves, the locality may offer to owners of included agricultural land the opportunity to enter into annually renewable contracts that restrict the land to agricultural use for at least 10 years (i.e., the contract continues to run for 10 years after the first date upon which the contract is not renewed). In return, the landowner is guaranteed a relatively stable tax base, founded on the value of the land for agricultural/open space use only and unaffected by its development potential.

Canceling a Williamson Act contract involves an extensive review and approval process, in addition to payment of fees of up to 12.5 percent of the property value. The local jurisdiction approving the cancellation must find that the cancellation is consistent with the purpose of the California Land Conservation Act or is in the public interest. Several subfindings must be made to support either finding, as defined in California Government Code Section 51282.

Farmland Security Zones

Farmland Security Zones (FSZ), also known as Super Williamson Act lands, were established by DOC with the same general intent as Williamson Act

contracts. An FSZ must be located in an agricultural preserve (area designated as eligible for a Williamson Act contract). Agricultural landowners in FSZs may enter into contracts with the county for 20-year increments, with an additional 35 percent tax benefit over and above the standard Williamson Act contract. The FSZ program has been adopted by 25 counties, although not all of those counties have executed contracts.

An FSZ must be located in an Agricultural Preserve (area designated as eligible for a Williamson Act contract) and designated as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, or Farmland of Local Importance. Land protected in an FSZ cannot be annexed by a city or county government or school district. FSZ contracts constitute nearly 2 percent of statewide Williamson Act enrollment.

An FSZ can be terminated through a nonrenewal or cancellation. The nonrenewal allows a rollout process to occur over the remainder of the term of the contract, when the tax rates would gradually rise to the full rate by the end of the 20-year term. A cancellation must be applied for and approved by the director of the DOC, and specific criteria must be met. The cancellation must be in the public interest and consistent with Williamson Act criteria. If a cancellation is approved, fees equal to 25 percent of the full market value of the property must be paid.

Agricultural Water Management Plans

By the end of 2004, 62 water districts, three environmental interest groups, and more than 53 other interested groups had signed the Agricultural Water Management Memorandum of Understanding as members of the Agricultural Water Management Council. The agricultural signatories represent more than 4.75 million acres of irrigated agricultural land statewide.

In 2004, the council endorsed an additional three agricultural water management plans that had been submitted by agricultural water suppliers to the council. Subsequently, these plans have become the basis for the districts' water conservation efforts. The districts with endorsed agricultural water management plans are expected to prepare and submit a biannual progress report to the Agricultural Water Management Council, starting from the date their plan was endorsed. DWR staff members provide technical review and evaluation of these plans. DWR also reviewed two biannual progress reports for the council. DWR staff also provided technical assistance to water districts to prepare water management plans and helped implement efficient water management practices, as well as administrative and programmatic assistance to both the Agricultural Water Management Council and water districts.

1992 Delta Protection Act

The 1992 Delta Protection Act identified the Delta as a natural resource of statewide significance, formalized the State's commitment to preserve its diverse values, and established the Delta Protection Commission. The purpose

of the Delta Protection Act is to ensure protection, maintenance, and enhancement of the Delta environment; ensure orderly and balanced use of Delta land resources; and improve flood protection to increase public health and safety. The Delta Protection Commission has planning jurisdiction over portions of five counties: Contra Costa, Sacramento, San Joaquin, Solano, and Yolo.

In Section 29703a of the Delta Protection Act, the Delta Primary Zone is designated as an area for protection from intrusion of nonagricultural uses. In 1995, the Delta Protection Commission adopted its regional plan, *Land Use and Resource Management Plan for the Primary Zone of the Delta* (also known as the Delta Plan). The current Delta Plan was approved by the California Office of Administrative Law on October 7, 2010, and became effective November 6, 2010. Policies in the Delta Plan are developed to project the conversion of agricultural resources. Policy P-2 states that conversion of land to non–agriculturally oriented uses should occur first where productivity and agricultural values are lowest. Policy P-6 encourages acquiring agricultural conservation easements from willing sellers as mitigation for projects within each county. Use of environmental mitigation is to be promoted in agricultural areas only when it is consistent and compatible with ongoing agricultural operations and when developed in appropriate locations designated on a countywide or Deltawide habitat management plan (DPC 2010).

10.2.3 Regional and Local

Shasta and Tehama Counties

The general plans of Shasta and Tehama counties contain goals, policies, and implementation measures to protect agricultural lands, as summarized below.

Shasta County General Plan The *Shasta County General Plan* (Shasta County 2004) identifies goals, policies, and implementation measures aimed at conserving large contiguous areas of productive agricultural land, providing opportunities for the future expansion of such uses, and protecting them from development pressures that would adversely affect or hinder existing or future agricultural operations. This includes the objective to protect water resources and supply systems vital for the continuation of agriculture.

Tehama County General Plan The *Tehama County General Plan* (2009) encourages and supports agriculture and forest resources in Tehama County. The policies are within the Agriculture and Timber Element of the general plan and divided into the Land Use, Open Space and Conservation, and Economic Development Elements to aid in implementation of the general plan, but focus on agriculture nonetheless.

Other

Sacramento River Conservation Area The Sacramento River Conservation Area seeks to promote the reestablishment of the 100-year floodplain along the Sacramento River. In 1986, the California Legislature passed Senate Bill 1086,

which called for a management plan for the Sacramento River that would help restore, protect, and enhance the riparian and aquatic habitat. After much debate, the *Upper Sacramento River Fisheries and Riparian Habitat Management Plan* was developed (Resources Agency 1989). This plan called for fish bypass structures on the Sacramento River and its tributaries, as well as the Shasta Dam temperature control structure. After implementation of these projects began, the advisory council reconvened to complete additional work. This effort led to the *Sacramento River Conservation Area Handbook* (Resources Agency 2003), which would guide riparian habitat management along the river. In 1999, a memorandum of agreement was signed by most entities involved in management activities along the river. The U.S. Bureau of Land Management has acquired roughly 15,000 acres of riparian lands along the Sacramento River.

10.3 Environmental Consequences and Mitigation Measures

10.3.1 Methods and Assumptions

Implementation of the project would result in construction, maintenance, and operational impacts that could substantially affect agricultural and forest resources. This analysis evaluates potential construction and operational activities that could directly or indirectly affect existing agricultural and forest resources in the primary study area. Indirect impacts on the extended study area could result from alteration of flow regimes downstream from Shasta Lake and downstream from other reservoirs with altered operations, as well as increased inundation width of the Sacramento River during the growing season. In addition, water supply reliability in the CVP and SWP service areas could increase, which could in turn reduce limitations on growth and increase development that could adversely affect agricultural and forest resources.

Evaluation of the project's potential impacts on agricultural resources was based on a review of the planning documents pertaining to the project areas, including goals and policies from the general plans of Shasta and Tehama counties. DOC's Important Farmland and Williamson Act maps were used to determine the agricultural significance of the lands in the primary study area. In addition, the results of CalSim-II simulations were reviewed to assess changes in flow regime in the primary and extended study areas.

Forest land that could be inundated or affected by the alternatives was determined from vegetation mapping as described in Chapter 12, "Botanical Resources and Wetlands." These forest lands include blue oak–foothill pine, blue oak, and closed-cone pine-cypress woodlands; and Douglas-fir, montane hardwood, montane hardwood-conifer, montane riparian, Ponderosa pine, and valley-foothill riparian forests. The following analysis summarizes information provided in Chapter 12, "Botanical Resources and Wetlands" as it relates to the potential conversion of forest land to nonforest uses.

10.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an environmental impact statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on agriculture and Important Farmland would be significant if project implementation would do any of the following:

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to nonagricultural use

- Conflict with existing zoning for agricultural use, or a Williamson Act contract

- Conflict with existing zoning for, or cause rezoning of, forest land (as defined in PRC Section 12220(g)), timberland (as defined in PRC Section 4526), or timberland zoned Timberland Production (as defined in PRC Section 51104(g))

- Result in the loss of forest land or conversion of forest land to nonforest use

- Involve other changes in the existing environment that, because of their location or nature, could result in conversion of farmland, to nonagricultural use or the conversion of forest land to nonforest use

10.3.3 Topics Eliminated from Further Consideration

None of the lands in the primary study area are zoned as forest land, timberland, or timberland zoned Timberland Production by the *Shasta County General Plan* (2004) or *Tehama County General Plan* (2009). Increasing water supply reliability within the lower Sacramento River to the Delta and within the CVP and SWP service areas would not conflict with existing zoning or directly result in the rezoning of forest land, timberland, or timberland zoned Timberland

Production. Therefore, no effects related to conflicts with existing zoning or causing rezoning of forest land are expected to occur in the study area; therefore, potential effects related to this issue area are not discussed further in this PDEIS.

10.3.4 Direct and Indirect Effects

No-Action Alternative

Under the No-Action Alternative, the existing Shasta Dam would be operated in the same manner as under current operations. Shasta Dam would not be enlarged and no infrastructure would be removed, modified, or relocated. Changes to the reservoir flow regime caused by changes in demand and other factors would be small, with a reduction in Shasta Lake storage of 2–4 percent during the fall of some years. Shasta Lake storage under the No-Action Alternative would be within -2 percent and 1 percent of Shasta Lake storage under existing conditions at most times.

Under the No-Action Alternative, changes to the flow regime of the upper Sacramento River as a result of changes in demand and other factors would be small; mean monthly flows in the Sacramento River would be within 5 percent of flows under existing conditions at most times. (Flows could increase by a greater amount during late summer and early fall of below-normal, dry, and critical years.)

Under the No-Action Alternative, the flow regime in the lower Sacramento River and Delta would not change as a result of Shasta Lake operations. It is anticipated that if the project alternatives were not implemented, CVP and SWP operations would continue under existing regulatory requirements. CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. Overall, CalSim-II modeling results suggest that there would be only a very small decrease in flows greater than 15,000 cubic feet per second.

Shasta Lake and Vicinity

Impact Ag-1 (No-Action): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No new facilities would be constructed at Shasta Lake and no operational changes would occur that would directly convert Important Farmland to nonagricultural uses or result in the cancellation of Williamson Act contracts in the vicinity of Shasta Lake. However, California's demand for water for irrigation and other uses is expected to continue to increase while the water supply will likely become less reliable. This trend could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts, resulting in an indirect impact. Therefore, this impact would be potentially significant.

Under the No-Action Alternative, Shasta Dam would not be enlarged; no infrastructure would be removed, modified, or relocated; and no changes in Reclamation's Shasta operations would occur. Changes to reservoir flow regime and reservoir storage caused by changes in demand and other factors would be small, and generally the same as under existing conditions at most times. Therefore, implementing the No-Action Alternative would not directly convert agricultural land to nonagricultural uses or result in the cancellation of Williamson Act contracts.

The demand for water for irrigation and other uses in California is expected to continue to increase in the future; at the same time, the water supply may become less reliable because of increasing environmental water requirements for special-status species, decreasing water quality, and climate change. Therefore, the No-Action Alternative could have an indirect, adverse impact on agricultural land uses and Important Farmland in the primary study area. Insufficient water supply, especially during drought periods, could indirectly lead to increased pressure on farmers to convert Important Farmland to other nonagricultural uses, or could cause land designated as Important Farmland to be fallowed. Additionally, the conversion of Important Farmland could also involve cancellation or expiration of many Williamson Act contracts.

The magnitude and extent of the agricultural land that could be converted from changes in water supply is unknown; however, any loss of Important Farmland would be significant because there are no measures to fully mitigate the loss of Important Farmland. Based on a review of future demand projections used in CalSim-II modeling and estimated deliveries under the No-Action Alternative, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Ag-2 (No-Action): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake No new facilities would be constructed at Shasta Lake and no operational changes would occur that would result in the direct or indirect conversion of forest land to nonforest uses. No impact would occur.

Under the No-Action Alternative, Shasta Dam would not be enlarged; no infrastructure would be removed, modified, or relocated; and no changes in Reclamation's Shasta operations would occur. Changes to reservoir flow regime and reservoir storage caused by changes in demand and other factors would be small and generally the same as under existing conditions at most times. Therefore, the No-Action Alternative would not result in the direct or indirect conversion to nonforest uses of blue oak–foothill pine, blue oak, and closed-cone pine-cypress woodlands; Douglas-fir, montane hardwood, montane hardwood-conifer, montane riparian, Ponderosa pine, and valley-foothill riparian forests; or other forest land. No impact would occur. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (No-Action): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Under the No-Action Alternative, changes to the flow regime of the upper Sacramento River resulting from changes in demand and other factors would be small; mean monthly flows in the Sacramento River would be within 5 percent of flows under existing conditions at most times. Implementing the No-Action Alternative would not directly convert Important Farmland to nonagricultural uses or result in the cancellation of Williamson Act contracts in the upper Sacramento River region (Shasta Dam to Red Bluff). However, California's demand for water for irrigation and other uses is expected to continue to increase while the water supply will likely become less reliable. This trend could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts, resulting in an indirect impact. Therefore, this impact would be potentially significant.

Under the No-Action Alternative, changes to the flow regime of the upper Sacramento River resulting from changes in demand and other factors would be small; mean monthly flows in the Sacramento River would be within 5 percent of flows under existing conditions at most times. Therefore, implementing the No-Action Alternative would not directly convert agricultural land to nonagricultural uses or result in the cancellation of Williamson Act contacts.

California's demand for water for irrigation and other uses is expected to continue to increase in the future; at the same time, the water supply may become less reliable because of increasing environmental water requirements for special-status species, population growth that place further demands on existing water supply resources, decreasing water quality, and climate change. Therefore, the No-Action Alternative could have an indirect, adverse impact on agricultural land uses and Important Farmland in the primary study area. Insufficient water supply, especially during drought periods, could indirectly lead to increased pressure on farmers to convert Important Farmland to other nonagricultural uses or cause land designated as Important Farmland to be fallowed. Additionally, conversion of Important Farmland could involve canceling many Williamson Act contracts or allowing such contracts to expire.

The magnitude and extent of the agricultural land that could be converted from changes in water supply is unknown; however, any loss of Important Farmland would be significant because there are no measures to fully mitigate the loss of Important Farmland. Based on a review of future demand projections used in CalSim-II modeling and estimated deliveries under the No-Action Alternative, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Ag-4 (No-Action): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River No operational changes

would occur that would directly convert forest land to nonforest uses along the upper Sacramento River. However, water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. The resulting changes in flow regime would likely result in minimal adverse effects on riparian forest and oak woodland habitats. Furthermore, management and restoration plans and programs would implement actions that would largely offset those adverse effects. Therefore, this impact would be less than significant.

Under the No-Action Alternative, no changes in Reclamation's Shasta operations would occur that would directly convert riparian and oak woodland habitats along the upper Sacramento River to nonforest uses. However, water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. As a consequence of these actions, the flow regime of the upper Sacramento River would change between 2005 and 2030. As described in Chapter 12, "Botanical Resources and Wetlands," this change in flow regime would likely result in minimal adverse effects on forest land, which along the upper Sacramento River consist of riparian forest and oak woodlands, and these effects would not be sufficient to alter the extent of these forest lands.

As discussed in Chapter 12, "Botanical Resources and Wetlands," under the No-Action Alternative several management and restoration plans and programs would be implemented. These actions would cause beneficial effects likely to be of a magnitude similar to or greater than the anticipated adverse effects of small changes in flow regime; thus, implementation of the plans and programs would largely offset those adverse effects. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (No-Action): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Under the No-Action Alternative, changes to the flow regime of the lower Sacramento River, Delta, and CVP and SWP service areas as a result of changes in demand and other factors would be small; mean monthly flows in the Sacramento River would be within 5 percent of flows under existing conditions at most times. Implementing the No-Action Alternative would not directly convert Important Farmland to nonagricultural uses or result in the cancellation of Williamson Act contracts along the lower Sacramento River, in the Delta, or in the CVP and SWP service areas. However, California's demand for water for irrigation and other uses is expected to continue to increase while the water supply will likely become less reliable. This trend could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts, resulting in an indirect impact. Therefore, this impact could be potentially significant.

This impact would be similar to Impact Ag-3 (No-Action) for the upper Sacramento River (Shasta Dam to Red Bluff). For the same reasons as described above for Impact Ag-3 (No-Action), this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Ag-6 (No-Action): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area No operational changes would occur under the No-Action Alternative that would directly convert forest land to nonforest uses along the upper Sacramento River. However, water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. The resulting changes in flow regime would likely result in minimal adverse effects on forest land, which consists of riparian forest and oak woodlands along the lower Sacramento River and in the Delta. Management and restoration plans and programs would implement actions that would largely offset those adverse effects. Therefore, this impact would be less than significant.

This impact would be similar to Impact Ag-4 (No-Action) for the upper Sacramento River (Shasta Dam to Red Bluff). For the same reasons as described above for Impact Ag-4 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

By increasing storage at Shasta Lake, this alternative would change the full pool elevation and seasonal pool elevations at Shasta Lake, and the flow regime downstream in the Sacramento River and potentially several other reservoirs and downstream waterways. The full pool elevation of Shasta Lake would increase by 8.5 feet and would periodically inundate this elevation zone. Existing facilities would be relocated from this periodically inundated zone to higher areas.

Potential impacts of CP1 on the upper Sacramento River's flow and stages and on deliveries of water supplies to the CVP and SWP service areas would be small. On average, in each month, changes in mean monthly flow relative to existing (2005) and No-Action Alternative (2030) conditions would be reductions or increases of about 5 percent or less. Generally, the relative magnitude of effects on river flows diminishes with distance downstream because of the influence of inflows from tributaries and the effects of diversions and flood bypasses.

Shasta Lake and Vicinity

Impact Ag-1 (CP1): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate

vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. Therefore, inundation of land and removal, modification, or relocation of infrastructure under CP1 would not directly or indirectly convert agricultural land to nonagricultural uses or result in the cancellation of Williamson Act contacts. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP1): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP1 would result in the conversion of forest land to nonforest uses. This impact would be significant.

A total of 1,051 acres of forest land would be affected by inundation under CP1 (Table 10-5). Also, approximately 107 acres of land in the relocation areas would be affected by removal, modification, or relocation of infrastructure under CP1 (acreages were calculated based on infrastructure relocation information presented in Chapter 2, "Alternatives"); and most of this acreage would involve conversion of forest land to nonforest uses. This impact would be significant. Mitigation for this impact is not proposed because no feasible mitigation is available to reduce the impact to a less than significant level.

Table 10-5. Acreage of Forest Land that Would Be Affected by Inundation Under CP1

Forest Land	Area (Acres)
Blue oak–foothill pine	10
Blue oak woodland	1
Closed-cone pine–cypress	247
Douglas-fir	<1
Montane hardwood	187
Montane hardwood–conifer	234
Montane riparian	26
Ponderosa pine	345
Total	1,051

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP1): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Within the upper Sacramento River portion of the primary study area, inundation of agricultural lands, including Important Farmland and Williamson Act contract lands, could result from increases in

mean monthly river flows. In general, the flow increases that would occur in some years would be expected to be small (5 percent or less) and would affect areas periodically inundated under existing and No-Action Alternative conditions. The effects of increased flow would diminish with distance downstream. CP1 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. Therefore, implementing CP1 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

Within the upper Sacramento River portion of the primary study area, inundation or soil saturation of agricultural lands, including Important Farmland and Williamson Act contract lands, could result from increases in mean monthly river flows associated with project implementation and operation. Based on CalSim-II model simulations, the increases in flow that would occur in some years under CP1 would be expected to be small (5 percent or less) relative to existing (2005) and No-Action Alternative (2030) conditions. These increased flows would affect small areas periodically inundated under existing conditions or under the No-Action Alternative. In addition, the effects would diminish with distance downstream because of the influence of inflows from tributaries and the effects of diversions and flood bypasses. As a result, implementing CP1 would not directly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts.

CP1 would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. A substantial portion of this water would substitute for groundwater pumping, allow for changes in agricultural irrigation practices, or return idle cropland to production. Therefore, implementing CP1 would not indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP1): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP1 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP1 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

Forest land along the upper Sacramento River from Shasta Dam to Red Bluff consists of riparian forest and oak woodlands. These habitats could be affected by changes in flow and stage along the upper Sacramento River in some years. In most years, changes in mean monthly flow would be reductions or increases of 5 percent or less. The areas affected would be areas periodically inundated under existing and No-Action Alternative conditions. Generally, these effects diminish with distance downstream because of the influence of inflows from tributaries and of diversions and flood bypasses.

The altered flow regime of the upper Sacramento River associated with implementation of CP1 could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture. This effect would occur during years when mean monthly stage during March–October differs from existing and No-Action Alternative conditions. Implementing CP1 could increase the average elevation of the water surface in this zone slightly (but would not increase the zone's elevational range). Because of the important influence of water availability and soil aeration on plant growth and survival, these changes have the potential to result in the loss of oak woodlands. These effects, however, are speculative, and may not all prove to be adverse.

The flow regime of a river or stream strongly influences the structure and species composition of riparian forests. CP1 would not alter the general annual pattern of flows, but it would reduce the magnitude, duration, and frequency of intermediate and large flows. Reductions in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River; however, changes in flow regime would not reduce the extent of riparian forest.

For the reasons described above, implementing CP1 would not result in the conversion of forest land to nonforest uses. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Ag-5 (CP1): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Within the extended study area, inundation or soil saturation of agricultural lands, including lands designated as Important Farmland and under Williamson Act contract, could result from increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or under the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP1 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. Therefore, implementing CP1 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

Within the extended study area, inundation or soil saturation of agricultural lands, including lands designated as Important Farmland and under Williamson Act contract, could be more extensive during some months because of increased mean monthly river flows associated with project implementation and operation. However, these increased flows would affect areas periodically inundated or saturated under existing conditions and/or the No-Action Alternative. In addition, the effects of inundation would diminish with distance downstream because of the influence of inflows from tributaries and the effect of diversions and flood bypasses. As a result, the direct conversion of agricultural land to nonagricultural uses or cancellation of Williamson Act contacts is unlikely to be substantial.

CP1 would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. A substantial portion of this water would substitute for groundwater pumping, allow for changes in agricultural irrigation practices, or return idle cropland to production. Therefore, implementing CP1 would not indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP1): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP1 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP1 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-4 (CP1) for the upper Sacramento River (Shasta Dam to Red Bluff). For the same reasons as described above for Impact Ag-4 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Like CP1, by increasing storage at Shasta Lake, CP2 would change the reservoir's full pool elevation and seasonal pool elevations, and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways.

The full pool elevation of Shasta Lake would increase by 14.5 feet and the pool elevation would average as much as 12–17 feet higher than under existing (2005) and No-Action Alternative (2030) conditions at various times of the year. The greatest change would occur during the wettest years. Raising the dam 12.5 feet would increase the reservoir's surface area at full pool by about 1,750 acres (6 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years.

In general, the proposed changes in flow and river stage on the upper Sacramento River associated with CP2 are similar to but slightly greater than the changes associated with CP1, as outlined above.

Shasta Lake and Vicinity

Impact Ag-1 (CP2): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

This impact would be the same as Impact Ag-1 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP2): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP2 would result in the conversion of forest land to nonforest uses. This impact would be significant.

A total of 1,440 acres of forest land would be affected by inundation under CP2 (Table 10-6). Also, approximately 116 acres of land in the relocation areas would be affected by removal, modification, or relocation of infrastructure under CP2 (acreages were calculated based on infrastructure relocation information presented in Chapter 2, "Alternatives"); and most of this acreage would involve conversion of forest land to nonforest uses. This impact would be significant. Mitigation for this impact is not proposed because no feasible mitigation is available to reduce the impact to a less than significant level.

Table 10-6. Acreage of Forest Land that Would Be Affected by Inundation Under CP2

Forest Land	Area (Acres)
Blue oak–foothill pine	15
Blue oak woodland	2
Closed-cone pine–cypress	343
Douglas-fir	<1
Montane hardwood	260
Montane hardwood–conifer	332
Ponderosa pine	488
Total	1,440

Source: Data compiled by AECOM in 2011

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP2): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Within the upper Sacramento River portion of the primary study area, inundation of agricultural lands, including Important Farmland and Williamson Act contract lands, could result from increases in mean monthly river flows. In general, the flow increases that would occur in some years would be expected to be small and would affect areas periodically inundated under existing and No-Action Alternative conditions. The effects of increased flow would diminish with distance downstream. CP2 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. Therefore, implementing CP2 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Ag-3 (CP1), because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP2): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP2 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in

the riparian corridor along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP2 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Ag-4 (CP1), because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (CP2): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Within the extended study area, inundation or soil saturation of agricultural lands, including lands designated as Important Farmland and under Williamson Act contract, could result from increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or under the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP2 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. Therefore, implementing CP2 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Ag-5 (CP1), because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP2): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP2 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP2 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Ag-6 (CP1), because alteration of the flow regime of the Sacramento River would be slightly

greater under CP2 than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

Like both of the alternatives discussed above, by increasing storage at Shasta Lake, CP3 would change the reservoir's full pool elevation and seasonal pool elevations and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways.

The full pool elevation of Shasta Lake would increase by 20.5 feet and the pool elevation would average as much as 18-24 feet higher than under existing (2005) and No-Action (2030) conditions at various times of the year. The greatest change would occur during the wettest years. Raising the dam 18.5 feet would increase the reservoir's surface area at full pool by about 2,570 acres (9 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years.

In general, the changes in flow and river stage on the upper Sacramento River associated with CP3 would be more substantial than the changes associated with CP1 and CP2. However, these anticipated changes are still within a few percentage points of the changes associated with CP1 and CP2, as outlined above.

Shasta Lake and Vicinity

Impact Ag-1 (CP3): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

This impact would be the same as Impact Ag-1 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP3): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP3 would result in the conversion of forest land to nonforest uses. This impact would be significant.

A total of 2,068 acres of forest land would be affected by inundation under CP3 (Table 10-7). Also, approximately 133 acres of land in the relocation areas would be affected by removal, modification, or relocation of infrastructure under CP3 (acreages were calculated based on infrastructure relocation information presented in Chapter 2, "Alternatives"); and most of this acreage would involve conversion of forest land to nonforest uses. This impact would be significant. Mitigation for this impact is not proposed because no feasible mitigation is available to reduce the impact to a less than significant level.

Table 10-7. Acreage of Forest Land that Would Be Affected by Inundation Under CP3

Forest Land	Area (Acres)
Blue oak–foothill pine	16.59
Blue oak woodland	6.81
Closed-cone pine–cypress	484.62
Douglas-fir	0.36
Montane hardwood	371.24
Montane hardwood–conifer	485.20
Ponderosa pine	702.82
Total	2,067.64

Source: Data compiled by AECOM in 2011

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP3): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Within the upper Sacramento River portion of the primary study area, inundation of agricultural lands, including Important Farmland and Williamson Act contract lands, could result from increased mean monthly river flows. In general, the flow increases that would occur in some years would be expected to be small (5 percent or less) and would affect areas periodically inundated under existing and No-Action Alternative conditions. The effects of increased flow would diminish with distance downstream. CP3 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. Therefore, implementing CP3 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-3 (CP1); however, the extent of the impact would be greater under CP3 than under CP1 and CP2 because it would entail greater alterations of flow regimes. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP3): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP3 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest.

Therefore, implementing CP3 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-4 (CP1); however, the extent of the impact would be greater under CP3 than under CP1 and CP2 because it would entail greater alterations of flow regimes. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (CP3): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Within the extended study area, inundation or soil saturation of agricultural lands, including lands designated as Important Farmland and under Williamson Act contract, could result from increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or under the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP3 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes primarily during drought periods. Therefore, implementing CP3 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-5 (CP1); however, the extent of the impact would be greater under CP3 than under CP1 and CP2 because it would entail greater alterations of flow regimes. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP3): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP3 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP3 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-6 (CP1); however, the extent of the impact would be greater under CP3 than under CP1 and CP2 because it would entail greater alterations of flow regimes. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Like each of the alternatives discussed above, by increasing storage at Shasta Lake, CP4 would change the reservoir's full pool elevation and seasonal pool elevations, and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways.

As under CP3, the full pool elevation of Shasta Lake would increase by 20.5 feet and the pool elevation would average as much as 18–24 feet higher than under existing (2005) and No-Action Alternative (2030) conditions at various times of the year. The greatest change would occur during the wettest years. However, the dedicated Shasta Lake storage of 378 TAF is unique to CP4 and would result in a different drawdown scenario than under CP3. In general, Shasta Lake storage would be 100–140 TAF greater under CP4 than under CP3 at various times of the year, with the greatest difference occurring during October and November. This equates to an increase in pool elevation of about 3 to 5 feet throughout the year.

Raising the dam 18.5 feet would increase the reservoir's surface area at full pool by about 2,570 acres (9 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years.

The changes in flow and river stage on the upper Sacramento River associated with CP4 would be the same as the changes associated with CP1, as outlined above, in that the operated storage of 256 TAF would be the same for CP1 and CP4.

CP4 includes a gravel augmentation program to restore Sacramento River flow through Anderson Slough, with the primary purpose of recreating habitat for anadromous salmonid fish species.

Shasta Lake and Vicinity

Impact Ag-1 (CP4): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

This impact would be the same as Impact Ag-1 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP4): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP4 would result in the conversion of forest land to nonforest uses. This impact would be significant.

This impact would be the same as Impact Ag-2 (CP3) and would be significant. Mitigation for this impact is not proposed because no feasible mitigation is available to reduce the impact to a less than significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP4): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Within the upper Sacramento River portion of the primary study area, inundation of agricultural lands, including Important Farmland and Williamson Act contract lands, could result from increases in mean monthly river flows. In general, the flow increases that would occur in some years would be expected to be small (5 percent or less) and would affect areas periodically inundated under existing and No-Action Alternative conditions. The effects of increased flow would diminish with distance downstream. CP4 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. In addition, there is no Important Farmland or Williamson Act contract land in the area proposed for gravel augmentation. Therefore, implementing CP4 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-3 (CP1). In addition, there is no Important Farmland or Williamson Act contract land in the area proposed for gravel augmentation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP4): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP4 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing of CP4 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (CP4): Direct and Indirect Conversion of Important Farmland and Cancellation of Williamson Act Contracts to Nonagricultural Uses in the Extended Study Area Within the extended study area, inundation or soil

saturation of agricultural lands, including lands designated as Important Farmland and under Williamson Act contract, could result from increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or under the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP4 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. Therefore, implementing CP4 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-5 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP4): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP4 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP4 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-6 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Like each of the alternatives discussed above, by increasing storage at Shasta Lake, CP5 would increase the reservoir's full pool elevation and seasonal pool elevations and change the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways.

The full pool elevation of Shasta Lake would increase by 20.5 feet and the pool elevation would average as much as 18-24 feet higher than under existing (2005) and No-Action Alternative (2030) conditions at various times of the year. The greatest change would occur during the wettest years. Raising the dam 18.5 feet would increase the reservoir's surface area at full pool by about 2,570 acres (9 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years.

Changes in flow and river stage on the upper Sacramento River associated with CP5 would be the same as those associated with CP3, as outlined above.

CP5 includes a gravel augmentation program to restore Sacramento River flow through Anderson Slough, with the primary purpose of recreating habitat for anadromous salmonid fish species. Also under consideration under this alternative are rehabilitation of the boat ramp for motorized boat use and construction of a handicap fishing access area.

Shasta Lake and Vicinity

Impact Ag-1 (CP5): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

This impact would be the same as Impact Ag-1 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP5): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP5 would result in the conversion of forest land to nonforest uses. This impact would be significant.

This impact would be similar to Impact Ag-2 (CP3) and would be significant. Mitigation for this impact is not proposed because no feasible mitigation is available to reduce the impact to a less than significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP5): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Within the upper Sacramento River portion of the primary study area, inundation of agricultural lands, including Important Farmland and Williamson Act contract lands, could result from increased mean monthly river flows. In general, the increases in flow that would occur in some years would be expected to be small (5 percent or less) and would affect areas periodically inundated under existing and No-Action Alternative conditions. The effects of increased flow would diminish with distance downstream. CP5 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes, primarily during drought periods. There is no Important Farmland or land under Williamson Act contract within the areas proposed for gravel augmentation and improvements to recreational facilities. Therefore, implementing CP5 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-3 (CP1). In addition, there is no Important Farmland or land under Williamson Act contract within the areas proposed for gravel augmentation and recreational facility improvements. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP5): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP5 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP5 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (CP5): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Within the extended study area, inundation or soil saturation of agricultural lands, including lands designated as Important Farmland and under Williamson Act contract, could result from increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or under the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP5 also would increase the reliability of the water supply by increasing firm water supplies for irrigation purposes primarily during drought periods. Therefore, implementing CP5 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-5 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP5): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP5 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are speculative, and may not all prove to be adverse. Changes in

the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP5 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-6 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

10.3.5 Mitigation Measures

Table 10-8 presents a summary of mitigation measures for agricultural and forest resources.

Table 10-8. Summary of Mitigation Measures for Agriculture and Important Farmland

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Ag-1: Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake	LOS before Mitigation	PS	NI	NI	NI	NI	NI
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	SU	NI	NI	NI	NI	NI

	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS

Notes:
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant
S = significant
SU = significant and unavoidable

No-Action Alternative

Under the No-Action Alternative, no action would be taken, including implementation of mitigation measures; rather, existing conditions would continue to change into the future. No mitigation measures are required to reduce the indirect effects of agricultural land conversion in the study area under the No-Action Alternative. Thus, Impacts Ag-1 (No-Action), Ag-3 (No-Action), and Ag-5 (No-Action) would be significant and unavoidable.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Ag-1 (CP1), Ag-3 (CP1), Ag-4 (CP1), Ag-5 (CP1), and Ag-6 (CP1). No feasible mitigation measures are available at the time of preparation of this PDEIS to reduce Impact Ag-2 (CP1) to a less than significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP1) would be significant and unavoidable.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Ag-1 (CP2), Ag-3 (CP2), Ag-4 (CP2), Ag-5 (CP2), and Ag-6 (CP2). As discussed above for CP1, no feasible mitigation measures are available at the time of preparation of this PDEIS to reduce Impact Ag-2 (CP2) to a less than significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP2) would be significant and unavoidable.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impacts Ag-1 (CP3), Ag-3 (CP3), Ag-4 (CP3), Ag-5 (CP3), and Ag-6 (CP3). As discussed above for CP1, no feasible mitigation measures are available at the time of preparation of this PDEIS to reduce Impact Ag-2 (CP3) to a less than significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP3) would be significant and unavoidable.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts Ag-1 (CP4), Ag-3 (CP4), Ag-4 (CP4), Ag-5 (CP4), and Ag-6 (CP4). As discussed above for CP1, no feasible mitigation measures are available at the time of preparation of this PDEIS to reduce Impact Ag-2 (CP4) to a less than significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP4) would be significant and unavoidable.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts Ag-1 (CP5), Ag-3 (CP5), Ag-4 (CP5), Ag-5 (CP5), and Ag-6 (CP5). As discussed above for CP1, no feasible mitigation measures are available at the time of preparation of this PDEIS to

reduce Impact Ag-2 (CP5) to a less than significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP5) would be significant and unavoidable.

10.3.6 Cumulative Effects

California's demand for water for irrigation and other uses is expected to continue to increase, while the water supply will likely become less reliable. This trend could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts, resulting in an indirect impact; this indirect impact would be potentially significant.

No operational changes would occur that would directly convert forest land to nonforest uses along the upper Sacramento River. However, CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. The resulting changes in flow regime would likely result in minimal adverse effects on riparian forest and oak woodlands. Several management and restoration plans and programs would implement actions that would largely offset those adverse effects. Although there would be reasonably foreseeable projects that would restore forest land or put land into agricultural production, there would be an overall significant cumulative effect on Important Farmlands and forest lands.

The effects of climate change on operations at Shasta Lake could potentially result in changes to conditions for agricultural land and forest land in downstream areas. As described in the Climate Change Projection Appendix, climate change could affect future demand for agricultural water by leading to increased rates of evapotranspiration and increasing the length of the growing season. On the other hand, increased precipitation could decrease overall water demand, depending on what adaptation strategies are used by agriculture and municipalities and how much more efficiently plants use water when carbon dioxide concentrations are higher. Changes in crop type, planting cycles, time of planting, and crop productivity may occur as the result of climate change, though consensus has not been reached on how changes will occur. As stated previously in this section, increases in California's demand for water and forecast reductions in water supply could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts.

In addition, changes to forest land and land cover could affect climate change. As stated in the Climate Change Projection Appendix, deforestation and land cover conversion have also been identified as contributing to global warming by reducing the Earth's capacity to remove carbon dioxide from the air and altering the Earth's albedo or surface reflectance, allowing more solar radiation to be absorbed.

In the primary study area, forest land would be affected by inundation of land and removal, modification, or relocation of infrastructure in the vicinity of Shasta Dam. Implementing any of the five project alternatives (CP1–CP5) would result in the conversion of forest land to nonforest uses in the vicinity of Shasta Dam. No feasible mitigation exists to create a similar large area of forest land to replace the area of forest land that would be inundated or converted to nonforest uses by relocation of facilities. Therefore, each of the five project alternatives would result in a cumulatively considerable incremental contribution to a cumulative impact related to conversion of forest land to nonforest uses. However, it is determined that there is not an overall significant cumulative impact related to conversion of forest land to nonforest uses because most of this area remains substantially in forest land and has not been converted to nonforest uses. Therefore, this impact would not be cumulatively significant.

In the extended study area, altered flow regimes associated with implementation of any of the five project alternatives could affect forest land. The altered flow regime could affect oak woodlands by prolonging inundation and changing the availability of soil moisture in some years; however, these effects are speculative, and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forest along the upper Sacramento River in the future; however, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing any of the five project alternatives would not result in the conversion of forest land to nonforest uses. Therefore, the five project alternatives would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to conversion of forest land to nonforest uses.

As stated previously climate change could result in changes to conditions for agricultural land and forest land in downstream areas. However, implementing any of the five project alternatives would promote improvements in the reliability of CVP water supply deliveries. Thus, the project alternatives would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to future demands for agricultural water.

The five project alternatives would result in a cumulatively considerable incremental contribution to a cumulative impact related to conversion of forest land to nonforest uses; however, there is not an overall significant cumulative impact related to conversion of forest land to nonforest uses because most of this area remains substantially in forest land and has not been converted to nonforest uses. Thus, when added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect on climate change resulting from changes to forest land and land cover.

Chapter 11
Fisheries and Aquatic Ecosystems

11.1 Affected Environment

This section describes the affected environment related to fisheries and aquatic ecosystems for the dam and reservoir modifications proposed under the SLWRI. For a more in-depth description of the affected environment, see the *Fisheries and Aquatic Ecosystems Technical Report*.

11.1.1 Aquatic Habitat

Shasta Lake and Vicinity

Water resources development, including the construction of dams and diversions, has affected the hydrology, geomorphology, and ecology of the watershed. Before the construction of Shasta Dam, the Sacramento River typically experienced large fluctuations in flow driven by winter storms, with late-summer flows averaging 3,000 cubic feet per second (cfs) or less. These fluctuations and periodic flows moved large amounts of sediment and gravel out of the mountainous tributaries and down the Sacramento River. The completion of Shasta Dam in 1945 resulted in general dampening of historic high and low flows, reducing the timing, magnitude, and duration of winter floods while maintaining higher summer flows between 7,000 and 13,000 cfs. The annual volume of flow in the Sacramento River continues to vary significantly from year to year. However, average monthly flows following the construction of Shasta Dam no longer exhibit pronounced seasonal winter highs and summer lows. This is primarily because of winter flood control operations that have reduced peak flood flows, and summer releases made for water supply purposes.

The current composition and distribution of fish species inhabiting the study area reflect habitat conditions, the historic fishery, the operational effects of Shasta Dam, effects of dams on several of the upstream tributaries, and the introduction of nonnative species.

The distribution and productivity of organisms and aquatic habitats of Shasta Lake are greatly affected by the reservoir's dynamic seasonal surface elevation fluctuations and thermal stratification. The reservoir's flood control, water storage, and water delivery operations typically result in declining water elevations during the summer through the fall months, rising or stable elevations during the winter months, and rising elevations during the spring months and

sometimes into the early-summer months, while storing precipitation and snowmelt runoff. During summer months, the relatively warm surface layer favors warm-water fishes such as bass and catfish. Deeper layers are cooler and are suitable for cold-water species. Shasta Lake is classified as a cool-water, mesotrophic, monomictic reservoir because it is moderately productive and has one period of mixing each year, although it never completely turns over (Bartholow et al. 2001). Shasta Lake tributary fish species comprise several native and nonnative species and have been managed to favor naturally produced ("wild") and stocked (hatchery-cultured) native and nonnative trout species (Rode 1989, Moyle 2002, Rode and Dean 2004). Major assemblages of non-fish aquatic animal species include benthic macroinvertebrates and zooplankton communities. Climate conditions and reservoir storage volume are the two most influential factors affecting cold-water habitat and primary productivity in Shasta Lake (Bartholow et al. 2001). Cold-water habitat provided by Shasta Lake is a function of the total storage and associated surface area provided by Shasta Lake. This relationship is influenced by variation in the water surface elevation (WSEL) throughout the year. Variation in WSEL is a function of water demand, water quality requirements, and inflow, and WSEL can change based on the water-year type. Typically, primary production in reservoirs is associated with storage volumes when all other factors are held constant (Stables et al. 1990). Increased storage and the corresponding increase in surface area results in a greater total biomass and a greater abundance of plankton and fish, because available habitat area is increased.

Upper Sacramento River (Shasta Dam to Red Bluff)

This river reach has cool water temperatures because of regulated releases from Shasta and Keswick Dams, and a stable, largely confined channel with little meander. Riffle habitat with gravel substrates and deep pool habitats are abundant in comparison with reaches downstream, although they are still insufficient to support healthy salmonid populations. Immediately below Keswick Dam, the river is deeply incised in bedrock with very limited riparian vegetation and limited functioning riparian ecosystems. Water temperatures are generally cool, even in late summer, because of regulated releases from Shasta and Keswick Dams. Near Redding, the river flows into the valley and the floodplain broadens. Historically, this area appears to have had wide expanses of riparian forests, but much of the river's riparian zone is currently subject to urban encroachment and noxious weed problems. This encroachment becomes quite extensive in the Anderson/Redding area, with homes placed directly within or adjacent to the riparian zone.

Despite net losses of gravel since construction of Shasta Dam, substrates in much of this reach contain gravel needed for spawning by salmonids, mostly derived from the Central Valley Project Improvement Act (CVPIA) gravel augmentation program. This reach provides much of the remaining spawning and rearing habitat of several listed anadromous salmonids, even though the amount of gravel available is insufficient. For this reason, it is one of the most sensitive and important stream reaches in the State.

Three water control structures, Keswick Dam, Anderson-Cottonwood Irrigation District, and Red Bluff Diversion Dam (RBDD), are located along the Sacramento River in this reach. Currently, revisions are being made at RBDD to improve fish passage. The main tributaries to the Sacramento River between Shasta Dam and Red Bluff are Battle, Bear, Clear, Cow, and Cottonwood creeks. The primary land uses along the Sacramento River between Shasta Dam and RBDD are urban, residential, and agricultural.

Lower Sacramento River and Delta

The roughly 300 miles of the Sacramento River can be subdivided into distinct reaches. The reaches in the lower Sacramento and Sacramento–San Joaquin River Delta (Delta) study area are discussed separately because of differences in morphology, water temperature, and aquatic habitat functions.

Sacramento River from Red Bluff Diversion Dam to Colusa In this reach, the Sacramento River functions as a large alluvial river with active meander migration through the valley floor. The river is classified as a meandering river, where relatively stable, straight sections alternate with more sinuous, dynamic sections (Resources Agency 2003). The active channel is fairly wide in some stretches and the river splits into multiple forks at many different locations, creating gravel islands, often with riparian vegetation. Historic bends in the river are visible throughout this reach and appear as scars of the historic channel locations with the riparian corridor and oxbow lakes still present in many locations. The channel remains active and has the potential to migrate in times of high water. Point bars, islands, high and low terraces, instream woody cover, early successional riparian plant growth, and other evidence of river meander and erosion are common in this reach. The channel has varying widths, and aquatic habitats consist of willow riffles, deep runs, deep pools at meander bends, glides, and willow vegetated floodplain areas that become inundated during high flows.

Sacramento River from Colusa to the Delta The general character of the Sacramento River changes drastically downstream from Colusa from a dynamic and active meandering channel to a confined, narrow channel restricted from migration. While setback levees exist along portions of the river upstream from Colusa, the levees become much narrower along the river edge as the river continues south to the Delta. Surrounding agricultural lands encroach directly adjacent to the levees, which have cut the river off from the majority of its riparian corridor, especially on the eastern side of the river. The majority of the levees in this reach are lined with riprap, allowing the river no erodible substrate. The channel width is fairly uniform and river bends are static as a result of confinement by levees. Therefore, aquatic habitats are fairly homogenous because depth profiles and substrate composition are fairly uniform throughout the reach. Multiple water diversion structures in this reach move floodwaters into floodplain bypass areas during high-flow events.

Tributaries to the Lower Sacramento River Lower reaches of primary tributaries are included because of the potential for project effects on flows and associated flow-related effects on fish species of management concern. However, potential changes in flows are diminished in these areas because of operation of upstream CVP and SWP reservoirs and increasing effects of inflows from tributaries and of diversions and flood bypasses.

Lower Feather River Aquatic habitats found in the lower Feather River vary as the river flows from releases at the DWR Oroville Dam facilities down to the confluence with the Sacramento River at Verona. At the upper extent, the approximate 8-mile low-flow (about 600 cfs) section contains mainly riffles and runs, which provide spawning habitat for the majority of Feather River Chinook salmon (*Oncorhynchus tshawytscha*) and steelhead (*O. mykiss*). Also present in the low-flow channel is a series of remnant gravel pit pools/ponds that connect to the main channel. This stretch is fairly confined by levees as it flows through the city of Oroville. From the downstream end of the low-flow channel, the Feather River is fairly active and meanders its way south to Marysville. However, this stretch is bordered by active farmland, which confines the river into an incised channel in certain stretches. Relatively large areas of adjacent farmlands are in the process of being restored to floodplain habitat with the relocation of levees to become setback levees.

Lower American River Flows in the lower American River (below Folsom and Nimbus dams) are generally cold and clear, providing habitat for anadromous and resident fish species. The river is fairly low gradient and is composed of riffle, run, glide, and pool habitats. Dams along the watershed have reduced gravel inputs to the system, but the lower American River contains large gravel bars and forks in many locations, leaving gravel/cobble islands within the channel. The majority of the lower American River is surrounded by the American River Parkway, preserving the surrounding riparian zone. The river channel does not migrate to a large degree because of the geologic composition that has allowed the river to incise deep into sediments, leaving tall cliffs and bluffs adjacent to the river.

Lower San Joaquin and Stanislaus Rivers The lower San Joaquin River is characterized by a relatively wide (approximately 300 feet) channel with little canopy or overhead vegetation and minimal bank cover. Aquatic habitat in the San Joaquin River is characterized primarily by slow-moving glides and pools, is depositional in nature, and has limited water clarity and habitat diversity. Many of the fish species using the lower San Joaquin River use this lower segment of the river to some degree, even if only as a migratory pathway to and from upstream spawning and rearing areas. The lower river also is used by certain fish species (e.g., delta smelt (*Hypomesus transpacificus*)) that make little to no use of areas in the upper segment of the river (see Delta discussion below). Aquatic habitats in the lower Stanislaus River vary longitudinally and provide fish spawning, rearing, and/or migratory habitat for a diverse assemblage of common Central Valley native and nonnative fish species.

Aquatic habitats include riffles, runs, pools, and glides. Floodplain and associated riparian habitat also varies with the development of levees and encroachment of agriculture and urban uses. Flows in both river systems are highly altered and are managed for flood control and water supply purposes.

Sacramento River Floodplain Bypasses There are three major floodplain bypasses – Butte Basin, Sutter Bypass, and Yolo Bypass – with a total of 10 overflow structures along the mainstem Sacramento River (six weirs, three flood relief structures, and an emergency overflow roadway) that provide access to broad, inundated floodplain habitat during wet years.

Unlike other Sacramento River and Delta habitats, floodplains and floodplain bypasses are seasonally dewatered (as high flows recede) during late spring through autumn. This prevents introduced fish species from establishing year-round dominance except in perennial water sources (Sommer et al. 2003). Moreover, many of the native fish are adapted to spawn and rear in winter and early spring (Moyle 2002) during the winter flood pulse. Introduced fish typically spawn during late spring through summer when the majority of the floodplain is not available to them.

Butte Basin The Butte Basin lies east of the Sacramento River and extends from the Butte Slough outfall gates near Meridian to Big Chico Creek near Chico Landing. Flood flows are diverted out of the Sacramento River into the Butte Basin and Sutter Bypass via several designated overflow areas (i.e., low points along the east side of the river) that allow high flood flows to exit the Sacramento River channel.

Sutter Bypass The Sutter Bypass is a narrow floodwater bypass conveying Sacramento River flood flows from the Butte Basin and the Tisdale Weir. The bypass area is an expansive land area in Sutter County used mainly for agriculture. In times of high water, Sacramento River water enters the bypass through the Butte Slough outfall and the Tisdale Weir (when the stage exceeds 45.45 feet) and inundates the bypass with as much as 12 feet of water. The Sutter Bypass, in turn, conveys flows to the lower Sacramento River region at the Fremont Weir near the confluence with the Feather River and into the Sacramento River and the Yolo Bypass (USACE and The Reclamation Board 2002).

Yolo Bypass The Yolo Bypass is an approximate 59,000-acre land area that conveys Sacramento River flood waters around Sacramento during times of high runoff. Flow is diverted from the Sacramento River into the bypass when the stage exceeds 33.5 feet (corresponding to 56,000 cfs at Verona). Diversion of the majority of Sacramento River, Sutter Bypass, and Feather River floodwaters to the Yolo Bypass from Fremont Weir controls Sacramento River flood stages at Verona. During large flood events, up to 80 percent of Sacramento River flows are diverted into the bypass.

Sacramento-San Joaquin Delta The Delta and Suisun Bay, on the western edge of the Delta, are located at the confluence of the Sacramento and San Joaquin rivers and may be considered to represent the most important, complex, and controversial geographic area for both anadromous and resident fisheries production and distribution of California water resources for numerous beneficial uses (Hanson 2009). The Delta's channels are used to transport water from upstream reservoirs to the south Delta, where Federal and State facilities (Jones Pumping Plant and Harvey O. Banks Delta Pumping Plant, respectively) pump water into CVP and SWP canals, respectively.

Environmental conditions in the Delta depend primarily on the physical structure of Delta channels, inflow volume and source, Delta Cross Channel (DCC) operations, Delta exports and diversions, and tides. The CVP affects Delta conditions primarily through control of upstream storage and diversions, Delta exports and diversions, and DCC operations. These factors also determine outflow and the location of the entrapment zone, which is an area of high organic carbon that is critically important to a number of fish and invertebrate species, as well as to the overall ecology of the Delta and Suisun Bay. In addition to these physical factors, environmental conditions such as water temperature, predation, food production and availability, competition with introduced exotic fish and invertebrate species, and pollutant concentrations all contribute to interactive, cumulative conditions that have substantial effects on Delta fish populations.

Water development has changed the volume and timing of freshwater flows through the San Francisco Bay/Sacramento–San Joaquin River Delta (Bay-Delta). Over the past several decades, the volume of the Bay-Delta's freshwater supply has been reduced by upstream diversions, in-Delta use, and Delta exports. As a result, the proportion of Delta outflow depleted by upstream and Delta diversions has grown substantially. In wet years, diversions reduce outflow by 10 to 30 percent. In dry years, diversions may reduce outflow by more than 50 percent.

Water development has also altered the seasonal timing of flows passing into and through the Bay-Delta. Flows have decreased in April, May, and June and have increased slightly during the summer and fall (SFEP 1992). Seasonal flows influence the transport of eggs and young organisms (e.g., zooplankton, fish eggs, larvae) through the Delta and into San Francisco Bay. Flows during April, May, and June play an especially important role in determining the reproductive success and survival of many estuarine species including salmon, striped bass, American shad, delta smelt, longfin smelt, splittail, and others (Stevens and Miller 1983, Stevens et al. 1985, Herbold 1994, Meng and Moyle 1995).

An estimated 25 percent of all warm-water and anadromous sport fishing and 80 percent of California's commercial fishery depend on species that live in or migrate through the Delta. The Delta serves as a migration path for all Central

Valley anadromous species returning to their natal rivers to spawn. Adult Chinook salmon move through the Delta during most months of the year. Salmon and steelhead juveniles depend on the Delta as transient rearing habitat during migration through the system to the ocean and could remain for several months, feeding in marshes, tidal flats, and sloughs. In addition, Delta outflow influences abundance and distribution of fish and invertebrates in the bay through changes to salinity, currents, nutrient levels, and pollutant concentrations. Delta smelt is a key species driving many of the ongoing water management decisions in the Delta.

Trinity River Sacramento River flow is augmented in average water years by transfer of up to 1 million acre-feet of Trinity River water through Clear Creek and Spring Creek tunnels to Keswick Reservoir (Reclamation 2004). Flows in the Trinity River (below Lewiston Dam) are generally cold, providing habitat for anadromous and resident fish species. Aquatic habitats in the river consist of riffle, run, glide, and pool habitats. Fish habitat values have increased in quantity and quality through restoration activities that have taken place over the last several years. Implementation of the Trinity River Restoration Program is expected to further increase the value of the habitat below Lewiston Dam over the next 10 to 15 years (NMFS 2000).

CVP/SWP Service Areas

The CVP/SWP service areas contain primarily highly altered aquatic habitat types, including reservoirs, canals, ditches, and other manmade water conveyance structures/facilities. Agricultural land and urban development are the dominate land uses within these service areas. As a result of all these factors, the aquatic communities that occupy the habitats are highly adapted to these disturbed environments and are dominated by nonnative species.

11.1.2 Fish Species

Special-status aquatic species within the primary and extended study areas are listed in Table 11-1. These include animals that are legally protected or are otherwise considered sensitive by Federal, State, or local resource conservation agencies and organizations, and fish species of primary management concern (recreationally and/or commercially important species). The *Fisheries and Aquatic Ecosystems Technical Report* describes life histories and environmental/habitat requirements of special-status species, and information on seasonal timing of important life stages. The following text describes the fishes in the primary and extended area that include special-status fish as well as other important species.

Table 11-1. Special-Status Aquatic Species Potentially Occurring in the Primary and Extended Study Areas

Species	Status[1]				Habitat	Potential to Occur in the Primary and Extended Study Areas
	USFWS/ NMFS	DFG	USFS	MSCS Goals		
Central Valley steelhead *Oncorhynchus mykiss*	T			R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Sacramento-San Joaquin River Delta (Delta).
Sacramento winter-run Chinook salmon *Oncorhynchus tshawytscha*	E	E		R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	T	T		R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.
Central Valley fall/late fall-run Chinook salmon *Oncorhynchus tshawytscha*		SSC	S	R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.
Southern Oregon Northern California Coasts coho salmon *Oncorhynchus kisutch*	T	T			Requires cold, freshwater streams with suitable gravel for spawning; rears in inundated floodplains, edgewater, off-channel habitat, rivers, tributaries, and estuaries.	Occurs in the extended study area in the Trinity River.

Table 11-1. Special-Status Aquatic Species Potentially Occurring in the Primary and Extended Study Areas (contd.)

Species	Status[1]				Habitat	Potential to Occur in the Primary and Extended Study Areas
	USFWS/ NMFS	DFG	USFS	MSCS Goals		
Klamath Mountain Province steelhead *Oncorhynchus mykiss*			S		Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta	Occurs in the extended study area in the Trinity River.
Southern DPS of the North American Green sturgeon *Acipenser medirostris*	T			R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.
Delta smelt *Hypomesus transpacificus*	T	E		R	Spawns in tidally influenced freshwater wetlands and seasonally submerged uplands; rears in seasonally inundated floodplains, tidal marsh, and Delta.	Occurs in the extended study area in the Delta.
Longfin smelt *Spirinchus thaleichthys*		T		R	Primary habitat is the open water of estuaries, both in seawater and freshwater areas, typically in the middle or deeper areas of the water column; spawn in estuaries in fresh or slightly brackish water over sandy or gravel substrates.	Occurs in the extended study area in the Delta.

Table 11-1. Special-Status Aquatic Species Potentially Occurring in the Primary and Extended Study Areas (contd.)

Species	Status[1]				Habitat	Potential to Occur in the Primary and Extended Study Areas
	USFWS/ NMFS	DFG	USFS	MSCS Goals		
Sacramento splittail *Pogonichthys macrolepidotus*	DT	SSC		R	Spawning and juvenile rearing from winter to early summer in willow weedy areas inundated during seasonal flooding in the lower reaches and flood bypasses of the Sacramento River, including the Yolo Bypass.	Occurs in the primary and extended study area in the Delta and Sacramento River and tributaries.
Hardhead *Mylopharodon conocephalus*		SSC	S	m	Spawning occurs in pools and side pools of rivers and creeks; juveniles rear in pools of rivers and creeks, and willow to deeper water of lakes and reservoirs.	Occurs in the primary and extended study areas in freshwater portions of Sacramento River and tributaries.
San Joaquin roach *Lavinia symmetricus* sp.		SSC			Spawning occurs in pools and side pools of small rivers and creeks; juveniles rear in pools of small rivers and creeks.	Occurs in the extended study area in the San Joaquin River and tributaries and Delta.
Rough sculpin (*Cottus asperrimus*)					Prefers sand or gravel substrate in cool streams or reservoirs. Spawns in streams.	Potentially occurs in the Shasta Lake and Vicinity portion of the primary study area in the Pit River and tributaries upstream from Shasta Lake.
Rainbow trout (*Oncorhynchus mykiss*)					Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries.	Occurs in Shasta Lake, Keswick Reservoir, and tributaries.

Table 11-1. Special-Status Aquatic Species Potentially Occurring in the Primary and Extended Study Areas (contd.)

Species	Status[1]				Habitat	Potential to Occur in the Primary and Extended Study Areas
	USFWS/ NMFS	DFG	USFS	MSCS Goals		
Redband trout (*Oncorhynchus mykiss stonei*)			S		Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries.	Occurs upstream from McCloud Dam.
Bull trout *Salvelinus confluentus*	T	E			Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries.	Previously found in the McCloud River. Now considered extirpated from California.
California floater *Anodonta californiensis*			S		Potentially occurring in willow areas of clean, clear ponds, lakes and rivers with silty substrate	Potentially occurs in Shasta Lake, Keswick Reservoir, and tributaries.
Nugget pebblesnail *Fluminicola seminalis*			M		Potentially occurring in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats)	Potentially occurs in the Shasta Lake and Vicinity portion of the primary study area in large creeks and rivers tributary to Shasta Lake.
Potem pebblesnail *Fluminicola* sp. 14			M		Potentially occurring in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats)	Potentially occurs in the Shasta Lake and Vicinity portion of the primary study area in tributaries to Shasta Lake.
Flat-top pebblesnail *Fluminicola* sp. 15			M		Potentially occurring in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats)	Potentially occurs in the Shasta Lake and Vicinity portion of the primary study area in tributaries to Shasta Lake.

Shasta Lake and Vicinity

Shasta Lake fish species include native and nonnative species, which are dominated by mostly introduced warm-water and cold-water species (Weidlein 1971) (Table 11-2). Major assemblages of non-fish aquatic animal species include benthic macroinvertebrates and zooplankton communities.

Table 11-1 lists special-status aquatic species within the primary and extended study areas. These include animals that are legally protected or are otherwise considered sensitive by Federal, State, or local resource conservation agencies and organizations, and fish species of primary management concern (recreationally and/or commercially important species).

Key:

DPS = Distinct Population Segment

Cold-Water Species Shasta Lake and its tributaries provide very productive habitats for cold-water fish species, which typically prefer or require temperatures cooler than 70 degrees Fahrenheit (°F). During the cooler months, cold-water species such as rainbow trout, brown trout, and landlocked Chinook salmon may be found rearing throughout the lake; however, these species do not

spawn in the lake, preferring to spawn in tributary streams, however, few Chinook salmon stocked in Shasta Lake have ever been observed to spawn in the reservoir tributaries (J. Zustak, USFWS, pers. comm., 2009). During the summer months, these cold-water species may be found rearing in association with the cold, deep hypolimnion and metalimnion layers within the reservoir, although the fish may make frequent forays into the epilimnion to feed on small prey fish and return to cooler depths to digest their prey (Finnell and Reed 1969, Koski and Johnson 2002, Moyle 2002, Quinn 2005).

Native species such as white sturgeon, hardhead, riffle sculpin, Sacramento sucker, and Sacramento pikeminnow tend to reside in cooler water strata in the reservoir and in and near tributary inflows (Moyle 2002). Trout may also congregate near the mouths of the reservoir's tributaries, including the upper Sacramento River, McCloud River, Pit River, and Squaw Creek, at various times of the year seeking thermal refuge, foraging, and spawning, when conditions are favorable for these species.

Hatchery- and pen-reared trout and salmon are stocked in Shasta Lake several times each year to support the sport fishery. About 60,000 pounds of juvenile rainbow trout and about 50,000 subcatchable Chinook salmon are planted annually (S. Baumgartner, DFG, pers. comm., 2008).

Climate conditions and reservoir storage volume are the two most influential factors affecting cold-water habitat and primary productivity in Shasta Lake (Bartholow et al. 2001). Cold-water habitat provided by Shasta Lake is a function of the total storage and associated surface area provided by Shasta Lake. This relationship is influenced by variation in the WSEL throughout the year. Variation in WSEL is a function of water demand, water quality requirements, and inflow, and WSEL can change based on the water-year type. Typically, primary production in reservoirs is associated with storage volumes when all other factors are held constant (Stables et al. 1990). Increased storage and the corresponding increase in surface area results in a greater total biomass and a greater abundance of plankton and fish, because available habitat area is increased.

Warm-Water Species The warm-water fish habitats of Shasta Lake occupy two ecological zones: the littoral (shoreline/rocky/vegetated) and the pelagic (open water) zones. The littoral zone lies along the reservoir shoreline down to the maximum depth of light penetration on the reservoir bottom, and supports populations of spotted bass, smallmouth bass, largemouth bass, black crappie, bluegill, channel catfish, and other warm-water species.

The upper, surface layer of the pelagic zone is the principal plankton-producing region of the reservoir. Plankton comprises the base of the food web for most of the reservoir's fish populations. Operation of the Shasta Dam temperature control device (TCD), which helps conserve the reservoir's cold-water pool by accessing warmer water for storage releases in the winter, spring, and early

summer, may reduce zooplankton biomass in the epilimnion. However, operations of the TCD may result in some increased plankton production at deeper levels as a result of a slight warming of the hypolimnetic layers within the reservoir during the fall months (Bartholow et al. 2001).

Warm-water species, such as largemouth bass, smallmouth bass, spotted bass, and other sunfishes, were introduced into Shasta Lake and have become well established with naturally sustaining populations. Spotted bass are currently the dominant warm-water species in Shasta Lake (S. Baumgartner, DFG, pers. comm., 2006). These warm-water fishes feed primarily on invertebrates while young and become predaceous on other fishes, including engaging in some cannibalism, as they grow. In Shasta Lake, threadfin shad, crayfish, and other invertebrates are most abundant in the diets of these fish (Saito et al. 2001). Spawning activity usually begins during late March or April when temperatures rise to around 60°F. Males generally build the nests in sand, fine gravel, rubble, or debris-covered bottoms at depths between 1 and 20 feet, which varies by species. Spotted bass and catfishes typically spawn at greater depths than the other warm-water species in Shasta Lake. Eggs generally hatch in 3 to 5 days at the predominant springtime water temperatures in Shasta Lake, and males guard the eggs and larvae for up to 4 weeks (Moyle 2002). Fry and juveniles disperse into willow water and prefer areas with vegetation and large rubble as protective cover from predators (Moyle 2002, Ratcliff 2006).

The primary factors affecting warm-water fish abundance and production in Shasta Lake include seasonal reservoir fluctuations, availability of high-quality littoral habitat, and annual climate variations (Ratcliff 2006). The effect of sport fishery harvests on Shasta Lake fish populations is not well understood, although it is generally thought that overfishing of naturally reproducing populations by sport fisheries seldom limits fish abundance (Moyle 2002).

Reservoir level fluctuations, associated shoreline erosion, and suppression of shoreline and emergent vegetation are thought to generally be the most significant factors affecting warm-water fish production in reservoirs, including Shasta Lake (Moyle 2002, Ratcliff 2006). Water level variations influence physical, chemical, and biological processes, which in turn affect fish populations. Reservoir drawdowns reduce water depths and influence thermal stratification and the resulting temperature, dissolved oxygen (DO), and water chemistry profiles.

The typical seasonality of reservoir fluctuations on Shasta Lake can affect year-to-year reproductive success of littoral-spawning fishes, especially the black bass species, by influencing nesting behavior (e.g., abandonment of nests) and dewatering of nests containing eggs in years when reservoir levels decline during the spring and early summer months. Under these same conditions, juveniles may be forced to move to areas with less protection from predation or lower food production. In years when the reservoir rises rapidly and/or extensively during the spring and early summer months, submergence of active

bass nests by more than 15 to 20 feet often results in high egg mortality (Stuber et al. 1982, Moyle 2002).

Shoreline and littoral vegetation are important warm-water fish habitat components for sustainable fishery production (Ratcliff 2006). Structural diversity (e.g., submerged trees, brush, rock, boulders, and rubble) provides shelter and feeding areas for fish. During construction of the reservoir, many trees and brush fields were cleared prior to inundation. Portions of the Pit River and Squaw Creek arms were not cleared, as evidenced by the large number of inundated trees observable in certain areas. Clearing efforts reduced the potential structural diversity of the inundated habitat. Vegetative clearing in many reservoirs has resulted in rocks, boulders, and man-made features (e.g., bridge pilings, riprap, marinas) being the only structural habitat features available, especially for bass and other warm-water fishes.

Annual reservoir fluctuations create highly variable conditions for establishment and maintenance of shoreline and littoral-zone vegetation and aquatic invertebrate communities that subsequently impose limitations on warm-water fish production. Exposed shoreline reservoir areas generally require 3 to 4 years to reestablish terrestrial vegetation. The absence of established, rooted aquatic vegetation is a common aquatic habitat factor that limits populations and fishery production for many fish species in reservoirs (Ploskey 1986, Moyle 2002).

The Shasta-Trinity National Forest (STNF), in cooperation with other Federal and State agencies and local nongovernmental organizations, has implemented a habitat improvement program at Shasta Lake. The objective of this program is to increase cover for warm-water fish. As the fishery management agency for Shasta Lake, DFG prepared a Draft Management Plan for Shasta Lake in 1991. This plan, which has not been finalized, acknowledges the benefit to warm-water fish of structural enhancement projects.

STNF, DFG, and nongovernmental organizations have used a variety of materials and techniques to construct structural enhancements (e,g., willow planting, brush structures) to provide warm-water fish habitat within the drawdown zone of Shasta Lake. The materials and techniques have varied because of differences in funding, available materials, site conditions (reservoir levels), longevity, and desired outcome.

According to STNF aquatic biologists, brush structures constructed from whiteleaf manzanita (*Arctostaphylos manzanita)* have been the STNF's preferred means of structural enhancement since about 1990. These structures have been constructed in areas where manzanita is available near the shoreline, typically in manner that provides varying degree of structural habitat as water levels change over time. The biologists have indicated that these structures have typically resulted in a threefold to tenfold increase in the abundance of warm-water fish in the treated areas (J. Zustak, USFWS, pers. comm., 2007).

Tributary Species The lower reaches of the tributaries draining to the reservoir provide spawning habitat for adfluvial fishes (i.e., fish that spawn in streams, but rear and grow to maturity in lakes) residing in Shasta Lake, as well as, stream-resident fishes, with rainbow trout the principal game species. Most native fish species found in Shasta Lake may also inhabit the lower reaches of the tributaries. Several tributaries to Shasta Lake (e.g., Squaw Creek[1], Little Backbone Creek) have been subjected to discharge from abandoned upslope copper mines. The Shasta Lake West Watershed analysis (Bachmann 2000) suggests that these creeks are "biologically dead" as a result of acid mine discharge from these mines. This watershed analysis also stated that "fish kills" have occurred in Shasta Lake in the vicinity of such tributaries during high runoff conditions.

The four main tributaries to Shasta Lake, which include the Sacramento River, McCloud River, Squaw Creek, and Pit River, are renowned for their high-quality recreational trout fisheries. Each of these streams drains considerable watershed areas comprising mixed conifer forests in the reaches above Shasta Lake. With the exception of the Pit River, which has a series of hydroelectric project dams that begin immediately upstream from Shasta Lake, each of these tributaries has more than 30 miles of high-quality, fish-bearing riverine habitat between the Shasta Lake and upstream dams on the Sacramento and McCloud rivers and steep headwater reaches on Squaw Creek.

For the most part, land use along the main Shasta Lake tributaries upstream from the reservoir is a mix of federal and privately managed forest and timberlands and except for sparse residential development, several small municipalities, and the hydropower projects on the Pit, McCloud, and Sacramento rivers much of the area is lightly developed. The Sacramento River above Shasta Lake is paralleled by a major interstate highway and railroad transportation corridor. In July 1991, a railroad accident spilled 19,000 gallons of the fumigant pesticide metam sodium into the Sacramento River near the town of Dunsmuir, approximately 35 stream miles upstream from Shasta Lake. Metam sodium is highly toxic and killed aquatic and riparian vegetation, aquatic macroinvertebrates, and fish and amphibians along the entire length of the river to Shasta Lake, where a massive chemical containment and neutralization effort was mounted. Ecological recovery efforts were implemented shortly after this spill incident and populations of fish, aquatic macroinvertebrates, and the vegetation adjacent to the stream have attained levels that appear to be in a natural dynamic equilibrium consistent with full recovery, although some amphibian and mollusk population remained depressed at least 15 years later (Cantara Trustee Council 2007).

There are about 2,903 miles of ephemeral, intermittent, and perennial stream channels that contribute to the main Shasta Lake tributaries within the study

[1] This refers to a stream draining the terrain and entering Shasta Lake northwest of Shasta Dam, a historic mining district; not to be confused with the Squaw Creek drainage forming the "Squaw Creek Arm" of the lake.

area. Most of these sub-tributaries are relatively short and steep and may be classified as confined, headwater channels that contribute water, sediment, and organic and inorganic material to Shasta Lake. Most (64 percent) of these stream channels are intermittent and have a slope greater than 10 percent. About 14 percent of the stream channels are perennial, with slopes of less than 7 percent. In the Pacific coast and Cascade ranges, stream channels with gradients up to about 4 percent to 7 percent and possessing sufficient flows typically exhibit a good potential to support habitation by fish and other aquatic organisms; although, steeper slopes do not necessarily, in and of themselves, preclude habitation by fish, particularly trout, sculpins, and dace (Naiman 1998; Reeves et al. 1998). About 79 percent of the tributaries with good fish-bearing potential in the study area occur within the Sacramento River, Squaw Creek, and Pit River arms (see Chapter 4, "Geology, Geomorphology, Minerals, and Soils," for more detail).

Most of the lower gradient, potentially fish-bearing reaches of tributary streams to Shasta Lake are near their confluence with the reservoir. The gradient of most of these tributaries rapidly increases upstream from the shoreline, and natural barriers to fish are common. These barriers are most often created by cascades, waterfalls, and steep reaches of stream channel (i.e., greater than 7-percent slope) that are more than one-quarter mile in length. Stream channel data generated from field inventories and analysis using Reclamation's geographic information system Digital Elevation Model indicate that most barriers on the perennial tributaries occur near the reservoir (see Chapter 4, "Geology, Geomorphology, Minerals, and Soils," for more detail).

Upper Sacramento River (Shasta Dam to Red Bluff)

Keswick Reservoir The USFWS conducts a propagation and captive broodstock program for endangered winter-run Chinook salmon at the Livingston Stone National Fish Hatchery located at the base of Shasta Dam on the Sacramento River upstream from Keswick Reservoir. The program consists of collecting adult winter-run Chinook salmon from the mainstem Sacramento River, holding and spawning the adults, rearing the juveniles in the hatchery environment and then releasing them back into the mainstem Sacramento River downstream from Keswick Dam. The overriding goal of the programs is to supplement the endangered population and provide an "insurance policy" against extinction. The propagation program (initiated in 1989), and the captive broodstock program (initiated in 1991) are recognized in both of NMFS's Draft Recovery Plans (1993, 2009) for this endangered species. Water is supplied to the hatchery from Shasta Dam.

Keswick Reservoir is operated by Reclamation as a reregulating facility. Levels in Keswick Reservoir are subject to operational changes at Whiskeytown and Shasta lakes. The reservoir provides habitat for a variety of aquatic organisms, including native and nonnative fish. Table 11-1 includes the fish species known to occur in Keswick Reservoir. In addition to water released from Shasta Dam and Whiskeytown Lake, this reservoir is the recipient of surface flows and

sediment from Spring Creek, as well as groundwater, emanating from the Iron Mountain Mine. Additional information on the relationship between Spring Creek and Keswick Reservoir is provided in Chapter 9, "Hazards and Hazardous Materials."

Keswick Dam to Red Bluff The upper Sacramento River (Keswick Dam to Red Bluff) provides vital fish spawning, rearing, and/or migratory habitat for a diverse assemblage of native and nonnative species. Native species present in this reach of the river can be separated into anadromous (i.e., species that spawn in freshwater after migrating as adults from marine habitat) and resident species. Native anadromous species include four runs of Chinook salmon, steelhead, green and white sturgeon (*Acipenser medirostris* and *A. transmontanus*), and Pacific lamprey (*Lampetra tridentata*). Native resident species include Sacramento pikeminnow (*Ptychocheilus grandis*), Sacramento splittail, Sacramento sucker (*Catostomus occidentalis*), hardhead (*Mylopharodon conocephalus*), California roach (*Lavinia symmetricus*), and rainbow trout (*O. mykiss*). Nonnative resident species include largemouth bass (*Micropterus salmoides*), smallmouth bass (*Micropterus dolomieu*), white and black crappie (*Pomoxis annularis* and *P. nigromaculatus*), channel catfish (*Ictalurus punctatus*), white catfish (*Ameiurus catus*), black bullhead (*Ameirus melas*), brown bullhead (*Ameirus nebulosus*), bluegill (*Lepomis* macrochirus), green sunfish (*Lepomois cyanellus*), and golden shiner (*Notemigonus crysaleucas*).

See Table 11-1 for a list of special-status species with the potential to occur in the upper Sacramento River.

Lower Sacramento River and Delta Like the primary study area, habitats in the extended study area also provides vital fish spawning, rearing, and/or migratory habitat for a diverse assemblage of native and nonnative species, many of which are the same as those found in the primary study area (see the *Fisheries and Aquatic Ecosystems Technical Report*), including Chinook salmon, steelhead and sturgeon.

Trinity River The Trinity River provides habitat for Southern Oregon/Northern California Coast coho salmon (*Oncorhynchus kisutch*), Southern Oregon/Northern California Coast Chinook salmon, Klamath Mountains Province steelhead, green sturgeon, white sturgeon, Pacific lamprey, resident rainbow trout, speckled dace, three-spine stickleback, Klamath small scale sucker (*Catostomus rimiculus*), prickly sculpin, and riffle sculpin (*Cottus gulosus*), brook trout (*Salvelinus fontinalis*), brown trout (*Salmo trutta*) American shad, brown bullhead, golden shiner, and green sunfish. Coho salmon and Klamath Mountains Province steelhead are included in this discussion because they are special-status species and CVP and SWP operations in response to changes at Shasta Dam have the potential to affect Trinity River flows.

See Table 11-1 for a list of special-status species with the potential to occur in the Trinity River.

CVP/SWP Service Areas

See Table 11-1 for a list of special-status species with the potential to occur in the CVP/SWP Service Areas.

11.1.3 Aquatic Macroinvertebrates

The constant flow of water in river systems provides an energetically convenient and economical way to disperse to new habitats; this movement downstream is known as drift. Some invertebrates passively enter the drift (e.g., benthic organisms may be entrained in the water column when a large current sweeps through), and others exhibit active drift behavior (individuals actively enter the water column by voluntary actions) (Waters 1965, 1972; Müller 1974; Wiley and Kohler 1984). Macroinvertebrates drift to colonize new habitats (for dispersal of various life stages or to find suitable resources), or leave unsuitable habitats (in response to habitat quality or predation pressure). Drift is one of the most important downstream dispersal mechanisms for macroinvertebrates. Macroinvertebrates drift more commonly in the evening, usually at dusk (Waters 1972, Müller 1974, Wiley and Kohler 1984, Smock 1996).

Drifting invertebrates are the primary source of prey for juvenile fish, including salmonids (Chapman and Bjornn 1969). Juvenile Chinook salmon will often seek refuge in slow-velocity habitats where they can rest and drifting invertebrates will tend to be deposited.

Shasta Lake and Vicinity

Aquatic macroinvertebrates provide an important food base for many fish and wildlife species. In general, published information on the taxonomy, distribution, and abundance of macroinvertebrates in the Sacramento River drainage is limited. A large-scale monitoring effort in 2001 coordinated by DWR from Keswick Dam to Verona on the Sacramento River found that benthic macroinvertebrate diversity and richness decreased as the river moved downstream. The constant flow of water in river systems provides an energetically convenient and economical way to disperse to new habitats; this movement downstream is known as drift. Drift is one of the most important downstream dispersal mechanisms for macroinvertebrates and drifting invertebrates are the primary source of prey for juvenile fish, including salmonids (Chapman and Bjornn 1969).

Invasive Species

New Zealand Mudsnail The New Zealand mudsnail (*Potamopyrgus antipodarum*), known to have been introduced to North America since about 1987 (Bowler 1991), was identified in Shasta Lake at the Bridge Bay Marina on September 10, 2007 (Benson and Kipp 2011). New Zealand mudsnail have also

been found lower in the Central Valley, including Sacramento River near Red Bluff, and the American, Mokelumne and Calaveras rivers (Benson and Kipp 2011). This invasive aquatic mollusk is known from a number of other locations within California and can reach densities of over 500,000 snails per square meter. Densities can fluctuate seasonally, with lowest densities coinciding with the freezing winter months (Proctor et al. 2007). New Zealand mudsnails are highly effective competitors and predators of many native North American benthic macroinvertebrates, including other mollusks, crustaceans, and important aquatic insects. Predators of the New Zealand mudsnail include rainbow trout, brown trout, sculpins, and mountain whitefish (Proctor et al. 2007). Unfortunately, snails are capable of passing through the digestive system of fish alive and intact (Bondesen and Kaiser 1949; Haynes et al.1985).

Possible pathways of introduction into Shasta Lake include contaminated recreational watercraft and trailers and recreational water users (Proctor et al. 2007). Other vectors known to spread the snails, such as contaminated livestock, commercial ships, and dredging/mining equipment, are less likely in the case of Shasta Lake's recent invasion given the lack of commercial activities on the lake. If the particular clone detected in Shasta Lake is tolerant of the local conditions, a rapid colonization of the lake and its tributaries could occur through a variety of vectors.

The potential involvement of recreational watercraft and trailers and recreational water users in the translocation of New Zealand mudsnails between State waters is of immediate concern. Enlargement of Shasta Lake could provide a larger perimeter of shoreline accessibility for the snail, but not necessarily increase preferred lake habitats. In lakes in North America, New Zealand mudsnails do not commonly occupy shoreline habitats. Highest densities of New Zealand mudsnails occur between 20-25 meters (m) in Lake Ontario (Proctor et al. 2007).

Quagga Mussel Quagga mussels (*Dressenia bugensis*), an invasive European aquatic mollusk introduced to North America in ship ballast water and first discovered in Lake Erie in 1989 (Spidle et al. 1994), have not been found in Shasta Lake, to date, but were discovered in California at Lake Havasu in 2007 (Cohen 2007). The DFG has begun monitoring at Lake Shasta for adult mussels and veligers (S. Baumgartner, DFG, pers. comm., 2008). Possible pathways of introduction into Shasta Lake include contaminated recreational watercraft and trailers and recreational water users. The potential involvement of recreational watercraft and trailers and recreational water users in the translocation of quagga mussels between State waters is of immediate concern. Enlargement of Shasta Lake could provide a greater area of deepwater and littoral habitat available for occupation by quagga mussels.

In a 2007 report produced for DFG, Cohen (2007) described the temperature, calcium, pH, DO, and salinity tolerances of quagga mussels in an effort to assess the vulnerability of various California waters to invasion by quagga

mussels and zebra mussels. Cohen identified calcium thresholds as the most important environmental factor influencing distribution of zebra mussels in North America and applied similar thresholds for quagga mussels. In an investigation of the upper Sacramento River region, including Whiskeytown Reservoir and the watersheds above Shasta Dam, Cohen found that the McCloud River above Shasta Reservoir and the Pit River near Canby have the proper range of salinity, DO, temperature and calcium (at less than or equal to 12 milligrams per liter to be of low and moderate suitability to invasion by quagga mussels.

Upper Sacramento River (Shasta Dam to Red Bluff)

A large-scale monitoring effort in 2001 coordinated by DWR from Keswick Dam to Verona on the Sacramento River found that benthic macroinvertebrate diversity and richness decreased as the river moved downstream. Oligochaetes, chironomids, and mollusks became more prominent in this reach than in the reach from Keswick Dam to Red Bluff (Sacramento River Watershed Program 2002). More recently, the diurnal feeding habits of juvenile Chinook salmon in the upper Sacramento River (River Mile 193 to River Mile 275) were examined in relation to drifting invertebrates by Petrusso and Hayes (2001). Chironomids and baetids dominated both the drift and stomach contents. Diets of 153 juvenile salmonids were examined; more than 63 percent of the diet was made up of chironomids of all life stages. Baetids comprised 14 percent of the total diet. It was concluded that based on measurements of mean stomach fullness and availability of drifting organisms, there was reasonable feeding opportunity during the sampling period in spring 1996. Mean drift densities ranged from 211 to 2,100 organisms per 100 cubic meters, with an overall mean of 617 organisms per 100 cubic meter (Petrusso and Hayes 2001). Daily mean drift density appeared to show no spatial patterns across the several sites sampled.

Lower Sacramento River and Delta

Aquatic macroinvertebrates provide an important food base for many fish and wildlife species. In general, published information on the taxonomy, distribution, and abundance of macroinvertebrates in the Sacramento River drainage is limited. Current macroinvertebrate monitoring efforts on the Sacramento River have focused on large-basin scale patterns, and survey sites on the mainstem have been at various locations along the study reach. Under the Sacramento River Watershed program, DFG collected snag samples at two sites, one site near Colusa and one site near Hamilton City. Dominant taxa found in fall 1999 at the Hamilton City site include Orthocladiinae, Naididae, Ephemeroptera (*Baetis* and *Acentrella* sp.) and Trichoptera (*Hydropsyche* sp.) (Sacramento River Watershed Program 2002). Schaffter et al. (1983) found no significant difference in abundance of drifting invertebrates near riprapped and natural habitats on the Sacramento River. More than 50 percent of the drift was composed of chironomids, baetids, and aphids. Analysis of fish diets found the same three families in 72 percent of the guts sampled.

A large-scale monitoring effort in 2001 coordinated by DWR from Keswick Dam to Verona on the Sacramento River found that benthic macroinvertebrate diversity and richness decreased as the river moved downstream. Oligochaetes, chironomids, and mollusks became more prominent in this reach than in the reach from Keswick Dam to Red Bluff (Sacramento River Watershed Program 2002). More recently, the diurnal feeding habits of juvenile Chinook salmon in the upper Sacramento River (River Mile 193 to River Mile 275) were examined in relation to drifting invertebrates by Petrusso and Hayes (2001). Chironomids and baetids dominated both the drift and stomach contents. Diets of 153 juvenile salmonids were examined; more than 63 percent of the diet was made up of chironomids of all life stages. Baetids comprised 14 percent of the total diet. It was concluded that based on measurements of mean stomach fullness and availability of drifting organisms, there was reasonable feeding opportunity during the sampling period in spring 1996. Mean drift densities ranged from 211 to 2,100 organisms per 100 cubic meters, with an overall mean of 617 organisms per 100 cubic meter (Petrusso and Hayes 2001). Daily mean drift density appeared to show no spatial patterns across the several sites sampled.

11.2 Regulatory Framework

Several Federal, State, and local agencies have regulatory authority or responsibility over activities that affect aquatic and fisheries resources. These regulatory authorities are described in the following sections.

11.2.1 Federal

Federal Endangered Species Act

Pursuant to the Federal Endangered Species Act (ESA), USFWS and NMFS have authority over projects that may result in take of a Federally listed species. Under the ESA, the definition of "take" is to "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." Under Federal regulation, "take" is further defined to include habitat modification or degradation where it would be expected to result in death or injury to listed wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. If the project may affect a Federally listed species, either an incidental take permit, under Section 10(a) of the ESA, or a Federal interagency consultation, under Section 7 of the ESA, is required. USFWS has regulatory jurisdiction over freshwater and estuarine fishes (such as delta smelt), while NMFS has jurisdiction over anadromous and marine species (such as Chinook salmon, steelhead, and green sturgeon).

NMFS Recovery Plan

Under Section 4(f) of the ESA, both NMFS and USFWS are required to publish a recovery plan for each species it lists as threatened or endangered. These plans must have objective and measureable criteria that would help the species

be removed from the ESA list, a description of site-specific management actions necessary for the species recovery, and estimates of time and cost to carry out the recommended recovery measures.

In 2009, NMFS published the *Public Draft Recovery Plan for Evolutionarily Significant Units of Sacramento River Winter-Run Chinook Salmon and Central Valley Spring-Run Chinook Salmon and Distinct Population Segments of Central Valley Steelhead* (NMFS 2009). In this recovery plan, NMFS states that the recovery of winter-run Chinook salmon is affected by the Shasta cold-water pool:

> *Although the status of the Sacramento River winter-run Chinook salmon population numbers has shown improvement over the last six years, there is still only one naturally-spawned component of the ESU, and this single population depends on coldwater releases from Shasta Dam on the Sacramento River. Lindley et al. (2007) considers the Sacramento River winter-run Chinook salmon population at a moderate risk of extinction primarily due to the risks associated with only one existing population. The viability of an ESU that is represented by a single population is vulnerable to changes in the environment through a lack of spatial geographic diversity and genetic diversity that result from having only one population. A single catastrophe with effects persisting for four or more years could extirpate the entire Sacramento River winter-run Chinook salmon ESU (Lindley et al. 2007). Such potential catastrophes include volcanic eruption of Mt. Lassen, prolonged drought which depletes the coldwater pool in Shasta Reservoir or some related failure to manage coldwater storage, a spill of toxic materials with effects that persist for four or more years, or a disease outbreak. Moreover, an ESU that is represented by a single population is vulnerable to the limitation in life history and genetic diversity that would otherwise increase the ability of individuals in the population to withstand environmental variation.*

While the action plans surrounding this issue of cold-water pool are focused primarily on reintroduction into the upper watershed (upstream from Shasta Dam), these actions may not be achievable. Improving the cold-water pool could negate any impacts to the species recovery if the reintroduction process is not successful. Additionally, NMFS includes management actions to improve gravel augmentation programs in the upper Sacramento River.

Sustainable Fisheries Act (Essential Fish Habitat)

In response to growing concern about the status of United States fisheries, Congress passed the Sustainable Fisheries Act of 1996 (Public Law 104-297) to amend the Magnuson-Stevens Fishery Conservation and Management Act

(Public Law 94-265), the primary law governing marine fisheries management in the Federal waters of the United States. Under the Sustainable Fisheries Act, consultation is required by NMFS on any activity that might adversely affect essential fish habitat. Essential fish habitat includes those habitats that fish rely on throughout their life cycles. It encompasses habitats necessary to allow sufficient production of commercially valuable aquatic species to support a long-term sustainable fishery and contribute to a healthy ecosystem.

Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act requires Federal agencies to consult with USFWS, NMFS, and State fish and wildlife resource agencies before undertaking or approving projects that control or modify surface water. The recommendations made by these agencies must be fully considered in project plans by Federal agencies.

Clean Water Act, Section 404

Section 404 of the Clean Water Act (CWA) requires project proponents to obtain a permit from the USACE before performing any activity that involves any discharge of dredged or fill material into "waters of the United States," including wetlands. Waters of the United States include navigable waters of the United States, interstate waters, all other waters where the use or degradation or destruction of the waters could affect interstate or foreign commerce, tributaries to any of these waters, and wetlands that meet any of these criteria or that are adjacent to any of these waters or their tributaries. Many surface waters and wetlands in California meet the criteria for waters of the United States.

Clean Water Act, Section 402

CWA Section 402 regulates construction-related stormwater discharges to surface waters through the National Pollutant Discharge Elimination System program, which is administered by the U.S. Environmental Protection Agency. In California, the State Water Resources Control Board (SWRCB) is authorized by the U.S. Environmental Protection Agency to oversee the National Pollutant Discharge Elimination System program through the regional water quality control boards (RWQCB), in this case, the Central Valley RWQCB.

Clean Water Act, Section 401

CWA Section 401(a)(1) specifies that any applicant for a Federal license or permit to conduct any activity that may result in any discharge into navigable waters will provide the Federal licensing or permitting agency with a certification that any such discharge will not violate State water quality standards. The RWQCBs administer the Section 401 program with the intent of prescribing measures for projects that are necessary to avoid, minimize, and mitigate adverse impacts on water quality and ecosystems.

Central Valley Project Improvement Act

Reclamation's evolving mission was written into law on October 30, 1992, with the passage by Congress and signing by President George H.W. Bush, of Public

Law 102-575, the Reclamation Projects Authorization and Adjustment Act of 1992. Included in the law was Title 34, the CVPIA. The CVPIA amended previous authorizations of the CVP to include fish and wildlife protection, restoration, and mitigation as project purposes having equal priority with irrigation and domestic water supply uses, and fish and wildlife enhancement having equal priority with power generation. The following are among the changes mandated by the CVPIA:

- Dedicating 800,000 acre-feet annually to fish, wildlife, and habitat restoration
- Authorizing water transfers outside the CVP service area
- Implementing the Anadromous Fish Restoration Program (AFRP)
- Creating a restoration fund financed by water and power users
- Providing for the Shasta temperature control device
- Implementing fish passage measures at RBDD
- Planning to increase the CVP yield
- Mandating firm water supplies for Central Valley wildlife refuges
- Meeting the Federal trust responsibility to protect fishery resources on the Trinity River

The CVPIA is being implemented on a broad front. The Final Programmatic Environmental Impact Statement for the CVPIA analyzes projected conditions in 2022, 30 years from the CVPIA's adoption in 1992. The Final Programmatic Environmental Impact Statement was released in October 1999, and the CVPIA Record of Decision (ROD) was signed on January 9, 2001.

Operations of the CVP reflect provisions of the CVPIA, particularly Sections 3406(b)(1), (b)(2), and (b)(3). The U.S. Department of the Interior's Decision on Implementation of Section 3406(b)(2) of the CVPIA, October 5, 1999, provides the basis for implementing upstream and Delta actions with CVP delivery capability. The AFRP assumes that Sacramento River water will be acquired under Section 3406(b)(2).

Ecosystem Restoration Program Plan of the CALFED Bay-Delta Program

The mission of the CALFED Bay-Delta Program (CALFED) is to develop a long-term comprehensive plan that will restore ecosystem health and improve water management for beneficial uses of the Bay-Delta system. The program addresses problems in four resource areas: ecosystem quality, water quality, system integrity, and water supply reliability. Programs to address problems in the four resource areas will be designed and integrated to fulfill the CALFED mission.

The goal for ecosystem quality is to improve and increase aquatic and terrestrial habitats and improve ecological functions in the Bay-Delta to support sustainable populations of diverse and valuable plant and animal species. The CALFED Ecosystem Restoration Program Plan (ERPP) addresses this goal. The foundation of the ERPP is restoration of ecological processes that are associated with streamflow, stream channels, watersheds, and floodplains. These processes create and maintain habitats essential to the life history of species dependent on the Delta. In addition, the ERPP aims to reduce the effects of stressors that inhibit ecological processes, habitats, and species.

Key restoration actions for Sacramento River fisheries being proposed by this ERPP include the following:

- Enhancing river flows
- Restoring the natural river meander process
- Enhancing riparian and riverine habitats
- Maintaining suitable river temperatures for salmonids
- Reducing fish losses at points of water diversion
- Improving anadromous fish passage at existing barriers
- Maintaining and improving water quality
- Improving hatchery and stocking programs
- Improving management of inland harvest of salmonids

Such restoration actions, when implemented over the next few decades, are expected to increase Sacramento River fish populations, including salmonid populations, over existing conditions. The ERPP establishes similar restoration goals for other major water courses throughout the Central Valley.

Operating Agreements and Constraints

Coordinated Operations Agreement With the goal of using coordinated management of surplus flows in the Delta to improve Delta export and conveyance capability, the Coordinated Operations Agreement (COA) received Congressional approval in 1986 and became Public Law 99-546. The COA, as modified by interim agreements, coordinates operations between the CVP and SWP and provides for the equitable sharing of surplus water supply. The COA requires that the CVP and SWP operate in conjunction to meet State objectives for water quality in the Bay-Delta estuary, except as specified. Under this agreement the CVP and SWP can each contract for the purchase of surplus water supplies from the other, potentially increasing the efficiency of water operations.

The COA specifies two basic conditions for operational purposes: balanced conditions and excess conditions. Balanced water conditions occur when releases from upstream reservoirs plus unregulated flow equal the water supply needed to meet Sacramento Valley in-basin uses plus exports. During balanced water conditions, storage releases required to meet the Sacramento in-basin uses are made 75 percent from the CVP and 25 percent from the SWP. If unstored water is available during balanced conditions, this water is allocated 55 percent to the CVP and 45 percent to the SWP. Excess water conditions occur when Delta inflows (combined releases from upstream reservoirs and unregulated flow) are greater than needed to meet in-basin uses plus export. Under this condition, flow through the Delta is adequate to meet all needs and no coordinated operation between the CVP and SWP is required.

Since 1986, the COA principles have been modified to reflect changes in regulatory standards, facilities, and operating conditions. At its inception, the COA water quality standards were those of the 1978 Water Quality Control Plan; these were subsequently modified in the 1991 Water Quality Control Plan. The adoption of the 1995 Bay-Delta Plan by the SWRCB superseded those requirements. The Environmental Water Account was established by CALFED in 2000 to protect the fish of the Bay-Delta estuary via changes in the operations of the CVP and SWP, without incurring uncompensated cost to the projects' water users. Evolution of the CWA over time has also impacted the implementation of the COA.

Biological Opinions Biological Opinions (BO) are prepared through formal consultation of Section 7 of the ESA (described above) by either NMFS or USFWS in response to a Federal action affecting a listed species. On February 12, 1993, NMFS issued a long-term BO regarding the operational impacts of the CVP on winter-run Chinook salmon (NMFS 1993). Based on Reclamation's *Long-Term Central Valley Project Operations Criteria and Plan* and biological assessment of impacts, the BO concluded that the proposed long-term operations of the CVP and SWP would likely jeopardize the continued existence of winter-run Chinook salmon, and identified "Reasonable and Prudent Alternatives" (RPA) to avoid jeopardy. The RPAs consisted of 13 separate actions that changed the pattern of storage and withdrawal at Shasta, Trinity, and Whiskeytown Reservoirs for the purpose of improving water temperature control and protecting Sacramento River winter-run Chinook salmon (NMFS 1993). Since that time, many of the original RPA actions have been amended or incorporated into the 1995 Water Quality Control Plan Decision 1641. Therefore, these components of the RPA have become part of the baseline conditions.

Actions that have not changed include:

- Water year forecasting based on a 90 percent probability of exceedence

- Maintaining a minimum 3,250 cfs flow below Keswick Dam from October 1 through March 30
- Implementing ramp-down rates for Shasta Dam releases from July 1 through March 31
- Locating temperature compliance points based on annual plans
- Raising RBDD gates between September 15 and May 15 every year
- Monitoring of winter-run Chinook salmon juveniles in the Delta
- Monitoring entrainment loss of winter-run Chinook salmon juveniles at Rock Slough Pumping Plant
- Monitoring of incidental take at the CVP and SWP Delta pumping facilities

On October 22, 2004, NMFS issued a BO regarding effects of the Long-Term Operations Criteria and Plan (OCAP) for the CVP in coordination with the SWP on Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley steelhead, Southern Oregon Northern California Coastal Coho salmon, and Central California Coast steelhead and their designated critical habitat. The 2004 BO supersedes the 1993 BO issued by NMFS. It contains reasonable and prudent measures and terms and conditions that specify all of the following:

- Fisheries monitoring actions
- Augmentation of spawning gravel
- Forecasting of deliverable water management of cold-water supply within reservoirs
- Temperature monitoring
- Adaptive management processes to analyze annual cold-water management
- Minimization of flow fluctuations
- Passage at RBDD
- Operation of gates in the Delta
- Fish screening at pumping facilities
- Numerous other effects minimization measures

With the signing of the Principles for Agreement for the Bay-Delta Plan, USFWS agreed to initiate immediate reconsultation on the BO it had issued on February 4, 1994, which addressed the effects of the combined operations of the CVP and SWP on delta smelt for the period of February 15, 1994, through February 15, 1995. In that opinion, USFWS had concluded that the proposed operations of the CVP and SWP would result in jeopardy; therefore, RPAs were included in the BO, which consisted of specific operational criteria that the CVP and SWP would implement (USFWS 1994).

On March 6, 1995, USFWS issued a revised BO for delta smelt. This opinion states that the proposed long-term combined CVP and SWP operations, as modified by the BO for winter-run Chinook salmon, the Principles for Agreement, and the Bay-Delta Plan (draft at the time), are not likely to jeopardize the continued existence of the threatened delta smelt or adversely modify its critical habitat. The BO identifies water quality standards and operational constraints that would provide benefits to delta smelt.

In response to litigation, the 2004 and 2005 BOs were remanded to USFWS and NMFS for revision, but were not vacated. USFWS and NMFS released revised BOs in 2008 and 2009, respectively. Since the revised BOs continue to be locked in controversy and litigation, the 2004 and 2005 BOs are assumed to be govern operations for SLWRI analysis. Further revised BOs are anticipated prior to the release of the final version of this document; final analysis will consider conditions dictated by the BOs in place at that time.

Real-Time Decision-Making to Assist Fishery Management

Reclamation and DWR work closely with USFWS, NMFS, DFG, and other agencies to coordinate the operation of the CVP and SWP with fishery needs. This coordination is facilitated through several forums, as discussed below.

CALFED Water Operations Management Team The Water Operations Management Team (WOMT) was established to facilitate decision making at the appropriate levels and provide timely support of decisions. This team, which first met in 1999, consists of management-level participants from Reclamation, DWR, USFWS, NMFS, and DFG. The WOMT meets frequently to provide oversight and decision making that must routinely occur within the CALFED Ops Group process. The WOMT relies heavily on other teams and work groups for recommendations on fishery actions. It also utilizes the CALFED Ops Group (see below) to communicate with stakeholders about its decisions. Although the goal of the WOMT is to achieve consensus on decisions, the agencies retain their authorized roles and responsibilities.

CALFED Ops Group The CALFED Ops Group consists of participants from Reclamation, DWR, USFWS, NMFS, DFG, SWRCB, and U.S. Environmental Protection Agency. The CALFED Ops Group generally meets 11 times a year in a public setting to discuss CVP and SWP operations, CVPIA implementation, and coordination with efforts to protect endangered species. The CALFED Ops

Group held its first public meeting in January 1995, and during the next 6 years the group developed and refined its process. The CALFED Ops Group is recognized within SWRCB D-1641 and elsewhere as a forum where agencies can consult and achieve consensus on coordinating CVP and SWP operations with endangered species, water quality, and CVPIA requirements. Decisions made by the CALFED Ops Group have been incorporated into the Delta standards to protect beneficial uses of water (e.g., export/inflow ratios and some closures of DCC gates).

Several teams were established as part of the Ops Group. These teams are described below.

Operations and Fishery Forum The stakeholder-driven Operations and Fishery Forum disseminates information about recommendations and decisions regarding CVP and SWP operations. Forum members are considered the contact people for their respective agencies or interest groups when the CALFED Ops Group needs to provide information about take of listed species or address other topics or urgent issues. Alternatively, the CALFED Ops Group may direct the Operations and Fishery Forum to recommend operational responses to issues of concern raised by member agencies.

Data Assessment Team The Data Assessment Team consists of technical staff members from the agencies and stakeholders. The team meets frequently during the fall, winter, and spring to review and interpret data relating to fish movement, location, and behavior. Based on its assessments and information about CVP and SWP operations, the Data Assessment Team recommends potential changes in operations to protect fish.

B2 Interagency Team The B2 Interagency Team was established in 1999 and consists of technical staff members from the agencies. The team meets weekly to discuss implementation of Section 3406(b)(2) of the CVPIA, which defines the dedication of CVP water supply for environmental purposes. It communicates with the WOMT to ensure coordination with the other operational programs or resource-related aspects of project operations.

Fisheries Technical Teams Several fisheries-specific teams have been established to provide guidance on resource management issues. These teams are described below.

The Sacramento River Temperature Task Group The Sacramento River Temperature Task Group (SRTTG) is a multiagency group formed pursuant to SWRCB Water Right Orders 90-5 and 91-1 to help improve and stabilize the Chinook salmon population in the Sacramento River. Reclamation develops temperature operation plans each year for the Shasta and Trinity Divisions of the CVP. These plans consider impacts of CVP operations on winter-run and other races of Chinook salmon. The SRTTG meets in the spring to discuss biological and operational information, objectives, and alternative operations

plans for temperature control, then recommends an operation plan for temperature control. Reclamation then submits a report to SWRCB, generally on or before June 1 each year.

After the operation plan is implemented, the SRTTG may perform additional studies and hold meetings to revise the plan based on updated biological data, reservoir temperature profiles, and operations data. Updated plans may be needed for summer operations to protect winter-run Chinook salmon, or in fall for the fall-run spawning season. If any changes are made to the plan, Reclamation submits a supplemental report to the SWRCB.

Salmon Decision Tree The fishery agencies and project operators use the Chinook Salmon Protection Decision Process to address the often-complex coordination issues surrounding DCC gate operations and the purposes of closures for fishery protection; Delta water quality; and/or export reductions. Inputs such as fish life stage and size development, current hydrologic events, fish indicators (such as the Knight's Landing Catch Index and Sacramento Catch Index), and salvage at the export facilities, as well as current and projected Delta water quality conditions, are used to determine potential DCC closures and/or export reductions. The coordination process has worked well during recent fall and winter DCC operations, and its continued use (in either the present form or a modified version) is expected in the future.

Delta Smelt Working Group The Delta Smelt Working Group was established in 1995 to resolve biological and technical issues regarding delta smelt and to develop recommendations for consideration by USFWS. The working group generally acts when Reclamation and DWR seek consultation with USFWS on delta smelt or when unusual salvage of delta smelt occurs. It also has assisted in developing strategies to improve habitat conditions for delta smelt.

The Delta Smelt Working Group employs a delta smelt decision tree when forming recommendations to send to the WOMT. The working group does not decide what actions will be taken and does not supplant the Data Assessment Team, but merely provides additional advice to the WOMT. The group may propose operations modifications that it believes will protect delta smelt, either by reducing take at the export facilities or by preserving smelt habitat. The decision tree is adapted by the working group as new knowledge becomes available.

American River Operations Work Group In 1996, Reclamation established an operational working group for the lower American River, known as the American River Operations Work Group. Although open to anyone, the working group's meetings generally include representatives from several agencies and organizations with ongoing concerns about management of the lower American River: Reclamation, USFWS, NMFS, DFG, the Sacramento Area Flood Control Agency, the Water Forum, the City of Sacramento, Sacramento County, the Western Area Power Administration, and the Save the

American River Association. The American River Operations Work Group convenes at least monthly to provide fishery updates and reports to enable Reclamation to better manage Folsom Reservoir for fish resources in the lower American River.

San Joaquin River Agreement Technical Committee The San Joaquin River Agreement Technical Committee meets to plan and implement the Vernalis Adaptive Management Plan each year. The committee oversees two subgroups, the Biology subgroup and the Hydrology subgroup, each of which are charged with certain responsibilities. The subgroups must also coordinate their activities within the San Joaquin River Agreement Technical Committee.

DCC Project Work Team The DCC Project Work Team is a multiagency group under CALFED. It determines and evaluates the effects of DCC gate operations on Delta hydrodynamics, water quality, and fish migration. The work team coordinates with the Data Assessment Team and Operations and Fishery Forum to conduct gate experiments; members may be used as a resource to estimate impacts of real-time gate operations.

National Forest Management Act

The National Forest Management Act requires the USFS to prepare the STNF Land and Resources Management Plan (LRMP) that provides the direction to manage the goods and services that are associated with National Forest System lands managed by the STNF. In addition to the requirement for LRMPs, National Forest Management Act also has a specific requirement to "provide for a diversity of plant and animal communities" [16 U.S.C. 1604(g)(3)(B)] as part of their multiple use mandate. The USFS must maintain “viable populations of existing native and desired non-native species in the planning area” (36 CFR. 219.19).

U.S. Forest Service Sensitive Species

The Sensitive Species program is designed to meet the National Forest Management Act requirement to demonstrate the USFS’s commitment to maintaining biodiversity on National Forest System lands. The program is a proactive approach to conserving species to prevent a trend toward listing under the ESA, and to ensure the continued existence of viable, well-distributed populations. A “Sensitive Species” is any species of plant or animal that has been recognized by the Regional Forester to need special management in order to prevent it from becoming threatened or endangered.

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF, LRMP adopted what is commonly referred to as the Northwest Forest Plan, a plan for the management of habitat for late-successional and old-growth forest-related species within the range of the northern spotted owl. The LRMP encompasses all the goals, standards and guidelines established in the 1994 ROD for the Northwest Forest Plan, as a well as establishing Forest goals, standards, and guidelines designed to guide the management of the STNF. As

adopted in 1995, this LRMP incorporates the following goals, standards, and guidelines related to aquatic and fisheries resource issues associated with the project site were excerpted from the STNF LRMP (USFS 2003).

Biological Diversity
Goals (LRMP, p. 4-4)

- Integrate multiple resource management on a landscape level to provide and maintain diversity and quality of habitats that support viable populations of plants, fish, and wildlife.

Threatened, Endangered, and Sensitive Species (Plants and Animals)
Goals (LRMP, p. 4-5)

- Monitor and protect habitat for Federally listed Threatened and Endangered and candidate species. Assist in recovery efforts for Threatened and Endangered species. Cooperate with the State to meet objectives for state listed species.

- Manage habitat for sensitive plants and animals in a manner that will prevent any species from becoming a candidate for Threatened and Endangered status.

Wildlife
Goals (LRMP, p. 4-6)

- Meet habitat or population objectives established for management indicators.

- Cooperate with Federal, State, and local agencies to maintain or improve wildlife habitat.

- Maintain natural wildlife species diversity by continuing to provide special habitat elements within Forest ecosystems.

Standards and Guidelines (LRMP, pp. 4-29 through 4-30)

- Consider transplants, introductions, or reintroductions of wildlife species only after ecosystem analysis and coordination with other agencies and the public.

- Develop interpretation/view sites for wildlife viewing, photography, and study. Provide pamphlets, slide shows, and other educational material that enhance the watchable wildlife and other interpretive programs.

- Maintain and/or enhance habitat for Federally listed threatened and endangered or USFS Sensitive species consistent with individual species recovery plans.

U.S. Forest Service Survey and Manage Species

In 1994, the U.S. Bureau of Land Management and USFS adopted standards and guidelines, The Northwest Forest Plan was designed to address human and environmental needs served by the Federal forests of the western part of the Pacific Northwest and Northern California. The development of the Northwest Forest Plan was triggered in the early 1990s by the listing of the northern spotted owl and marbled murrelet as threatened under the ESA.

To mitigate potential impacts to plant and wildlife species that have the potential to occur within the range of the northern spotted owl, surveys are required for species thought to be rare or whose status is unknown due to a lack of information. These species became known as the Survey and Manage species. The Northwest Forest Plan has gone through several revisions since its implementation in 1994, including the elimination of the Survey and Manage Mitigation Measure Standards and Guidelines in 2004. However, these guidelines were re-instated in January 2006 as the result of a court order.

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area contains management strategies intended to achieve or maintain a desired condition. These strategies take into account opportunities, management recommendations for specific projects, and mitigation measures needed to achieve specific goals. The following strategies related to biological resource issues associated with the project were excerpted from the Management Guide (USFS 2003).

Wildlife (Management Guide, pp. IV-19 through IV-20)

- Management activities will assure population viability for all native and non-native desirable species. Management to insure viability will occur within occupied habitat for bald eagle, peregrine falcon, northern spotted owl, northern goshawk, willow flycatcher, northwestern pond turtle, Pacific fisher, Shasta salamander, and candidate species in accordance with species and/or territory management plans, Forest Orders, and appropriate laws and policy.

- Surveys will continue within potential suitable habitats to determine occupancy status for Threatened, Endangered, sensitive, and candidate species.

- Cooperation will continue with DFG and the USFWS regarding habitat management of wildlife species inhabiting the National Recreation Area. Consultation with USFWS will continue regarding habitat management for threatened and endangered species.

11.2.2 State

California Endangered Species Act

Pursuant to the California Endangered Species Act (CESA), a permit from DFG is required for projects that could result in take of a State-listed threatened or endangered species. Under CESA, "take" is defined as an activity that would directly or indirectly kill an individual of a species, but the definition does not include "harming" or "harassing," as the ESA does. As a result, the threshold for take under CESA is higher than under the ESA (e.g., habitat modification is not necessarily considered take under CESA). Authorization for take of State-listed species can be obtained through a California Fish and Game Code Section 2080.1 Consistency Determination or Section 2081 Incidental Take Permit.

"Fully Protected" Fish Species

California law (Fish and Game Code, Section 5515) also identifies 10 "fully protected fish" that cannot lawfully be "taken," even with an incidental take permit. None of these species are present in the primary study area.

California Fish and Game Code Section 1602—Streambed Alteration

All diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by DFG under Section 1602 of the California Fish and Game Code. Under Section 1602, it is unlawful for any person, governmental agency, or public utility to do the following without first notifying DFG: substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake. A stream is defined as a body of water that flows at least periodically or intermittently through a bed or channel that has banks and supports fish or other aquatic life. This definition includes watercourses with a surface or subsurface flow that supports or has supported riparian vegetation. DFG's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife. A DFG streambed alteration agreement must be obtained for any project that would result in an impact on a river, stream, or lake.

California Public Resources Code, Sections 5093.50-5093.70

The California Public Resources Code Sections 5093.50 – 5093.70 were established through 1972 enactment of the Wild and Scenic Rivers Act, which was subsequently amended on several occasions. The essential policy of the State in regard to the matters addressed by the PRC is expressed in Section 5093.50:

> *5093.50 It is the policy of the State of California that certain rivers which possess extraordinary scenic, recreational, fishery, or wildlife values will be preserved in their free-flowing state, together with their immediate environments, for the benefit and*

> *enjoyment of the people of the state. The Legislature declares that such use of these rivers is the highest and most beneficial use and is a reasonable and beneficial use of water within the meaning of Section 2 of Article X of the California Constitution.*

The PRC identifies, classifies, and provides protection for specific rivers or river segments, as approved by the Legislature (much of the text of the PRC is devoted to detailed descriptions of river segment locations). Rivers or river segments that are specifically identified and classified in the PRC comprise the State Wild and Scenic Rivers System. As described in Section 5093.50 of the PRC, rivers or river segments included in the State Wild and Scenic Rivers System must possess "extraordinary scenic, recreational, fishery, or wildlife values"; however, the PRC does not define these "extraordinary values."

Various amendments to the California Wild and Scenic Rivers Act have been passed, modifying the PRC. Rivers or river segments are added to (or, as in a few past cases, removed from) the System by Legislative action. In 1986, Assembly Bill 3101 (Statutes of 1986, Chapter 894) established a study process to help determine eligibility for potential additions to the State Wild and Scenic Rivers System (Section 5093.547 and Section 5093.548). In 1982, the original mandate in the PRC requiring management plans for designated rivers was eliminated; however, the California Resources Agency is required to coordinate activities affecting the State Wild and Scenic Rivers System with other Federal, State, and local agencies (Section 5093.69).

The PRC has also been modified to protect river segments without formally identifying them as part of the State Wild and Scenic Rivers System. Such protective language for the McCloud River was added to the PRC in Section 5093.542, emphasizing protection of the wild trout fishery in the McCloud River.

California Wild Trout Program

The California Wild Trout Program was established by the California Fish and Game Commission in 1971 to protect and enhance high-quality fisheries sustained by wild strains of trout. The primary purpose of the wild trout program is to identify, enhance, and perpetuate natural and attractive trout fisheries where wild strains of trout are given major emphasis, in contrast to the majority of the State's accessible waters that are managed by planting domesticated catchable-sized trout on a "put and take" basis (Rode 1989; Rode and Dean 2004). The Commission adopted a wild trout policy that provides for the designation of "aesthetically pleasing and environmentally productive" streams and lakes to be managed exclusively for wild trout, where the trout populations are managed with appropriate regulations to be "largely unaffected by the angling process."

All designated waters must meet the following policy criteria (Rode 1989, Rode and Dean 2004):

- Be open to public angling
- Be of sufficient size to accommodate a significant number of anglers without overcrowding
- Be able to support, with appropriate angling regulations, wild trout populations of sufficient magnitude to provide satisfactory trout catches in terms of number or size of fish

Designated wild trout waters are required to have a management plan and must be subject to angling restrictions that "emphasize unique values and diversity of opportunity in the geographic area" (Rode 1989, Rode and Dean 2004). Wild trout waters are required to be managed in accordance with the following stipulations:

- Domestic strains of catchable-sized trout will not be planted in designated wild trout waters.
- Hatchery-produced trout of suitable wild and semiwild strains may be planted in designated waters, but only if necessary to supplement natural trout reproduction.
- Habitat protection is of utmost importance for maintenance of wild trout populations. All necessary actions, consistent with State law, will be taken to prevent adverse impacts by land or water development projects affecting designated wild trout waters.

The California Fish and Game Commission in 1976 designated a 10.5-mile river segment immediately below McCloud Dam for special management and habitat protection under the Commission's wild trout program (Rode 1988).

11.2.3 Regional and Local

County and City Policies and Ordinances

Shasta, Tehama, Glenn, Sutter, Sacramento, and Yolo counties and the cities of Redding, Colusa, and Sacramento have established codes and policies that address protection of natural resources, including fisheries, sensitive species, and aquatic resources, and are applicable to the project.

Shasta County's general plan emphasizes that the maintenance and enhancement of quality fish and wildlife habitat is critical to the recreation and tourism industry, and acknowledges that any adverse and prolonged decline of these resources could result in negative impacts on an otherwise vibrant industry. The general plan identifies efforts to protect and restore these habitats to sustain the long-term viability of the tourism and recreation industry (Shasta County 2004).

The City of Redding's general plan strives to strike a balance between development and conservation by implementing several measures such as creek-corridor protection and habitat protection (City of Redding 2000).

Tehama County's general plan update provides an overarching guide to future development and establishes goals, policies, and implementation measures designed to address potential changes in county land use and development.

Glenn County's general plan provides a comprehensive plan for growth and development in Glenn County for the next 20 years (2007 through 2027). This plan recognizes that public lands purchased for wildlife preservation generate economic activity as scientists and members of the public come to view and study remnant ecosystems (Glenn County 1993).

The City of Colusa's general plan seeks to promote its natural resources through increased awareness and improved public access (City of Colusa 2007).

Sutter County's general plan contains policies that generally address preservation of aquatic resources.

Sacramento County's general plan contains policies that promote protection of marsh and riparian areas, including specification of setbacks and "no net loss" of riparian woodland or marsh acreage (Sacramento County 1993).

Yolo County's general plan aims to provide an active and productive buffer of farmland and open space separating the Bay Area from Sacramento, and integrating green spaces into its communities.

11.2.4 Federal, State, and Local Programs and Projects

Watershed Conservancies

Several watershed conservancy groups exist within the study area. These include, but may not be limited to Butte Creek, Mill Creek, Deer Creek and Cottonwood Creek Watershed Conservancies. Watershed conservancies tend to focus on developing and implementing conservation efforts on watershed lands.

California Bay-Delta Authority

The California Bay-Delta Authority was established as a State agency in 2003 to oversee implementation of CALFED for the 25 Federal and State agencies working cooperatively to improve the quality and reliability of California's water supplies while restoring the Bay-Delta ecosystem. CALFED Ecosystem Restoration Program has provided a funding source for projects that include those involving acquisition of lands within the Sacramento River Conservation Area (SRCA), initial baseline monitoring and preliminary restoration planning, and preparation of long-term habitat restoration management and monitoring plans.

Cantara Trustee Council

The Cantara Trustee Council administers a grant program that has provided funding for numerous environmental restoration projects in the primary study area, including programs in the Fall River watershed, Sulphur Creek, the upper Sacramento River, Middle Creek, lower Clear Creek, Battle Creek, Salt Creek, and Olney Creek. The Cantara Trustee Council is a potential local sponsor for future restoration actions in the primary study area. The Cantara Trustee Council includes representatives from DFG, USFWS, the Central Valley RWQCB, California Sportfishing Protection Alliance, and Shasta Cascade Wonderland Association.

Resource Conservation Districts

There are numerous resource conservation districts (RCD) within the study area. Once known as soil conservation districts, RCDs were established under California law with a primary purpose to implement local conservation measures. Although RCDs are locally governed agencies with locally appointed, independent boards of directors, they often have close ties to county agencies and the National Resources Conservation Service. RCDs are empowered to conserve resources within their districts by implementing projects on public and private lands and to educate landowners and the public about resource conservation. They are often involved in the formation and coordination of watershed working groups and other conservation alliances. In the Shasta Lake and upper Sacramento River vicinity, districts include the Western Shasta County RCD and the Tehama County RCD. To the east are the Fall River and Pit River RCDs, and to the west and north are the Trinity County and Shasta Valley RCDs.

Riparian Habitat Joint Venture

The Riparian Habitat Joint Venture (RHJV) was initiated in 1994 and includes signatories from 18 Federal, State, and private agencies. The RHJV promotes conservation and the restoration of riparian habitat to support native bird population through three goals:

- Promote an understanding of the issues affecting riparian habitat through data collection and analysis.
- Double riparian habitat in California by funding and promoting on-the-ground conservation projects.
- Guide land managers and organizations to prioritize conservation actions.

RHJV conservation and action plans are documented in the *Riparian Bird Conservation Plan* (RHJV 2004). The conservation plan targets 14 “indicator” species of riparian-associated birds and provides recommendations for habitat protection, restoration, management, monitoring, and policy. The report notes habitat loss and degradation as one of the most important factors causing the

decline of riparian birds in California. The RHJV has participated in monitoring efforts within the Sacramento National Wildlife Refuge Complex and other conservation areas. The RHJV's conservation plan identifies lower Clear Creek as a prime breeding area for yellow warblers and song sparrows, advocating a continuous riparian corridor along lower Clear Creek. Other recommendations of the conservation plan apply to the North Delta Off stream Storage Investigation study area.

Sacramento River Advisory Council

In 1986, the California Legislature passed Senate Bill 1086, which called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance fisheries and riparian habitat in an area stretching from the confluence of the Sacramento River with the Feather River and continuing northward to Keswick Dam. The law established an advisory council that included representatives of Federal and State agencies, county supervisors, and representatives of landowners, water contractors, commercial and sport fisheries, and general wildlife and conservation interests. Responsibilities of the advisory council included development of the *Sacramento River Conservation Area Forum Handbook* to guide management of riparian habitat and agricultural uses along the river (Resources Agency 2003). This action also resulted in formation in May 2000 of the SRCA Forum, a nonprofit, public benefit corporation with a board of directors that includes private landowners and public interest representatives from a seven-county area, an appointee of the California Resources Agency, and ex-officio members from six Federal and State resource agencies. The work of the organization is generally focused on planning actions and river management within the SRCA planning area.

Sacramento River Conservation Area Program

Senate Bill 1086 called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance both fisheries and riparian habitat. The SRCA Program has an overall goal of preserving remaining riparian habitat and reestablishing a continuous riparian ecosystem along the Sacramento River between Redding and Chico, and reestablishing riparian vegetation along the river from Chico to Verona. The program is to be accomplished through an incentive-based, voluntary river management plan. The Upper Sacramento River Fisheries and Riparian Habitat Management Plan (Resources Agency 1989), identifies specific actions to help restore the Sacramento River fishery and riparian habitat between the Feather River and Keswick Dam. The Sacramento River Conservation Area Forum Handbook (Resources Agency 2003) is a guide to implementing the program. The Keswick Dam-to-Red Bluff portion of the conservation area includes areas within the 100-year floodplain, existing riparian bottomlands, and areas of contiguous valley oak woodland, totaling approximately 22,000 acres. The 1989 fisheries restoration plan recommended several actions specific to the study area:

- Fish passage improvements at RBDD (final Environmental Impact Statement/Environmental Impact Report released May 2008)

- Modification of the Spring Creek Tunnel intake for temperature control (completed)
- Spawning gravel replacement program (ongoing)
- Development of side-channel spawning areas, such as those at Turtle Bay in Redding (ongoing)
- Structural modifications to the Anderson-Cottonwood Irrigation District Dam to eliminate short-term flow fluctuations (completed)
- Maintaining instream flows through coordinated operation of water facilities (ongoing)
- Improvements at the Coleman National Fish Hatchery (partially complete)
- Measures to reduce acute toxicity caused by acid mine drainage and heavy metals (ongoing)
- Various fisheries improvements on Clear Creek (partially complete)
- Flow increases, fish screens, and revised gravel removal practices on Battle Creek (beginning summer 2006)
- Control of gravel mining, improvements of spawning areas, improvements of land management practices in the watershed, and protection and restoration of riparian vegetation along Cottonwood Creek

The Nature Conservancy

The Nature Conservancy (TNC) is a private, nonprofit organization involved in environmental restoration and conservation throughout the United States and the world. TNC approaches environmental restoration primarily through strategic land acquisition from willing sellers and obtaining conservation easements. Some of the lands are retained by TNC for active restoration, research, or monitoring activities, while others are turned over to government agencies such as USFWS or DFG for long-term management. Lower in the Sacramento River basin, TNC has been instrumental in acquiring and restoring lands in the Sacramento River National Wildlife Refuge and managing several properties along the Sacramento River. It also has pursued conservation easements on various properties at tributary confluences, including Cottonwood and Battle creeks.

11.3 Environmental Consequences and Mitigation Measures

11.3.1 Methods and Assumptions

The following sections describe the methods, processes, procedures, and/or assumptions used to formulate and conduct the environmental impact analysis.

This analysis of impacts on fisheries and aquatic ecosystems resulting from implementation of the project alternatives under consideration is based on extensive review of existing documentation that addresses aquatic habitats and fishery resources in the primary and extended study areas, and on water resources modeling analysis.

Summary of Water Resources Modeling

Extensive hydrologic, water temperature, and salmon production and mortality modeling was performed to provide a quantitative basis from which to assess potential operation-related effects of the project alternatives on fisheries resources and aquatic habitats within the primary and extended study areas. Model selection and use for each of the variables were as follows:

- **Hydrologic modeling** – CalSim-II (primary and extended study areas)
- **Water temperature modeling** – Sacramento River water temperature model (primary study area)
- **Salmon production and mortality** – SALMOD (primary study area)

Modeling output provided monthly values for each year of the 82-year period of record modeled for river flows, reservoir storage and elevation, and river water temperatures. The period of record is based on records from 1921 through 2003. River flow and water temperature output was put into weekly form and used in SALMOD to characterize flow- and water temperature-induced production and mortality of salmon under each simulated condition.

The models used in the fisheries analyses (i.e., CalSim-II, Sacramento river water temperature model, and SALMOD) are tools that have been developed for comparative planning purposes, rather than for predicting actual river conditions at specific locations and times. The 82-year period of record for CalSim-II and water temperature modeling provides an index of the kinds of changes that would be expected to occur with implementation of a specified set of operational conditions. Reservoir storage, river flows, water temperature, and salmon survival output for the period modeled should not be interpreted or used as definitive absolutes depicting actual river conditions that would occur in the future. Rather, output for the project alternatives was compared to that for the Existing Condition (2005) and No-Action Alternative (future 2030) alternatives simulation to determine the following:

- Whether reservoir storage or river flows and water temperatures would be expected to change with implementation of the SLWRI alternatives.

- Months in which potential reservoir storage and river flow and water temperature changes could occur.

- Relative magnitude of change that could occur during specific months of particular water-year types, and whether the relative magnitude anticipated would be expected to result in effects on fisheries resources and aquatic habitats within the regional area.

The models used, although mathematically precise, should be viewed as having "reasonable detection limits." Establishing reasonable detection limits is useful in interpreting modeling output for impact assessment purposes, and prevents making inferences beyond the capabilities of the models and beyond an ability to actually measure changes.

Simulated water temperature differences of less than 1°F were lower than the reasonable detection limit. In situ temperature loggers used to collect water temperature data used for the model typically have a precision of ±0.36°F, yielding a potential error of 0.72°F (Deas et al. 1997). Therefore, modeled differences in water temperature of 0.36°F or less could not be consistently detected in the river by actual monitoring of water temperatures. In addition, as mentioned above, output from Reclamation's water temperature models provides a "relative index" of water temperatures under the various operational conditions modeled. Output values indicate whether the water temperatures would be expected to increase, remain unchanged, or decrease, and provide insight regarding the relative magnitude of potential changes under one operational condition compared to another.

The Modeling Appendix provides a more detailed discussion of the modeling process and its application to the project analysis, including (1) the primary assumptions and model inputs used to represent hydrologic, regulatory, structural and operational conditions; and (2) the simulations performed from which effects were estimated. SALMOD is discussed in more detail below.

Modeling Uncertainties and Real-Time Decision-Making A process exists for real-time decision-making on CVP and SWP operations to allow fishery management that promotes flexible decision-making able to be adjusted for uncertainties as outcomes of management actions and other events become better understood.

It should be noted that modeling simulations conducted to support the analysis of the project alternatives do not always capture potential operational changes associated with the human element of real-time decision-making. Therefore, although the modeling is based on operational assumptions that are generally accepted, there may be isolated inaccuracies regarding real-time human

decisions on operations to ensure compliance with existing objectives, standards, and/or agreements.

For example, the NMFS BO for the long-term CVP and SWP Operations Criteria and Plan and SWRCB orders require that CVP and SWP operations for the Sacramento River meet specific water temperature criteria. In 1997, construction was completed on the TCD at Shasta Dam. The TCD was designed to selectively withdraw water from elevations within Shasta Lake to better manage water temperatures in the upper river, while allowing power generation. SRTTG is an interagency team that identifies water management alternatives and TCD operations in real time, interprets the availability of cold-water resources in Shasta Lake, and designs an annual/seasonal river temperature compliance strategy, as outlined in SWRCB Water Right Order 90-5 and multiple BOs.

Reservoir Fisheries Analysis

Monthly values for WSEL, surface area, and cold-water storage in Shasta Lake were calculated for 1922 to 2003 using data outputs from CalSim-II. Values were produced for five alternative dam raise scenarios (project alternatives) using a 2005 water supply demand, and a projected 2030 water supply demand for a total of 10 scenarios. Each year of the hydrologic record was categorized as one of five water year categories (wet, above-normal, below-normal, dry, critical) based on the Sacramento River Inflow Index. Model outputs for the last day of each month from February to July (e.g., February 29, March 31) were used for analysis of potential changes in surface area and WSEL. End-of-month values for April, June, August, and October were used to analyze the potential changes in Shasta Lake's cold-water storage. Potential impacts of the enlargement of Shasta Dam and Shasta Lake on the fisheries resources of Shasta Lake were investigated using several habitat-based metrics that are associated with factors known to limit or otherwise regulate warm-water and cold-water reservoir fish populations. The following metrics were computed and used:

- **Surface Area** – Surface area is the metric used to investigate changes in the amount of available littoral (i.e., shoreline) and limnetic (i.e., open water) habitat, which could impact warm-water and cold-water fisheries, under each of the project alternatives. Variations in surface area influence biological productivity (including fish production) because the upper, lighted layer of the pelagic zone is the principal plankton-producing region of the reservoir. Reservoir enlargement may initially produce a "trophic upsurge" phenomenon that occurs in response to terrestrial habitat inundation, nutrient loading, and increases in labile detritus (Kimmel and Groeger 1986). The initial trophic enrichment will decline and stabilize over time as the reservoir ecosystem approaches its natural trophic equilibrium (Kimmel and Groeger 1986). Trophic depression is a response to decreased nutrient loading and decreased labile detritus. Fisheries production experiences a depression in response to the same factors as well as decreases in

available terrestrial organic detritus and loss of cover as inundated vegetation deteriorates (Stables et al. 1990).

- **Cold-Water Storage to Surface Area Ratio** – Cold-water storage to surface area ratio (a dimensionless value) is a useful metric for assessing the potential impact of project alternatives on Shasta Lake's cold-water fishery. Stables et al. (1990) suggest that an increase in pelagic and littoral trout habitat accompanied by lake enlargement should lead to higher total fish yield. While increases in water surface area, such as those that might result from reservoir enlargement, can stimulate primary and secondary productivity (Jones and Stokes Associates 1988), access to cold-water refuge can be a limiting factor for cold-water fish production. Therefore, increases in reservoir surface area without proportional increases in cold-water storage are likely to result in little change in cold-water fish production. Conversely, a proportional increase in the cold-water storage to surface area ratio should result in increased cold-water fish productivity.

- **WSEL** –WSEL is a metric that is useful in analyzing the impact of project alternatives on the Shasta Lake warm-water fishery. The timing and duration of WSEL fluctuation can have a great impact on the reproductive success of nearshore spawning fishes (Ploskey 1986). Stable or increasing WSEL during spring months (March through June) can contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of several warm-water species, including the black basses (Lee 1999, Ploskey 1986). Inundation of shoreline habitat may also lead to increased structural diversity and availability of spawning substrate or cover for juvenile fishes, depending on vegetation removal activities (Miranda et al. 1984, Ratcliff 2006). Conversely, reduced or variable WSEL due to reservoir drawdown during spring spawning months can cause reduced spawning success for warm-water fishes through nest dewatering, egg desiccation, and physical disruption of spawning or nest guarding activities (Lee 1999, Ploskey 1986).

WSEL values were obtained from CalSim-II outputs, as described above, and were graphed for each comparison set. Monthly change in surface elevation (monthly change in elevation) was calculated by subtracting the previous month's surface elevation from each month. For example, change in elevation for March was calculated by subtracting the February 29 WSEL from the March 31 WSEL. The relative difference in monthly change in elevation from the basis-of-comparison and the relative percent difference in monthly change in elevation were graphed for each comparison set, with the basis-of-comparison as the Existing Condition in sets one and three, and the No-Action Alternative in set two. The relative difference and relative percent difference in monthly change in elevation between CP3 and CP4 were also graphed for comparison sets one and three.

Surface area values obtained from CalSim-II outputs were graphed for each comparison set. Relative differences in monthly surface area values from the basis-of-comparison were graphed for each comparison set, as described for WSEL.

Cold-Water Storage Values obtained from CalSim-II outputs were divided by surface area outputs to generate monthly cold-water storage to surface area ratios. The cold-water storage to surface area ratios were graphed for comparison set two only. The relative difference and relative percent difference in monthly cold-water storage to surface area ratio from the basis-of-comparison were also calculated and graphed for comparison set two only.

For each metric, CalSim-II projections for monthly change under the Existing Condition were graphed against the No-Action Alternative.

Additionally, graphs were prepared depicting the expected ratio of monthly cold-water storage to surface area, monthly surface area, and expected monthly changes in elevation under 2005 and 2030 water demands (separately) for all water-year types for CP1, CP2, CP3, and CP4 for the Shasta Lake and vicinity portion of the primary study area. For example, in the discussion of potential impacts associated with implementation of CP1 is a graph comparing monthly surface area under CP1 with a 2005 water supply demand to monthly surface area under the Existing Condition, and a separate graph making this comparison for CP1 with a 2030 water supply demand versus the No-Action Alternative.

Values for the three habitat metrics were compared in graphical form to address the following issues:

- How reservoir cold-water storage, WSEL, or the cold-water storage to surface area ratio would be expected to change with implementation of the project alternatives

- Months or seasons when potential changes in the habitat metrics could occur

- Relative magnitude of change that could occur during specific months of particular water-year types, and the potential impacts these changes could have on fisheries resources, aquatic resources, and habitats within the reservoir

All analyses were based on CalSim-II model outputs. CalSim-II is California's primary water operations planning model, used by both Reclamation and DWR. While model sensitivity and accuracy calibrations are still being developed for CalSim-II, the model's widespread use for water planning and management operations in Central California makes it useful and its projections easily comparable between projects. However, model outputs should be used as tools

for interpretation of anticipated impacts rather than actual projections (Close et al. 2003).

Tributaries to Shasta Lake

The primary study area is composed of Shasta Dam and Shasta Lake, the lower reaches of the tributaries draining into Shasta Lake, and the Sacramento River downstream to Keswick Dam. Thirteen representative tributary streams to Shasta Reservoir were selected for focused examination as part of this assessment, including the five primary tributaries: Sacramento River, McCloud River, Pit River, Squaw Creek, and Big Backbone Creek.

Considerations for reservoir and tributary fisheries include the following:

- Connectivity to tributary spawning/refuge habitat.
- Potential connectivity to nonfish-bearing streams.
- Potential impacts to special-status species or their habitat from inundation of stream habitat (e.g., through increased turbidity/erosion/sedimentation that may affect connectivity or create a barrier).

Chinook Salmon Between Keswick Dam and Red Bluff Diversion Dam

SALMOD is a computer model that simulates the dynamics of freshwater salmonid populations, but for the SLWRI, SALMOD simulates population dynamics for all four runs of Chinook salmon between Keswick Dam and RBDD. SALMOD was applied to this project because the model had been previously used on the upper Sacramento River (from Keswick Dam to Battle Creek), and has been updated using model parameters and techniques developed for use on the Klamath River and from Sacramento River-specific Chinook salmon information obtained from USFWS and DFG fisheries biologists (Bartholow 2003; Modeling Appendix, Chapter 5). Also, resource agency personnel were presented with the capabilities of the model by John Bartholow (formerly with the U.S. Geological Survey) under contract by Reclamation, and agreed that using SALMOD was the appropriate means of evaluating potential conditions. John Bartholow and John Heasley (contractor to U.S. Geological Survey) were instrumental in extending SALMOD to assess fish production and mortality between Keswick Dam and the RBDD. They also assisted in preparation of the SALMOD description included in the Modeling Appendix, Chapter 5, which contains a detailed discussion of the SALMOD model.

Comprehensive Plans Evaluated SALMOD used weekly streamflow and water temperature to evaluate six different scenarios: the Existing Condition, No-Action Alternative, CP1, CP2, CP3, and CP4. The Existing Condition is based on a 2005 level of development. The No-Action Alternative represents the Future Conditions (2030) without completion of a project to address the objectives of the SLWRI. CP1 is based on a 6.5-foot dam raise; CP2 is based

on a 12.5-foot dam raise; and CP3 is based on an 18-foot dam raise. CP4 was developed based on an 18.5-foot dam raise with operations modified to create a more “fish-friendly” environment, with one-third of the reservoir storage dedicated to fish, to either improve flows or water temperatures.

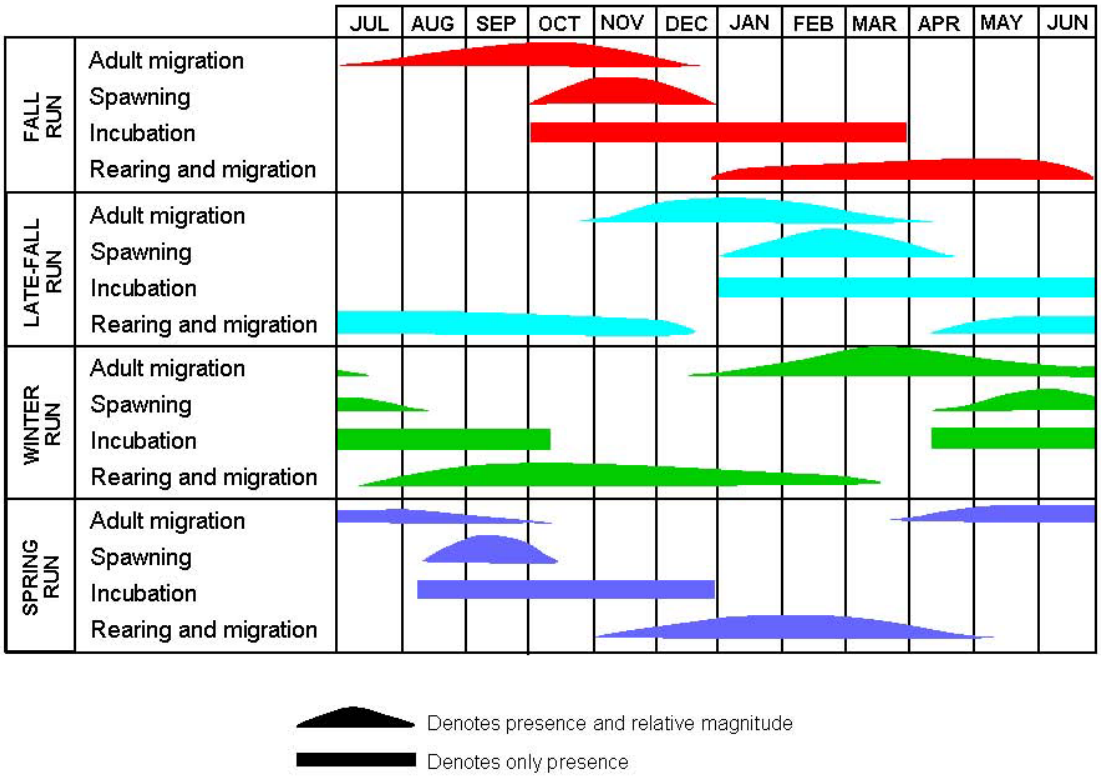
Additional scenarios were evaluated, but not pursued further, due to inconsistencies or lack of achievement of the primary goals of the project.

In the original presentation (August 16, 2005) of the SALMOD model to resource agency personnel, interest was expressed in setting the number of spawning adults at the AFRP production goal for the Sacramento River upstream from the RBDD. The AFRP defined natural production to be that portion of Chinook salmon not produced in hatcheries, and defined total production to be the sum of harvest and escapement. The production goals include adult fish removed from the system due to both sport and commercial fishing in both freshwater and marine environments. Therefore, SALMOD was run using the appropriate number of spawners (Table 11-3).

SALMOD was also conducted using a spawning population based on the 1999 to 2006 average adult return provided by DFG (2011), which documents spawning escapement estimates for each year in the Central Valley. Using this average was expected to result in a more realistic effect of the project operations on salmon under the Existing Condition, and on the premise that the AFRP goals should take the populations closer to a state of carrying capacity. Thus, if a population is already at or nearing carrying capacity, increases in the populations are unlikely. The starting year for calculating the average number of spawners was in 1999 because the effects of the TCD began in 1999, and ended in 2006, which was the extent of collected and processed data.

Populations of 500 or more salmon are considered necessary for accurate results using SALMOD because it is a deterministic model that relies on the "law of large numbers." When populations are "low" (an arbitrary term), mean responses are quickly affected by environmental stochasticity and individual variability, which are factors SALMOD was not designed to address. Therefore, because the 1999 to 2006 average for spring-run Chinook salmon was 207 adult spawners, the criterion of 500 or more fish was not met. However, because of concerns expressed by DFG and USFWS, the spawning population was left at 207 fish for purposes of the model.

Table 11-3. Number of Spawning Fish Incorporated into SALMOD Model



Reach	Fall-Run	Late Fall-Run	Winter-Run	Spring-Run
California Department of Fish and Game (Grand Tab, 1999 through 2006 average)				
Keswick to ACID	6,658	4,725	3,591	9
ACID to Highway 44 Bridge	4,011	2,096	1,761	39
Highway 44 Bridge to Airport Road Bridge	7,175	3,123	3,041	67

ACID = Anderson-Cottonwood Irrigation District
AFRP = Anadromous Fish Restoration Program

SALMOD Output SALMOD produces many forms of output files, but two basic output files – production and mortality (both weekly and annual) – were used in this assessment. Two types of mortality were calculated – those caused by the operations (triggered by changes in flow and water temperature) and those that are nonoperations-related (mortalities caused by factors that would still occur without the project in effect, such as disease, predation, and entrainment). Mortality was calculated for each life stage, from migrating/holding adult to the emigrating juvenile.

SALMOD evaluated five separate life stages of Chinook salmon – adult, egg, fry, presmolt, and immature smolt. Figure 11-1 shows the timing for each life stage. Mortality of adults in SALMOD was calculated during the adult migration and spawning time periods. Mortality of eggs (both eggs and in-gravel alevins) was calculated during the adult migration, spawning, and

incubation stages, while fry, presmolts, and immature smolts were calculated during the rearing and migration time period.

Source: Vogel and Marine 1991

Figure 11-1. Approximate Timing of the Four Runs of Chinook Salmon in the Sacramento River

Production SALMOD defines production as follows:

Production = (Potential eggs + entrants) – (prespawn egg mortality + other mortality + residuals)

Where:

- Production is the number of young fish surviving to migrate downstream from the RBDD
- Potential eggs are the number of eggs that could be spawned, providing there is no prespawn mortality of either adult females or eggs *in vivo*
- Entrants are the number of young fish entering the project reach (Keswick Dam to RBDD) from the tributaries
- Mortality is the number of eggs and/or fish that die before leaving the project reach

- Residuals are the number of young fish under 60 mm that, after 52 weeks, have not left the project reach

Mortality The mortality process computed all mortality not explicitly included with one of the other processes. This includes mortality from unsuitable water temperature (Reclamation 1991), population density, superimposition, and eggs while *in vivo* and incubating. In addition, a base mortality for all causes not related to any other process (e.g., entrainment, predation) was also computed.

Categories of mortality calculated in SALMOD include the following and are further described in Chapter 5 of the Modeling Appendix:

- **Nonoperations Related Mortality**
  - **Base (Nonoperational) –** An accounting of mortality of adults, eggs, fry, presmolts, and immature smolts for everything other than what is in the model, or background mortality (mortality that would occur regardless of the project operations) from factors such as predation, disease, etc.
  - **Seasonal (Nonoperational) –** Extra outmigration mortality of presmolts or immature smolts, including diversion-related mortality.
- **Operations-Related Mortality**
  - **Habitat –** Operations-related mortality resulting from forced movement of fry, presmolts, or immature smolts due to habitat constraints.
  - **Temperature –** Operations-related mortality to adults, eggs, fry, presmolts, and/or immature smolts caused by unsuitable water temperatures.
  - **Lost Egg –** Number of eggs lost due to the lack of spawning habitat (a single adult Chinook salmon female cannot spawn because all redds are guarded). It was assumed that these eggs are shed, but as they are alive when leaving the female spawners, they were tallied in the mass balance table. The lack of spawning habitat could be due to lack of spawning gravel, or lower flows precluding access to suitable spawning habitat.
  - ***In Vivo* –** Number of eggs lost because of operations-related water temperature mortality within the female either prior to spawning, or prespawning, thermal mortality in which exposure kills the egg or malformed young fish after spawning.

  - **Incubation –** Number of eggs lost if redds (or portions of redds) are affected by changing egg incubation habitat through the duration of the incubation season due to flushing flows scouring out the redds (occurs at a minimum of 60,000 cfs) or redd dewatering from a drop in streamflows resulting from operations-related actions.

  - **Superimposition –** Number of eggs lost due to new spawning on top of a currently incubating redd resulting from operations-related activities.

- **Analysis –** To evaluate the effects of the project, productions and mortalities were calculated and the differences between the project alternatives and the No-Action Alternative and the Existing Condition were then compared. Most of the years for each run showed minimal differences from the No-Action Alternative, creating an overall average production approaching zero. Each model has its own inherent level of error. In addition, flow data derived from CalSim-II had to be disaggregated from monthly data to weekly, resulting in potential additional error. Because water-year type affects Chinook salmon populations, separate production trends based on water-year type were evaluated for each run.

  Starting populations used in SALMOD were derived from an average population for the years 1999 through 2006, based on the DFG Grandtab table (2011), which lists population estimates on a yearly basis. The AFRP populations were based on the goals identified for the Sacramento River for each run of Chinook salmon.

  Although water year classifications are somewhat arbitrary, and the biological year for each run of Chinook salmon encompasses portions of two separate water years, mortalities caused by operations were separated by water-year types to identify trends, such as changes in mortality in critical water years due to unsuitable water temperatures. Once the years were separated by water-year type, the mortality categories were ranked to determine which mortality category under each alternative was the primary factor affecting production for each run.

  The SLWRI has the greatest variations in project operations from the Existing Condition, No-Action Alternative, and the Comprehensive Plans during critical and dry water years (for further detail, refer to the *Hydrology, Hydraulics and Water Management Technical Report*). Besides providing a more reliable water source for delivery, CP1 through CP5 are able to provide more suitable flows and water temperatures during critical and dry water years. This is shown in increased production and/or decreased operations-related mortalities.

Because CP5 is operated the same as CP3, all results for CP5 are synonymous with CP3 and are not listed in the table of results.

Delta Fisheries

Delta Outflow Water development has changed the volume and timing of freshwater flows through the Bay-Delta. Over the past several decades, the volume of the Bay-Delta's freshwater supply has been reduced by upstream diversions, in-Delta use, and Delta exports. As a result, the proportion of Delta outflow depleted by upstream and Delta diversions has grown substantially. In wet years, diversions reduce outflow by 10 percent to 30 percent. In dry years, diversions may reduce outflow by more than 50 percent.

Water development has also altered the seasonal timing of flows passing into and through the Bay-Delta. Flows have decreased in April, May, and June and have increased slightly during the summer and fall (SFEP 1992). Seasonal flows influence the transport of eggs and young organisms (e.g., zooplankton, fish eggs, larvae) through the Delta and into San Francisco Bay. Flows during the months of April, May, and June play an especially important role in determining the reproductive success and survival of many estuarine species, including salmon, striped bass, American shad, delta smelt, longfin smelt, splittail, and others (Stevens and Miller 1983; Stevens et al. 1985; Herbold 1994; Meng and Moyle 1995).

For purposes of evaluating the potential effect of changes in outflow on fish habitat within the Bay-Delta, and considering the accuracy and inherent noise within the hydrologic model, it was assumed that changes in the average monthly flows that were less than 5 percent (plus or minus) relative to the basis-of-comparison would not be expected to result in a significant (detectable) effect on habitat quality or availability. It would also not be expected to result in a significant effect on the transport mechanisms provided by Delta outflow, on resident or migratory fish or the zooplankton and phytoplankton on which they rely for a food resource.

Delta Inflow Changes in upstream reservoir storage have the potential to affect Delta inflow (water entering the Delta). Delta inflow may affect hydrologic conditions within Delta channels, hydraulic residence times, salinity gradients, and the transport and movement of various life stages of fish, invertebrates, phytoplankton, and nutrients into and through the Delta. Delta inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly or indirectly affect fish and other aquatic resources.

The comparison includes the estimated average monthly inflow under the basis-of-comparison conditions (Existing Condition and No-Active Alternative), the average monthly flow under each of project alternatives evaluated, and the percentage change between base flows and operations. For purposes of evaluating the potential effect of changes in Delta inflow on fish habitat within the Bay-Delta, and considering the accuracy and inherent noise within the

hydrologic model, it was assumed that changes in the average monthly flows that were less than 5 percent (plus or minus) relative to the basis-of-comparison would not be expected to result in a significant (detectable) effect on habitat quality or availability, or the transport mechanisms provided by Delta inflow, on resident or migratory fish or the zooplankton and phytoplankton that they rely on for a food resource.

Sacramento River Inflow Flow within the Sacramento River has been identified as an important factor affecting the survival of emigrating juvenile Chinook salmon, important to the downstream transport of planktonic fish eggs and larvae such as delta smelt and longfin smelt, striped bass, and shad, and important for seasonal floodplain inundation that has been identified as important habitat for successful spawning and larval rearing by species such as Sacramento splittail and as seasonal foraging habitat for juvenile Chinook salmon and steelhead. Sacramento River flows are also important in the transport of organic material and nutrients from the upper regions of the watershed downstream into the Delta. A reduction in Sacramento River flow as a result of SLWRI alternative operations, depending on the season and magnitude of change, could adversely affect habitat conditions for both resident and migratory fish species. An increase in river flow is generally considered to be beneficial for aquatic resources within the normal range of typical project operations and flood control. Very large changes in river flow could also affect sediment erosion, scour, deposition, suspended and bedload transport, and other geomorphic processes within the river and watershed.

For purposes of evaluating the potential effect of changes in Sacramento River inflow on fish habitat within the Bay-Delta, and considering the accuracy and inherent noise within the hydrologic model, it was assumed that changes in the average monthly flows less than 5 percent (plus or minus) relative to the basis-of-comparison would not be expected to result in a significant (detectable) effect on habitat quality or availability, or the transport mechanisms provided by Sacramento River inflow, on resident or migratory fish or the zooplankton and phytoplankton that they rely on for a food resource.

San Joaquin River Flow at Vernalis Flow within the San Joaquin River has been identified as an important factor affecting the survival of juvenile Chinook salmon migrating downstream from the tributaries through the mainstem San Joaquin River and Delta, important to the downstream transport of planktonic fish eggs and larvae such as striped bass, and important for seasonal floodplain inundation that is considered to be important habitat for successful spawning and larval rearing by species such as Sacramento splittail and as seasonal foraging habitat for juvenile Chinook salmon. San Joaquin River flows are also important in the transport of organic material and nutrients from the upper regions of the watershed downstream into the Delta. A reduction in San Joaquin River flow as a result of SLWRI alternative operations, depending on the season and magnitude of change, could adversely affect habitat conditions for both resident and migratory fish species. An increase in river flow is

generally considered to be beneficial for aquatic resources within the normal range of typical project operations and flood control. Very large changes in river flow could also affect sediment erosion, scour, deposition, suspended and bedload transport, and other geomorphic processes within the river and watershed.

For purposes of evaluating the potential effect of changes in San Joaquin River flow at Vernalis on fish habitat within the Bay-Delta, and considering the accuracy and inherent noise within the hydrologic model, less than a 5 percent change (plus or minus) relative to the basis-of-comparison, would not be expected to result in a significant (detectable) effect on habitat quality or availability, or the transport mechanisms provided by San Joaquin River flow at Vernalis, on resident or migratory fish or the zooplankton and phytoplankton that they rely on for a food resource.

Entrapment Zone and X2 In many segments of the Bay-Delta, but particularly in Suisun Bay and the Delta, salinity is controlled by the balance of saltwater intrusion from San Francisco Bay and freshwater flow from the tributaries to the Delta. By altering the timing and volume of flows, water development has affected salinity patterns in the Delta and in parts of San Francisco Bay (SFEP 1992). Under natural conditions, the Carquinez Strait/Suisun Bay region marked the approximate boundary between saltwater and freshwater in the Bay-Delta during much of the year. In the late summer and fall of drier years, when Delta outflow was minimal, seawater moved into the Delta from San Francisco Bay. Beginning in the 1920s, following several dry years and because of increased upstream storage and diversions, salinity intrusions became more frequent and extensive.

Since the 1940s, releases of freshwater from upstream storage facilities have increased Delta outflows during summer and fall. These flows have correspondingly limited the extent of salinity intrusion into the Delta. Reservoir releases have helped to ensure that the salinity of water diverted from the Delta is acceptable during the summer and late fall for farming, municipal, and industrial uses (SFEP 1992).

Salinity is an important habitat factor in the Bay-Delta. All estuarine species are assumed to have optimal salinity ranges, and their survival may be affected by the amount of habitat available within the species' optimal salinity range. Because the salinity field in the Bay-Delta is largely controlled by freshwater outflows, the level of outflow may determine the surface area of optimal salinity habitat that is available to the species (Hieb and Baxter 1993, Unger 1994).

The transition area between saline waters within the Bay and freshwater within the rivers, frequently referred to as the low salinity zone, is located within Suisun Bay and the western Delta. The low salinity zone has also been associated with the entrapment zone, a region of the Bay-Delta characterized by higher levels of particulates, higher abundances of several types of organisms,

and a turbidity maximum. It is commonly associated with the position of the 2 parts per thousand salinity isopleth (X2), but actually occurs over a broader range of salinities (Kimmerer 1992). Originally, the primary mechanism responsible for this region was thought to be gravitational circulation, a circulation pattern formed when freshwater flows seaward over a dense, landward-flowing marine tidal current. However, recent studies have shown that gravitational circulation does not occur in the entrapment zone in all years, nor is it always associated with X2 (Burau et al. 1998). Lateral circulation within the Bay-Delta or chemical flocculation may play a role in the formation of turbidity maximum of the entrapment zone.

As a consequence of higher levels of particulates, the entrapment zone may be biologically significant to some species. Mixing and circulation in this zone concentrates plankton and other organic material, thus increasing food biomass and production. Larval fish such as striped bass, delta smelt, and longfin smelt may benefit from enhanced food resources. Since about 1987, however, the introduced Asian overbite clam population has cropped much of the primary production in the Bay-Delta and there has been virtually no enhancement of phytoplankton production or biomass in the entrapment zone (CUWA 1994).

This region continues to have relatively high levels of invertebrates and larval fish, even though the base of the food chain may not have been enhanced in the entrapment zone during the past decade. Vertical migration of these organisms through the water column at different parts of the tidal cycle has been proposed as a possible mechanism to maintain high abundance in this region, but recent evidence suggests that vertical migration does not provide a complete explanation (Kimmerer et al. 2002).

Although evidence indicates that X2 and the entrapment zone are not as closely related as previously believed (Burau et al. 1998), X2 continues to be used as an index of the location of the entrapment zone and area/or of increased biological productivity. Historically, X2 has varied between San Pablo Bay (River Kilometer 50) during high Delta outflow and Rio Vista (River Kilometer 100) during low Delta outflow. In recent years, it has typically been located between approximately Honker Bay and Sherman Island (River Kilometer 70 to 85). X2 is controlled directly by the volume of Delta outflow, although changes in X2 lag behind changes in outflow. Minor modifications in outflow do not greatly alter X2.

Jassby and Powell (1994) showed that when X2 is in the vicinity of Suisun Bay, several estuarine organisms tend to show increased abundance. However, it is by no means certain that X2 has a direct effect on any of the species. The observed correlations may result from a close relationship between X2 and other factors that affect these species.

Operations of upstream storage reservoirs have the potential to affect the location of X2 as a result of changes in freshwater flows from the upstream

tributaries through the Delta. For purposes of evaluating changes in habitat quantity and quality for estuarine species, a significance criterion of an upstream change in X2 location within 1 kilometer (km) of the basis-of-comparison condition was considered to be less than significant. The criterion was applied to a comparison of hydrologic model results for basis-of-comparison conditions and project alternatives, by month and water year, for the months from February through May.

Old and Middle River Reverse Flows Reverse flows occur when Delta exports and agricultural demands exceed San Joaquin River inflow plus Sacramento River inflow through the DCC, Georgiana Slough, and Threemile Slough. The capacities of the DCC, Georgiana Slough, and Threemile Slough are fixed; therefore, if pumping rates exceed that total capacity, plus flows in Old River and Eastside streams, the pumping causes Sacramento River water to flow around the west end of Sherman Island and then eastward up the San Joaquin River. This condition occurs frequently during dry years with low Delta inflows and high levels of export at the CVP and SWP pumps. The reverse flow condition within the lower San Joaquin River is typically referred to as Qwest. As second reverse flow condition occurs within Old and Middle rivers as the rate of water diverted at the CVP and SWP export facilities exceeds tidal and downstream flows within the central region of the Delta.

Reverse flows in Old and Middle rivers, resulting from low San Joaquin River inflows and increased exports to the CVP and SWP, have been identified as a potential cause of increased delta smelt mortality at the CVP and SWP fish facilities within recent years (Simi and Ruhl 2005, Ruhl et al. 2006, Wanger 2007 Case 1:05-cv-01207-OWW-NEW). Results of analyses of the relationship between the magnitude of reverse flows in Old and Middle rivers and salvage of adult delta smelt in the late winter shows a substantial increase in salvage as reverse flows exceed approximately -5,000 cfs. Concerns regarding reverse flows in Old and Middle rivers have also focused on planktonic egg and larval stages of striped bass, splittail, and on Chinook salmon smolts, in addition to delta smelt, and while these species do not spawn to a significant extent in the south Delta, eggs and larvae may be transported into the area by reverse flows in Old and Middle rivers. As discussed previously, these early life stages are generally entrained, since they are too small to be effectively screened from export waters.

Old and Middle river reverse flows have been calculated for project alternatives that equate San Joaquin River flow at Vernalis and exports to Old and Middle river flows. Summaries of Old and Middle river reverse flows are included for Existing Conditions, No-Action and action alternatives, by month and water-year type. The most biologically sensate period when the potential effects of reverse flows could affect delta smelt, Chinook salmon, and many other species extends from the late winter through early summer. For purposes of these analyses, a comparison of reverse flows within Old and Middle rivers under the

basis-of-comparison and proposed alternative project operations was prepared for the seasonal period extending from January through June.

CVP and SWP Export Operations Increased exports could increase the risk of entrainment and salvage of resident and migratory fish present in the south Delta, which may include adult delta smelt, juvenile Chinook salmon, steelhead, striped bass, and other species of fish as well as macroinvertebrates and nutrients. Increased exports during drier water years in the summer could result in an increased risk of entrainment and salvage for juvenile delta smelt and salmon (June) and resident warm-water fish such as striped bass, threadfin shad, catfish, and others during the warmer summer months (July through August). Increased exports could also increase the entrainment and removal of phytoplankton, zooplankton, macroinvertebrates, organic material, and nutrients from the Delta.

Estimated Fish Entrainment/Losses Changes in the volume of water exported at the CVP and SWP facilities is assumed to result in a direct proportional increase or decrease in the risk of fish being entrained and salvaged at the facilities. Using information from the hydrodynamic operations model, in combination with information on the densities of various fish species observed at the salvage facilities, an index in the form of a change in the numbers of a fish species theoretically affected by a change in export operations can be developed. Fish lost to entrainment/salvage at the CVP and SWP were estimated based on monthly estimated combined exports. The project alternatives were modeled in CalSim and assume, for each alternative, that the project would be implemented under the Existing Condition, and under the Future Condition. Both the Existing Condition, or "existing base" conditions, and future base conditions, or "future No-Action Alternative" conditions – which assumes no project was implemented, were assessed.

Data sources used to calculate fish losses at the CVP and SWP consisted of 1995 through 2005 monthly average density data, collected by DWR (2006) at the Skinner Fish Facility and at the Jones Fish Facility located at each export facility, respectively. These density data were calculated for delta smelt, longfin smelt, Chinook salmon, steelhead, striped bass, and splittail. Green sturgeon were considered for this analysis; however, they are seldom collected at the fish facilities, and thus, have not been modeled in the entrainment loss estimates. Fish density data was combined with CalSim results export flows modeled.

From CalSim modeling results, average monthly flows, and average flows per each year from 1922 to 2003 in cfs were converted to acre-feet per each month (January through December), and were then multiplied by monthly average densities (number of fish per acre-foot), for each of the selected fish species. Average monthly fish losses calculated for each year were then averaged by water-year type (e.g., wet, above-normal, normal, below-normal, dry, and critical) for each month, as well as an average across all years (all water-year types), for each month. Fish losses, for each species, were totaled across months

to show the total fish loss for a given species for an average year (all water-year types), wet, above-normal, normal, below-normal, dry, and critical years.

Fish losses resulting from entrainment were calculated two ways, which both produced identical entrainment indices to represent the change in entrainment based on changes in CVP and SWP exports as a result of the SLWRI alternatives:

- Fish losses were estimated by calculating losses under the base conditions, and then by calculating losses under the project alternative, from CalSim modeling. The total number of fish lost under the base case was subtracted from the number lost under the project alternative, indicating whether a net benefit (negative number) or a net loss (positive number) would result from the project alternatives.

- Fish losses were estimated by calculating losses directly from the "Alt minus Base" modeling results in CalSim.

The general calculation of the change in entrainment/salvage risk is shown below:

A = Density of fish per acre-foot for a given fish species (e.g., delta smelt, longfin smelt, salmon, striped bass, steelhead, splittail)

B = Monthly cfs, by year

C = [B x 1.983 x (number of days/month)] = average monthly exports (for CVP+SWP) for a given year, 1922 to 2003, in acre-feet

D = [A] [C] = Average monthly fish loss, per species, in a given year

$D_A = \sum (C_{1922,} C_{1923} \ldots C_{2003})$ = Average monthly fish losses at the CVP + SWP

$D_W = \sum$ (*wet water years*) = Fish losses, by month, at the CVP + SWP, based on wet water years, 1922 to 2003

$D_{AN} = \sum$ (*above-normal water years*) = Fish losses, by month, at the CVP + SWP, based on above-normal water years, 1922 to 2003

$D_N = \sum$ (*normal water years*) = Fish losses, by month, at the CVP + SWP, based on normal water years, 1922 to 2003

$D_{BN} = \sum$ (*below-normal water years*)) = Fish losses, by month, at the CVP + SWP, based on below-normal water years, 1922 to 2003

D_D = $\sum$ (*dry water years*) = Fish losses, by month, at the CVP + SWP, based on dry water years, 1922 to 2003

D_C = $\sum$ (*critical water years*) = Fish losses, by month, at the CVP + SWP, based on critical water years, 1922 to 2003

E_A = ($D_{A\text{-}JANUARY}$ +$D_{A\text{-}FEBRUARY...}$+ $D_{A\text{-}DECEMBER}$) = Total yearly average fish losses, based on monthly average 1922 to 2003 fish losses

E_W = ($D_{W\text{-}JANUARY}$ +$D_{W\text{-}FEBRUARY...}$+ $D_{W\text{-}DECEMBER}$) = Total yearly fish losses in a wet year, based on monthly average 1922 to 2003 fish losses

E_{AN} = ($D_{AN\text{-}JANUARY}$ +$D_{AN\text{-}FEBRUARY...}$+ $D_{AN\text{-}DECEMBER}$) = Total yearly fish losses in a wet year, based on monthly average 1922 to 2003 fish losses

E_N = ($D_{N\text{-}JANUARY}$ +$D_{N\text{-}FEBRUARY...}$+ $D_{N\text{-}DECEMBER}$) = Total yearly fish losses in a wet year, based on monthly average 1922 to 2003 fish losses

E_{BN} = ($D_{BN\text{-}JANUARY}$ +$D_{BN\text{-}FEBRUARY...}$+ $D_{BN\text{-}DECEMBER}$) = Total yearly fish losses in a wet year, based on monthly average 1922 to 2003 fish losses

E_D = ($D_{D\text{-}JANUARY}$ +$D_{D\text{-}FEBRUARY...}$+ $D_{D\text{-}DECEMBER}$) = Total yearly fish losses in a wet year, based on monthly average 1922 to 2003 fish losses

E_C = ($D_{C\text{-}JANUARY}$ +$D_{C\text{-}FEBRUARY...}$+ $D_{C\text{-}DECEMBER}$) = Total yearly fish losses in a wet year, based on monthly average 1922 to 2003 fish losses

Impact Mechanisms

The project could potentially affect fisheries and aquatic ecosystems through the following impact mechanisms:

- Construction-related impacts:
  - Temporary construction-related loss or degradation of aquatic habitat
- Operations-related impacts, including the following:
  - Flow- and/or water temperature-related impacts on species of primary management concern

  - Geomorphic impacts resulting from reduced frequency, duration, and/or magnitude of ecologically important intermediate and peak flows

- Delta flow-related effects, including the following:

  - Delta outflow and inflow related effects on species of primary management concern

  - Effects related to changes in Sacramento River inflow to the Delta

  - San Joaquin River flow-related effects

  - Effects on species of primary management concern resulting from changes in the location of the entrapment zone and X2

  - Effects resulting from reverse flows in Old and Middle rivers

  - Effects of changes in CVP and SWP exports to fish entrainment and salvage

Potential effects resulting from these impact mechanisms were assessed for fish species of primary management concern (i.e., special-status, ecologically important, and recreationally/commercially important fish species) and important aquatic ecological processes that may be affected by construction activities and/or operation located between Shasta Dam and RBDD (i.e., in the primary study area) and within the extended study area.

Fish species of primary management concern for the upper Sacramento River (Shasta Dam to RBDD) portion of the primary study area include the following:

- Four runs of Chinook salmon (winter-, spring-, fall-, and late fall-run)
- Steelhead
- Green sturgeon
- Sacramento splittail
- American shad
- Striped bass

Fish species of primary management concern for the lower Sacramento River to Delta portion of the extended study area include the same fish identified above but also include delta smelt and exclude American shad.

Fish species of primary management concern for the Trinity River portion of the extended study area include the following:

- Chinook salmon
- Steelhead
- Coho salmon
- Green sturgeon
- White sturgeon

The analysis of potential impacts on primary fish species of management concern considered species life history stages (adult migration, spawning, egg incubation, and juvenile rearing and emigration) and biological requirements. For all fish species of primary management concern in the Sacramento River, evaluation of potential impacts on individual life stages was based on life history descriptions provided in the *Fisheries and Aquatic Ecosystems Technical Report*.

Increased water supplies or increased supply reliability also could reduce a limitation on growth or on other activities that could affect aquatic habitats and fishery resources in the primary and extended study areas, resulting in potentially significant impacts. The impacts of this growth would be analyzed in general plan Environmental Impact Report and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these impacts would be the responsibility of these local jurisdictions, and not of Reclamation. The expected increase in water yield relative to the entire CVP and SWP service areas would be small, however, and assuming that this new yield could be provided to any number of geographic areas within the CVP and SWP service areas, the project's impact on growth that could affect aquatic habitats would be minor.

Similarly, projects potentially affecting most aquatic habitats and listed species would require permits from DFG, USACE, USFWS, and NMFS; it is anticipated that effects on aquatic habitats and listed species would be avoided, minimized, and/or mitigated during those agency consultations. Because the extent, location, and timing of induced growth is currently highly uncertain, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects, growth-inducing effects on aquatic habitats and fisheries resources are not discussed further in this chapter.

11.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project.

A "[s]ignificant effect of the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

Significance criteria (sometimes called "thresholds of significance") used in this analysis are based on the checklist presented in Appendix G of the State CEQA Guidelines; factual or scientific information and data; and regulatory standards of Federal, State, and local agencies. These thresholds also encompass the factors taken into account under NEPA to determine the significance of an action in terms of the context and the intensity of its effects.

For the assessment of impacts on fisheries and aquatic ecosystems, habitat indicators for project operations such as water temperature, flows, and important ecological processes have been used to evaluate whether the project alternatives would have an adverse effect on the species and/or species' habitat. For example, exceedence of monthly mean water temperatures identified by NMFS for certain species (e.g., 56ºF at Bend Bridge from April 15 through September 30 for winter-run Chinook salmon) is one such impact on a habitat indicator. Reduction of reservoir WSELs can reduce the availability of nearshore littoral habitat used by warm-water fish for spawning and rearing, thereby reducing spawning and rearing success and subsequent year class strength; therefore, reservoir WSEL is another habitat indicator used. Changes in river flows and water temperatures during certain periods of the year have the potential to affect spawning, fry emergence, and juvenile emigration. Therefore, changes in monthly mean river flows and water temperatures during certain times of the year (during spawning, incubation, and initial rearing) have also been used as habitat impact indicators for species of primary management concern.

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on fisheries and aquatic ecosystems would be significant if project implementation would do any of the following:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by DFG, USFWS, or NMFS.

- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or State habitat conservation plan or policies or ordinances protecting biological resources.

- Interfere substantially with the movement of any native resident or migratory fish species or with established habitat, or impede the use of native fish nursery/rearing sites.

- Conflict with a local policy or ordinance that protects aquatic and fishery resources.

- Substantially reduce the habitat of a fish species, cause a fish species to drop below self-sustaining levels, threaten to eliminate a fish or macroinvertebrate community, or substantially reduce the number or restrict the range of an endangered, rare, or threatened fish species.

Significance statements are relative to both the Existing Conditions (2005) and Future Conditions (2030), unless stated otherwise.

11.3.3 Direct and Indirect Effects

This section identifies how aquatic habitats and fish communities could be affected by the project. The project could affect fisheries and aquatic ecosystems through the following:

- Causing construction-related loss or degradation of aquatic habitat in the vicinity of and downstream from Shasta Dam.

- Altering flow regimes and water temperatures downstream from Shasta Dam and downstream from other reservoirs with altered releases.

- Causing a reduction in ecologically important geomorphic processes resulting from reduced frequency and magnitude of intermediate to high flows.

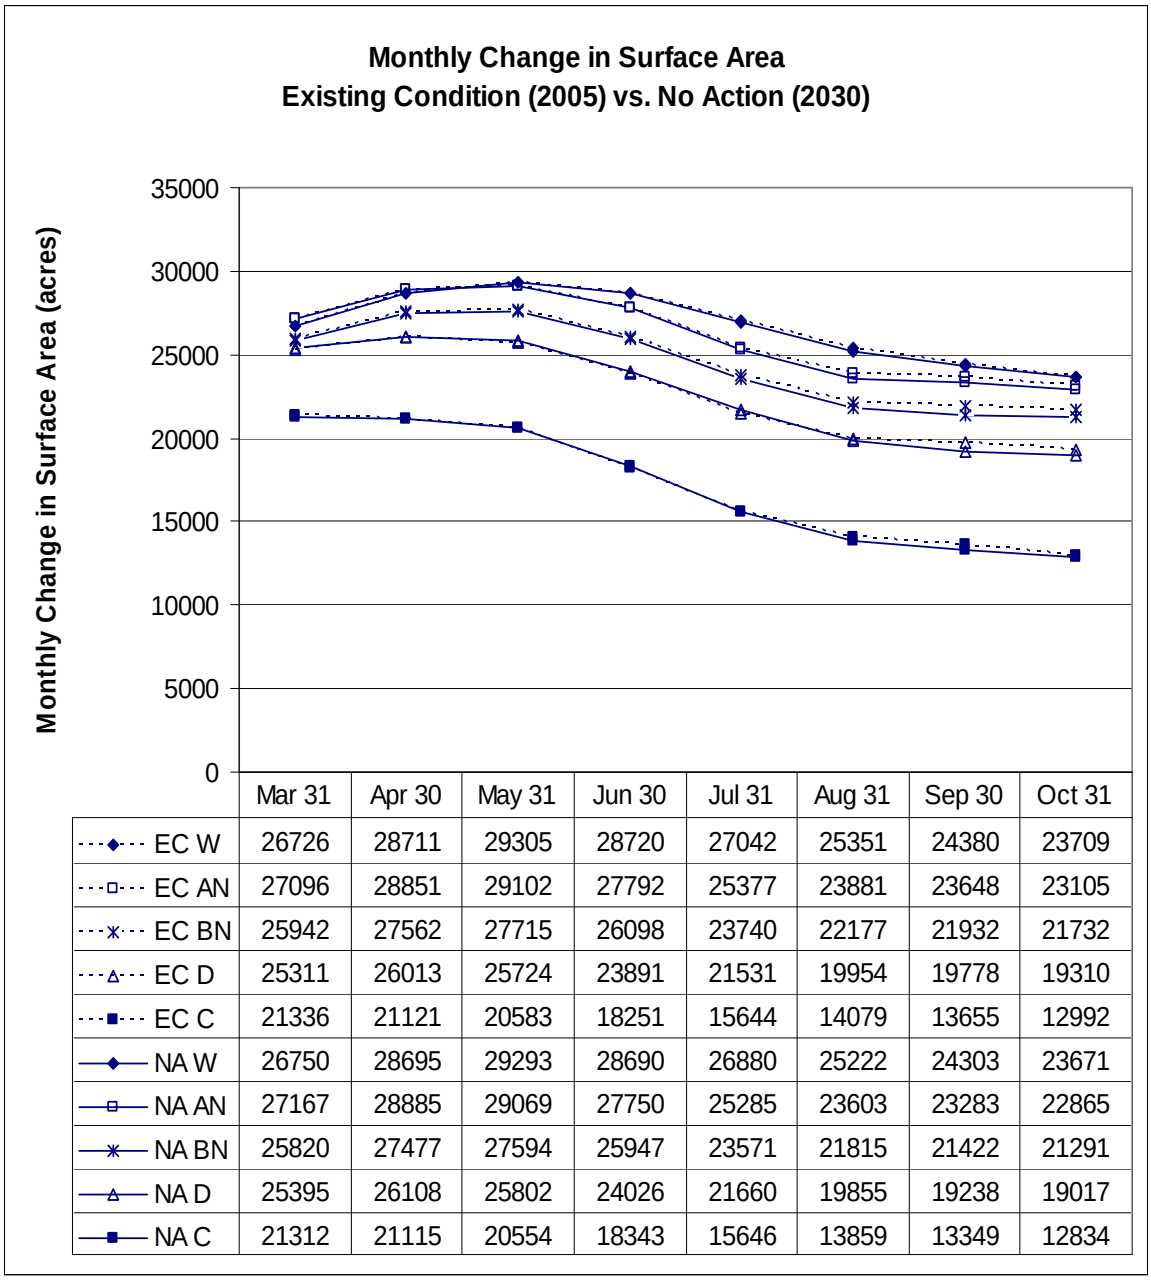
By altering reservoir storage and releases, the project would change flow regimes in downstream waterways. In turn, these alterations to the flow regime could affect fishery resources and important ecological processes on which the fish community depends, particularly their instream and seasonal floodplain habitats along waterways immediately downstream from reservoirs.

No-Action Alternative

Under the No-Action Alternative, the Federal government would take no additional action beyond existing regulatory requirements toward implementing a specific plan to help increase survival of anadromous fish in the Sacramento River, nor would it help address the growing water reliability issues in California. The following discussions highlight the consequences of implementing the No-Action Alternative, as they relate to the objectives of the SLWRI.

Shasta Lake and Vicinity

Impact Aqua-1 (No-Action): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under the No-Action Alternative, dam enlargement activities would not be implemented. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could be affected, however, by changing water supply demand and regulatory conditions, which could in turn affect the amount of nearshore, warm-water habitat in Shasta Lake. This impact would be potentially significant.

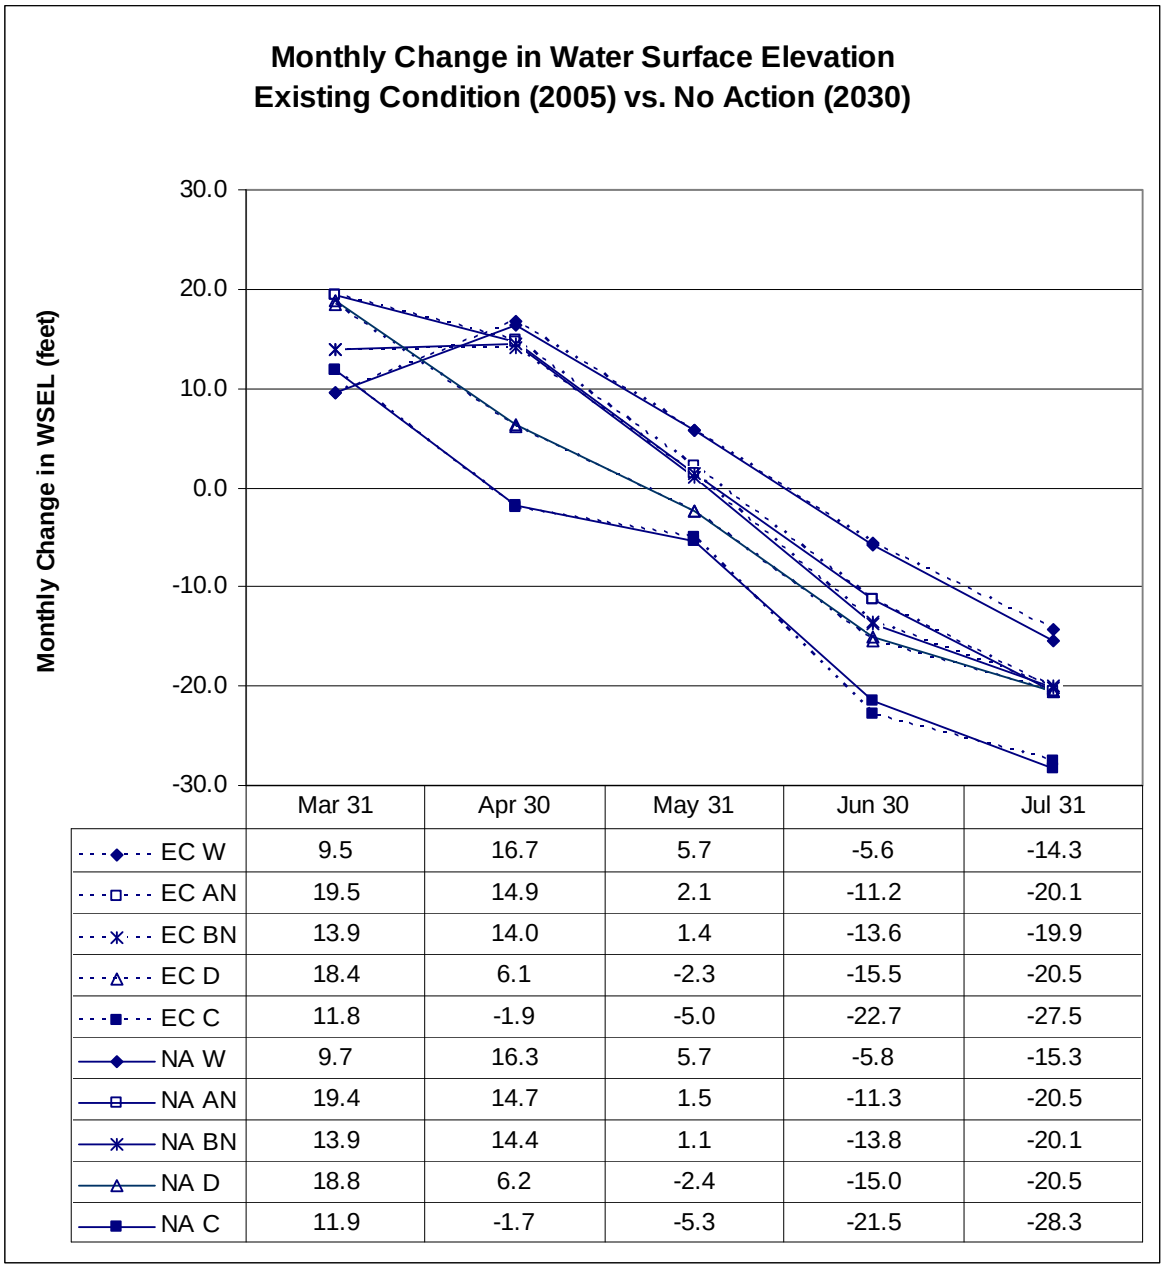


Under the No-Action Alternative with a 2030 water supply demand, the mean surface area of Shasta Lake in all months and all water-year types would be slightly less than under the Existing Condition. The greatest potential decreases would be experienced from September through November in below-normal water years (Figure 11-2). Fluctuations in WSELs are similar for the No-Action Alternative and the Existing Condition for all months except April in a wet water year (Figure 11-3). Overall, the monthly change between March and July trends downward.

Seasonal fluctuations in the surface area and WSEL of Shasta Lake could be affected by changing water supply demand and regulatory conditions. Such fluctuations could have an adverse effect on the quality and quantity of nearshore, warm-warm habitat in the lake. Therefore, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-2 (No-Action): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction Under the No-Action Alternative, dam enlargement activities would not be implemented, and no new facilities would be constructed within the vicinity of Shasta Lake. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Aqua-3 (No-Action): Effects on Cold-Water Habitat in Shasta Lake Under the No-Action Alternative, dam enlargement activities would not be implemented. Under this alternative, seasonal fluctuations in the ratio of the volume of cold-water storage in Shasta Lake to the surface area of the lake could be affected by changing water supply demand and regulatory conditions, which could affect the amount of cold-water habitat, including habitat for rainbow trout, a USFS sensitive species. This impact would be potentially significant. Mitigation is not required for the No-Action Alternative.



Impact Aqua-4 (No-Action): Effects on Special-Status Aquatic Mollusks Under the No-Action Alternative, dam enlargement activities would not be implemented. Seasonal fluctuations in the surface area and WSEL of Shasta Lake in response to water demand and regulatory conditions could affect special-status aquatic mollusks that may occupy habitat in or near Shasta Lake and its tributaries. These impacts would continue to occur under this alternative. This impact would be less than significant.

Figure 11-3. Monthly Change in WSEL (in feet) for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, Existing Condition vs. No-Action Alternative

One special-status mollusk, the California floater, occurs in Shasta Lake, and nine other special-status mollusks could occupy seeps, springs, or tributaries surrounding the reservoir. However, information regarding these species' distributions and abundance is limited, which precludes fully quantifying the impacts of the No-Action Alternative on these organisms and their habitat.

Except for the California floater, it is not known if other special-status mollusks occupy habitat in or near Shasta Lake and its tributaries. The California floater is a bivalve that resides in soft sediment on stream and lake beds and, therefore, could be adversely affected by seasonal fluctuations in the WSEL of the lake that currently exists. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-5 (No-Action): Effects on Special-Status Fish Species Under the No-Action Alternative, dam enlargement activities would not be implemented. However, one fish species occurring within the primary study area and designated as sensitive by USFS could be affected by seasonal fluctuations in the surface area and WSEL of Shasta Lake in response to changing water demand and regulatory conditions; however, this impact would be less than significant.

The hardhead minnow is designated as sensitive by USFS and is known to occur in Shasta Lake. Two other USFS sensitive species, rough sculpin (in the Pit River) and redband trout (in the upper McCloud River), are known to occur upstream from Shasta Lake, but their presence have not been documented in Shasta Lake or in their respective tributaries within the primary study area. The analysis of the No-Action Alternative therefore excludes consideration of these two special-status species.

Fluctuations in the surface area and WSEL of Shasta Lake under the No-Action Alternative could interfere with the connectivity to riverine habitat preferred by hardhead in tributaries that drain into Shasta Lake. However, access to riverine habitat among all the main tributaries to the reservoir would not likely become any more limiting than under current conditions. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-6 (No-Action): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under the No-Action Alternative, dam enlargement activities would not be implemented, and tributaries to Shasta Lake would continue to respond to fluctuations in reservoir levels. New barriers would not be created or removed that could impede or facilitate the movement of native and nonnative fish species between Shasta Lake and its tributaries. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Aqua-7 (No-Action): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake Under the No-Action Alternative, dam enlargement activities would not be implemented, and there would be no change to spawning and rearing habitat for adfluvial salmonids in low-gradient tributaries to Shasta Lake. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Aqua-8 (No-Action): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake Under the No-Action Alternative, dam enlargement activities would not be implemented. Therefore, aquatic connectivity in non-fish-bearing streams would not be affected. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Aqua-9 (No-Action): Effects on Water Quality at Livingston Stone Hatchery Under the No-Action Alternative, dam enlargement activities would not be implemented. Therefore, there would be no changes to the water system that supplies high-quality water to the Livingston Stone Hatchery. There would be no impact. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to RBDD)

Impact Aqua-10 (No-Action): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Under the No-Action Alternative, there would be no construction-related loss or degradation of aquatic habitat and no variation in CVP and SWP reservoir storage levels in the upper Sacramento River or tributaries associated with project alternatives. It is anticipated that, if the project alternatives were not implemented, actions to protect the fisheries and aquatic resources would continue under existing regulatory requirements, including other CALFED actions intended to protect and enhance fisheries resources. Therefore, there would be no construction-related impacts on fisheries and aquatic ecosystems associated with the No-Action Alternative. Mitigation is not required for the No-Action Alternative.

Impact Aqua-11 (No-Action): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Under the No-Action Alternative, there would be no construction-related contaminant exposure in the upper Sacramento River or tributaries associated with project alternatives. It is anticipated that, if the project alternatives were not implemented, actions to protect the fisheries and aquatic resources would continue under existing regulatory requirements, including other CALFED actions intended to protect and enhance fisheries resources. Therefore, there would be no construction-related impacts on fisheries and aquatic ecosystems associated with the No-Action Alternative. Mitigation is not required for the No-Action Alternative.

Impact Aqua-12 (No-Action): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon Flow releases would continue to be operated in compliance with existing BOs, which represent the regulatory baseline. However, it is anticipated that climate

change would result in an increase in water temperatures in the upper Sacramento River (NMFS 2009), which could make it much more difficult, especially in critical water years, to meet the water temperature requirements needs for all runs of Chinook salmon, particularly winter-run Chinook salmon. As a result, Chinook salmon in the upper Sacramento River could experience potentially significant impacts. Mitigation is not required for the No-Action Alternative.

Impact Aqua-13 (No-Action): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass Flow releases would continue to be operated in compliance with existing BOs, which represent the regulatory baseline. However, it is anticipated that climate change would result in an increase in water temperatures (NMFS 2009). This could make it much more difficult, especially in critical water years, to meet the water temperature requirements needs for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. As a result, fishes in the upper Sacramento River could experience potentially significant impacts. Mitigation is not required for the No-Action Alternative.

Impact Aqua-14 (No-Action): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Under the No-Action Alternative, there would be no change to the geomorphic processes in the upper Sacramento River. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River, Tributaries, Delta and Trinity River Under the No-Action Alternative, there would be no project-related alteration of CVP and SWP reservoir storage levels, river flows, or water temperatures in the lower Sacramento River or Delta. It is anticipated that if the project alternatives were not implemented, actions to protect fisheries and benefit aquatic environments would continue under existing regulatory requirements, including other CALFED actions intended to protect and enhance fisheries resources. Compliance with existing BOs would result in continued pumping curtailments, particularly in dry years. Reclamation and the DWR would continue to attempt to reoperate the CVP and SWP, respectively, to avoid decreased deliveries to export users. Therefore, there would be no project-related impacts changes on fisheries and aquatic ecosystems associated with the No-Action Alternative.

Under the No-Action Alternative, there would be no project-related alteration of CVP and SWP reservoir storage levels, river flows, or water temperatures in the Trinity River. Therefore there would be no impacts associated with the No-Action Alternative to the aquatic resources in the Trinity River.

CVP/SWP Service Areas Under the No-Action Alternative, there would be no project-related change in CVP and SWP operations or deliveries to the CVP and SWP service areas. It is anticipated that if the project alternatives were not

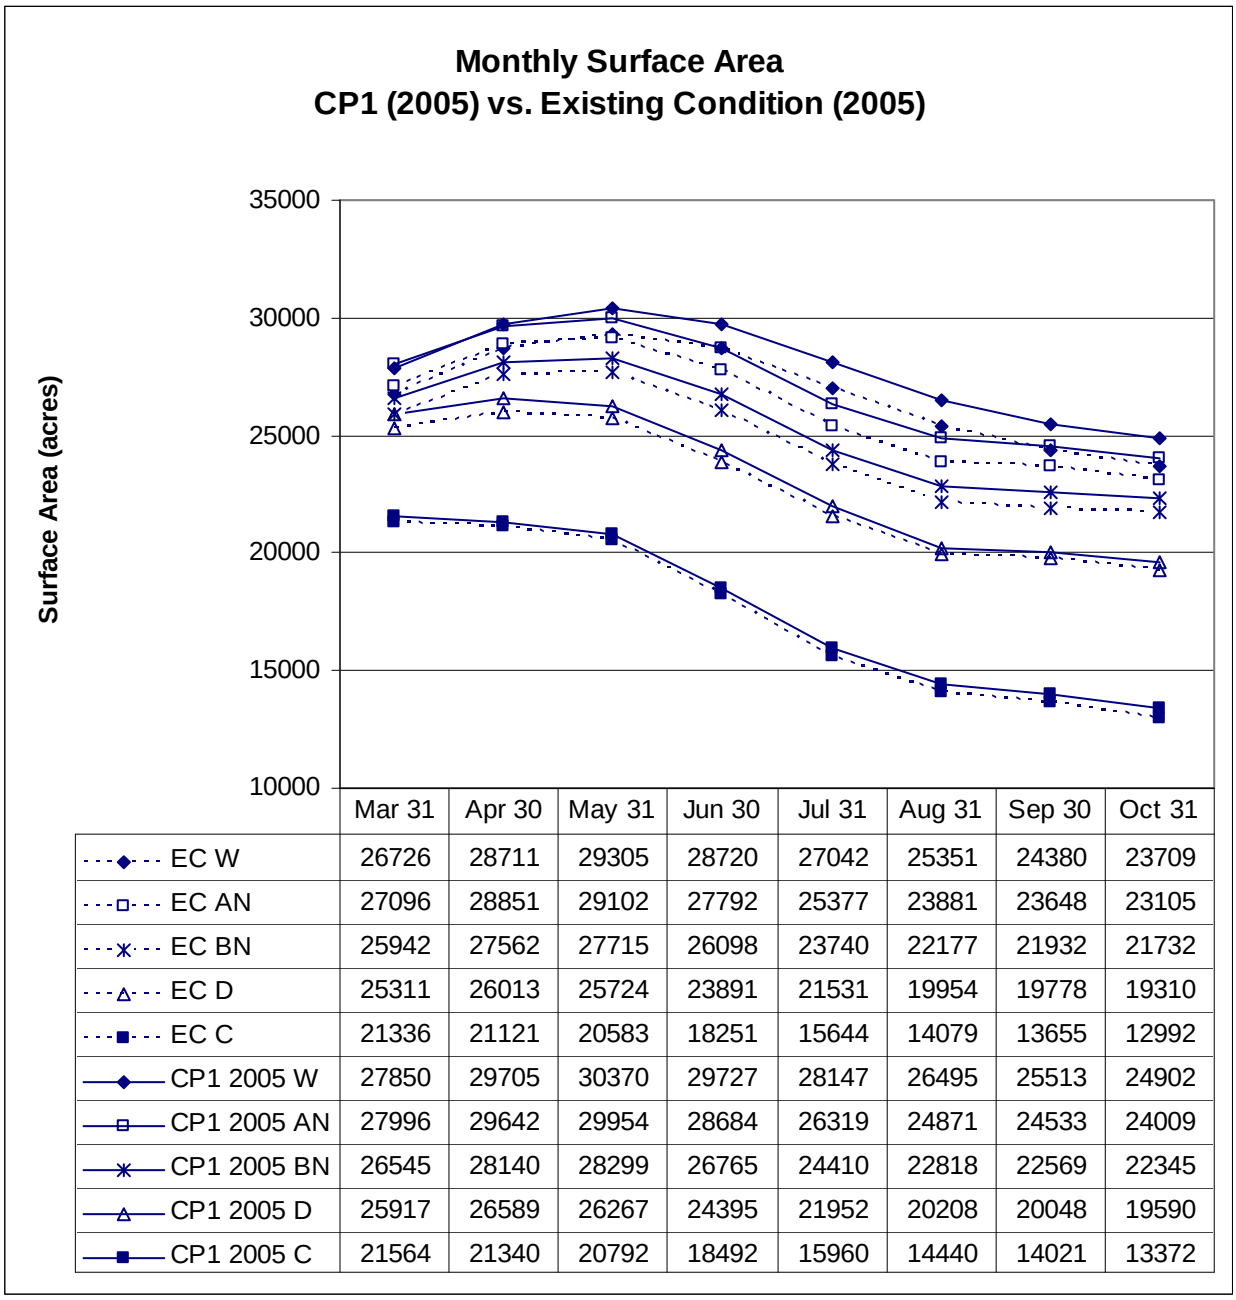
implemented, actions to protect fisheries and benefit aquatic environments would continue under existing regulatory requirements, including other CALFED actions and existing BOs intended to protect and enhance fisheries resources.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability while contributing to increased survival of anadromous fish, actions that are consistent with the 2000 CALFED ROD. CP1 consists primarily of raising Shasta Dam by 6.5 feet, an elevation change that would increase the reservoir's full pool elevation by 8.5 feet and would enlarge the total storage space in the reservoir by 256,000 acre-feet. Under CP1, Shasta Dam operational guidelines would continue unchanged, with the additional storage retained for water supply reliability. CP1 would help to reduce future water shortages by increasing the reliability of the water supply in drought and average water years. The increased pool depth and volume would also contribute to maintaining lower seasonal water temperatures and more reliable flows on the upper Sacramento River for anadromous fish.

Shasta Lake and Vicinity

Impact Aqua-1 (CP1): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP1, project operations would contribute to an increase in the surface area and WSEL of Shasta Lake, which would in turn increase the area and productivity of nearshore, warm-water habitat. Project operations would also result in reduced monthly fluctuations in the WSEL, which would contribute to increased reproductive success, young-of-the-year production, and the juvenile growth rate of warm-water fish species. The increase in the WSEL will influence riparian vegetation, including willow species planted to enhance lacustrine habitat, likely resulting in some amount of willow mortality. The increase in the WSEL will also influence the effectiveness of the brush structures that have been introduced by the STNF at various locations within the current drawdown zone of Shasta Lake. While the value of these structural improvements will be influenced by an overall increase in the maximum WSEL, these structures will continue to function to varying degrees under the operational conditions established for CP1. These impacts to structural habitat improvements are expected to be localized and will vary as the brush structures age and riparian vegetation readjusts to a new baseline condition. The retention of vegetation along more than 40 percent of the increased shoreline area that would be subject to inundation as a result of CP1 is expected to offset reductions in effective structural habitat improvements for a period of time. The benefits of inundated vegetation will decrease over time (e.g., 10-20 years) as the vegetation decays and the shoreline erosion processes expand into the new drawdown zone. . This impact would be less than significant..

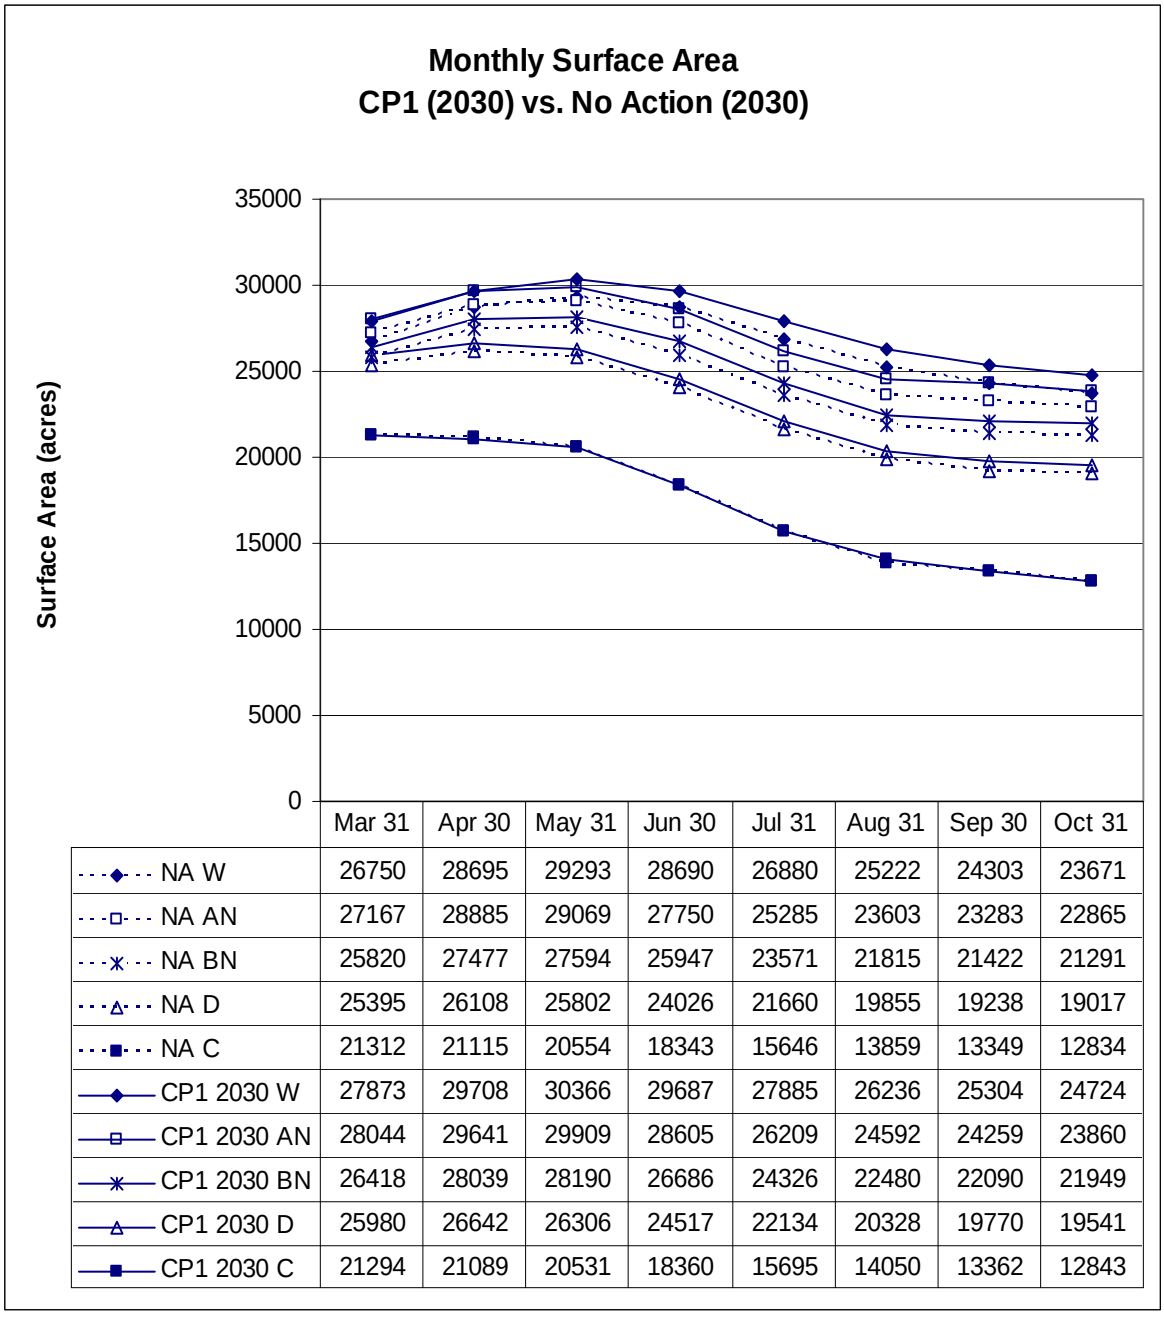


Biological productivity is greatest in the upper, lighted layer of the reservoir, where most plankton production occurs. An increase in the surface area of the

reservoir could affect warm-water habitat by increasing the area of littoral (nearshore) habitat, which could result in increased biological productivity. Increased inundation of terrestrial habitat, leading to increased nutrient loading from vegetative debris along the shore for some period of time, could increase plankton production, causing an upsurge in nutritional sources for warm-water species (Kimmel and Groeger 1986).

CalSim-II modeling indicated that the surface area of Shasta Lake would be larger under CP1 with a 2005 water supply demand than under the Existing Condition or under the No-Action Alternative for all five water-year types. The Shasta Lake surface area would be larger under CP1 with a 2030 water supply demand than under the Existing Condition or under the No-Action Alternative in wet, above-normal, and below-normal water years. In dry water years, the surface area under CP1 would be larger than under the No-Action Alternative in all months modeled, and would be larger than the Existing Condition in all months except September, when it would be only 8 acres less; given the size of Shasta Lake, a decrease of 8 acres would be essentially equivalent to the Existing Condition. In critical water years from March through May, which is the beginning of the spawning period for warm-water fishes, the surface area under CP1 with a 2030 water supply demand would be smaller than both the Existing Condition and the No-Action Alternative by an average of 23 acres and 42 acres, respectively, but would be larger at the end of the spawning period (June and July) than both the Existing Condition and the No-Action Alternative. From August until sometime in October in critical water years, the surface area under CP1 with a 2030 water supply demand would continue to be larger than the surface area under the No-Action Alternative, but would be less than the Existing Condition by an average of 160 acres (Figures 11-4 and 11-5).

An increase in the WSEL could benefit fish by increasing the amount and quality of available warm-water habitat in Shasta Lake. According to Ozen and Noble (2002), inundation of a reservoir creates an area that is sparsely populated by fish (i.e., decreases fish density per unit of habitat); the low population numbers stimulate the natural reproductive and growth processes of the fish. The newly inundated vegetation creates temporary cover for shoreline-dwelling fishes. As the vegetation decomposes, it releases nutrients for phytoplankton and periphyton, which are in turn consumed by the fish.



According to CalSim-II modeling, the Shasta Lake WSEL would be higher under CP1 with a 2005 water supply demand than under the Existing Condition or the No-Action Alternative for all five water-year types. The Shasta Lake WSEL would be higher under CP1 with a 2030 water supply demand than under the Existing Condition or under the No-Action Alternative in all but critical water years. In critical water years, the WSEL under CP1 with a 2030 water supply demand would be similar to the No-Action Alternative.

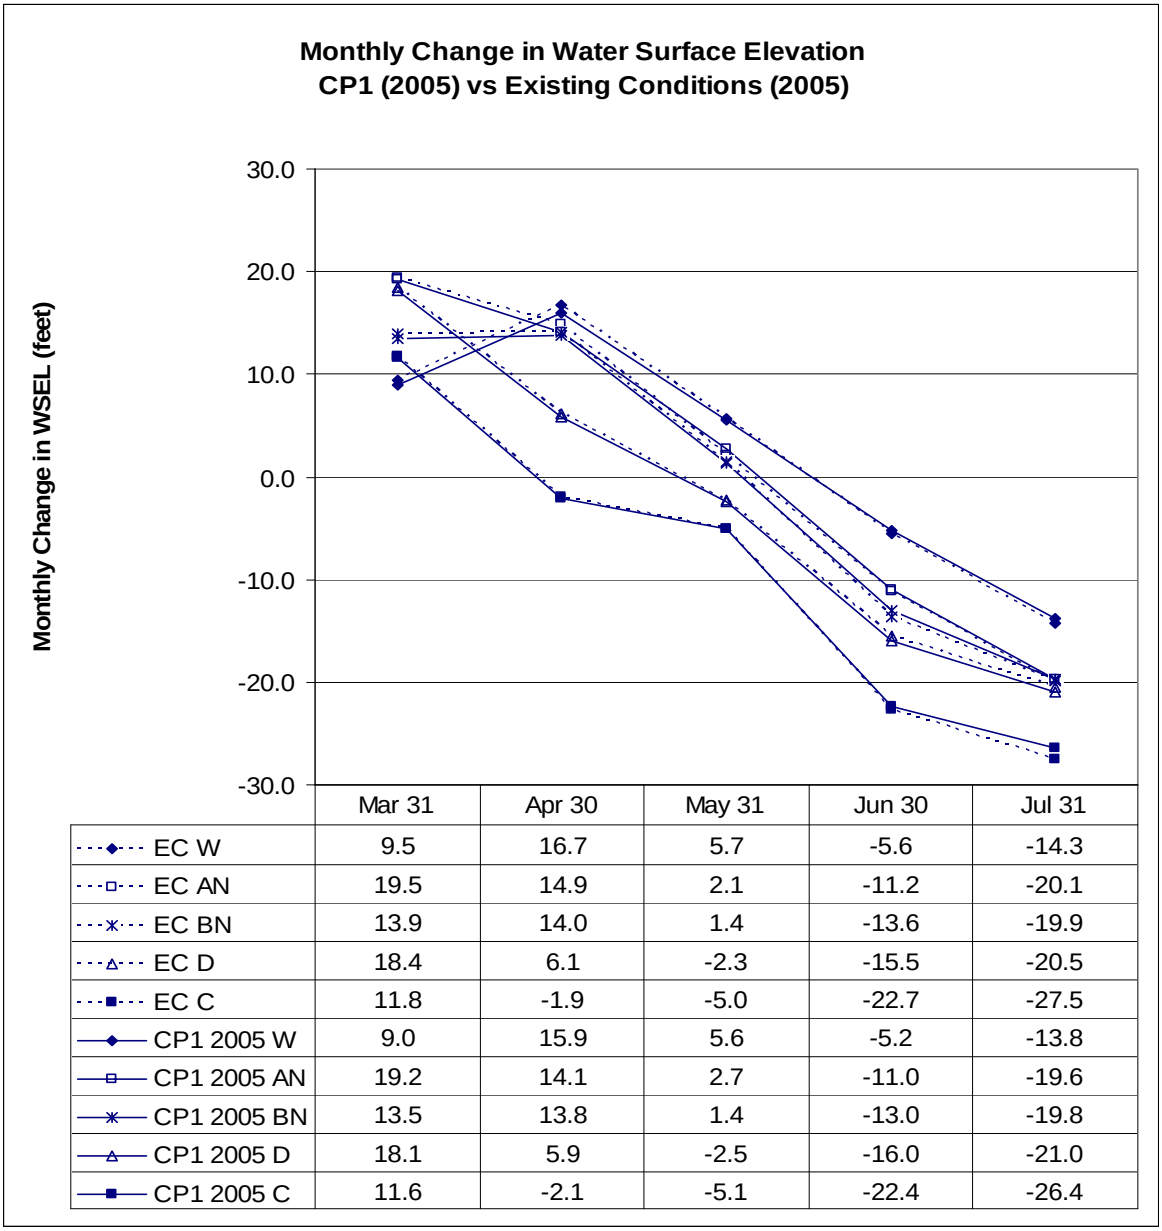

Figure 11-5. Monthly Change in Surface Area for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP1 (2030) vs. No-Action Alternative

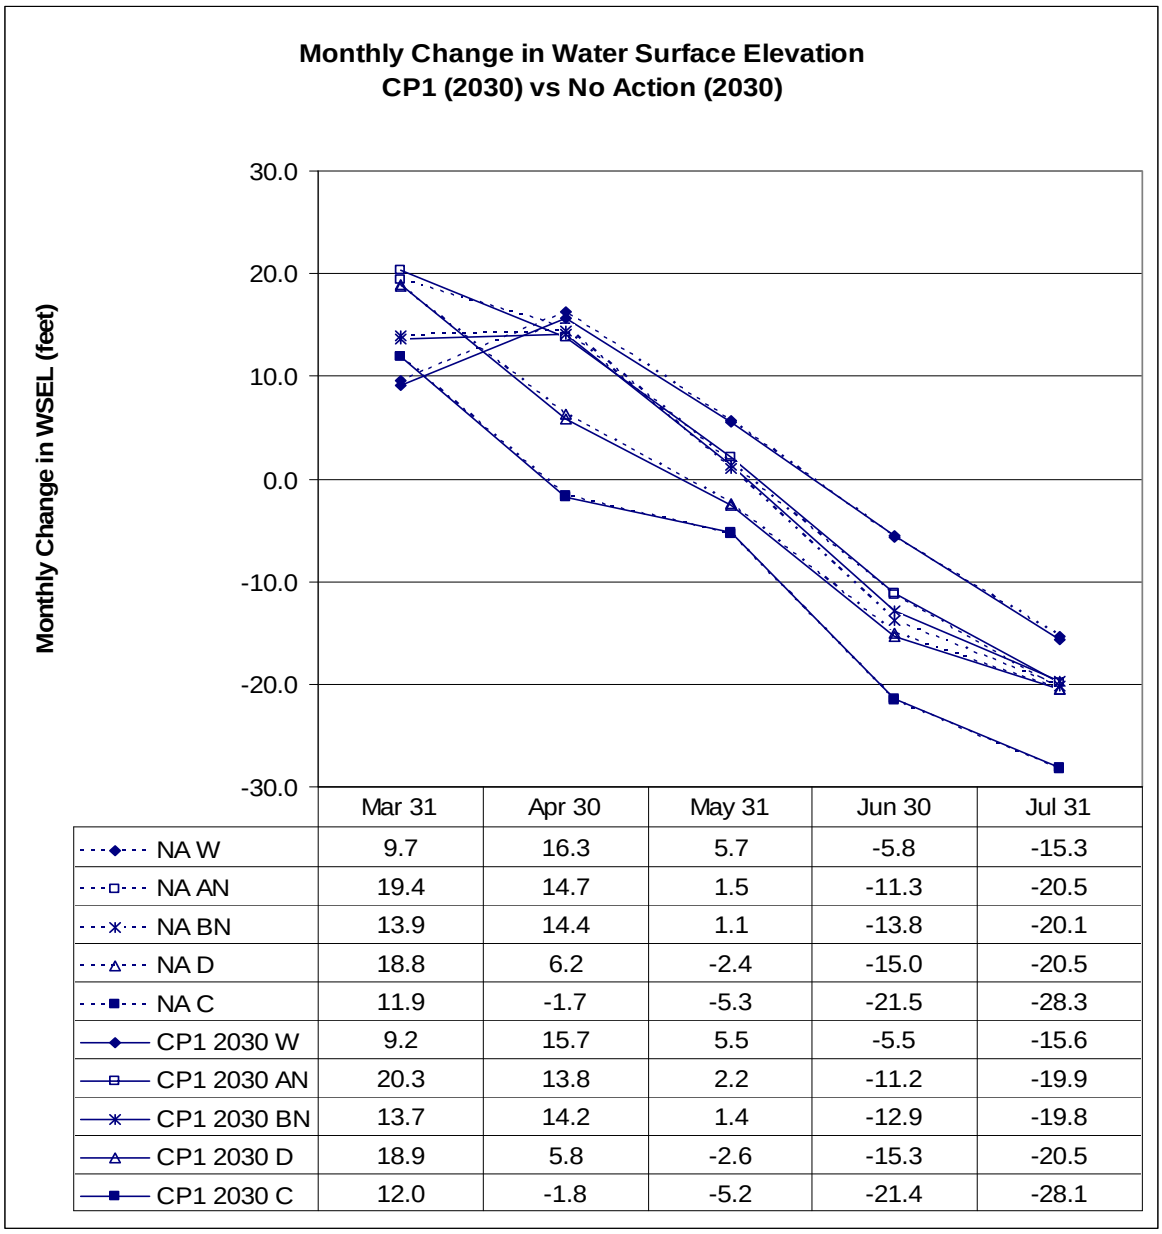
Rapid rates of increase in WSEL during the critical spring nesting period can lead to such adverse effects as decreased spawning success through nest abandonment or decreased egg survival (Mitchell 1982). Jones and Stokes (1998) reported that mortality approaches 10 percent for eggs in nests submerged under more than 15 feet of water during periods of rapid increase in reservoir elevations.

Rapidly decreasing WSELs can also have an adverse effect on aquatic organisms. According to Lee (1999), the maximum rate of drawdown that would allow a nesting success rate of 10 percent varied between species, with receding water level rates of less than 0.07, less than 0.03, and less than 0.02 feet per day for largemouth, smallmouth, and spotted bass nests, respectively. Lee found that daily drawdown rates of 0.36, 0.36, and 0.72 feet per day for largemouth, smallmouth, and spotted bass, respectively, resulted in 20 percent nest survival. Under CP1, none of the changes in monthly WSEL fluctuation were substantially different from the Existing Condition.

Monthly WSEL fluctuations were compared with projections for water supply demand. For CP1 with a 2005 water supply demand, 20 percent of monthly changes in projected WSELs (i.e., 5 of the 25 total projections made for the 5 months from March through July for all five water-year types) showed increased monthly WSEL fluctuations relative to the Existing Condition and 80 percent showed reduced monthly WSEL fluctuations (Figure 11-6). For CP1 with a projected 2030 water supply demand, 36 percent of monthly changes in projected WSELs showed increased WSEL fluctuations relative to the No-Action Alternative and 64 percent showed reduced monthly WSEL fluctuations (Figure 11-7).



Increases in the overall surface area and WSEL under CP1 would increase the area of available warm-water habitat and stimulate biological productivity, including fish production, of the entire lake, although the value of structural and vegetative improvements that currently provide effective structural habitat at specific locations will be decreased to some extent. Overall, CP1 would result in reductions in the magnitude of monthly WSEL fluctuations and would contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of warm-water species, and provide for an increase in structural habitat (inundated vegetation) for some period of time. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

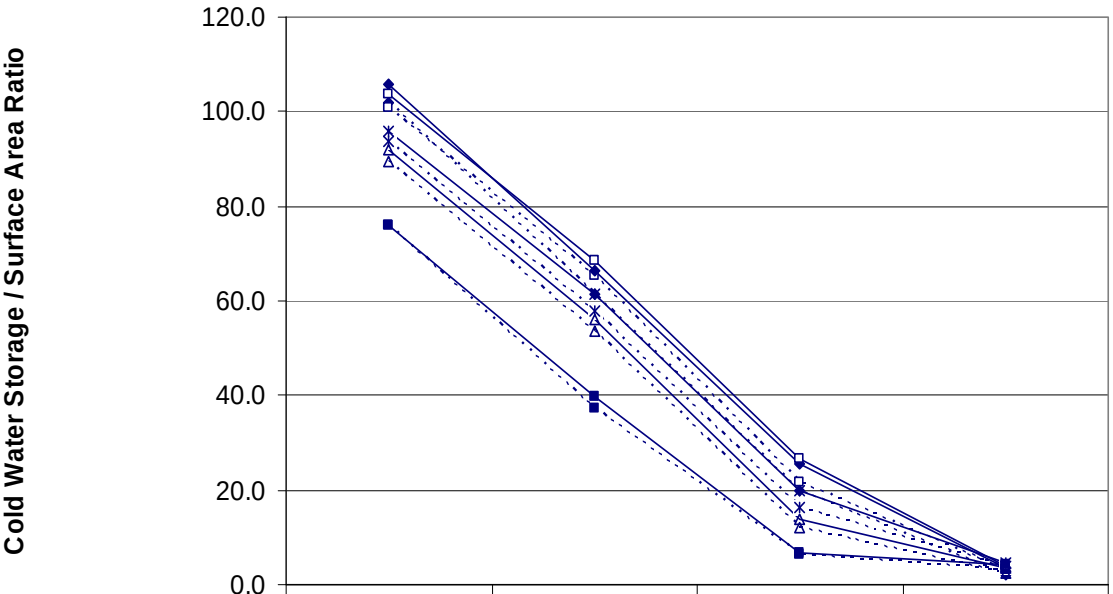
Figure 11-7. Monthly Change in WSEL for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP1 vs. No-Action Alternative

Impact Aqua-2 (CP1): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction Localized increases in soil erosion and resulting runoff sedimentation, and turbidity resulting from project construction in the vicinity of Shasta Dam and at utility, road, and other facility relocation areas could affect nearshore warm-water habitat. However, the environmental commitments for all action alternatives include the development and implementation of a Construction Management Plan, Erosion and Sediment Control Plan, Stormwater Pollution Prevention Plan, and Revegetation Plan as well as water quality and fisheries conservation measures and compliance with all required permit terms and conditions. These environmental commitments would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed.



Impact Aqua-3 (CP1): Effects on Cold-Water Habitat in Shasta Lake Under CP1, operations-related changes in the ratio of the volume of cold-water storage to surface area would increase the availability of suitable habitat for cold-water fish in Shasta Lake, including rainbow trout. This impact would be beneficial.

Access to cold-water refuge can be a limiting factor for the production of cold-water fish, even when the benefits of increased surface area are present. Increases in the surface area of a reservoir without proportional increases in the volume of cold-water storage result in little change to cold-water fisheries production (Jones and Stokes Associates 1988).

CalSim-II modeling showed that under CP1 with a 2030 water supply demand, the ratio of the volume of cold-water storage to surface area was slightly higher than under the No-Action Alternative in all water years and during all months modeled. The greatest projected increases over the No-Action Alternative occurred between June 30 and August 31, which is the critical holding and rearing period for cold-water fishes in reservoirs; the increases were highest in wet water years (Figure 11-8).

CP1 would increase the availability of suitable habitat for cold-water fish in Shasta Lake. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-4 (CP1): Effects on Special-Status Aquatic Mollusks Under CP1, habitat for special-status mollusks may become inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could also adversely affect special-status aquatic mollusks that may occupy habitat in or near Shasta Lake and its tributaries. This impact would be potentially significant.

Figure 11-8. Monthly Cold-water Storage to Surface Area Ratio for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP1 vs. No-Action Alternative

One special-status mollusk, the California floater, occurs in Shasta Lake, and nine other special-status mollusks could occupy affected seeps, springs, or tributaries. However, information regarding these species' distributions and abundance is limited, which precludes fully quantifying the impacts of CP1 on these organisms and their habitat. Tributary investigations are ongoing and will provide additional information for inclusion in the Final Environmental Impact Statement (FEIS). Except for the California floater, it is not known if other special-status mollusks occupy habitat in or near Shasta Lake and its tributaries. If they do occur in these habitats, they could be adversely affected by increased WSEL and seasonal fluctuations in the surface area under CP1. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-5 (CP1): Effects on Special-Status Fish Species The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat under CP1 could affect one species designated as sensitive by USFS, the hardhead. This impact would be less than significant.

The hardhead minnow is designated as sensitive by USFS and is known to occur in Shasta Lake. Two other USFS sensitive species, rough sculpin (in the Pit River) and redband trout (in the upper McCloud River), are known to occur upstream from Shasta Lake, but their presence have not been documented in Shasta Lake or in their respective tributaries within the primary study area. The analysis of the CP1 therefore excludes consideration of these special-status species.

Expansion of the surface area of Shasta Lake could be modestly beneficial to hardhead because it could expand the amount of habitat available to this species in the lake. Hardhead prefer low gradient stream habitat, which can be created by the backwater effect of the reservoir within the transition reaches of the main tributaries at their confluence; however, this would not be expected to be much greater than under existing conditions, since reservoir enlargement would simply move the transition reaches farther upstream in the tributaries. Tributary investigations, including an analysis of barriers are ongoing and will provide additional information for inclusion in the FEIS. Although there is some evidence that a physical barrier at the upper end of the Squaw Creek Arm may be modified by an increase in WSEL (J. Zustak, USFWS, pers. comm., 2009), there is no evidence that other barriers exist in a form that would impact this species or its habitat. Pending new information, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP1): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP1, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,080-foot contour, the maximum inundation level under this alternative. Tributary investigations are ongoing and will provide additional information for inclusion in the FEIS. However, based on digital topographic

data and stream channel data generated from limited field inventories, no substantial barriers appear to exist between the 1,070-foot and 1,080-foot contours that would be inundated under this alternative. This impact would be less than significant.

Most of the tributaries are too steep (i.e., greater than 7 percent) up to the 1,080-foot contour to be passable by fish; the tributaries that are low-gradient up to the 1,080-foot contour and thus allow fish passage remain low-gradient well upstream from the 1,080-foot contour. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP1): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake CP1 would result in additional periodic inundation of riverine habitat potentially suitable for spawning and rearing habitat for adfluvial salmonids (trout and land-locked salmon that spawn in streams and rear in lakes) in tributaries to Shasta Lake. In addition to modification of the flow regimes of these affected reaches, changes in the WSEL as a result of CP1 will affect the character and location of substrate (e.g., spawning gravel) at some locations, thereby influencing the suitability and availability of spawning and rearing habitat for adfluvial salmonids. Tributary investigations are ongoing and will provide additional information for inclusion in the FEIS. Only 5.4 miles of low-gradient reaches that could potentially provide some spawning and rearing habitat for adfluvial salmonids would be affected by CP1, which is only about 1.4 percent of the low-gradient habitat upstream from Shasta Lake. This impact would be less than significant.

CP1 would inundate perennial stream reaches with gradients of less than 7 percent that could provide suitable spawning and rearing habitat for adfluvial salmonids. Chapter 4, “Geology, Geomorphology, Minerals, and Soils,” discusses the periodic inundation of low-gradient stream reaches. The lengths of low-gradient tributaries to each arm of Shasta Lake that would be periodically affected are as follows:

- Sacramento River Arm 2.2 miles
- McCloud River Arm 1.1 miles
- Pit River Arm 1.0 mile
- Big Backbone Creek Arm 0.5 miles
- Squaw Creek Arm 0.6 miles

Only about 1.4 percent of the low-gradient habitat upstream from Shasta Lake would be periodically inundated. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-8 (CP1): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP1 would result in periodic inundation of varying amounts of non-fish-bearing tributaries to Shasta Lake. Only 12.6 miles of non-fish-bearing tributary habitat would be affected by CP1, which is a length of only about 0.4 percent of non-fish-bearing tributary upstream from Shasta Lake. This impact would be less than significant.

As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils," CP1 would inundate tributary segments with channel slopes in excess of 7 percent. Although these segments do not typically support salmonid populations, they do provide riparian and aquatic habitat for a variety of organisms and serve as corridors that connect habitat types. The lengths of non-fish-bearing tributaries for each arm of Shasta Lake that would be periodically inundated are as follows:

- Sacramento River Arm 2.9 miles
- McCloud River Arm 2.1 miles
- Pit River Arm 1.8 miles
- Big Backbone Creek Arm 1.3 miles
- Squaw Creek Arm 0.9 miles
- Main Body 3.6 miles

Only 12.6 miles of non-fish-bearing tributary habitat would be periodically inundated under CP1, which is only about 0.4 percent of the habitat upstream from Shasta Lake. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP1): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP1. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to RBDD)

Impact Aqua-10 (CP1): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Construction-related activities could temporarily increase sedimentation and turbidity, which would adversely affect aquatic habitats and fish populations within the upper Sacramento River immediately downstream from project construction activities. However, environmental commitments would be in place to reduce these levels. This impact would be less than significant.

Construction activities could disturb sediments and soils within and adjacent to waterways. These activities include increasing the height of the dam, constructing haul roads, using staging areas, and placing of removed material.

Any resulting erosion or disturbance of sediments and soils would temporarily increase turbidity and sedimentation downstream from the construction sites throughout the primary study area if soils are transported in river flows, stormwater runoff, or reservoir water. Construction-related sedimentation and increased turbidity, or other contamination, would be most pronounced in the segment of river from Shasta Dam to Keswick Dam due to the backwater effect that Keswick Reservoir has on flow conditions in the Sacramento River. It is also important to note that Keswick Dam acts as a barrier to upstream migration; therefore, all anadromous fish species are downstream from this facility. (See Chapter 7, "Water Quality," for additional discussion of this issue.)

Fish population abundance, distribution, and survival have been linked to levels of turbidity and silt deposition. Prolonged exposure to high levels of suspended sediment would create a loss of visual capability in fish in aquatic habitats within the study area, leading to reduced feeding and growth rates; a thickening of the gills, potentially causing the loss of respiratory function; clogging and abrasion of gills; and increases in stress levels, reducing the tolerance of fish to disease and toxicants (Waters 1995). Turbidity also could result in increased water temperature, especially in willow quiet pools, and in turn affect DO levels, both effects thereby stressing respiration.

Also, high levels of suspended sediments would cause the movement and redistribution of fish populations, and could diminish the character and quality of the physical habitat important to fish survival. Once suspended sediment is deposited, it would reduce water depths in stream pools, decreasing the water's physical carrying capacity for juvenile and adult fish (Waters 1995). Increased sediment loading would degrade food-producing habitat downstream from construction areas. Sediment loading would interfere with photosynthesis of aquatic flora and displace aquatic fauna. Many fish, including salmonids, are sight feeders, and turbid waters reduce the ability of these fish to locate and feed on prey. Some fish, particularly juveniles, likely would become disoriented and leave areas where their main food sources are located, ultimately reducing their growth rates. Prey (e.g., macroinvertebrates) of fish populations would be adversely affected by decline in habitat quality (i.e., water quality and substrate conditions) as a result of increased turbidity, decreased DO content, increased level of pollutants (Coull and Chandler 1992), or (although unlikely) an extreme change in pH or water temperatures (Rundle and Hildrew 1990). Decreases in the diversity and abundance of smaller organisms living on or in the sediments have been associated with smaller sediment grain sizes (Coull 1988) and the associated DO decreases in those sediments (Boulton et al. 1991).

Avoidance of adverse habitat conditions by fish is the most common result of increases in turbidity and sedimentation. Fish will not occupy areas unsuitable for survival unless they have no other option. Some fish, such as bluegill and bass species, will not spawn in excessively turbid water (Bell 1990) and salmonids require gravels that are relatively clean and free of excess amounts of

fine sediments. Therefore, if high turbidity results from construction activities, fish species may be precluded from occupying habitat required for specific life stages. In some locations, few opportunities for escape from turbid waters may be available, particularly during lower flow conditions.

Construction-related sedimentation and increased turbidity or other contamination could temporarily degrade water quality and reduce or adversely affect fish habitat and fish populations in localized areas. However, the environmental commitments for all action alternatives include the development and implementation of a Construction Management Plan, Erosion and Sediment Control Plan, Stormwater Pollution Prevention Plan, and Revegetation Plan as well as water quality and fisheries conservation measures and compliance with all required permit terms and conditions. These environmental commitments would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-11 (CP1): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Construction-related activities could result in the release and exposure of contaminants resulting in adverse effects on aquatic habitats, the aquatic food web, and fish populations, including special-status species, within the primary study area downstream from project construction activities. However, environmental commitments would be in place to reduce the impacts to less than significant.

Potential exists for contaminants such as fuels, oils, other petroleum products, cement, and various chemicals used in construction activities to be introduced accidentally in spills into the water system directly or incrementally through surface runoff from haul routes and construction sites. Contaminants in sufficient concentrations would be toxic to fish and prey organisms (e.g., benthic macroinvertebrates) occupying habitats in the study area or may alter oxygen diffusion rates and cause acute and chronic toxicity to aquatic organisms, thereby reducing growth and survival and/or leading to mortality.

The potential release of hazardous materials into Shasta Lake or the Sacramento River could result in the reduction of aquatic habitats and fish populations if proper procedures are not implemented to contain the discharge. However, the environmental commitments for all action alternatives include the development and implementation of a Construction Management Plan, Erosion and Sediment Control Plan, Stormwater Pollution Prevention Plan, and Revegetation Plan as well as water quality and fisheries conservation measures and compliance with all required permit terms and conditions. These environmental commitments would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-12 (CP1): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon Project operation would result in improved flow and water temperature conditions in

the upper Sacramento River for fish species of management concern relative to both the No-Action Alternative and the Existing Condition. This impact would be beneficial.

Winter-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, CP1 had a slight overall average increase in winter-run Chinook salmon production relative to the No-Action Alternative. The maximum increase in production relative to the No-Action Alternative was 43 percent for CP1. The largest decrease in production relative to the No-Action Alternative was 39 percent for CP1 (Attachment 1A of the *Fisheries and Aquatic Ecosystems Technical Report*). Separating production by water-year type to focus on critical water years (when water storage is more reliable) showed a 4 percent increase over the No-Action Alternative. With one exception (1977 at 39 percent decrease), years with the lowest production over the simulation period showed the largest increase in production under CP1 conditions.

Under CP1, critical water years 1924, 1931, 1933, 1934, and 1992 resulted in an increase in winter-run production relative to the No-Action Alternative, ranging from 7 percent to 43 percent. Above-normal water years, 1928, 1954 and 1993, resulted in an increase in production of 3 to 5 percent relative to the No-Action Alternative. Critical water years, 1976 and 1977, resulted in a decrease (4 to 39 percent) in production relative to the No-Action Alternative. One dry water year (1932) showed a decrease in production of 7 percent.

CP1 production was relatively similar to the Existing Condition. The maximum increase in production relative to the Existing Condition was 23 percent for CP1. The largest decrease in production relative to the Existing Condition was 5 percent for CP1 (Attachment 2A of the *Fisheries and Aquatic Ecosystems Technical Report*).

Under CP1, critical water years 1931, 1933, 1934, and 1977 resulted in an increase in winter-run production relative to the Existing Condition ranging from 5 percent to 23 percent. Production in dry water year 1985 and wet water year 1974 decreased by 5 percent.

Based on AFRP population goals, the overall average winter-run Chinook salmon production was similar for CP1 relative to the No-Action Alternative (Attachment 3A of the *Fisheries and Aquatic Ecosystems Technical Report*). The maximum increase in production relative to the No-Action Alternative was 28 percent for CP1. The largest decrease in production relative to the No-Action Alternative was 33 percent for CP1. Years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP1, with one exception – 1977 (34-percent decrease).

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to winter-run under CP1 occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under CP1. Table 11-4 displays the overall mortalities for each Comprehensive Plan that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 1B and 2B of the *Fisheries and Aquatic Ecosystems Technical Report* contain further detail). Mortalities caused by the project decrease as the proposed dam height increases from 6.5 to 18.5 feet.

Table 11-4. Percent Mortality to Winter-Run Chinook Salmon Caused by Nonoperations-Related Effects and Operations-Related Effects Under Each Comprehensive Plan When the Starting Population is Based on the 1999 Through 2006 Average

Plan	% Nonoperations-Related Mortality	% of the Total Mortality	% Operations-Related Mortality	% of the Total Mortality
Future Condition (2030)				
No-Action Alternative	59.8	86.0	9.7	14.0
CP1	60.1	86.6	9.3	13.4
CP2	60.1	86.6	9.3	13.3

Key:
CP = Comprehensive Plan

Mortality was separated by operations-related mortality versus nonoperations-related mortality to assess the level of impacts on the four runs of Chinook salmon caused by the actions of the project. Nonoperations-related mortality are the base and seasonal mortality that would occur even without the effects of Shasta operations (changes in flow and/or water temperature). Operations-related mortality is that caused by altering flow and water temperatures.

When removing nonoperations-related mortality, allowing the comparison of mortality for operations-related activities only, fry were the primary life stage affected, but operations-related activities had a greater effect on eggs than on presmolts, and no effect on immature smolts, with both water temperature and flow causing the mortality (Table 11-5).

Table 11-5. Average Annual Mortality Under Each Comprehensive Plan Caused by Project Activities to Winter-Run Chinook Salmon When the Starting Population is Based on the 1999 Through 2006 Average

Plan	Mortality Factor						Total

CP = Comprehensive Plan

In critical water years, mortality to eggs due to unsuitable water temperatures was the primary cause of operations-related mortalities for CP1, followed by mortality to fry (more by flow and density than water temperature), then to eggs from redd dewatering, followed by presmolts (affected first by water temperature then flow) and, finally, immature smolts (affected by flow). Attachments 1C and 2C of the *Fisheries and Aquatic Ecosystems Technical Report* contain tables of mortality to winter-run Chinook salmon sorted by water-year type, and Table 11-6 outlines the ranks classified under each Comprehensive Plan for each water-year type.

In dry water years, mortality to fry when moving to new habitats was the primary cause of operations-related mortalities for all Comprehensive Plans, followed by mortality to eggs due to redd dewatering. Third was the mortality to eggs due to unsuitable water temperatures.

Below-normal, above-normal, and wet water years also had the greatest number of winter-run Chinook salmon perish as fry caused by forced movement to habitat downstream, followed by mortality to eggs due to redd dewatering or scouring, then the loss of eggs from unsuitable water temperatures, and forced movement of presmolts to downstream habitats.

Table 11-6. Mortality Parameters Ranked by Importance for Winter-Run Chinook Salmon by No-Action and Comprehensive Plans by Water-Year Type When the Starting Population Is Based on the 1999 Through 2006 Average

CP = Comprehensive Plan

Years with the highest operations-related mortality were the same for the No-Action Alternative, Existing Condition, and CP1 (1924, 1931, 1933, 1934, 1977, and 1992). Each of these years was a critical water year, and was preceded by either a critical (1933, 1976, 1991), dry (1930, 1932) or below-

normal (1923) water-year type. Years in which the project had the greatest impact on winter-run were also the years in which the lowest production occurs (Attachments 1C and 2C of the *Fisheries and Aquatic Ecosystems Technical Report*).

Based on AFRP population goals, winter-run Chinook salmon mortality caused by operations-related activities decreased under CP1 compared to the No-Action Alternative conditions (Attachment 3B). Under CP1, mortality caused by operations-related activities would decrease from non-operations related mortality by over 10 percent. Under CP1, the greatest mortality to winter-run occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because winter-run Chinook salmon have, overall, a reduced mortality, particularly in critical water years, winter-run Chinook salmon would benefit from actions taken in CP1. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, the overall average spring-run Chinook salmon production for the 82-year period remained relatively similar to the No-Action Alternative and the Existing Condition (Attachments 4A and 5A of the *Fisheries and Aquatic Ecosystems Technical Report*). The maximum increase in production relative to the No-Action Alternative was 109 percent for CP1, while the largest decrease in production relative to the No-Action Alternative was 39 percent for CP1 (Attachment 4A). The maximum increase in production relative to the Existing Condition was 125 percent for CP1, while the largest decrease in production relative to the Existing Condition was 50 percent for CP1 (Attachment 5A of the *Fisheries and Aquatic Ecosystems Technical Report*).

Years in which production was the lowest under the No-Action Alternative typically had the largest increase under CP1 conditions, except for 1934, which had a 15-percent reduction, and 1992, which decreased by 39 percent.

Under CP1, critical water years 1924, 1931, 1933 and 1977 resulted in an increased production relative to the No-Action Alternative ranging from 13 percent to 109 percent. Dry water years, 1925, 1926, and 1932 resulted in increased production (4 percent to 22 percent) relative to the No-Action Alternative. Critical water years 1934, 1992, 1994 and 2001 resulted in a decrease in production relative to the No-Action Alternative (4 percent to 40 percent).

Under CP1, critical water years 1931, 1933, 1934, 1988, 1994, and 2001 resulted in an increased production relative to the Existing Condition ranging

from 5 percent to 83 percent. Dry water year 1932 resulted in a substantial increase in production (125 percent) relative to the Existing Condition. Critical water years 1977 and 1992 resulted in a decrease in production relative to the Existing Condition (7 percent to 50 percent).

When using AFRP goals as the spawning population, overall average spring-run Chinook salmon production was similar for CP1 relative to the No-Action Alternative (Attachment 6A of the *Fisheries and Aquatic Ecosystems Technical Report*). The maximum increase in production relative to the No-Action Alternative was 99 percent for CP1. The largest decrease in production relative to the No-Action Alternative was 47 percent for CP1. Years with the lowest production under the No-Action Alternative typically had the largest increase under CP1 conditions, except for 1934, which had a 13-percent reduction, and 1992, which decreased by 47 percent.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to spring-run occurred to eggs, followed by presmolts, then fry. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-7 displays overall mortalities for each Comprehensive Plan that are caused by nonoperational factors versus those caused by operations (i.e., water temperature, flow) (Attachments 4B and 5B of the *Fisheries and Aquatic Ecosystems Technical Report*). Mortalities caused by the project decreased as the proposed dam height increases from 6.5 to 18.5 feet (Tables 11-7 and 11-8).

Table 11-7. Percent Mortality to Spring-Run Chinook Salmon Caused by Nonoperations-Related and Operations-Related Effects Under the No-Action Alternative and Comprehensive Plans When Starting Population Is Based on the 1999 Through 2006 Average

Alternative/ Plan	% Nonoperations-Related Mortality	% of the Total Mortality	% Operations-Related Mortality	% of the Total Mortality
Future Condition (2030)

CP = Comprehensive Plan

Only eggs and fry were affected by operation (Table 11-8). Critical water years showed mortality to eggs due to unsuitable water temperatures as the primary cause of operations-related mortalities, followed by mortality to eggs prespawned and during incubation caused by dewatering the redds, then to fry from forced movement to downstream habitats. Attachments 4C and 5C contain tables of mortality to spring-run sorted by water-year type, and Table 11-9 outlines the ranks classified under each Comprehensive Plan for each water-year type.

In dry, below-normal and above-normal water years, all Comprehensive Plans were dominated by egg temperature mortality, followed by mortality resulting from redd dewatering. Mortality to prespawned eggs occurred in only two dry years, not in any below-normal water years. Mortality to fry from forced movement was relatively low and occurred in only a few more years (Table 11-9).

In wet water years, spring-run eggs under conditions created by CP1 were more affected by redd dewatering than by unsuitable water temperatures (Table 11-9).

Table 11-9. Mortality Parameters Ranked by Importance for Spring-Run Chinook Salmon by Comprehensive Plan and Water-Year Type When Starting Population Is Based on 1999 Through 2006 Average

Alternative/Plan Water-Year Type	Mortality Factor

CP = Comprehensive Plan

Years with the highest operations-related mortality were the same for all the Comprehensive Plans: 1924, 1931, 1932, 1933, 1934, 1977, and 1992. Except in 1932 (a dry water year), each of these years was a critical water-year type and was preceded by either a below, dry, or (predominantly) a critical water year. However, years with the lowest mortality varied between all water-year types. Project operations were responsible for years where spring-run Chinook salmon had the lowest mortality, with nearly all the mortality occurring in the egg incubation life stage (Attachments 4C and 5C).

Based on AFRP population goals, spring-run Chinook salmon mortality caused by operations-related activities decreased under CP1 compared to No-Action Alternative conditions (Attachment 6B). Under CP1, the greatest mortality to spring-run occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because spring-run Chinook salmon have, overall, a reduced mortality, particularly in critical water years, spring-run Chinook salmon would benefit from actions taken in CP1. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, the overall average fall-run Chinook salmon production for the 82-year period was similar for CP1 relative to the No-Action Alternative and the Existing Condition (Attachments 7A and 8A). The maximum increase in production relative to the No-Action Alternative was 112 percent for CP1. The largest decrease in production relative to the No-Action Alternative was 7 percent for CP1 (Attachment 7A). In critical, dry, and below-normal water years, years with the lowest production typically had the greatest increase in production resulting from operations-related activities. The maximum increase in production relative to the Existing Condition was 43 percent for CP1. The largest decrease in production relative to the Existing Condition was 38 percent for CP1 (Attachment 8A).

In critical, dry, and below-normal water years, when production was lowest over the simulation period, the increase in production resulting from operations-related activities was greatest. In above-normal and wet water years, however, the lowest production years typically had a slight decrease in production under CP1 conditions relative to the No-Action Alternative.

Under CP1, critical water years 1931, 1933, 1934, and 1977 and dry water year 1932 resulted in increases in production relative to the No-Action Alternative ranging from 6 percent to 113 percent. Below-normal water years, 1937 and 1945, resulted in an increase in production ranging from 13 percent to 18 percent relative to the No-Action Alternative. Only critical water year 1992 and

wet water year 1999 resulted in a decrease of 7 percent in production relative to the No-Action.

Under CP1, critical water years 1931 and 1934 resulted in increases in production relative to the Existing Condition ranging from 14 to 43 percent. Dry water years 1926, 1932, 1955, 1964, and 1985 showed an increase production of between 5 and 7 percent relative to the Existing Condition. Below-normal water years 1937 and 1945 resulted in an increase in production (6 to 11 percent) relative to the Existing Condition. Critical water years 1977 and 1992 and wet water years 1969 and 1999 resulted in decreases in production relative to the Existing Condition ranging from 6 percent to 47 percent.

When evaluating the project under AFRP spawning population goals, the overall average fall-run Chinook salmon production was similar for CP1 relative to the No-Action Alternative (Attachment 9A). The maximum increase in production relative to the No-Action Alternative was 94 percent for CP1. The largest decrease in production relative to the No-Action Alternative was 10 percent for CP1. In critical, dry, and below-normal water years, years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP1. In above-normal and wet water years, however, the lowest production years typically remained similar or had a slight decrease in production under CP1 conditions relative to the No-Action Alternative.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to fall-run Chinook salmon under CP1 occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-8 displays the overall mortalities for each alternative that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 7B and 8B). Mortalities caused by the operations-related activities were less under CP1 than under the No-Action Alternative and Existing Condition (Tables 11-10 and 11-11).

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, egg incubation was still the primary life stage affected, but operations-related activities had a greater effect on fry than on presmolts and an even lesser effect on immature smolts. Flow effects triggered a higher percentage of the operations-related mortality (Table 11-11).

In all water-year types, the greatest portion of mortality under CP1 occurred to fry caused by forced movement to downstream habitats. Prespawn, incubation,

and superimposition mortality were greater than mortality to eggs caused by unsuitable water temperatures and presmolt habitat movement.

Table 11-10. Percent Mortality to Fall-Run Chinook Salmon Caused by Nonoperations-Related Effects and Operations-Related Effects Under the Comprehensive Plans When Starting Population Is Based on the 1999 Through 2006 Average

Alternative /Plan	% Nonoperations-Related Mortality	% of the Total Mortality	% Operations-Related Mortality	% of the Total Mortality

In critical water years, mortality to prespawning females was the primary cause of operations-related mortalities for CP1, followed by mortality to fry due to forced movement, and then to eggs from redd dewatering or scouring and superimposition. Least affected were presmolts and then immature smolts by both water temperatures and forced movement. Attachments 7C and 8C contains tables of mortality to fall-run sorted by water-year type, and Table 11-12 outlines the ranks classified under each Comprehensive Plan for each water-year type.

As with critical water years, dry water years were dominated by mortality to fry due to forced movement downstream, followed by redd dewatering or scouring and redd superimposition. Additional mortality occurred to fall-run Chinook salmon presmolts and immature smolts from both forced movement and unsuitable water temperatures (Table 11-12).

Below-normal and above-normal water years were relatively similar for all Comprehensive Plans. Mortality factors were dominated by mortality to fry due to forced movement downstream, followed by redd superimposition, dewatering, or scouring. Mortality to presmolts caused by forced downstream movement was a greater factor affecting fall-run populations than was egg mortality caused by unsuitable water temperatures, or to immature smolts and fry due to unsuitable water temperatures (Table 11-12).

As with the water-year types discussed above, under wet water year conditions, the majority of mortality also occurred to fry due to forced downstream movement, followed by redd superimposition, and redd dewatering or scouring. Mortality to presmolts and immature smolts from downstream movement were the lowest rates resulting from operations-related activities. Least affected were eggs due to unsuitable water temperatures, both pre- and post-spawn.

Years with the highest mortality were the same for the No-Action Alternative and CP1: 1934, 1935, 1970, 1978, and 1993. With the exception of 1970, each of these years was preceded by a critical water year. Overall, years with the lowest mortality tended to be dry or critical water years (Attachment 7C).

Years with the highest mortality were the same for the Existing Condition and CP1: 1957, 1982, 1985, 1994, and 1997. Overall, years with the lowest mortality tended to be dry or critical water years (Attachment 8C).

Table 11-12. Mortality Parameters Ranked by Importance for Fall-Run Chinook Salmon by the No-Action Alternative or Comprehensive Plan and Water-Year Type When the Starting Population Is Based on the 1999 Through 2006 Average

5 = last significant

Results derived from SALMOD.

Key:

CP = Comprehensive Plan

When using AFRP population goals as the spawning population, fall-run Chinook salmon mortality caused by operations-related activities decreased under CP1 compared to No-Action Alternative conditions. Under CP1, mortality caused by operations-related activities would decrease from nonoperations related mortality by more than 13 percent. Under CP2, the greatest mortality to fall-run occurred to the egg incubation life stage, followed by fry, then presmolts, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives (Attachment 9B).

Because fall-run Chinook salmon have, overall, a reduced mortality, fall-run Chinook salmon would benefit from actions taken in CP1. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average late fall-run Chinook salmon production for the 82-year period was similar for CP1 relative to the No-Action Alternative and the Existing Condition. The maximum increase in production relative to the No-Action Alternative was 6 percent for CP1, while the largest decrease in production relative to the No-Action Alternative was 3 percent for CP1 (Attachment 10A). Production remained relatively similar regardless of water-year type.

Overall average late fall-run Chinook salmon production for the 82-year period was similar for CP1 relative to the Existing Condition. The maximum increase in production relative to the Existing Condition was 13 percent for CP1 (1985), while the largest decrease in production relative to the Existing Condition was -5 percent for CP1 (1934) (Attachment 11A).

Under CP1, no critical water years resulted in an increase in production relative to the Existing Condition ranging greater than 5 percent when model noise was removed. Four dry water years (1926, 1961, 1930, and 1985) resulted in a 5 to 13-percent increase in production relative to the Existing Condition. No below-normal, above-normal, or wet water years resulted in a greater than 5-percent difference from the Existing Condition.

When the starting population was the AFRP goal, overall average late fall-run Chinook salmon production was similar for CP1 relative to the No-Action Alternative (Attachment 12A). The maximum increase in production relative to the No-Action Alternative was 8 percent for CP1. The largest decrease in production relative to the No-Action Alternative was 4 percent for CP1. Production remained relatively similar regardless of water-year type.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to late fall-run Chinook salmon under CP1 occurred to the egg incubation life

stage, followed by fry, then presmolts and lastly to immature smolts. Nonoperational conditions were primary causes of mortality for all life stage. Table 11-13 displays the overall mortalities for each Comprehensive Plan that are caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 10B and 11B). Mortalities caused by the project decreased for all Comprehensive Plans relative to the No-Action Alternative.

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, fry became the primary life stage affected, and operations-related activities had a greater effect on eggs than on presmolts and an even lesser effect on immature smolts. Most of the mortality occurred as a result of flow conditions rather than water temperature (Table 11-14).

Table 11-13. Percent Mortality to Late Fall-Run Chinook Salmon Caused by Nonoperations-Related and Operations-Related Effects Under the No-Action Alternative and Comprehensive Plans When Starting Population is Based on 1999 Through 2006 Average

CP = Comprehensive Plan

Under CP1, mortality to fry resulting from unsuitable water temperatures only occurred at low levels to late fall-run Chinook salmon during critical, dry, and below-normal water years only. In all water-year types, mortality to fry during forced movement to downstream habitats was the primary cause of operations-related mortality.

In critical, dry, and below-normal water years, the causes of operations-related mortality follow similar trends for all alternatives with a few exceptions. In general, the effects of flow (and density) had the greatest effect on mortality. Forced movement of fry resulted in the greatest mortality, followed by flow effects on eggs via scouring, dewatering, or superimposition. Next affected were presmolts and immature smolts by unsuitable water temperatures, and lastly temperature effects on eggs and flow effects on presmolts and immature smolts and fry (Table 11-15).

Wet and above-normal water years were overall similar to critical, dry, and below-normal water years except that mortality to fry due to unsuitable water temperatures disappears.

Years with the highest mortality under CP1 were 1937, 1957, 1982, 1985, 1994 and 1997. Three years were preceded by a wet water year, one was preceded by an above-normal water year, and at least one was preceded by a below-normal water year (Attachments 10C and 11C).

When starting with a spawning population equal to the AFRP goal, late fall-run Chinook salmon mortality caused by the operations-related activities was slightly less under CP1 than under No-Action Alternative conditions (Attachment 12B). Under CP1, mortality caused by operations-related activities would decrease from non-operations related mortality by more than 28 percent. Under CP1, the greatest mortality to late fall-run Chinook salmon occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because late fall-run Chinook salmon have, overall, a reduced mortality, late fall-run Chinook salmon would benefit from actions taken in CP1. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-13 (CP1): Changes in Flow and Water Temperatures in the Upper Sacramento River Resulting from Project Operations—Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass Project operation would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be less than significant.

Table 11-15. Mortality Parameters Ranked by Importance for Late Fall-Run Chinook Salmon by Comprehensive Plan and Water-Year Type When Starting Population Is Based on 1999 Through 2006 Average

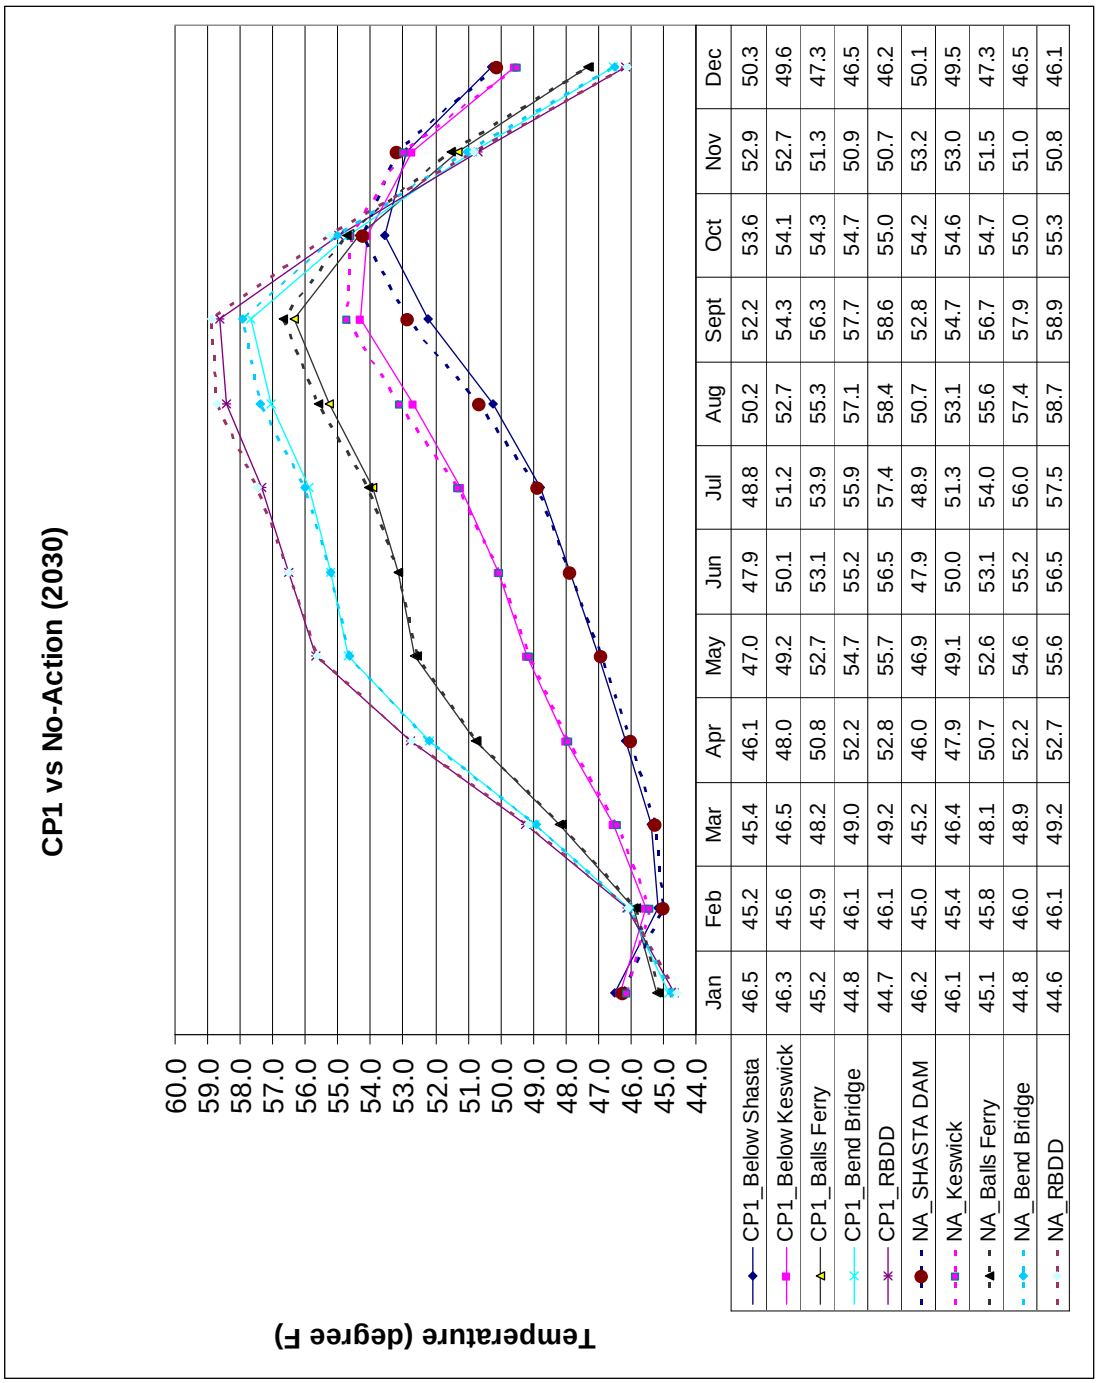
CP = Comprehensive Plan

Flow-Related Effects Monthly mean flows at all model locations (i.e., below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBDD) within the upper Sacramento River under CP1 would be essentially equivalent (less than 2-percent difference) to flows under the Existing Condition and No-Action Alternative simulated for all months (see the *Hydrology, Hydraulics and Water Management Technical Report*). Potential flow-related effects on fish species of management concern in the upper Sacramento River from this alternative would be minimal. During most years, releases from Shasta Lake would be unchanged. In average and wet years, river flows would decrease slightly in some years during the December-through-February period because of the use of increased capacity within Shasta Lake, usually following an extended dry period. Also, flows (and stages) would increase slightly during the June-through-August period of most years. Although small, this increase would be most pronounced during dry periods, as more water is released from Shasta Dam for water supply reliability purposes. However, also during dry periods, few to no changes would occur in water flows or changes during winter and spring. The average changes in mean monthly flow would be reductions or increases of several percent, although the changes in mean monthly flow would be greater in some years. Nonetheless, differences generally would be small (less than 2 percent). All potential changes in flows and stages would diminish downstream from RBDD because of the increasing effect of inflows from tributaries and of diversions and flood bypasses.

There would be no discernable flow-related effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River related to changes in monthly mean flows under CP1, relative to the Existing Condition and No-Action Alternative. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow-related effects on these fish species would be less than significant.



Water Temperature-Related Effects Monthly mean water temperatures at all model locations (i.e., below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBDD) within the upper Sacramento River under CP1 would be the same, or fractionally less, than those under the Existing Condition and No-Action Alternative conditions simulated for all months (Figures 11-9 and 11-10) (see also the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). As discussed above, the modeling simulations may not fully account for real-time management of the cold-water pool and TCD (through the SRTTG) to achieve maximum cold-water benefits. Therefore, the modeled changes in water temperature (i.e., small benefits) are likely conservative and understated to some degree. Nevertheless, potential water temperature–related effects on fish species of management concern in the upper Sacramento River from this alternative would be minimal. During most years, annual releases from Shasta Lake would be unchanged.

RBDD = Red Bluff Diversion Dam

Figure 11-10. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area (No-Action Alternative)

Overall, the greatest cooling effect (less than 1°F) would occur during critical years and during the late summer (i.e., July through September), because of the increased cold-water pool volume within Shasta Lake, even following an extended dry period. This would benefit incubating eggs. All potential changes in flows and stages would diminish downstream from RBDD because of the increasing effect of inflows from tributaries, and of diversions and flood bypasses.

There would be very small water temperature-related effects on steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass in the upper Sacramento River related to slightly cooler monthly mean water temperatures under CP1, relative to the Existing Condition and the No-Action Alternative. Mean monthly water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River. Therefore, water temperature-related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-14 (CP1): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operations could result in the reduction of the magnitude, duration, or frequency of intermediate to large flows that are necessary for channel formation and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate communities. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and shaded riverine aquatic (SRA) habitat. These processes are regulated by the magnitude, duration, and frequency of flows, with relatively large floods providing the energy required to mobilize sediment from the bed, produce meander migration, and create seasonally inundated floodplains. Project operations could result in reduced intermediate to large flows that are necessary for channel formation and maintenance, meander migration, and the creation of seasonally inundated floodplains.

Channel Forming and Maintenance In undisturbed alluvial rivers, channels and bedforms develop in response to flow and sediment loading conditions that may vary by orders of magnitude within a few hours. In many cases, the frequency distribution of flow and sediment supply are such that rivers convey the greatest fraction of their sediment load at an intermediate "dominant" discharge, which is often close to the bankfull flow (Leopold et al. 1964). Although the recurrence interval of bankfull flow varies from river to river, it is often close to 1.5 to 2 years (Leopold et al. 1964). This provides a

rational basis for assuming that coarse sediment is routed as bedload during the 1.5-year (Q) flood. Flow regulation of the Sacramento River has reduced its Q1.5 by 30 percent from 86,000 cfs to 61,000 cfs (Kondolf et al. 2000).

Whereas bankfull flow may provide a good first approximation for assessing the threshold for bed mobilization, it is not necessarily indicative of flows that are required to maintain the health of habitats in the alluvial system. For example, it has been estimated that the naturally occurring 5- to 10-year recurrence interval flood may often be required for maintenance of a mobile alternating bar-pool sequence (Trush et al. 2000) – an ecologically desired condition. In the regulated flow regime of the Sacramento River, the 10-year flood has been reduced by 38 percent from 218,000 cfs to 134,000 cfs (Kondolf et al. 2000).

At many locations between Keswick Dam and RBDD, the channel is characterized by bedrock control of its base level and its banks. This implies that, compared to alluvial reaches downstream, the channel in this area has been limited in its ability to adjust hydraulic geometry (i.e., channel width and depth) in response to dam-related changes in flow. Thus, it is possible that the channel is not in balance with the current flow regime, such that typical recurrence intervals of mobilization and bedform alteration are much longer than they were before the dams reduced the magnitude of Q1.5 and Q10. This implies that the bed and point bars may have become static in the postdam era, such that only remnants of gravel of once abundant spawning habitat in this reach remain.

The flow required for mobilization and scour of a channel bed depends in part on the grain-size distribution of the bed sediment. On the Sacramento River, the grain-size distributions of deposits between Keswick Dam and Cottonwood Creek may have increased since construction of Shasta Dam because of winnowing associated with dam-related reductions in sediment supply (Stillwater Sciences 2006). This would tend to increase the threshold for mobilization and scour of the channel bed, even as the frequency of high flows was reduced by operations of Shasta Dam. The hypothesized coarsening of the bed would thus tend to make mobilization of sediment and bedforms even less likely under the regulated flow regime in the upper Sacramento River.

Changes (reductions) in intermediate to large flows in the Sacramento River also has the potential to affect the lower reaches (confluence areas) of tributaries by reducing the backwater effect that the mainstem river has on the lower reaches of the tributaries. A decrease in the frequency, duration, and intensity of intermediate to large flows on the Sacramento River, and associated decrease in the stage elevation of the river surface, could result in increased downcutting in the lower reaches of the tributaries. Downcutting of the lower tributaries could result in bank erosion, channel widening, and the channel becoming disconnected from its floodplain, which in turn could affect riparian recruitment and succession processes.

Meander Migration Suitable spawning habitat on the mainstem currently extends from Keswick Dam to Princeton. Since 1945, Shasta (and later Keswick) Dam has altered mainstem flow and sediment supply, and has thus affected the quantity and grain-size distributions of gravel in the channel bed. This in turn has affected the extent and quality of salmonid spawning habitat. The expected evolution of spawning gravel in the Sacramento River can be summarized in the following three working hypotheses (Stillwater Sciences 2006):

1. Bed coarsening in the upper Sacramento River has occurred and is continuing such that spawning habitat has been progressively reduced in the reach between Keswick Dam and Anderson Bridge, despite the effects of recent gravel augmentation.

2. Bed coarsening has progressed downstream since 1980 and has now reduced spawning habitat area between Anderson Bridge and Cottonwood Creek.

3. Although the concentration of fine sediment in the subsurface has appeared to remain suitably low between Keswick Dam and Cottonwood Creek, it may have become higher in downstream reaches, because of dam-related reductions in large flows coupled with high sediment supply from Cottonwood Creek and local hydraulic conditions (i.e., a break in slope) that promote local deposition, such that successful spawning of fall-run Chinook salmon in reaches below Cottonwood Creek may have been compromised.

Whereas the success of anadromous salmonids depends strongly on gravel dynamics in the mainstem, other fish species of primary management concern rely much more heavily on the dynamics of meander migration, which affects the quality and availability of near- and off-channel habitat such as SRA.

SRA habitat is composed of vegetation and instream tree and shrub debris that provides important fish habitat. SRA habitat is defined as the nearshore aquatic habitat occurring at the interface between a river and adjacent woody riparian habitat. The principal attributes of this cover type are (1) an adjacent bank composed of natural, eroding substrates supporting riparian vegetation that either overhang or protrude into the water, and (2) water that contains variable amounts of woody debris, such as leaves, logs, branches, and roots and has variable depths, velocities, and currents. Riparian habitat provides structure (through SRA habitat) and food for fish species. Shade decreases water temperatures, while low overhanging branches can provide sources of food by attracting terrestrial insects. As riparian areas mature and banks erode, the vegetation sloughs off into the rivers, creating structurally complex habitat consisting of instream woody material that furnishes refugia from predators, creates higher water velocities, and provides habitat for aquatic invertebrates. For these reasons, many fish species are attracted to SRA habitat.

On the upper Sacramento River, actively migrating reaches alternate with stable reaches, which migrate slowly or not at all because they are confined by erosion-resistant geologic deposits or revetment placed to protect adjacent uses. Meander migration and bank erosion occur by progressive channel migration and episodic meander-bend cutoff. Over decadal timescales, cutoffs generally affect less than 10 percent of the actively migrating length of the Sacramento River. Even so, cutoffs can account for well over 20 percent of the integrated lateral channel change, because they affect relatively large areas when they do occur (Stillwater Sciences 2006).

Chute cutoff and progressive migration interact to produce a characteristic pattern of planform development over time. Individual bends evolve greater sinuosity and curvature via progressive channel migration. Cutoffs reduce sinuosity when it exceeds a local threshold for the initiation of cutoff processes. This should produce measurable changes in local geomorphology over time. Averaged over larger timescales, however, changes in morphology in one reach should be balanced by changes in morphology in others, such that the overall pattern of planform geometry for migrating portions of rivers should approach a state of dynamic equilibrium in the absence of human modifications. Recent studies indicate that the sinuosity of cutoff bends is decreasing over time on the Sacramento River (Stillwater Sciences 2006). This suggests that the Sacramento River is not in a state of dynamic equilibrium. The fact that cutoff migration has increased in frequency and is increasingly dominated by partial cutoffs (which affect smaller areas than complete cutoffs) provides further evidence that nonequilibrium conditions may prevail.

Process-based interpretations suggest that potential project alternative-related changes in flow (i.e., reductions in peak flow and overbank discharge) could tend to reduce the frequency of these important geomorphic processes. This would generally be accompanied by a reduction in average sinuosity; however, observations from the Sacramento River indicate that the overall number of channel cutoffs has nevertheless increased in recent times. This supports the hypothesis that the erodibility of banks and floodplains has increased (and thus enhanced the likelihood of cutoff) because of the effects of agricultural clearing of riparian forests on floodplains (Micheli et al. 2004).

Floodplain Inundation Inundation of floodplains reduces floodflow magnitude (i.e., peak volume of flood flows) and promotes exchange of nutrients, organisms, sediment, and energy between the terrestrial and aquatic systems. Flood pulses contribute to high rates of primary productivity in functioning floodplain systems (Junk et al. 1989). On the Sacramento River, floodplains provide important winter and spring spawning and rearing habitats for native fish, such as Sacramento splittail and Chinook salmon (Moyle et al. 2004, Sommer et al. 2001).

Typically, the floodplain immediately adjacent to the river is maintained at an elevation equal to the bankfull stage of the channel, such that discharge

magnitudes greater than the bankfull flow inundate the adjacent floodplains (Leopold et al. 1964). As bankfull flow typically has a recurrence interval of Q1.5-2 on alluvial rivers, flow magnitudes greater than the Q1.5 flow event are often assumed to initiate floodplain inundation.

These effects would likely occur along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. Therefore, these impacts would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Lower Sacramento River and Tributaries, Delta, and Trinity River
Impact Aqua-15 (CP1): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern Project operation would result in no discernable change in mean monthly flow or water temperature conditions in the lower Sacramento River; however, predicted changes in flow in the Feather River, American River, and Trinity River could result in an adverse effect on Chinook salmon, steelhead, coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass, if they were to occur. This impact would be potentially significant.

Monthly mean flows at model locations (i.e., Verona, Freeport) within the lower Sacramento River under CP1 would be comparable to flows under Existing Condition and No-Action Alternative conditions simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete CalSim-II modeling results). All potential changes in flows diminish rapidly downstream from RBDD because of increasing effect of inflows from tributaries and of diversions and flood bypasses. Potential flow-related effects on fish species of management concern in the lower Sacramento River from this alternative would be minimal. Differences in mean monthly flow are generally small (less than 2 percent) and within the existing range of variability.

Monthly mean flows at all model locations within the lower Feather River (i.e., below Thermalito Afterbay) and the American River (i.e., near the H Street Bridge in Sacramento) under CP1 would be essentially equivalent (less than 2-percent difference) to flows under the Existing Condition and No-Action Alternative conditions simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete CalSim-II modeling results). All potential changes in flows are diminished in these areas because of operation of upstream CVP and SWP reservoirs (i.e., Lake Oroville and Folsom Lake) and increasing effects of inflows from tributaries and of diversions and flood bypasses. Potential flow-related effects on fish species of management concern in the Feather River and American River from this alternative would be minimal and within the existing range of variability. All potential changes in

water temperatures in the lower Sacramento River due to small changes in releases would diminish rapidly downstream because of increasing effect of inflows, atmospheric influences, and groundwater. Therefore, flow- and water temperature-related impacts on fish species in the lower Sacramento River would be less than significant.

Effects of altered flow regimes resulting from implementation of CP1 are unlikely to extend into the lower Sacramento River (i.e., downstream from Verona) and Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the CVP and SWP). The guidelines for this management, which are described in the CVP/SWP OCAP, have been designed to maintain standards for flow to the lower Sacramento River and Delta. CVP and SWP operations must be consistent with the OCAP to allow ESA coverage by the OCAP permits and BOs. Thus, under CP1, this project is not anticipated to cause an alteration in flow to the Delta nor cause an alteration to water temperatures in the lower Sacramento River and primary tributaries within the extended study area sufficient to cause effects on Chinook salmon, steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the lower Sacramento River or tributaries relative to the Existing Condition and No-Action Alternative. Functional flows for fish migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow- and water temperature-related effects on these fish species would be less than significant.

Monthly mean flows at model locations within the lower Feather River (i.e., below Thermalito Afterbay) and the American River (i.e., near the H Street Bridge in Sacramento) under CP1 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative conditions simulated for most months; however, several months within the modeling record show substantial changes (based on model simulations) to flows in tributaries (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete CalSim-II modeling results). All potential changes in flows could be reduced in these areas because of real-time operations to meet existing operational rules and operation of upstream CVP and SWP reservoirs (i.e., Lake Oroville and Folsom Lake). Nevertheless, based on predicted changes in flow and associated flow-habitat relationships (including water temperature) for fish, potential flow-related impacts on species of management concern in the American and Feather rivers would be a potentially significant impact.

Similar to the lower Feather River and lower American River, monthly mean flows at all model locations within the Trinity River under CP1 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative simulated for most months; however, several months within the modeling record show substantial changes (based on model simulations) to flows in tributaries (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete CalSim-II

modeling results). Based on predicted changes in flow and associated flow-habitat relationships for fish, potential flow-related impacts on species of management concern in the Trinity River would be a potentially significant impact. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-16 (CP1): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the lower Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

As discussed under Impact Aqua-14 (CP1), sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. These processes are regulated by the magnitude, duration, and frequency of flow, with relatively large flows providing the energy required to mobilize sediment from the bed, produce meander migration, and create seasonally inundated floodplains. Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains (including floodplain bypasses) in the lower Sacramento River.

Relative to the upper Sacramento River, there is significantly less bedrock control between RBDD and Colusa. Consequently, sediment transports and meander migration processes are more pronounced in this more alluvial reach. This is supported by widespread evidence of frequent lateral migration in the upper reaches of the lower Sacramento River (between RBDD and Colusa) (e.g., Micheli et al. 2004). This implies that these reaches of the Sacramento River experience much more frequent bed and bar mobilization than the upper Sacramento River.

As discussed under Impact Aqua-14 (CP1), changes (reductions) in intermediate to large flows in the Sacramento River has the potential to affect the lower reaches (confluence areas) of tributaries by reducing the backwater effect that the mainstem river has on the lower reaches of the tributaries. Decreases in the frequency, duration, and intensity of intermediate to large flows on the Sacramento River, and associated decrease in the stage elevation of the river surface, could result in increased downcutting in the lower reaches of the tributaries. Downcutting of the lower tributaries could result in bank erosion, channel widening, and the channel becoming disconnected from its floodplain, which in turn could affect riparian recruitment and succession processes.

Reaches of the Sacramento River differ in the extent of floodplain inundation. Most of the upper Sacramento River between Keswick Dam and RBDD is also bounded by high banks and terraces, such that there is limited opportunity for floodplain inundation in this reach. Also along the upper reaches of the lower Sacramento River, between Chico Landing and Colusa, the river is bounded by levees that provide flood protection for cities and agricultural areas. However, the levees of this reach of the Sacramento River are for the most part set back from the mainstem channel such that flooding can be significant within the river corridor. In the lower Sacramento River between RBDD and Chico Landing, the mainstem channel is flanked by broad floodplains. Evidence of ongoing sediment deposition of these areas testifies to continued inundation in floodplains in this reach (Buer 1994).

An important attribute of the middle and lower reaches of the Sacramento River is the presence of floodplain bypasses (e.g., Butte Basin, Sutter Bypass, and Yolo Bypass). In winter and spring, agricultural fields and wetland habitats throughout the floodplain bypasses often flood during high flows and are used by Sacramento splittail for spawning and rearing, and by Chinook salmon and steelhead for rearing (Sommer et al. 2001, 2003). For this reason, a key restoration goal of CALFED is to improve the connectivity between rivers and floodplain habitats, including floodplain bypasses, as well as increase the amount of willow-water habitat in the Central Valley (CALFED 2001). Numerous studies have shown that willow water and dense vegetation in these areas provide highly productive rearing areas for numerous species, including Chinook salmon and splittail. Seasonally flooded habitat provides rearing habitat for Chinook salmon and spawning, rearing, and foraging habitat for splittail (Sommer et al. 1997, 2001, 2002; Baxter et al. 1996; USACE 1999). Floodplain habitat offers protection from large piscivorous fish such as striped bass. The temporary nature of the flooded habitat and the protection offered by relatively willow water and dense vegetative cover serve to exclude predatory fish. The productivity of floodplains is generally related to the frequency, timing, water depths, velocities, vegetation, water quality, and duration of inundation relative to the life history and habitat requirements of fish species. Physical conditions (e.g., type and extent of vegetation, soil conditions, and drainage patterns) may also contribute to habitat quality.

Flooded vegetation provides an abundant source of food, including detrital material, insect larvae, crustaceans, and other invertebrates. Juvenile Chinook salmon and splittail apparently forage among a variety of vegetation types, including trees, brush, and herbaceous vegetation, but their relative importance, alone or in combination, is unknown. Juvenile Chinook salmon that rear in seasonally flooded habitat have higher survival and growth rates than juveniles that remain in the main river channel to rear (USACE 1999, Sommer et al. 2001). The increased growth rate may be related to the higher water temperatures in the willow water in this habitat, and the higher associated rate of production of invertebrates, which are a substantial source of food for rearing juveniles, and of the grasses that support the invertebrates. Increases in the area

available to juveniles could also reduce competition for food and space, and could reduce the likelihood of encounters with predators (Sommer et al. 2001). In addition, juvenile Chinook salmon that grow faster are likely to migrate downstream sooner, which helps to reduce the risks of predation and competition in freshwater systems.

In summary, CP1 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These impacts would likely occur along the upper reaches of the lower Sacramento River. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. These impacts would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-17 (CP1): Effects to Delta Fishery Habitat Resulting from Changes to Delta Outflow Based on the results of hydrologic modeling comparing Delta outflow under basis-of-comparison conditions, and under CP1 under the Existing Condition and No-Action Alternative, CP1 would have a less than significant impact on Delta fisheries and hydrologic transport processed within the Bay-Delta.

Results of the comparison of Delta outflows are summarized by month and water-year type in Table 11-16. The comparison includes the estimated average monthly outflow under the basis-of-comparison conditions (Existing Condition and No-Action Alternative), the average monthly flow under CP1, and the percentage change between base flows and CP1 operations. Results of the analysis (Table 11-16) showed that Delta outflows were observed to be slightly lower under many of the CP1 operations, and slightly higher than basis-of-comparison conditions depending on month and water-year type. However, none of the changes were greater than 5 percent. Based on the results of this comparison of CP1, it was concluded that CP1 would have a less than significant impact on Delta fisheries and hydrologic transport processed within the Bay-Delta under Existing Condition and No-Action Alternative. Based on results of this analysis, it was concluded that CP1 would result in a less than significant impact on Delta fisheries as a consequence of changes in Delta outflow. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-18 (CP1): Effects to Delta Fishery Habitat Resulting from Changes to Delta Inflow Changes in upstream reservoir storage have the potential to affect Delta inflow. Delta inflow may affect hydrologic conditions within Delta channels, hydraulic residence times, salinity gradients, and the transport and movement of various life stages of fish, invertebrates, phytoplankton, and nutrients into and through the Delta. Delta inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources. Based on the results of hydrologic modeling comparing Delta inflow under Existing Condition, No-Action Alternative, and CP1, CP1 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta.

Results of the comparison of Delta inflows under the Existing Condition and No-Action Alternative with CP1 are summarized by month and water-year type in Table 11-17. The comparison includes the estimated average monthly inflow under the basis-of-comparison conditions, the average monthly flow under CP1, and the percentage change between base flows and CP1 operations. Delta inflows were observed to be slightly lower under many of the CP1 operations and slightly higher than basis-of-comparison conditions, depending on month and water-year type. None of the Existing Condition or No-Action Alternative comparisons with CP1 exceeded 5 percent. Based on the results of this comparison of CP1, it was concluded that CP1 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta as a consequence of changes in Delta inflow relative to the Existing Condition and No-Action Alternative. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP1): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow Project operation would result in a variable response in Sacramento River flow, resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water year. This impact would be less than significant.

Flow within the Sacramento River has been identified as an important factor affecting the survival of emigrating juvenile Chinook salmon; important to the downstream transport of planktonic fish eggs and larvae such as delta and longfin smelt, striped bass and shad; and important for seasonal floodplain inundation that has been identified as important habitat for successful spawning and larval rearing by species such as Sacramento splittail and as seasonal foraging habitat for juvenile Chinook salmon and steelhead. Sacramento River flows are also important in the transport of organic material and nutrients from the upper regions of the watershed downstream into the Delta. A reduction in Sacramento River flow as a result of CP1, depending on the season and magnitude of change, could adversely affect habitat conditions for both resident and migratory fish species. An increase in river flow is generally considered to be beneficial for aquatic resources within the normal range of typical project operations and flood control. Very large changes in river flow could also affect sediment erosion, scour, deposition, suspended and bedload transport, and other geomorphic processes within the river and watershed.

Results of hydrologic modeling, by month and year type, for Sacramento River flow are presented in Table 11-18. Results of these analyses show a variable response in Sacramento River flow with CP1 operations resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water-year type. One comparison showed a change greater than 5 percent between the basis-of-comparison and an alternative. The model river flow under the future condition for CP1 in a critical year in February was greater than 5 percent from the basis-of-comparison; however, in this case, the river flow under CP1 was higher than the basis-of-comparison and would not be expected to result in an adverse fishery impact, but rather would be expected to contribute to improved habitat conditions under this low-flow condition. All other comparisons between the basis-of-comparison and CP1 operations were less than 5 percent. Based on these results it was concluded that the impact of CP1 on fish habitat and transport mechanisms within the lower Sacramento River and Delta would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP1): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis Project operation would result in no discernable change in San Joaquin River flows at Vernalis, and, therefore, no effect on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta from CP1 relative to No-Action Alternative and the Existing Condition.

Flow within the San Joaquin River has been identified as an important factor affecting the survival of juvenile Chinook salmon migrating downstream from the tributaries through the mainstem San Joaquin River and Delta; important to the downstream transport of planktonic fish eggs and larvae such as striped bass; and important for seasonal floodplain inundation that is considered to be important habitat for successful spawning and larval rearing by species such as Sacramento splittail and as seasonal foraging habitat for juvenile Chinook salmon. San Joaquin River flows are also important in the transport of organic material and nutrients from the upper regions of the watershed downstream into the Delta. A reduction in San Joaquin River flow as a result of CP1 operations, depending on the season and magnitude of change, could adversely affect habitat conditions for both resident and migratory fish species. An increase in river flow is generally considered to be beneficial for aquatic resources within the normal range of typical project operations and flood control. Very large changes in river flow could also affect sediment erosion, scour, deposition, suspended and bedload transport, and other geomorphic processes within the river and watershed.

Results of the comparative analysis of CalSim-II, by month and year-type, for the Existing Condition and CP1 for San Joaquin River flow are summarized in Table 11-19. Results of these analyses show that CP1 would have no effect on seasonal flows under existing conditions within the San Joaquin River. Similarly, modeling results showed that CP1 would have no effect on flows or fish habitat under Future Conditions. Therefore, CP1 would have no effect on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta under CP1 relative to the Existing Condition and No-Action Alternative. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP1): Reduction in Low Salinity Habitat Conditions Resulting from an Upstream Shift in X2 *Location* Project operation would result in a less than 0.5 km movement upstream or downstream from the X2 location. This impact would be less than significant.

Operations of upstream storage reservoirs have the potential to affect the location of X2 as a result of changes in freshwater flows from the upstream tributaries through the Delta. For purposes of evaluating changes in habitat quantity and quality for estuarine species, a significance criterion of an upstream change in X2 location within 1 km of the basis-of-comparison condition was considered to be less than significant. The criterion was applied to a comparison of hydrologic model results for basis-of-comparison conditions and CP1, by month and water year, for February through May. Results of the comparison for the Existing Condition versus CP1 are summarized in Table 11-20. These results showed that changes in X2 location under CP1 were less than 1 km (all were less than 0.5 km) with both variable upstream and downstream movement of the X2 location, depending on month and water year. These results are consistent with model results for Delta outflow that showed a less than significant change in flows under CP1.

Results of a comparative analysis of changes in X2 location between the No-Action Alternative and CP1 assuming future operating conditions are also summarized in Table 11-20. Results of these comparisons showed very little difference (less than 0.2 km) in the X2 location between the No-Action Alternative and CP1. Based on these results, it was concluded that CP1 would have a less than significant impact on low salinity habitat conditions within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP1): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in Old and Middle Rivers Project operation would result in an increase of reverse flows in Old and Middle rivers. The increase in reverse flows would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses. This impact would be potentially significant.

Results of the analysis showed several occurrences when reverse flows within Old and Middle rivers were greater under CP1 than basis-of-comparison

conditions by more than 5 percent. These events occurred typically in dry and critical water years, which would be expected as a result of greater export operations under CP1. During February, operations under CP1 resulted in an increase in reverse flow greater than 5 percent during critical years (Table 11-21). Based on results of the delta smelt analysis of the relationship between reverse flows and delta smelt salvage, the increase from approximately 4,300 cfs under the basis-of-comparison in a critical water year to approximately 4,700 cfs would not be expected to result in a significant increase in adverse impacts to delta smelt. Juvenile Chinook salmon and steelhead are migrating through the Delta during February, and an increase in average monthly reverse flows of 300 to 400 cfs would be expected to increase the potential risk of increased mortality. However, given the tidal volumes and hydrodynamics of the Old and Middle river region, it is not expected that the change in reverse flows in February in a critical year would result in a detectable change in fish survival. The majority of juvenile Chinook salmon emigrating from the San Joaquin River typically migrate downstream later in dry years and would not be expected to occur in high numbers within Old and Middle rivers in February.

The increase in reverse flows estimated to occur under CP1 in critical years in June, and under critical, dry, and below-normal years in July, exceeded 5 percent. The increased reverse flows in June of critical years occurred at a time of the year when water temperatures in the Delta were elevated and juvenile Chinook salmon or steelhead would not be expected to occur in the area. Juvenile delta smelt may occur in the area in June; however, a change in Old and Middle river flows of approximately 100 to 200 cfs may result in a small increase in their vulnerability to CVP and SWP salvage, but this increase is expected to be less than significant. As water temperatures increase in the Delta during June and July, the majority of delta smelt are located farther downstream in Suisun Bay where water temperatures are more suitable. The increase in reverse flows estimated from modeling in June of a critical year and in July of below-normal, dry, and critical years would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses as a result of increased reverse flows. The increased reverse flows in low-flow years would be expected to result in a low, but potentially significant, increase in mortality for resident warm-water fish inhabiting the south Delta under CP1 relative to the Existing Condition.

Results of the comparison of Old and Middle river reverse flows are summarized in Table 11-21. Results of the analysis show that in the majority of years and months, reverse flows under CP1 do not exceed basis-of-comparison conditions by more than 5 percent. CP1 exceeded basis-of-comparison conditions during February of a critical year by approximately 700 cfs. The increase in reverse flows would be expected, particularly in a critical year, to contribute to an increase in the potential for losses of adult delta smelt and other species, which is considered to be potentially significant. During June in a critical water year, under CP1, the magnitude of reverse flows was reduced more than 5 percent but would be expected to contribute to a less than significant biological benefit based on both the low reverse flow under the basis-of-comparison and under CP1. An increase in reverse flow above the basis-of-comparison of approximately 300 to 600 cfs during dry years in July would be expected to contribute to an increase in the risk of losses to resident warm-water fish species. Increased reverse flows in July would not be expected to adversely affect delta or longfin smelt, juvenile Chinook salmon, or steelhead based on their seasonal migration patterns and geographic distribution. The potential increase in losses during February and July under future operating conditions is considered to be potentially significant. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

Impact Aqua-23 (CP1): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports Proposed operations may result in an increase in CVP and SWP exports, which is assumed to result in a direct proportional increase in the risk of fish being entrained and salvaged at the facilities. This is a considered a less than significant impact to Chinook salmon,

steelhead, and longfin smelt. This is considered a potentially significant impact to delta smelt, striped bass, and splittail. Future operations of the SWP and CVP export facilities would continue to be managed and regulated in accordance with incidental take limits established for each of the protected fish by USFWS, NMFS, and DFG.

Results of the entrainment loss modeling at the CVP and SWP export facilities are presented in Table 11-22 for CP1. The initial modeling was conducted using average fish densities developed from past fish salvage monitoring at the SWP and CVP export facilities. Average monthly water exports were used in the analysis based on hydrologic simulation modeling. The indices of the potential risk of entrainment for some species, such as Chinook salmon, were not estimated separately for each species (e.g., winter-run Chinook salmon) in these initial analyses. If the proposed project is developed in the future a more detailed species-specific analysis of potential changes in fish salvage losses, in addition to an assessment of the population-level effects on each species, would be required for use as a basis for developing a biological assessment and BOs and incidental take permits for project operations. These indices were calculated for wet, above-normal, below-normal, dry, and critical water-year types, and for an average across all years (no water-year type specified). The total numbers of fish lost annually, by species, are presented in Attachment 13. The difference between the non-operations related and operations related fish mortality is represented as the entrainment index, shown in the tables, to represent the effect of project operations on each fish species for the CVP and SWP.

The greatest change in the risk of entrainment at the CVP and SWP export facilities would be expected to occur in dry and critical water-year types when export rates are increased, especially during February and summer months. Entrainment indices as a result of CP1 operations show a relatively minor increase, on average, in salvage for most species (e.g., delta smelt, steelhead, Chinook salmon, and longfin smelt). Although the risk of entrainment showed both increases and decreases depending on species and water-year type, the general trend was a small incremental increase in the risk of entrainment/salvage losses at the CVP and SWP export facilities when compared to the Existing Condition. Species with relatively lower abundance at the CVP and SWP, such as longfin smelt, during months of the highest exports, would appear to be less affected by CP1 operations, with entrainment indices representing a net benefit as a result of CP1 relative to the Existing Condition. Species with relatively higher abundance at the CVP and SWP fish facilities, such as splittail and striped bass, show increased mortality due to higher exports during June and July, as these species are generally collected at their highest abundances during these months. Chinook salmon entrainment, whose mortality at the facilities is highest during February, March, and June, appears to increase as a result of generally higher project export rates during these months when compared to the Existing Condition.

C = critical
CP = Comprehensive Plan
CVP = Central Valley Project
D = dry
SWP = State Water Project
W = wet

Results of the entrainment risk calculations for delta smelt showed a change of less than 1 percent from Existing Condition in wet, above-normal, and below-normal water years and an increase in risk ranging from approximately 1 to 4 percent (Table 11-22) during dry and critical water years. The risk of increased losses of delta smelt was greatest in the dry years with a net reduction in losses under CP1 relative to the No-Action Alternative. Although the incremental change in the risk of delta smelt losses resulting from CVP and SWP export operations are small, the delta smelt population abundance is currently at such critically low levels that even a small increase in the risk of losses is considered to be potentially significant. The increase in risk is also expected to contribute to cumulative factors affecting the survival of delta smelt.

The estimated change in the risk of losses for Chinook salmon under CP1 follow a similar pattern to that described for delta smelt. Overall, CP1 resulted in a small increase in the risk of losses relative to both the Existing Condition and No-Action Alternative. The loss index for salmon under CP1 also showed increased risk in wet, below-normal, dry, and critical years. Given the numbers of juvenile Chinook salmon produced each year in the Central Valley, the relatively small incremental increase in the risk of entrainment/salvage at the CVP and SWP export facilities is considered to be a less than significant direct effect but would contribute incrementally to the overall cumulative factors affecting juvenile Chinook salmon survival within the Delta and population dynamics of the stocks.

The estimated change in the risk of longfin smelt entrainment/salvage compared with the Existing Condition and No-Action Alternative shows small positive and negative changes depending on water-year type (Table 11-22). These small changes in the risk of entrainment are considered to be less than significant.

The estimated change in the risk to steelhead of entrainment/salvage at the CVP and SWP export facilities under CP1 are summarized in Table 11-22. The small positive and negative changes in risk under wet, above-normal, below-normal, and dry water years are considered to be less than significant. The increase in risk of steelhead losses in critical water years is considered to be less than significant based on the abundance of juvenile steelhead migrating through the Delta, but would contribute directly to cumulative factors affecting the survival and population dynamics of Central Valley steelhead. The predicted increase in potential entrainment risk for steelhead under critically dry water years represents an initial estimate of the change (percentage) between the proposed project operations and the existing conditions and no-project alternatives and does not allow the predicted losses to be evaluated at the population-level. As noted above, more detailed modeling and analysis of potential steelhead losses would be required as part of preparing a project-specific analysis of entrainment losses for use in the Section 7 biological assessment and BOs for future project operations and incidental take of steelhead. As part of this more detailed analysis additional actions may be identified to further reduce and avoid potential adverse effects to steelhead.

The change in risk to juvenile striped bass for entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-22. The change in risk in wet, above-normal, and below-normal water years are considered to be less than significant based on the abundance of striped bass but would contribute to the cumulative factors affecting striped bass survival and population dynamics in the Delta. The losses of juvenile striped bass increased substantially under dry and critical year conditions, which would be expected with an increase in exports during the summer months. Under existing conditions, the risk of increased losses ranged from 3.8 to 7.6 percent (approximately 30,000 to 60,000 fish), which is considered to be potentially significant. The increased losses under the three alternatives, particularly in drier water years when juvenile striped bass production is lower, would be expected to contribute to the cumulative effects of factors affecting juvenile striped bass survival in the Delta.

Results of the risk estimates for juvenile splittail losses relative to the Existing Condition and No-Action Alternative show a pattern similar to other species (Table 11-22). The increased risk index was 1.3 percent or less in wet, above-normal, and below-normal water years, and was considered to be a less than significant impact. The loss index increased during dry and critically dry water years. Higher risk of entrainment/salvage losses in drier water years has a potentially greater effect of abundance of juvenile splittail since reproductive success and overall juvenile abundance is typically lower within the Delta in dry years. The increased risk of losses in drier years was considered to be potentially significant. The increased losses would also contribute to cumulative factors affecting survival of juvenile splittail within the Delta.

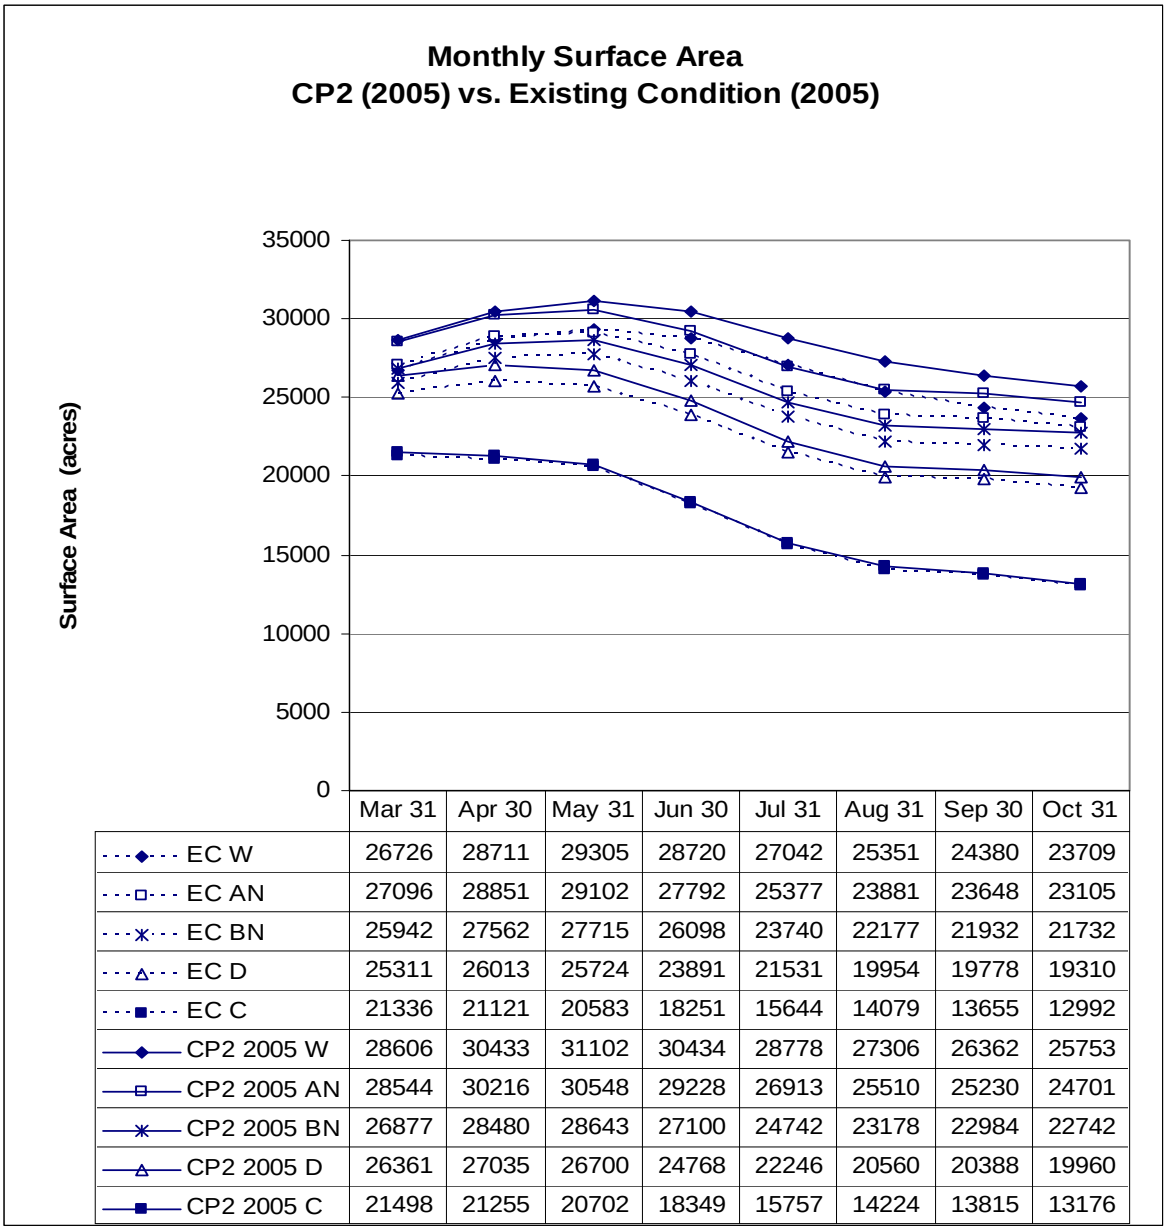
Impact Aqua-23 (CP1) is considered to be less than significant for Chinook salmon, steelhead, and longfin smelt, but potentially significant for delta smelt, striped bass, and splittail. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

CVP/SWP Service Areas

Impact Aqua-24 (CP1): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes Project implementation could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, hydrologic effects in tributaries and reservoirs with CVP and SWP dams are expected to be less than impacts on the lower Sacramento River. Changes in hydrology could affect aquatic habitats that provide habitat for the fish communities. However, these changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. Therefore, this impact would be less than significant.

Project implementation could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River;

however, the hydrologic effects in tributaries (e.g., San Joaquin River, canals) and reservoirs (e.g., New Melones and San Luis) with CVP and SWP dams are expected to be less than impacts on the lower Sacramento River. The change in hydrology and reservoir levels could affect aquatic habitats that provide habitat for the fish communities, but these changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. The effects from CP1 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and the resulting flows downstream from those reservoirs, would be small and well within the range of variability that commonly occurs in these reservoirs and downstream. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

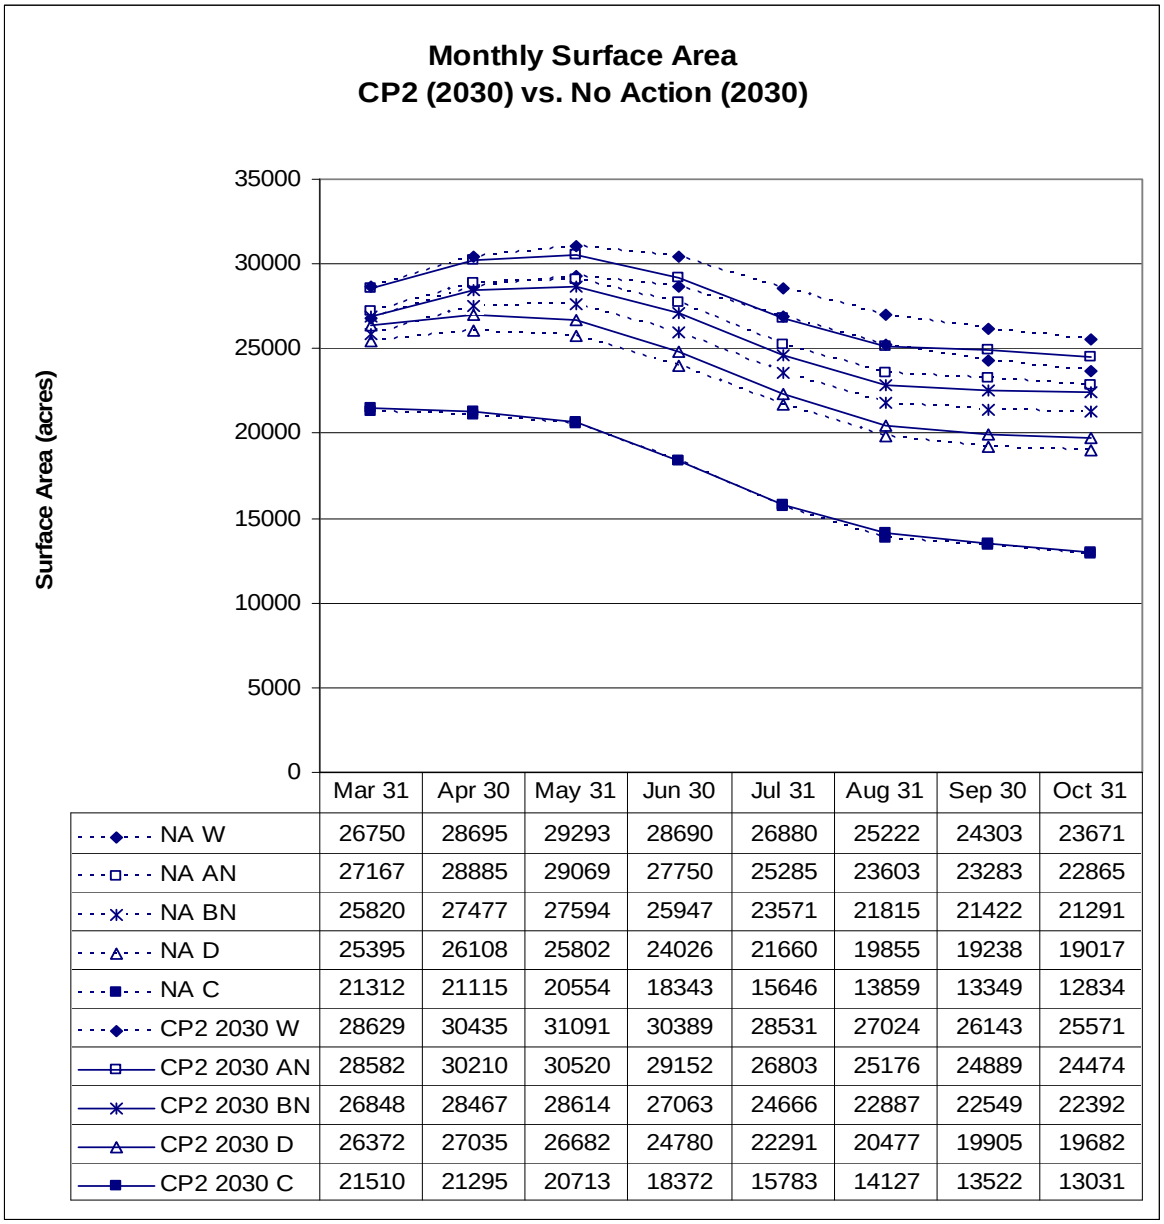


CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Like CP1, CP2 focuses on enlargement of Shasta Dam and Reservoir consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increased water supply reliability and increased survival of anadromous fish. CP2 consists of raising Shasta Dam by 12.5 feet, an elevation change that would increase the full pool by 14.5 feet and enlarge the total storage space in the reservoir by 443,000 acre-feet. This alternative would help reduce future shortages by increasing the reliability of the water supply in drought and average years. The increased cold-water pool also would contribute to improved seasonal water temperatures on the upper Sacramento River for anadromous fish.

Shasta Lake and Vicinity

Impact Aqua-1 (CP2): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP2, project operations would contribute to an increase in the surface area and WSEL of Shasta Lake, which would in turn increase the area and productivity of nearshore, warm-water habitat. CP2 operations would also result in reduced monthly fluctuations in WSEL, which would contribute to increased reproductive success, young-of-the-year production, and the juvenile growth rate of warm-water fish species. Similar to CP1, the value of existing structural improvements would be diminished, large areas of the shoreline would not be cleared, and the vegetation along these sections will be inundated periodically. In the short term, this vegetation will provide warm-water lacustrine habitat, with decay expected to occur over several decades. This impact would be less than significant.



This impact would be similar to Impact Aqua-1 (CP1), but the surface area would be larger under the 12.5-foot dam raise than under the 6.5-foot dam raise. CalSim-II modeling shows that the surface area of Shasta Lake would be larger under the CP2, the Existing Condition or No-Action Alternative in all five water-year types (Figures 11-11 and 11-12).

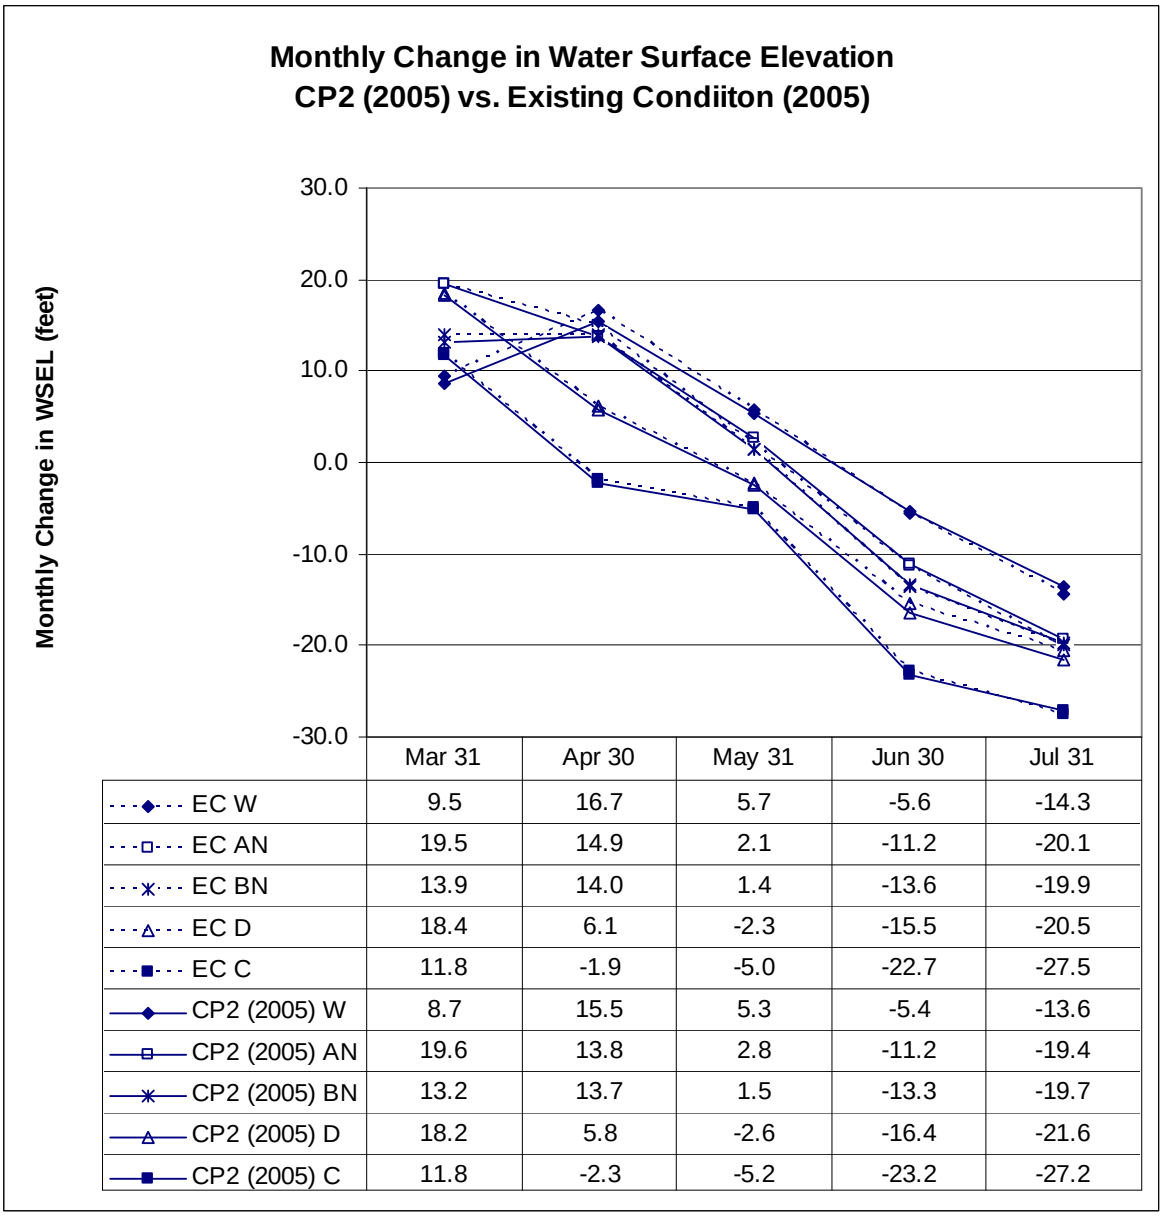
Figure 11-12. Monthly Surface Area for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP2 vs. No-Action

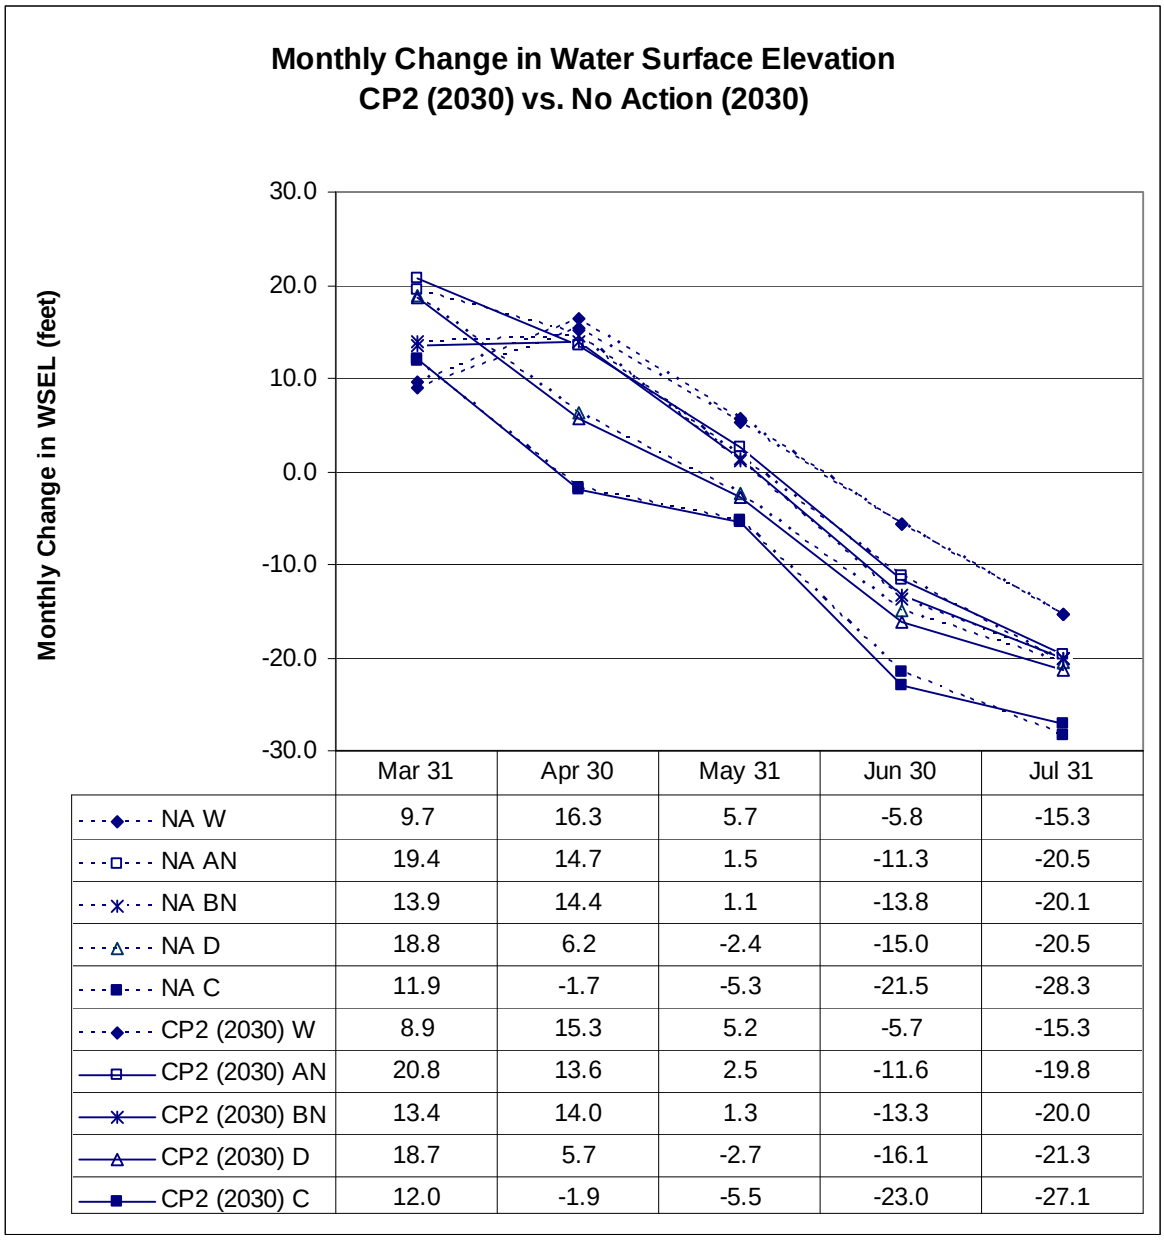


Monthly WSEL fluctuations were compared with projections for water supply demand. For CP2, with a 2005 water supply demand, 20 percent of monthly changes in projected WSEL (i.e., 5 of the 25 total projections made for the 5 months from March through July for all five water-year types) showed increased monthly WSEL fluctuations relative to the Existing Condition and 80 percent showed reduced monthly WSEL fluctuations (Figure 11-13). For CP2, with a projected 2030 water supply demand, 36 percent of monthly changes in projected WSEL showed increased WSEL fluctuations relative to the No-Action Alternative and 64 percent showed reduced monthly WSEL fluctuations (Figure 11-14). Under CP2, none of the changes in monthly WSEL fluctuation is different enough from the Existing Condition to warrant the investigation of daily WSEL fluctuation.

Increases in the overall surface area and WSEL under CP2 would increase the area of available warm-water habitat and stimulate biological productivity, including fish production, of the entire lake for a period of time, possibly for several decades. Furthermore, reductions in the magnitude of monthly WSEL fluctuations could contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of warm-water fish species. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-2 (CP2): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction Localized increases in soil erosion and resulting runoff sedimentation, and turbidity resulting from project construction in the vicinity of Shasta Dam and at utility, road, and other facility relocation areas could affect nearshore warm-water habitat. This impact would be similar to Impact Aqua-2 (CP1). However, CP2 would have a larger project footprint and would take longer to implement. However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-3 (CP2): Effects on Cold-Water Habitat in Shasta Lake Under CP2, operations-related changes in the ratio of the volume of cold-water storage to surface area would increase the availability of suitable habitat for cold-water fish in Shasta Lake, including rainbow trout. This impact would be beneficial.



This impact would be similar to Impact Aqua-3 (CP1). However, it would be of greater magnitude owing to a greater increase in the ratio of the volume of cold water storage in the lake to the surface area of the lake. CalSim-II modeling shows that under CP2 with a 2030 water supply demand, the ratio of cold-water storage to surface area is higher than under the No-Action Alternative in all water years and during all months modeled. The greatest projected increases over the No-Action Alternative occur between June 30 and August 31, which is the critical holding and rearing period for cold-water fishes in reservoirs, and the increases are greatest in wet and above-normal water years (Figure 11-15).

Figure 11-15. Monthly Cold-water Storage to Surface Area Ratio for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP2 vs. Existing Condition

CP2 would increase the availability of suitable habitat for cold-water fish in Shasta Lake. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-4 (CP2): Effects on Special-Status Aquatic Mollusks Under CP2, habitat for special-status mollusks could become inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could also adversely affect special-status aquatic mollusks that may occupy habitat in or near Shasta Lake and its tributaries. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-5 (CP2): Effects on Special-Status Fish Species The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat under CP2 could affect one species designated as sensitive by USFS, the hardhead. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP2): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP2, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,084-foot contour, the maximum inundation level under this alternative. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. However, based on digital topographic data and stream channel data generated from field inventories, there do not appear to be any substantial barriers between the 1,070-foot and 1,084-foot contours that would be inundated under this alternative. This impact would be less than significant.

This impact would be similar to Impact Aqua-6 (CP1). However, the maximum inundation level would be higher under CP2. Most of the tributaries are too steep (i.e., greater than 7 percent) up to the 1,084-foot contour to be passable by fish; the tributaries that are low-gradient up to the 1,084-foot contour, and thus allow fish passage remain low-gradient well upstream from this contour. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP2): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake CP2 would result in additional periodic inundation of potential spawning and rearing habitat for adfluvial salmonids in low-gradient tributaries. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. A total of 7.4 miles of low-gradient reaches that could provide some spawning and rearing habitat for adfluvial salmonids would be affected by CP2,

which is only about 1.8 percent of the low-gradient habitat upstream from Shasta Lake. This impact would be less than significant.

As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils," CP2 would inundate perennial reaches with gradients of less than 7 percent that could provide potentially suitable spawning and rearing habitat for adfluvial salmonids. The lengths of low-gradient tributaries to each arm of Shasta Lake that would be periodically inundated are as follows:

- Sacramento River Arm 3.1 miles
- McCloud River Arm 1.4 miles
- Pit River Arm 1.4 miles
- Big Backbone Creek Arm 0.6 miles
- Squaw Creek 0.9 miles

This impact would be similar to Aqua-7 (CP1). However, it would periodically inundate a larger amount of habitat in low-gradient reaches to Shasta Lake, but the total amount inundated would be only 1.8 percent of the low-gradient habitat upstream from the lake. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-8 (CP2): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP2 would result in periodic inundation of the lower reaches of high-gradient, non-fish-bearing tributaries to Shasta Lake. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. Only 17.3 miles of non-fish-bearing tributary habitat would be affected by CP2, which is only about 0.7 percent of this habitat upstream from Shasta Lake. This impact would be less than significant.

As described in Chapter 4, CP2 would inundate tributary segments with channel slopes in excess of 7 percent. Although these segments do not typically support salmonid populations, they do provide riparian and aquatic habitat for a variety of organisms and serve as corridors that connect habitat types. The lengths of non-fish-bearing tributaries for each arm of Shasta Lake that would be periodically inundated are as follows:

- Sacramento River Arm 3.9 miles
- McCloud River Arm 2.8 miles
- Pit River Arm 2.5 miles
- Big Backbone Creek Arm 1.8 miles
- Squaw Creek Arm 1.3 miles
- Main Body 5.0 miles

This impact would be similar to Aqua-8 (CP1). However, it would periodically inundate a larger amount of habitat in low-gradient reaches to Shasta Lake, but the total amount inundated would be only 0.7 percent of the low-gradient habitat upstream from the lake. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP2): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP2. There would be no impact.

This impact is the same as Impact Aqua-9 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to RBDD)

Impact Aqua-10 (CP2): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Construction-related increases in sediments and turbidity would adversely affect aquatic habitats and fish populations within the upper Sacramento River immediately downstream from project construction activities. This impact would be less than significant.

This impact would be similar to Impact Aqua-10 (CP1). The impact could be greater because of the increased activity associated with a 12.5-foot raise compared to a 6.5-foot raise. However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-11 (CP2): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Construction-related activities could result in the release and exposure of contaminants, resulting in adverse effects on aquatic habitats, the aquatic food web, and fish populations, including special-status species, within the primary study area downstream from project construction activities. However, environmental commitments would be in place to reduce the impacts to less than significant.

This impact would be similar to Impact Aqua-11 (CP1). The impact could be greater because of the increased activity associated with a 12.5-foot raise compared to a 6.5-foot raise. The potential release of hazardous materials into Shasta Lake or the Sacramento River could result in the reduction of aquatic habitats and fish populations if proper procedures are not implemented to contain the discharge. However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-12 (CP2): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon Project operation would result in improved flow and water temperature conditions in

the upper Sacramento River for fish species of management concern. This impact would be beneficial.

Winter-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, the overall average winter-run production for the 82-year period was similar for CP2 relative to the No-Action Alternative and the Existing Condition (Attachments 1A and 2A). The maximum increase in production relative to the No-Action Alternative was 44 percent for CP2, while the largest decrease in production relative to the No-Action Alternative was 29 percent under CP2 (Attachment 1A). The maximum increase in production relative to the Existing Condition was 34 percent for CP2, while the largest decrease in production relative to the Existing Condition was 4 percent under CP2 (Attachment 2A).

With one exception (1977 at -32 percent), years with the lowest production over the simulation period showed the largest increase in production under CP2 conditions.

Under CP2, critical water years 1924, 1931, and 1934 had substantial increases in production relative to the No-Action Alternative for winter-run Chinook salmon, ranging from 8 percent to 65 percent. Dry water year 1944 had a substantial increase (7 percent) compared to the No-Action Alternative. Critical water year 1977 had a decrease in production of around 32 percent, and dry water year 1932 had a decrease in production of 7 percent.

Under CP2, critical water years 1924, 1933, and 1977 had increases in production relative to the Existing Condition for winter-run Chinook salmon, ranging from 5 percent to 23 percent. Only one below-normal water year, 1936, had a substantial increase (5 percent) compared to the Existing Condition. No years had decreases in production greater than 5 percent.

When the spawning population was set at AFRP goal, the overall average winter-run Chinook salmon production was similar for CP2 relative to the No-Action Alternative (Attachment 3A). The maximum increase in production relative to the No-Action Alternative was 28 percent for CP2. The largest decrease in production relative to the No-Action Alternative was 20 percent for CP2. All years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP2, with one exception, 1977, a 20-percent decrease.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to winter-run Chinook salmon under CP2 occurred to the egg incubation life stage, followed by fry, and lastly to presmolts and immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-4 displays the overall mortalities for each

Comprehensive Plan that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 2B and 3B). Mortalities caused by the project decrease as the proposed dam height increases from 6.5 to 18.5 feet.

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, fry were the primary life stage affected, but operations-related activities had a greater effect on eggs than on presmolts and no effect on immature smolts. The same trends for each alternative were observed, with the bulk of the mortality affecting the fry and egg incubation life stages, and both water temperature and flow causing mortality (Table 11-5).

In critical water years, mortality to eggs due to unsuitable water temperatures was the primary cause of operations-related mortalities for CP2, followed by mortality to fry (more by flow and density than water temperature), then to eggs from redd superimposition, followed by presmolts (affected first by temperature then flow), and then immature smolts (affected by flow). Attachments 2C and 3C contain tables of mortality to winter-run sorted by water-year type, and Table 11-6 outlines the rankings classified under each Comprehensive Plan for each water-year type.

In dry water years, mortality to fry when moving to new habitats was the primary cause of operations-related mortalities for all Comprehensive Plans, followed by mortality to eggs due to redd superimposition. Third was mortality to eggs due to unsuitable water temperatures, followed by mortality to presmolts while moving to new habitats.

Below-normal, above-normal, and wet water years also had the greatest number of winter-run perish as fry caused by forced movement to habitat downstream, followed by mortality to eggs due to redd superimposition, then the loss of eggs from unsuitable water temperatures, and forced movement of presmolts to downstream habitats.

Years with the highest mortality were the same for the No-Action Alternative and the Existing Condition and CP2, and were 1924, 1931, 1933, 1934, 1977, and 1992. Each of these years was a critical water year, and was preceded by either a critical (1933, 1976, 1991), dry (1930, 1932) or below-normal (1923) water-year type. Years with the lowest mortality varied between all water-year types. Years in which the project has the greatest effect on winter-run were also years in which the lowest production occurred (Attachments 2C and 3C).

When the spawning population was set at the AFRP goal, winter-run Chinook salmon mortality caused by operations-related activities decreased under CP2 compared to No-Action Alternative conditions. Under CP2, mortality caused by operations-related activities would decrease from non-operations related mortality by over 10 percent. Under CP2, the greatest mortality to winter-run

occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because winter-run Chinook salmon have, overall, a reduced mortality, winter-run Chinook salmon would benefit from actions taken in CP2. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, similar to CP1, overall average spring-run Chinook salmon production for CP2 remained relatively close to the No-Action Alternative and the Existing Condition (Attachments 4A and 5A). The maximum increase in production relative to the No-Action Alternative was 37 percent for CP2. The largest decrease in production relative to the No-Action Alternative was 21 percent under CP2 (Attachment 4A). The maximum increase in production relative to the Existing Condition was 49 percent for CP2 in 1932. The largest decrease in production relative to the Existing Condition was 49 percent under CP2 in 1977 (Attachment 5A).

Under CP2, critical water years 1924, 1931, 1977, 1992, and 1994 had increases in production relative to the No-Action Alternative, ranging from 13 to 37 percent. Dry water years 1925 and 1932, and below-normal water year 1959, had increases in production ranging from 6 percent to 10 percent. Critical water year 1934 had a decrease in production of 21 percent.

Under CP2, six critical water years (1924, 1933 1934, 1992, 1994, 2001) had substantial increases in production relative to the Existing Condition, ranging from 6 percent to 19 percent. Two dry water years, 1932 and 2002, had increases ranging from 6 percent to 70 percent compared to the Existing Condition. One below-normal water year (1959) had a 7 percent increase in production relative to the No-Action Alternative. Two critical water years (1977 and 1988) and one dry water year (1926) resulted in decreases in production relative to the Existing Condition (6 percent to 49 percent).

When the spawning population equaled the AFRP goal, overall average spring-run Chinook salmon production was similar for CP2 relative to the No-Action Alternative (Attachment 6A). The maximum increase in production relative to the No-Action Alternative was 100 percent for CP2. The largest decrease in production relative to the No-Action Alternative was 32 percent for CP2. Years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP2, with one exception, 1934, a 33-percent decrease.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to spring-run Chinook salmon under CP2 occurred to eggs, followed by presmolts,

then fry. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-7 displays the overall mortalities for each Comprehensive Plan that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 4B and 5B). Mortalities caused by CP2 decrease as the proposed dam height increases from 6.5 to 18.5 feet (Tables 11-7 and 11-8). When removing nonoperations-related mortality, leaving mortality due to operations-related activities, only eggs and fry were affected (Table 11-8).

Similar to the No-Action Alternative, critical water years had mortality to eggs due to unsuitable water temperatures as the primary cause of operations-related mortalities, followed by mortality to eggs both prespawned and during incubation caused by dewatering the redds, then to fry from forced movement to downstream habitats. Attachments 4C and 5C contains tables of mortality to spring-run Chinook salmon sorted by water-year type. Table 11-11 outlines the rankings classified under each Comprehensive Plan for each water-year type based.

In dry, below-normal and above-normal water years, CP2 was dominated by egg temperature mortality, followed by mortality resulting from redd dewatering. Mortality to prespawned eggs occurred in only two dry years but no below-normal water years. Mortality to fry from forced movement was relatively low in only several more years (Table 11-9).

In wet water years, spring-run eggs under conditions created by CP2 were more affected by redd dewatering than by unsuitable water temperatures (Table 11-9).

Years with the highest operations-related mortality were the same for all the Comprehensive Plans and were 1924, 1931, 1932, 1933, 1934, 1977, and 1992. Except for 1932 (a dry water year), each of these years was a critical water-year type and was preceded by either a below, dry, or (predominantly) a critical water year. However, years with the lowest mortality varied between all water-year types. Years in which the project had the greatest impact on spring-run Chinook salmon were also years in which the lowest production occurred, with nearly all of the mortality occurring in the egg incubation life stage (Attachments 4C and 5C).

When the spawning population was equal to the AFRP goal, spring-run Chinook salmon mortality caused by the operations-related activities decreased under CP2 compared to No-Action Alternative conditions (Attachment 6B). Under CP2, mortality caused by operations-related activities would decrease from non-operations related mortality by over 34 percent. Under CP2, the greatest mortality to spring-run occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because spring-run Chinook salmon have, overall, a reduced mortality, spring-run Chinook salmon would benefit from actions taken in CP2. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average fall-run Chinook salmon production for the simulation period was similar for CP2 relative to the No-Action Alternative and the Existing Condition (Attachments 7A and 8A). The maximum increase in production relative to the No-Action Alternative was 83 percent for CP2. The largest decrease in production relative to the No-Action Alternative was 8 percent under CP2 (Attachment 7A). The maximum increase in production relative to the Existing Condition was 44 percent for CP2. The largest decrease in production relative to the Existing Condition was 34 percent under CP2 (Attachment 8A).

In critical, dry, and below-normal water years, when production was lowest over the simulation period, the increase in production resulting from operations-related activities was greatest. In above-normal and wet water years, however, the lowest production years typically had a slight decrease in production under CP2 conditions relative to the No-Action Alternative.

Under CP2, critical water years 1931, 1934, and 1977 had increases in production relative to the No-Action Alternative, ranging from 8 to 83 percent. Four dry water years (1926, 1932, 1955, and 1964) had between 5 and 12 percent increases in production compared to the No-Action Alternative. Production increased by 9 percent to 47 percent in below-normal water years 1937 and 1945 relative to the No-Action Alternative. Below-normal water year 1979 and wet water year 1999 resulted in a decreased production relative to the No-Action Alternative of between 6 and 8 percent.

Under CP2, critical water year 1924 and dry water years 1926, 1939, and 1964 had increases in production relative to the Existing Condition of between 6 and 44. Three below-normal water years (1937, 1945 and 1950) had an increase in production relative to the Existing Condition of 6 percent to 30 percent. One critical (1977), one below-normal (1979), one above-normal (1957) and five wet (1969 and 1999) water years resulted in decreased production relative to the Existing Condition of between 5 and 34 percent.

When the spawning population was equal to the AFRP goal, overall average fall-run Chinook salmon production was similar for CP2 relative to the No-Action Alternative (Attachment 9A). The maximum increase in production relative to the No-Action Alternative was 81 percent for CP2. The largest decrease in production relative to the No-Action Alternative was 6 percent for CP2. In critical, dry, and below-normal water years, years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP2. In above-normal and wet water years,

however, the lowest production years typically had a slight decrease in production under CP2 conditions relative to the No-Action Alternative. In above-normal and wet water years, however, the lowest production years typically remained similar or had a slight decrease in production under CP1 conditions relative to the No-Action Alternative.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to fall-run Chinook salmon under CP2 occurs to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages. Table 11-8 displays the overall mortalities for each alternative that were caused by nonoperational factors versus those caused by the operations (i.e., water temperature and flow) (Attachments 7B and 8B). Mortalities caused by operations-related activities were lower for CP2 than for the No-Action Alternative (Tables 11-10 and 11-11).

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, egg incubation was still the primary life stage affected, but operations-related activities had a greater effect on fry than on presmolts and an even lesser effect on immature smolts. The same trends for each Comprehensive Plan were observed, with the bulk of the mortality affecting the egg incubation life stage, with flow triggering more of the mortality (Table 11-11).

In all water-year types the greatest portion of mortality occurred to fry caused by forced movement to downstream habitats. Prespawn, incubation, and superimposition mortality were greater than mortality to eggs caused by unsuitable water temperatures and presmolt habitat movement.

In critical water years, CP2 show the same general trend in mortality factors as the No-Action Alternative and Existing Condition, except CP2 had greater mortality during the prespawn phase, than to fry caused by forced movement. Least affected were presmolts and then immature smolts by both water temperatures and forced movement. Attachments 7C and 8C contain tables of mortality to fall-run sorted by water-year type, and Table 11-12 outlines the rankings classified under each Comprehensive Plan for each water-year type.

As with critical water years, dry water years were dominated by mortality to fry due to forced movement downstream, followed by redd dewatering or scouring and redd superimposition. There was additional mortality to fall-run Chinook salmon presmolts and immature smolts from both forced movement and unsuitable water temperatures (Table 11-12).

Below-normal and above-normal water years were relatively similar for CP2 compared with the No-Action Alternative and the Existing Condition. The mortality factors were dominated by mortality to fry due to forced movement

downstream, followed by redd superimposition, dewatering or scouring. Mortality to presmolts caused by forced downstream movement was a greater factor affecting fall-run populations than was egg mortality caused by unsuitable water temperatures or mortality to immature smolts and fry due to unsuitable water temperatures (Table 11-12).

As with the water-year types discussed above, under wet water year conditions, the majority of the mortality also occurred to fry due to forced downstream movement, followed by redd superimposition, and redd dewatering or scouring, mortality to presmolts and immature smolts from downstream movement were the lowest mortality rates resulting from operations-related activities. Least affected were eggs due to unsuitable water temperatures, both prespawn and postspawn.

Years with the highest mortality were the same for CP2 as for the No-Action Alternative and CP1: 1934, 1935, 1970, 1978, and 1993. With the exception of 1970, each of these years was preceded by a critical water year. Overall, years with the lowest mortality tended to be dry or critical water years.

Years with the highest mortality were the same for CP2 as for the Existing Condition and CP1: 1957, 1982, 1985, 1994, and 1997. Overall, years with the lowest mortality tended to be dry water years.

When the spawning population was set at the AFRP goal, fall-run Chinook salmon mortality caused by the operations-related activities decreased under CP2 compared to No-Action Alternative conditions (Attachment 9B). Under CP2, mortality caused by operations-related activities would decrease from non-operations related mortality by 14 percent. Under CP2, the greatest mortality to fall-run Chinook salmon occurred to the egg incubation life stage, followed by fry, then presmolts, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because fall-run Chinook salmon have, overall, a reduced mortality, fall-run Chinook salmon would benefit from actions taken in CP2. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average late fall-run Chinook salmon production for the 82-year period was similar for CP2 relative to the No-Action Alternative and the Existing Condition (Attachments 10A and 11A). The maximum increase in production relative to the No-Action Alternative was 8 percent for CP2. The largest decrease in production relative to the No-Action Alternative was 6 percent under CP2 (Attachment 10A). The maximum increase in production relative to the Existing Condition was 14 percent for CP2 in 1985. The largest decrease in production relative to the Existing Condition was 5 percent under CP2 (Attachment 11A).

Under CP2, production increased for critical water year 1976, dry water years 1926 and 1985, and below-normal water year 1923 by 6 to 7 percent relative to the No-Action Alternative. One dry (1944) had decreased production of 6 percent compared to the No-Action Alternative.

Under CP2, two dry water years (1926 and 1985), and one wet water year (1975) had increases (ranging from 5 to 14 percent) compared to the Existing Condition. No year had decreases greater than 5 percent compared to the Existing Condition.

When the spawning population equaled the AFRP goal, overall average late fall-run Chinook salmon production was similar for CP2 relative to the No-Action Alternative (Attachment 12A). The maximum increase in production relative to the No-Action Alternative was 12 percent for CP2. The largest decrease in production relative to the No-Action Alternative was 7 percent for CP2. Production remained relatively similar regardless of water-year type.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to late fall-run Chinook salmon under CP2 occurred to the egg incubation life stage, followed by fry, then presmolts, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under CP2. Table 11-13 displays overall mortalities for each Comprehensive Plan that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 10B and 11B). Mortalities caused by the project decreased for all Comprehensive Plans relative to the No-Action Alternative.

When removing nonoperations-related mortality, allowing the comparison of mortality for operations-related activities only, fry became the primary life stage affected, and operations-related activities had a greater effect on eggs than on presmolts, and an even lesser effect on immature smolts. Most of the mortality occurred as a result of flow conditions rather than water temperature (Table 11-14).

Mortality to fry resulting from unsuitable water temperatures only occurred at low levels to late fall-run during critical, dry, and below-normal water years. In all water-year types, under CP2, mortality to fry during forced movement to downstream habitats was the primary cause of operations-related mortality.

In critical, dry, and below-normal water years, the causes of operations-related mortality follow similar trends for all Comprehensive Plans with a few exceptions. In general, the effects of flow (and density) had the greatest effect on mortality. Forced movement of fry resulted in the greatest mortality, followed by flow effects on eggs via scouring, dewatering, or superimposition. Next affected were presmolts and immature smolts by unsuitable water

temperatures, and lastly temperature effects on eggs and flow effects on presmolts and immature smolts and fry (Table 11-15).

Wet and above-normal water years were overall similar to critical, dry, and below-normal water years except that mortality to fry due to unsuitable water temperatures disappeared.

Years with the highest mortality were the same as for the No-Action Alternative, Existing Condition, and CP1. All water-year types were covered. Three years were preceded by a wet water year, one preceded by an above-normal water year, and at least one below-normal water year (Attachments 10C and 11C).

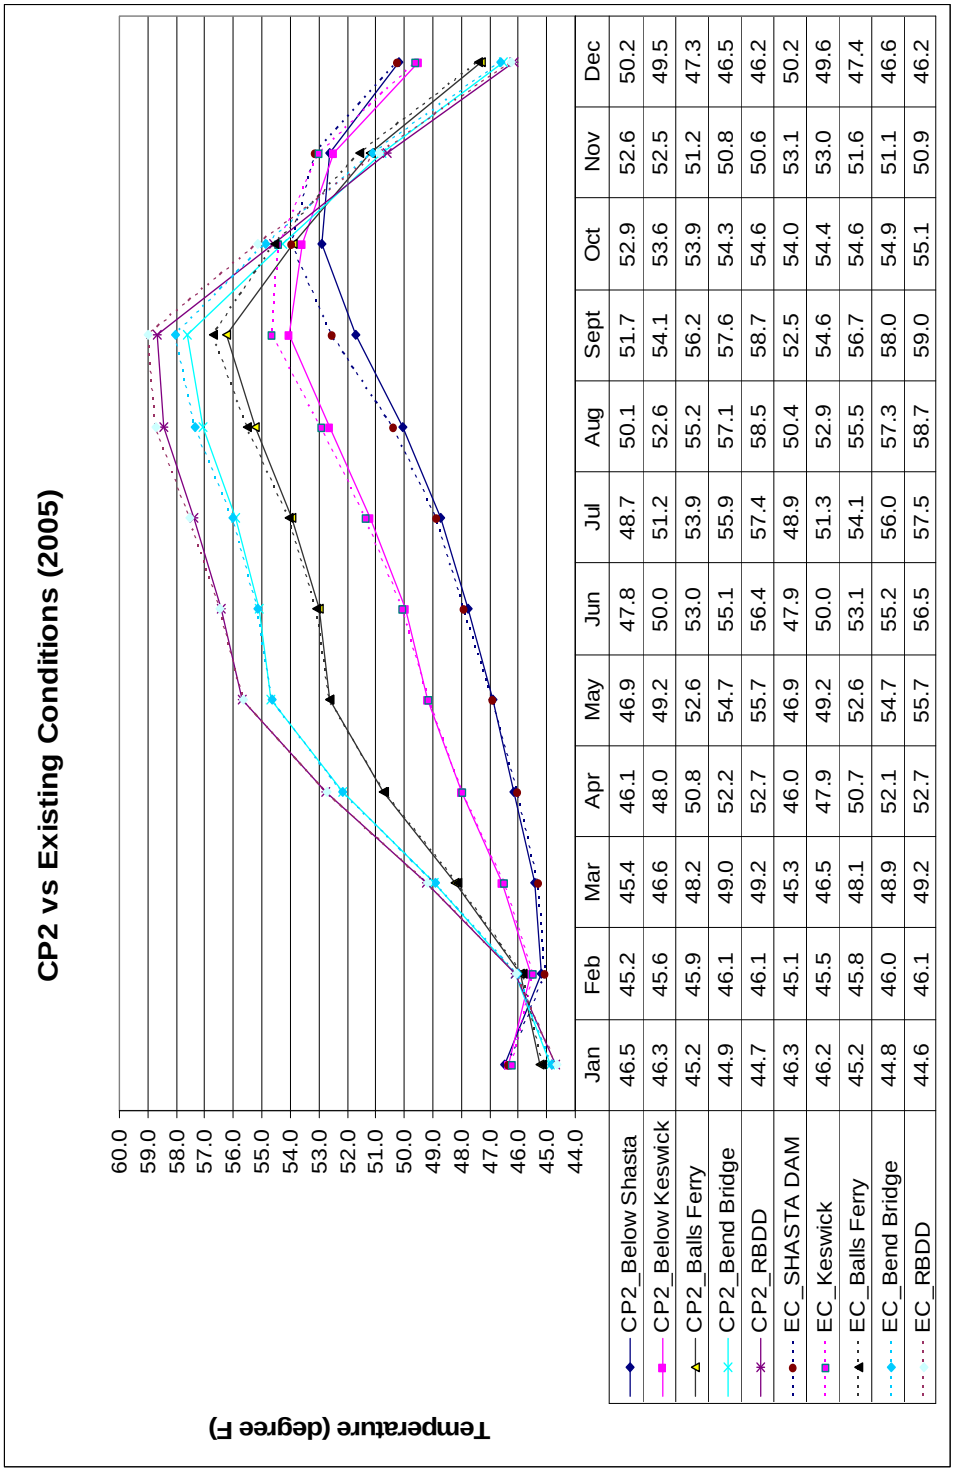
When the spawning population was equal to the AFRP goal, late fall-run Chinook salmon mortality caused by the operations-related activities was slightly less under CP2 than under No-Action Alternative conditions. Under CP2, mortality caused by operations-related activities would decrease from non-operations related mortality by 29 percent. Under CP2, the greatest mortality to late fall-run occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives (Attachment 12B).

Because late fall-run Chinook salmon have, overall, a reduced mortality, late fall-run Chinook salmon would benefit from actions taken in CP2. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-13 (CP2): Changes in Flow and Water Temperatures in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass Project operation would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be less than significant.

This impact would be similar to Impact Aqua-13 (CP1). The impact could be greater because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and flows) to be stored behind the raised dam.

Flow-Related Effects Similar to CP1, monthly mean flows at all model locations (i.e., below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBDD) within the upper Sacramento River under CP2 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). Potential flow-related effects on fish species of management

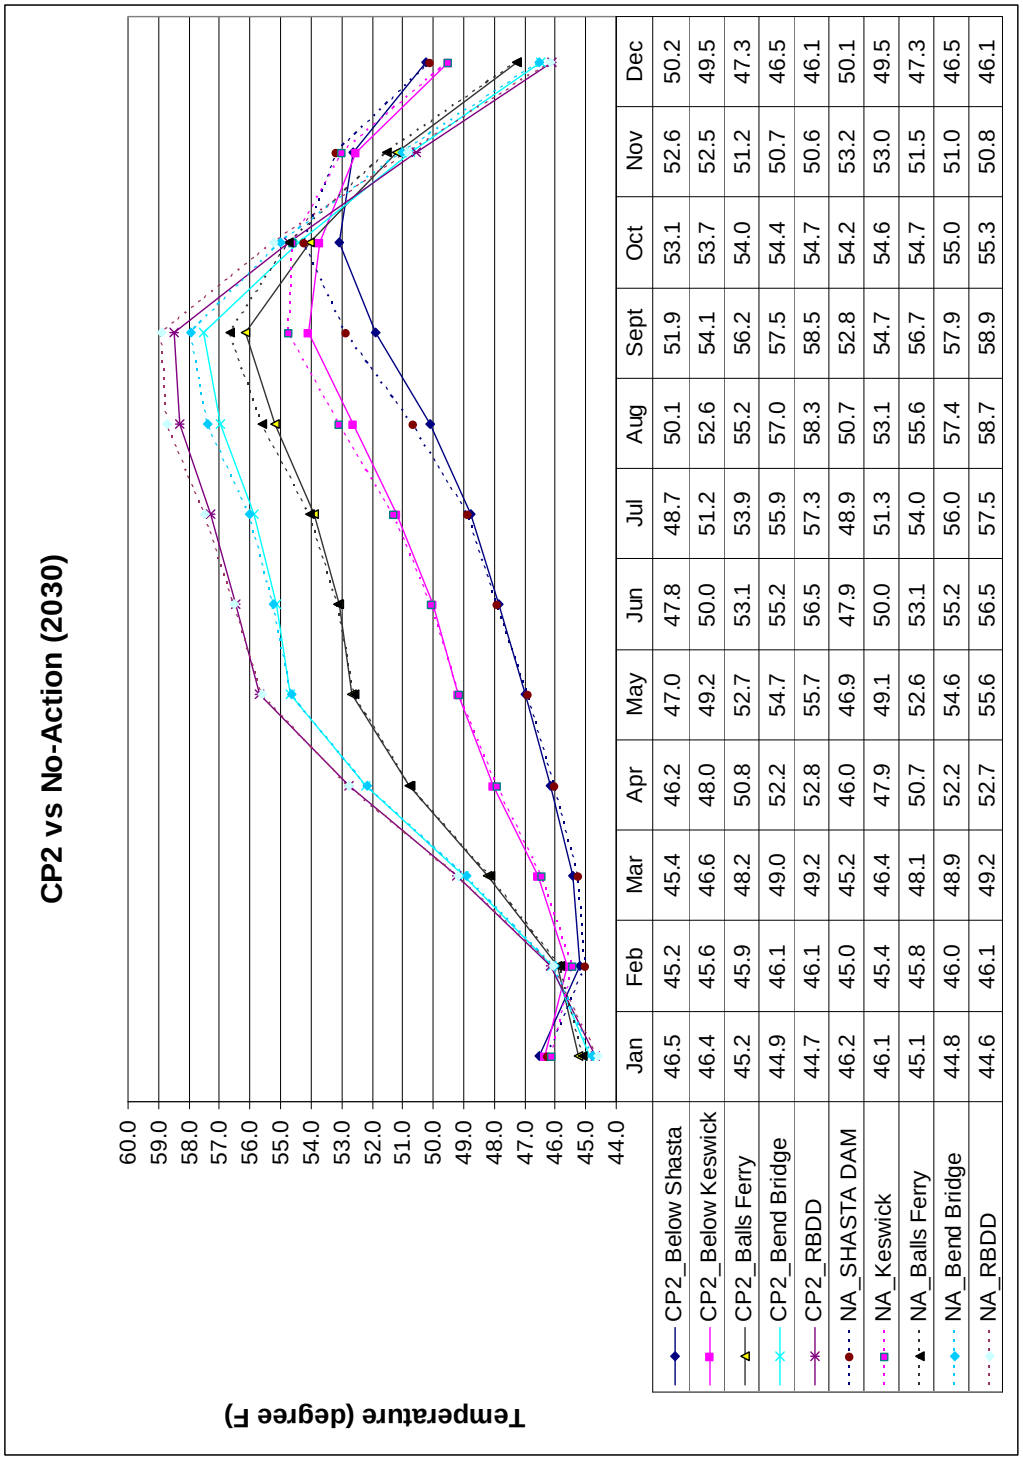


concern in the upper Sacramento River from this alternative would be minimal. All potential changes in flows and stages would diminish rapidly downstream from RBDD because of the increasing effect of inflows from tributaries and of diversions and flood bypasses.

There would be no discernable flow-related effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River related to changes in monthly mean flows under CP2, relative to the Existing Condition and No-Action Alternative. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow-related impacts on these fish species would be less than significant.

Water Temperature-Related Effects Similar to CP1, monthly mean water temperatures at all model locations (i.e., below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBDD) within the upper Sacramento River under CP2 would be the same or fractionally less than those under the Existing Condition and No-Action Alternative simulated for all months (Figures 11-16 and 11-17) (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). As discussed above, the modeling simulations may not fully account for real-time management of the cold-water pool and TCD (through the SRTTG) to achieve maximum cold-water benefits. Therefore, the modeled changes in water temperature (i.e., small benefits) are likely conservative and understated to some varying degree. Nevertheless, potential water temperature-related effects on fish species of management concern in the upper Sacramento River from CP2 would be minimal. During most years, releases from Shasta Lake would be unchanged.

Overall, the greatest cooling effect (less than 1°F) would occur during critical years and during the late summer (i.e., July through September), because of the increased cold-water pool volume within Shasta Lake, even following an extended dry period. All potential changes in flows and stages would diminish downstream from RBDD because of increasing effect of inflows from tributaries and of diversions and flood bypasses.



There would be very small water temperature-related effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River related to slightly cooler monthly mean water temperatures under CP2, relative to the Existing Condition and the No-Action Alternative. Mean monthly water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River. Therefore, water temperature-related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-17. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area (No-Action Alternative)

Impact Aqua-14 (CP2): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows CP2 operations could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

This impact would be similar to Impact Aqua-14 (CP1). The impact could be greater because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow for additional water volume (and flows) to be stored behind the raised dam. Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and associated stage elevation of water surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flow, with relatively large floods providing the energy required to mobilize sediment from the river bed, produce meander migration, increase stage elevation, and create seasonally inundated floodplains. CP2 operations could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains.

CP2 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from the operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains.

These impacts would likely occur along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. These impacts would be potentially significant within the primary study area. Mitigation for this impact is proposed in Section 11.3.4.

Lower Sacramento River and Delta

Impact Aqua-15 (CP2): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern Project operation would result in no discernable change in mean monthly flow or water temperature conditions in the lower Sacramento River; however, predicted

changes in flow in the Feather River, American River, and Trinity River could result in an adverse effect on Chinook salmon, steelhead, coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass if they were to occur. This impact would be potentially significant.

This impact would be similar to Impact Aqua-15 (CP1). The impact could be greater because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and increased cold-water pool) to be stored behind the raised dam.

Similar to CP1, monthly mean flows at model locations (i.e., Verona, Freeport) within the lower Sacramento River under CP2 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative conditions simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). All potential changes in flows diminish rapidly downstream from RBDD because of the increasing effect of inflows from tributaries and of diversions and flood bypasses. Potential flow-related effects on fish species of management concern in the lower Sacramento River from this alternative would be minimal. Differences in mean monthly flow are generally small (less than 2 percent) and within the existing range of variability. All potential changes in water temperatures in the lower Sacramento River due to small changes in releases would diminish rapidly downstream because of increasing effect of inflows, atmospheric influences, and groundwater. Therefore, flow- and temperature-related impacts on fish species in the lower Sacramento River would be less than significant.

Also similar to CP1, monthly mean flows at all model locations within the lower Feather River, the American River, and Trinity River under CP2 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative simulated for most months; however, there are several months within the modeling record that show substantial changes (based on model simulations) to flows in tributaries (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete CalSim-II modeling results). All potential changes in flows could be diminished in these areas per existing operational rules and because of operation of upstream reservoirs (i.e., Lake Oroville, Folsom Lake, and Trinity Lake) and increasing effects of inflows from tributaries and of diversions and flood bypasses. Nevertheless, based on predicted changes in flow and associated flow-habitat relationships, potential flow-related impacts on species of management concern in the American, Feather, and Trinity rivers could occur and would be a potentially significant impact.

All potential changes in water temperatures in the lower Sacramento River and primary tributaries (i.e., Feather River and American River) due to altered releases from reservoirs diminished downstream because of the increasing effect of inflows, and atmospheric and groundwater influences.

As under CP1, effects of altered flow regimes resulting from implementation of CP2 are unlikely to extend into the lower Sacramento River and Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the SWP and the CVP). The guidelines for this management, which are described in the CVP/SWP OCAP, have been designed to maintain standards for flow to the lower Sacramento River and Delta. CVP and SWP operations must be consistent with the OCAP to allow coverage by the OCAP permits and BOs. Thus, under CP2, this project is not anticipated to cause an alteration in flow to the Delta nor cause an alteration to water temperatures in the lower Sacramento River and primary tributaries within the extended study area sufficient to cause discernable effects on Chinook salmon, steelhead, green sturgeon, Sacramento splittail, American shad or striped bass relative to the Existing Condition and No-Action Alternative. Functional flows for fish migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow- and temperature-related effects on these fish species would be less than significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-16 (CP2): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows CP2 operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the lower Sacramento River and lowermost (confluence) areas of tributaries) would be a potentially significant impact.

This impact would be similar to Impact Aqua-16 (CP1). The impact could be greater because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow for additional water volume (and flows) to be stored behind the raised dam. Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and associated stage elevation of water surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flow, with relatively large floods providing the energy required to mobilize sediment from the bed, produce meander migration, increase stage elevation, create seasonally inundated floodplains, and inundate floodplain bypasses. Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

CP2 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These impacts would likely occur along the upper reaches of the lower Sacramento River. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. These impacts would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-17 (CP2): Effects to Delta Fishery Habitat Resulting from Changes to Delta Outflow Based on results of hydrologic modeling comparing Delta outflow under the No-Action Alternative, Existing Condition, and CP2, CP2 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta.

Results of the comparison of Delta outflows between CP2 and the Existing Condition and No-Action Alternative are summarized by month and water-year type in Table 11-23. The comparison includes the estimated average monthly outflow under the basis-of-comparison conditions, the average monthly flow under CP2, and the percentage change between base flows and CP2 operations. Results of the analysis (Table 11-23) showed that Delta outflows were observed to be slightly lower under many of the CP2 operations as well as slightly higher than basis-of-comparison conditions, depending on month and water-year type. However, none of the changes were larger than 5 percent. Based on the results of this comparison of CP2, it was concluded that CP2 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta relative to the No-Action Alternative and Existing Condition. Based on results of this analysis, it was concluded that CP2 would result in a less than significant effect on fish habitat as a consequence of changes in Delta outflow relative to the Existing Condition. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-18 (CP2): Effects to Delta Fishery Habitat Resulting from Changes to Delta Inflow Changes in upstream reservoir storage have the potential to affect Delta inflow. Delta inflow may affect hydrologic conditions within Delta channels, hydraulic residence times, salinity gradients, and the transport and movement of various life stages of fish, invertebrates, phytoplankton, and nutrients into and through the Delta. Delta inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources. Based on the results of hydrologic modeling comparing Delta inflow under CP2 to the Existing Condition and No-Action Alternative, CP2 would have a less than significant impact on Delta fisheries and hydrologic transport processed within the Bay-Delta.

Results of the comparison of Delta inflows between the No-Action Alternative, Existing Condition, and CP2 are summarized by month and water-year type in Table 11-24. The comparison includes the estimated average monthly inflow under the basis-of-comparison conditions, the average monthly flow under CP2, and the percentage change between base flows and CP2 operations. Delta inflows were observed to be slightly lower under many of the CP2 operations and slightly higher than basis-of-comparison conditions, depending on month and water-year type. None of the comparisons between the basis-of-comparison conditions and CP2 exceeded 5 percent. Based on the results of this comparison of CP2, it was concluded that CP2 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta as a consequence of changes in Delta inflow. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP2): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow CP2 operation would result in a variable response in Sacramento River flow, resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water-year type. This impact would be less than significant.

Results of hydrologic modeling, by month and water-year type, comparing Sacramento River flow under CP2 relative to the Existing Condition and No-Action Alternative are presented in Table 11-25. Results of these analyses show a variable response in Sacramento River flow with CP2 operations resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water-year types. All comparisons between the basis-of-comparison and CP2 operations were less than 5 percent. Based on these results it was concluded that the impact of CP2 on fish habitat and transport mechanisms within the lower Sacramento River and Delta would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP2): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis Project operation would result in no discernable change in San Joaquin River flows at Vernalis, and therefore no impact to Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta would occur under CP2 relative to the No-Action Alternative or Existing Condition.

Results of the comparative analysis of model results, by month and water-year type, for basis-of-comparison conditions and CP2 for San Joaquin River flow under existing conditions are summarized in Table 11-26. Results of these analyses show that the proposed CP2 would have no effect on seasonal flows compared with Existing Conditions within the San Joaquin River. Similarly, modeling results showed that CP2 would have no effects on flows or fish habitat compared to the No-Action Alternative. Based on these results it was concluded that CP2 would have no impact on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP2): Reduction in Low Salinity Habitat Conditions Resulting from an Upstream Shift in X2 *Location* CP2 operation would result in less than 0.5 km movement upstream or downstream from the X2 location. This impact would be less than significant.

The 1 km X2 criterion was applied to a comparison of CalSim-II results for the Existing Condition and No-Action Alternative and CP2, by month and water-year type, for February through May. Results of the comparison between Existing Condition and CP1 are summarized in Table 11-27. These results showed that changes in X2 location under CP2 were less than 1 km (all were less than 0.4 km) with both variable upstream and downstream movement of the X2 location, depending on month and water-year type. These results are consistent with model results for Delta outflow that showed a less than significant change in flows.

Results of a comparative analysis of changes in X2 location between the Existing Condition and No-Action Alternative and CP2 conditions are summarized in Table 11-27. Results of these comparisons showed very little difference (less than 0.1 km) in the X2 location between the No-Action Alternative and CP2. Based on these results, it was concluded that CP2 would have a less than significant impact on low salinity habitat conditions within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP2): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in the Old and Middle Rivers CP2 operation would result in an increase of reverse flows in

Old and Middle rivers. The increase in reverse flows would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses. This impact would be potentially significant.

Results of the analysis showed several occurrences when reverse flows within Old and Middle rivers were greater than basis-of-comparison conditions by more than 5 percent. These events occurred typically in dry and critical water years, which would be expected as a result of greater export operations under CP2. During February (Table 11-28), operations under CP2 resulted in an increase in reverse flow greater than 5 percent during critical years. Based on results of the delta smelt analysis of the relationship between reverse flows and delta smelt salvage, the increase from approximately 4,300 cfs under the basis-of-comparison in a critical water year to approximately 4,700 cfs would not be expected to result in a significant increase in adverse effects to delta smelt. Juvenile Chinook salmon and steelhead are migrating through the Delta during February, and an increase in average monthly reverse flows of 300 to 400 cfs would be expected to increase the potential risk of increased mortality. However given the tidal volumes and hydrodynamics of the Old and Middle river region it is not expected that the change in reverse flows in February in a critical year would result in a detectable change in fish survival. The majority of juvenile Chinook salmon emigrating from the San Joaquin River typically migrate downstream later in dry years and would not be expected to occur in high numbers within Old and Middle rivers in February.

The increase in reverse flows estimated to occur under CP2 in critical water years in June and under critical, dry, and below-normal years in July exceeded 5 percent. The increased reverse flows in June of critical water years occurred at a time of the year when water temperatures in the Delta were elevated and juvenile Chinook salmon or steelhead would not be expected to occur in the area. Juvenile delta smelt may occur in the area in June; however a change in Old and Middle rivers flow of approximately 100 to 200 cfs may result in a small increase in their vulnerability to CVP and SWP salvage, but this increase is expected to be less than significant. As water temperatures increase in the Delta during June and July, the majority of delta smelt are located further downstream in Suisun Bay where temperatures are more suitable. The increase in reverse flows estimated from the modeling in June of a critical year and in July of below-normal, dry, and critical years would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses as a result of increased reverse flows. The increased reverse flows in low-flow years would be expected to result in a low, but potentially significant, increase in mortality for resident warm-water fish inhabiting the south Delta under CP2 relative to the Existing Condition.

W = wet

Results of the comparison of Old and Middle river reverse flows are summarized in Table 11-28. Results of the analysis show that in the majority of years and months reverse flows under CP2 do not exceed basis-of-comparison conditions by more than 5 percent. CP2 exceeded basis-of-comparison conditions during February of a critical year by approximately 700 cfs. The increase in reverse flows would be expected, particularly in a critical year, to contribute to an increase in the potential for losses of adult delta smelt and other species, which is considered to be potentially significant. During June in a critical water year under CP2, the magnitude of reverse flows was reduced more than 5 percent but would be expected to contribute to a less than significant biological benefit based on both the low reverse flow under the basis-of-comparison and under CP2. An increase in reverse flow above the basis-of-comparison of approximately 300 to 600 cfs during dry years in July would be expected to contribute to an increase in the risk of losses to resident warm-water fish species. Increased reverse flows in July would not be expected to adversely affect delta or longfin smelt, juvenile Chinook salmon, or steelhead based on their seasonal migration patterns and geographic distribution. The potential increase in losses relative to the No-Action Alternative during February and July under future operating conditions is considered to be potentially significant. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

Impact Aqua-23 (CP2): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP2 operations may result in an increase in CVP and SWP exports, which is assumed to result in a direct proportional increase in the risk of fish being entrained and salvaged at the facilities. This is considered a less than significant impact to Chinook salmon, steelhead, and longfin smelt. This is considered a potentially significant impact to delta smelt, striped bass, and splittail. Future operations of the SWP and CVP export facilities would continue to be managed and regulated in accordance with incidental take limits established for each of the protected fish by USFWS, NMFS, and DFG.

Results of the entrainment loss modeling at the CVP and SWP export facilities are presented in Table 11-29 for CP2. The initial modeling was conducted using average fish densities developed from past fish salvage monitoring at the SWP and CVP export facilities. Average monthly water exports were used in the analysis based on hydrologic simulation modeling. The indices of the potential risk of entrainment for some species, such as Chinook salmon, were not estimated separately for each species (e.g., winter-run Chinook) in these initial analyses. If the proposed project is developed in the future a more detailed species-specific analysis of potential changes in fish salvage losses, in addition to an assessment of the population-level effects on each species, would be required for use as a basis for developing a biological assessment and Section 7 BOs and incidental take permits for project operations. These indices were calculated for wet, above-normal, below-normal, dry, and critical water-

year types, and for an average across all years (no water-year type specified). The total numbers of fish lost annually, by species, are presented in Attachment 13. The difference between fish losses under CP2 relative to the No-Action Alternative and the Existing Condition is represented as the entrainment index, shown in the tables, to represent the effect of project operations on each fish species at the CVP and SWP facilities.

Results of the entrainment risk calculations for delta smelt showed a change of less than 1 percent from Existing Condition in wet, above-normal, and below-normal water years and an increase in risk ranging from approximately 1 to 4 percent during dry and critical water years (Table 11-29). The greatest increase in risk (3.9 percent) was estimated for CP2 in a critical year.

The risk of increased losses of delta smelt relative to the No-Action Alternative was greatest in the dry years with a net reduction in losses under CP2 in critical water years (Table 11-29). Although the incremental change in the risk of delta smelt losses resulting from CVP and SWP export operations are small, the delta smelt population abundance is currently at such critically low levels that even a small increase in the risk of losses is considered to be potentially significant. The increase in risk is also expected to contribute to cumulative factors affecting the survival of delta smelt.

The estimated change in the risk of losses for salmon follows a similar pattern to that described for delta smelt (Table 11-29). Overall, the CP2 results in a small increase in the risk of losses compared with both the No-Action Alternative and Existing Condition. The change in risk was less than 5 percent in wet, above-normal, and below-normal water years under CP2 compared with the Existing Condition, and is considered to be less than significant. The risk index increased from 1.1 percent to 3.7 percent in dry and critical years with the greatest increase observed for CP2 (3.7 percent). The loss index for salmon compared with No-Action Alternative also showed increased risk in wet, below-normal, dry, and critical years. Given the numbers of juvenile Chinook salmon produced each year in the Central Valley the relatively small incremental increase in the risk of entrainment/salvage at the CVP and SWP export facilities is considered to be a less than significant impact but would contribute incrementally to the overall cumulative factors affecting juvenile Chinook salmon survival within the Delta and population dynamics of the stocks.

The estimated change in the risk of longfin smelt entrainment/salvage under CP2 compared with the No-Action Alternative and Existing Condition shows small positive and negative changes depending on water-year type (Table 11-27). These small changes in the risk of entrainment are considered to be less than significant.

Table 11-29. Entrainment at the CVP and SWP Facilities under Existing Conditions, No-Action Alternative, and CP2

BN = below-normal
C = critical
CP = Comprehensive Plan
D = dry
W = wet

The estimated change in the risk to steelhead of entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-29. The small positive and negative changes in risk under wet, above-normal, below-normal, and dry water years are considered to be less than significant. The increase in risk of steelhead losses in critical water years is considered to be less than significant based on the abundance of juvenile steelhead migrating through the Delta, but would contribute directly to cumulative factors affecting the survival and population dynamics of Central Valley steelhead. The predicted increase in potential entrainment risk for steelhead under critically dry water years represents an initial estimate of the change (percentage) between the proposed project operations and the existing conditions and no-project alternatives and does not allow the predicted losses to be evaluated at the population-level. As noted above, more detailed modeling and analysis of potential steelhead losses would be required as part of preparing a project-specific analysis of entrainment losses for use in the Section 7 biological assessment and BOs for future project operations and incidental take of steelhead. As part of this more detailed analysis additional actions may be identified to further reduce and avoid potential adverse effects to steelhead.

The change in risk to juvenile striped bass for entrainment/salvage at the CVP and SWP export facilities is summarized in Table 11-29. The change in risk in wet, above-normal, and below-normal water years is considered to be less than significant based on the abundance of striped bass, but would contribute to the cumulative factors affecting striped bass survival and population dynamics in the Delta. The losses of juvenile striped bass increased substantially under dry and critical year conditions, which would be expected with an increase in exports during the summer months. Compared with the Existing Condition, the risk of increased losses ranged from 3.8 percent to 7.6 percent (approximately 30,000 to 60,000 fish), which is considered to be potentially significant. The increased losses, particularly in drier water years when juvenile striped bass production is lower, would be expected to contribute to the cumulative effects of factors affecting juvenile striped bass survival in the Delta.

Results of the risk estimates for juvenile splittail losses show a pattern similar to other species (Table 11-29). The increased risk index was 1.3 percent or less in wet, above-normal, and below-normal water years, and was considered to be a less than significant effect. The loss index increased during dry and critically dry water years. Higher risk of entrainment/salvage losses in drier water years has a potentially greater effect of abundance of juvenile splittail since reproductive success and overall juvenile abundance is typically lower within the Delta in dry years. The increased risk of losses in drier years was considered to be potentially significant. The increased losses would also contribute to cumulative factors affecting survival of juvenile splittail within the Delta.

Impact Aqua-23 (CP1) is considered to be less than significant for Chinook salmon, steelhead, and longfin smelt, but potentially significant for delta smelt,

striped bass, and splittail. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

CVP/SWP Service Areas

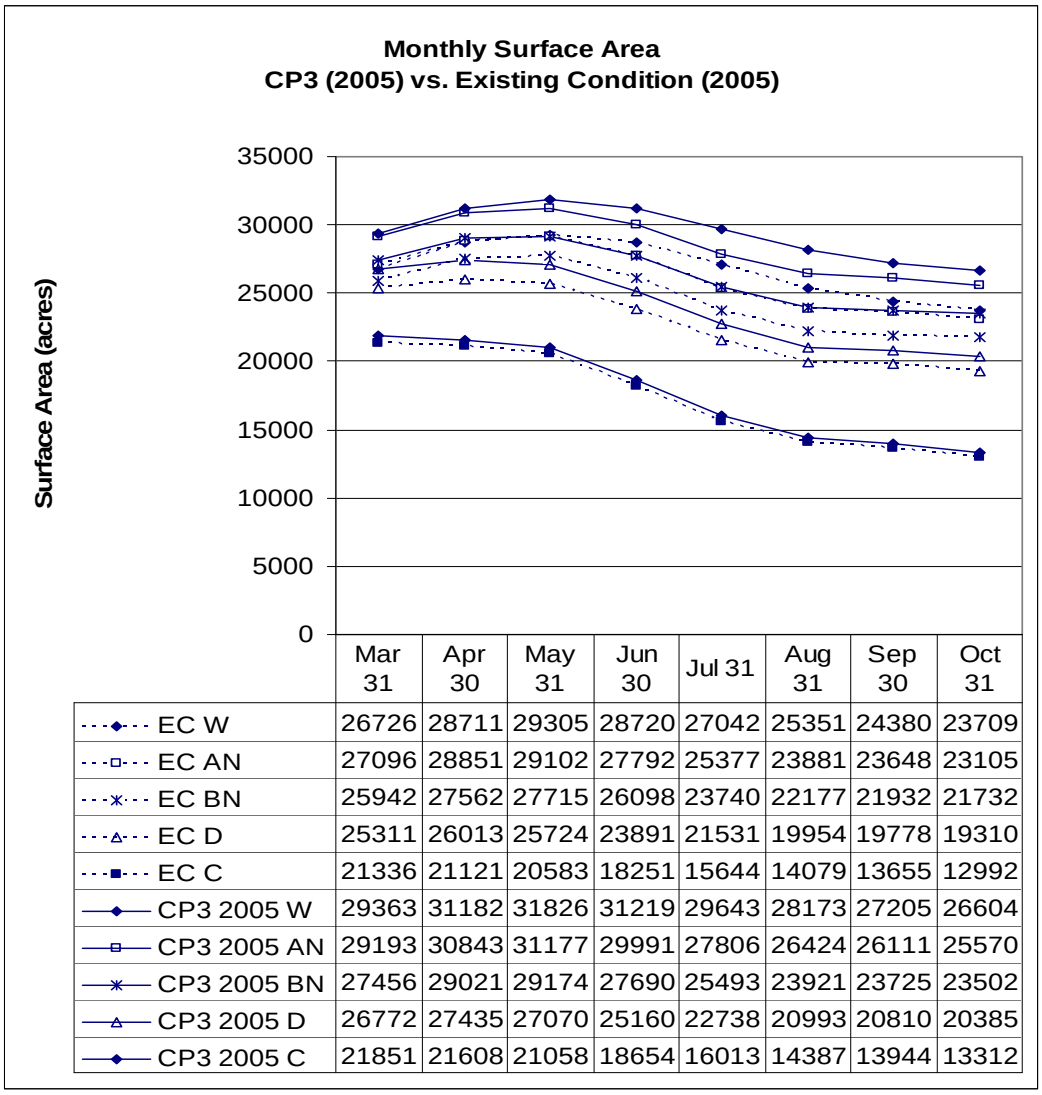
Impact Aqua-24 (CP2): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes Project implementation could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects in tributaries and reservoirs (e.g., New Melones and San Luis) with CVP and SWP dams are expected to be less than impacts on the lower Sacramento River. The change in hydrology could affect aquatic habitats that provide habitat for the fish community. These changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-24 (CP1). The impact could be greater because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow for additional water volume (and flows) to be stored behind the raised dam. However, these changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. The effects from CP2 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and the resulting flows downstream from those reservoirs would be small and well within range of variability that commonly occurs in these reservoirs and downstream. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

CP3 would be similar to CP1 and CP2. It focuses on the greatest practical enlargement of Shasta Dam and Reservoir consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increased water supply reliability and increased survival of anadromous fish. CP3 consists of raising Shasta Dam by 18.5 feet, an elevation change that would increase the full pool by 20.5 feet and enlarge the total storage space in the reservoir by 634,000 acre-feet to 5.19 million acre-feet. CP3 would help reduce future shortages by increasing the reliability of the water supply in drought and average years. The increased pool depth and volume would also contribute to improving seasonal water temperatures on the upper Sacramento River for anadromous fish.

Shasta Lake and Vicinity

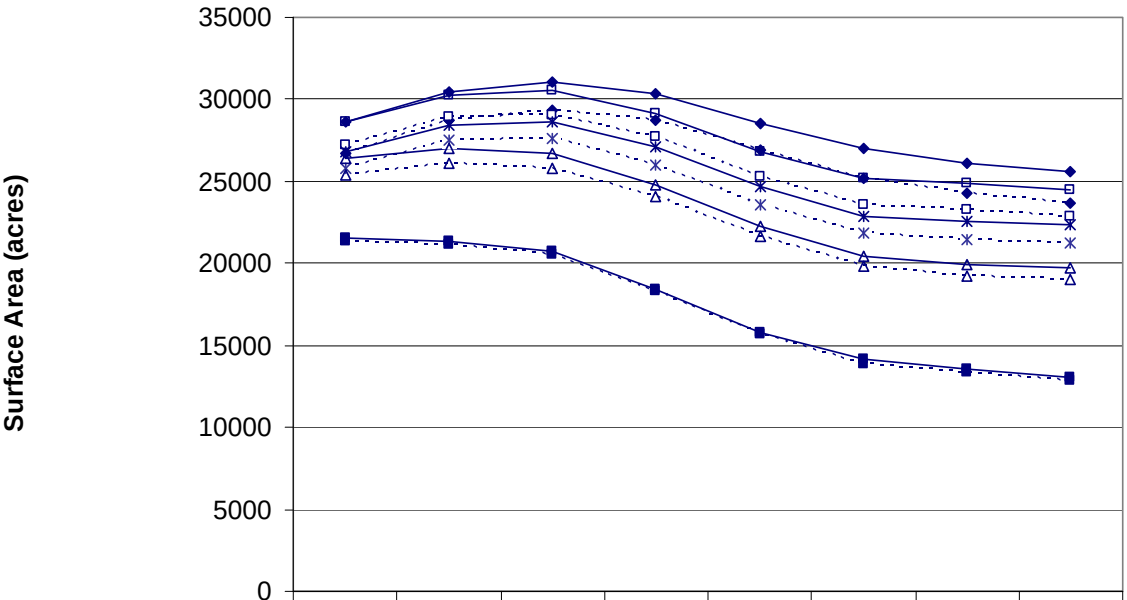


Impact Aqua-1 (CP3): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP3, project operations would contribute to an increase in the surface area and WSEL of Shasta Lake, which would in turn increase the area and productivity of nearshore, warm-water habitat. CP3 operations would also result in reduced monthly fluctuations in WSEL, which

would contribute to increased reproductive success, young-of-the-year production, and the juvenile growth rate of warm-water fish species. Similar to CP-1 the value of existing structural habitat improvements would be diminished to varying degrees, large areas of the shoreline would not be cleared, and the vegetation along these sections will be inundated periodically. In the short term, this vegetation will provide warm-water lacustrine habitat, with decay expected to occur over several decades. This impact would be less than significant.

This impact would be similar to Impacts Aqua-1 (CP1 and CP2), but the surface area would be larger under the 18.5-foot dam raise than under the 6.5-foot and 12.5-foot dam raises. CalSim-II modeling shows that the surface area of Shasta Lake would be larger under CP3 for both a 2005 and a 2030 water supply demand than under the Existing Condition or the No-Action Alternative in all five water-year types (Figures 11-18 and 11-19).

Monthly WSEL fluctuations were compared with projections for water supply demand. For CP3, with a 2005 water supply demand, 20 percent of monthly changes in projected WSELs (i.e., 5 of the 25 total projections made for the 5 months from March through July for all five water-year types) showed increased monthly WSEL fluctuations relative to the Existing Condition and 80 percent showed reduced monthly WSEL fluctuations (Figure 11-20). For CP3, with a projected 2030 water supply demand, 36 percent of monthly changes in projected WSELs showed increased WSEL fluctuations relative to the No-Action Alternative and 64 percent showed reduced monthly WSEL fluctuations (Figure 11-21). Under CP3, none of the changes in monthly WSEL fluctuation are different enough from the Existing Condition to warrant the investigation of daily WSEL fluctuation.



Increases in the overall surface area and WSEL under CP3 would increase the area of available warm-water habitat and stimulate biological productivity, including fish production, of the entire lake for a period of time, possibly for several decades. Furthermore, reductions in the magnitude of monthly WSEL fluctuations could contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of warm-water fish species. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

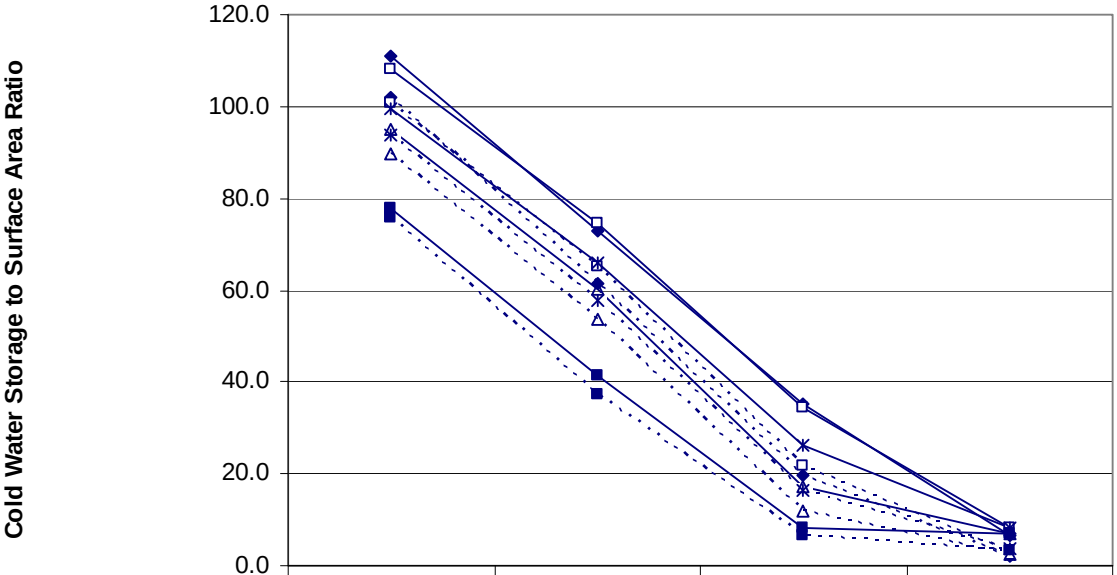
Figure 11-21. Monthly Change in WSEL for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP3 vs. No-Action Alternative

Impact Aqua-2 (CP3): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction Localized increases in soil erosion and resulting runoff sedimentation, and turbidity resulting from project construction in the vicinity of Shasta Dam and at utility, road, and other facility relocation areas could affect nearshore warm-water habitat. However, the environmental commitments for all action alternatives would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed.



Impact Aqua-3 (CP3): Effects on Cold-Water Habitat in Shasta Lake Operations-related changes in the ratio of the volume of cold-water storage to surface area would increase the availability of suitable habitat for cold-water fish in Shasta Lake, including rainbow trout. This impact would be beneficial.

This impact would be similar to Impacts Aqua-3 (CP1 and CP2). However, it would be of greater magnitude owing to a greater increase in the ratio of the volume of cold-water storage in the lake to the surface area of the lake. CalSim-II modeling shows that under CP3 with a 2030 water supply demand, the ratio of cold-water storage to surface area is higher than under the No-Action Alternative in all water years and during all months modeled. The greatest projected increases over the No-Action Alternative occurred between June 30 and August 31, which is the critical holding and rearing period for cold-water fishes in reservoirs, and are greatest in wet, above-normal, and below-normal water years (Figure 11-22).

CP3 would increase the availability of suitable habitat for cold-water fish in Shasta Lake. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-4 (CP3): Effects on Special-Status Aquatic Mollusks Under CP3, habitat for special-status mollusks could be inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could also adversely affect special-status aquatic mollusks that could occupy habitat in or near Shasta Lake and its tributaries. This impact would be potentially significant.

This impact would be similar to Impacts Aqua-4 (CP1 and CP2). However, a larger area would be inundated under CP3, which could result in an increase in impacts to these species and their habitat. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could adversely affect special-status mollusks that may occupy habitat in or near Shasta Lake and its tributaries. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

D = dry water years
NA = No-Action
W = wet water years

Figure 11-22. Monthly Cold-water Storage to Surface Area Ratio for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP3 vs. Existing Condition

Impact Aqua-5 (CP3): Effects on Special-Status Fish Species The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat under CP3 could affect one species designated as sensitive by USFS, the hardhead. This impact would be less than significant.

This impact would be similar to Impact Aqua-5 (CP1 and CP2), but its magnitude would be greater owing to an increase in surface area and WSEL and expansion of the area subject to inundation. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP3): Creation or Removal of Barriers to Fish between Tributaries and Shasta Lake Under CP3, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,090-foot contour, the maximum inundation level under this alternative. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. However, based on digital topographic data and stream channel data generated from field inventories, there do not appear to be any substantial barriers between the 1,070-foot and 1,090-foot contours that would be inundated under this alternative. This impact would be less than significant.

This impact would be similar to Impacts Aqua-6 (CP1 and CP2). However, the maximum inundation level would be higher under this alternative. Most of the tributaries are too steep (i.e., greater than 7 percent) up to the 1,090-foot contour to be passable by fish; the tributaries that are low-gradient up to the 1,090-foot contour, and thus, allow fish passage remain low-gradient well upstream from this contour. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP3): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake CP3 would result in additional periodic inundation of potentially suitable spawning and rearing habitat for adfluvial salmonids in the Sacramento River, McCloud River, Pit River, Big Backbone Creek, and Squaw Creek upstream from Shasta Lake. Eleven miles of low-gradient reaches that could potentially provide some spawning and rearing habitat for adfluvial salmonids would be affected by CP2, which is only about 2.8 percent of the low-gradient habitat upstream from Shasta Lake. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be less than significant.

As described in Chapter 4, “Geology, Geomorphology, Minerals, and Soils,”CP3 would inundate perennial reaches with gradients of less than 7 percent that could provide spawning and rearing habitat for adfluvial salmonids.

The lengths of low-gradient tributaries to each arm that would be periodically inundated are as follows:

- Sacramento River Arm 4.0 miles
- McCloud River Arm 2.7 miles
- Pit River Arm 1.9 miles
- Big Backbone Creek Arm 1.1 miles
- Squaw Creek Arm 1.3 miles

This impact would be similar to Aqua-7 (CP1 and CP2). However, it would periodically inundate a larger amount of habitat in low-gradient reaches to Shasta Lake, but the total amount inundated would be only 2.8 percent of the low-gradient habitat upstream from the lake. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-8 (CP3): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP3 would result in periodic inundation of the lower reaches of high-gradient, non-fish-bearing tributaries to Shasta Lake. Only 24.0 miles of non-fish-bearing tributary habitat would be affected by CP3, which is only about 1 percent of the total length of non-fish-bearing tributaries upstream from Shasta Lake. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be less than significant.

As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils" CP3 would inundate tributary segments with channel slopes in excess of 7 percent. Although these segments do not typically support salmonid populations, they do provide riparian and aquatic habitat for a variety of organisms and serve as corridors that connect habitat types. The lengths of non-fish-bearing tributaries for each arm of Shasta Lake that would be periodically inundated are as follows:

- Sacramento River Arm 5.5 miles
- McCloud River Arm 4.1 miles
- Pit River Arm 3.5 miles
- Big Backbone Creek Arm 2.7 miles
- Squaw Creek Arm 1.9 miles
- Main Body 6.3 miles

This impact would be similar to Aqua-8 (CP1 and CP2). However, it would periodically inundate a larger amount of habitat in high-gradient reaches to Shasta Lake, but the total amount inundated would be only 1 percent of the

non-fish-bearing tributaries upstream from the lake. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP3): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP3. There would be no impact.

This impact is the same as Impact Aqua-9 (CP1), and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to RBDD)

Impact Aqua-10 (CP3): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River during Construction Activities Construction-related increases in sediments and turbidity would adversely affect aquatic habitats and fish populations within the upper Sacramento River immediately downstream from project construction activities. This impact would be less than significant.

This impact would be similar to Impact Aqua-10 (CP1). The impact could be greater because of the increased activity associated with an 18.5-foot dam raise compared to a 6.5-foot dam raise. However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed

Impact Aqua-11 (CP3): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Construction-related activities could result in the release and exposure of contaminants, resulting in adverse effects on aquatic habitats, the aquatic food web, and fish populations, including special-status species, within the primary study area downstream from project construction activities. This impact would be less than significant.

This impact would be similar to Impact Aqua-11 (CP1). The impact could be greater because of the increased activity associated with an 18.5-foot raise compared to a 6.5-foot raise. However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed

Impact Aqua-12 (CP3): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon Project operation would result in improved overall flow and water temperature conditions in the upper Sacramento River for fish species of management concern. This impact would be beneficial.

Winter-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average winter-run production for the 82-year period was similar for CP3 relative to the No-Action

Alternative and the Existing Condition (Attachments 1A and 2A). The maximum increase in production relative to the No-Action Alternative was 74 percent for CP3, and the largest decrease in production relative to the No-Action Alternative was 5 percent (Attachment 1A). The maximum increase in production relative to the Existing Condition was 27 percent for CP3 in 1977, and the largest decrease in production relative to the Existing Condition was 8 percent in 1931 (Attachment 2A).

With one exception (1977, a 3 percent decrease), years with the lowest production over the simulation period had the largest increase in production under CP3 conditions.

Under CP3, critical water years 1924, 1931, 1933, and 1934, and dry water year 1944 had increases in production compared to the No-Action Alternative, ranging from 8 to 74 percent.

Under CP3, critical water years (1924, 1934, 1977, 1992) had increases in production compared to the Existing Condition, ranging from 5 to 27 percent. One critical (1931), and one above-normal (1978) water year had decreases in production of 5 and 8 percent.

When the spawning population equaled the AFRP goal, overall average winter-run Chinook salmon production was similar for CP3 relative to the No-Action Alternative (Attachment 3A). The maximum increase in production relative to the No-Action Alternative was 42 percent for CP3. The largest decrease in production relative to the No-Action Alternative was 8 percent for CP3. Years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP3.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to winter-run Chinook salmon under CP3 occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-4 displays the overall mortalities for each Comprehensive Plan that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 1B and 2B). Mortalities caused by the project decrease as the proposed dam height increases from 6.5 to 18.5 feet.

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, fry were the primary life stage affected, but operations-related activities had a greater effect on egg incubation than on presmolts and no effect on immature smolts. The same trends for each Comprehensive Plan were observed, with the bulk of the mortality affecting the fry and egg incubation life stages, and both water temperature and flow causing the mortality (Table 11-5).

In critical water years, mortality to eggs due to unsuitable water temperatures was the primary cause of operations-related mortalities for CP3, followed by mortality to fry (more by flow and density than water temperature), then to eggs from redd superimposition, followed by presmolts (affected first by water temperature then flow) and then immature smolts (affected by flow). Attachments 1C and 2C contains tables of mortality to winter-run Chinook salmon sorted by water-year type, and Table 11-6 outlines the ranks classified under each Comprehensive Plan for each water-year type.

In dry water years, mortality to fry when moving to new habitats was the primary cause of operations-related mortalities for CP3, as for the No-Action Alternative, followed by mortality to eggs due to redd superimposition. Third was the mortality to eggs due to unsuitable water temperatures, and then followed by mortality to presmolts while moving to new habitats.

Below-normal, above-normal, and wet water years also had the greatest number of winter-run Chinook salmon perish as fry caused by forced movement to habitat downstream, followed by mortality to eggs due to redd superimposition, then the loss of eggs from unsuitable water temperatures, and forced movement of presmolts to downstream habitats.

Years with the highest mortality were the same for the No-Action Alternative and CP1 through CP3: 1924, 1931, 1933, 1934, 1977, and 1992. Each of these years was a critical water year, and was preceded by either a critical (1933, 1976, 1991), dry (1930 and 1932), or below-normal (1923) water-year type. Years in which CP3 had the greatest impact on winter-run were also the years in which the lowest production occurred (Attachments 1C and 2C).

When the spawning population equaled the AFRP goal, winter-run Chinook salmon mortality caused by the operations-related activities decreased under CP3 compared to No-Action Alternative conditions (Attachment 3B). Under CP3, mortality caused by operations-related activities would decrease from non-operations related mortality by 11 percent. Under CP3, the greatest mortality to winter-run Chinook salmon occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because winter-run Chinook salmon have, overall, a reduced mortality, winter-run Chinook salmon would benefit from actions taken in CP3. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average spring-run Chinook salmon production for the 82-year period remained relatively close to the No-Action Alternative and Existing Condition. The maximum increase in

production relative to the No-Action Alternative was 162 percent for CP3. The largest decrease in production relative to the No-Action Alternative was 8 percent for CP3 (Attachment 4A). The maximum increase in production relative to the Existing Condition was 121 percent for CP3. The largest decrease in production relative to the Existing Condition was 79 percent for CP3 (Attachment 5A).

Under CP3, critical water years 1924, 1931, 1933, 1977, 1988, 1992, and 1994 had increases in production compared to the No-Action Alternative, ranging from 6 to 162 percent. Dry water years 1925, 1926, and 1932, and below-normal water year 1959 resulted in increases in production over the No-Action Alternative ranging from 5 to 118 percent. Wet water year 1969 resulted in a production decrease of around 8 percent.

Under CP3, five critical water years (1924, 1933, 1934, 1992, and 2001) had increases in production compared to the Existing Condition, ranging from 6 to 121 percent. Two dry water years (1932 and 2002) resulted in increases over the Existing Condition ranging from 6 to 70 percent. Two below-normal water years (1935 and 1959), and one above-normal water year (2000), had increases in production ranging from 5 to 8 percent. Three critical water years (1931, 1977 and 1988), and one wet water year (1969) had decreases in production relative to the Existing Condition ranging from 8 to 79 percent.

When the spawning population equaled the AFRP goal, overall average spring-run Chinook salmon production was similar for CP3 relative to the No-Action Alternative (Attachment 6A). The maximum increase in production relative to the No-Action Alternative was 123 percent for CP3. The largest decrease in production relative to the No-Action Alternative was 8 percent for CP3. Years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP3.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to spring-run Chinook salmon under CP3 occurred to the eggs, followed by presmolts, then fry. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-5 displays the overall mortalities for each Comprehensive Plan that were caused by nonoperational factors versus those caused by the operations (i.e., water temperature and flow) (Attachments 4B and 5B). Mortalities caused by the project decrease as the proposed dam height increases from 6.5 to 18.5 feet (Tables 11-7 and 11-8). When removing nonoperations-related mortality, leaving mortality due to operations-related activities, only eggs and fry were affected (Table 11-8).

Critical water years under CP3 had mortality to eggs due to unsuitable water temperatures as the primary cause of operations-related mortalities, followed by mortality to prespawned eggs and during incubation caused by dewatering the

redds, and then to fry from forced movement to downstream habitats. Attachments 4C and 5C contain tables of mortality to spring-run sorted by water-year type, and Table 11-9 outlines the rankings classified under each Comprehensive Plan for each water-year type.

In dry, below-normal, and above-normal water years, CP3 was dominated by egg temperature mortality, followed by mortality resulting from redd dewatering. Mortality to prespawned eggs occurred in only two dry years but not in any below-normal water years. Mortality to fry from forced movement was relatively low in only several more years (Table 11-9).

In wet water years, spring-run eggs under conditions created by CP3 were more affected by redd dewatering than by unsuitable water temperatures (Table 11-9).

Years with the highest operations-related mortality were the same for all the Comprehensive Plans: 1924, 1931, 1932, 1933, 1934, 1977, and 1992. Except 1932 (a dry water year), each of these years was a critical water-year type and was preceded by either a below-normal, dry, or (predominantly) a critical water year. However, years with the lowest mortality varied between all water-year types. Years in which the project had the greatest impact on spring-run Chinook salmon were also years in which the lowest production occurred, with nearly all of the mortality occurring in the egg incubation life stage (Attachments 4C and 5C).

When the spawning population equaled the AFRP goal, spring-run Chinook salmon mortality caused by operations-related activities decreased under CP3 compared to No-Action Alternative conditions (Attachment 6B). Under CP3, mortality caused by operations-related activities would decrease from non-operations related mortality by over 35 percent. Under CP3, the greatest mortality to spring-run Chinook salmon occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because spring-run Chinook salmon have, overall, a reduced mortality, spring-run Chinook salmon would benefit from actions taken in CP3. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average fall-run Chinook salmon production for the 82-year period was similar between CP3 and the No-Action Alternative and the Existing Condition (Attachments 7A and 8A). The maximum increase in production relative to the No-Action Alternative was 148 percent for CP3 while the largest decrease in production relative to the No-Action Alternative was 9 percent (Attachment 7A). The maximum increase in production relative to the Existing Condition was 59

percent for CP3. The largest decrease in production relative to the Existing Condition was 69 percent for CP3 (Attachment 8A).

In critical, dry, and below-normal water years, when production was lowest over the simulation period, the increase in production resulting from operations-related activities was greatest. In above-normal and wet water years, however, the lowest production years typically had a slight decrease in production under CP1 conditions relative to the No-Action Alternative.

Under CP3, critical water years 1931, 1933, 1934, and 1977 had increases in production relative to the No-Action Alternative, ranging from 8 to 148 percent. Dry water years 1926, 1932, 1939, 1955, and 1964, and below-normal water years 1937 and 1945 had an 8 to 76 percent increase in production compared to the No-Action Alternative. Above-normal water years 1957 and 1945, and 1999, a wet water year had decreases in overall production relative to the No-Action Alternative, from 6 to 17 percent.

Under CP3, critical water years 1924 and 1934 had increases in production relative to the Existing Condition, ranging from 14 to 37 percent. Five dry water years (1926, 1939, 1955, 1964, and 1985) increased production by 7 to 57 percent compared to the Existing Condition. Three below-normal water years, 1937, 1945, and 1950, had increases in production relative to the Existing Condition, from 5 to 60 percent. Critical water years 1931 and 1977 had decreased production relative to the Existing Condition from 27 to 69 percent. One below-normal (1979) and one above-normal (1957) and four wet (1941, 1942, 1969, and 1999) water years resulted in a substantial decrease in production relative to the Existing Condition ranging from 5 to 17 percent.

When the spawning population equaled the AFRP goal, overall average fall-run Chinook salmon production was similar for CP3 relative to the No-Action Alternative (Attachment 9A). The maximum increase in production relative to the No-Action Alternative was 150 percent for CP3. The largest decrease in production relative to the No-Action Alternative was 9 percent for CP3. In critical, dry, and below-normal water years, years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP3. In above-normal and wet water years, however, the lowest production years typically remained similar or had a slight decrease in production under CP3 conditions relative to the No-Action Alternative.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to fall-run Chinook salmon under CP3 occurs to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-10 displays the overall mortalities for each alternative that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 7B and 8B).

Mortalities caused by the operations-related activities were greatest under the No-Action Alternative and lowest under CP3, but CP1 had a slightly lower mortality than CP2 (Tables 11-10 and 11-11).

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, egg incubation was still the primary life stage affected, but operations-related activities had a greater effect on fry than on presmolts and an even lesser effect on immature smolts. The same trends for each Comprehensive Plan were observed, with the bulk of the mortality affecting the egg incubation life stage, and flow triggering more of the mortality (Table 11-11).

In all water-year types, under all Comprehensive Plans, the greatest portion of mortality occurred to fry caused by forced movement to downstream habitats. Prespawn, incubation, and superimposition mortality were greater than mortality to eggs caused by unsuitable water temperatures and presmolt habitat movement.

In critical water years, mortality to eggs during the prespawn phase was the primary cause of operations-related mortalities for CP3, followed by mortality to eggs prior to spawning, and then to fry caused by forced movement. Least affected were presmolts and then immature smolts by both water temperatures and forced movement. Attachments 7C and 8C contain tables of mortality to fall-run sorted by water-year type, and Table 11-12 outlines the ranks classified under each Comprehensive Plan for each water-year type.

As with critical water years, dry water years were dominated by mortality to fry due to forced movement downstream, followed by redd dewatering or scouring and redd superimposition. Additional mortality occurred to fall-run Chinook salmon presmolts and immature smolts from both forced movement and unsuitable water temperatures (Table 11-12).

Below-normal and above-normal water years were relatively similar for all Comprehensive Plans. The mortality factors were dominated by mortality to fry due to forced movement downstream, followed by redd superimposition, dewatering or scouring. Mortality to presmolts caused by forced downstream movement was a greater factor affecting fall-run Chinook salmon populations than was egg mortality caused by unsuitable water temperatures or to immature smolts and fry due to unsuitable water temperatures (Table 11-12).

As with the water-year types discussed above, under wet water year conditions, the majority of the mortality also occurred to fry due to forced downstream movement, followed by redd superimposition, and redd dewatering or scouring. Mortality to presmolts and immature smolts from downstream movement was the lowest mortality rates resulting from operations-related activities. Least affected were eggs due to unsuitable water temperatures, both pre- and post-spawn.

Years with the highest mortality were the same for the No-Action Alternative, CP1, CP2, and CP3: 1934, 1935, 1970, 1978, and 1993. With the exception of 1970, each of these years was preceded by a critical water year. Overall, years with the lowest mortality tended to be dry or critical water years.

Years with the highest mortality were the same for the Existing Condition, CP1, CP2, and CP3: 1957, 1982, 1985, 1994, and 1997. Overall, years with the lowest mortality tended to be dry or critical water years.

When the spawning population equaled the AFRP goal, fall-run Chinook salmon mortality caused by operations-related activities decreased under CP3 compared to No-Action Alternative conditions (Attachment 9B). Under CP3, mortality caused by operations-related activities would decrease from non-operations related mortality by over 15 percent. Under CP3, the greatest mortality to fall-run Chinook salmon occurred to the egg incubation life stage, followed by fry, then presmolts, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because fall-run Chinook salmon have, overall, a reduced mortality, fall-run Chinook salmon would benefit from actions taken in CP3. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average late fall-run Chinook salmon production for the 82-year period was similar to CP3 and the No-Action Alternative and the Existing Condition (Attachments 10A and 11A). The maximum increase in production relative to the No-Action Alternative was 11 percent for CP3, while the largest decrease in production relative to the No-Action Alternative was 5 percent for CP3 (Attachment 10A). The maximum increase in production relative to the Existing Condition was 18 percent for CP3, while the largest decrease in production relative to the Existing Condition was 7 percent for CP3 (Attachment 11A).

Under CP3, dry water years 1926, 1930, 1932, and 1985 had greater than 7 to 11 percent increases in production compared to the No-Action Alternative. No decreases in production greater than 5 percent occurred.

Under CP3, three dry (1926, 1955, and 1985), had greater than 5 percent increases in production compared to the Existing Condition. One wet water year (1983) had a 6 percent increase relative to the Existing Condition. One critical water year (1976), and one wet water year (1984) had substantial decreases in production over the Existing Condition by 5 to 7 percent.

When the spawning population equaled the AFRP goal, overall average late fall-run Chinook salmon production was similar for CP3 relative to the No-

Action Alternative (Attachment 12A). The maximum increase in production relative to the No-Action Alternative was 27 percent for CP3. The largest decrease in production relative to the No-Action Alternative was 5 percent for CP3. In critical, dry, below-normal, and above-normal water years, years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP3, with two exceptions – 1994 and 1937 (1 percent decrease for both). In wet water years, however, the lowest production years typically remained similar or had a slight decrease in production under CP3 conditions relative to the No-Action Alternative.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to late fall-run under CP3 occurred to the egg incubation life stage, followed by fry, then presmolts and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-13 displays the overall mortalities for each Comprehensive Plans that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 10 B and 11B). Mortalities caused by the project decreased for all Comprehensive Plans relative to the No-Action Alternative.

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, fry became the primary life stage affected, and operations-related activities had a greater effect on eggs than on presmolts and an even lesser effect on immature smolts. Most of the mortality occurred as a result of flow conditions rather than water temperature (Table 11-14).

Under all Comprehensive Plans, mortality to fry resulting from unsuitable water temperatures only occurred at low levels to late fall-run Chinook salmon during critical, dry and below-normal water years only. In all water-year types, under all Comprehensive Plans, mortality to fry during forced movement to downstream habitats was the primary cause of operations-related mortality.

In critical, dry, and below-normal water years, the causes of operations-related mortality follow similar trends for all Comprehensive Plans, with a few exceptions. In general, the effects of flow (and density) had the greatest effect on mortality. Forced movement of fry resulted in the greatest mortality, followed by flow effects on eggs via scouring, dewatering, or superimposition. Next affected were presmolts and immature smolts by unsuitable water temperatures, and lastly temperature effects on eggs and flow effects on presmolts and immature smolts and fry (Table 11-15).

Wet and above-normal water years were overall similar to critical, dry, and below-normal water years except that mortality to fry due to unsuitable water temperatures disappear.

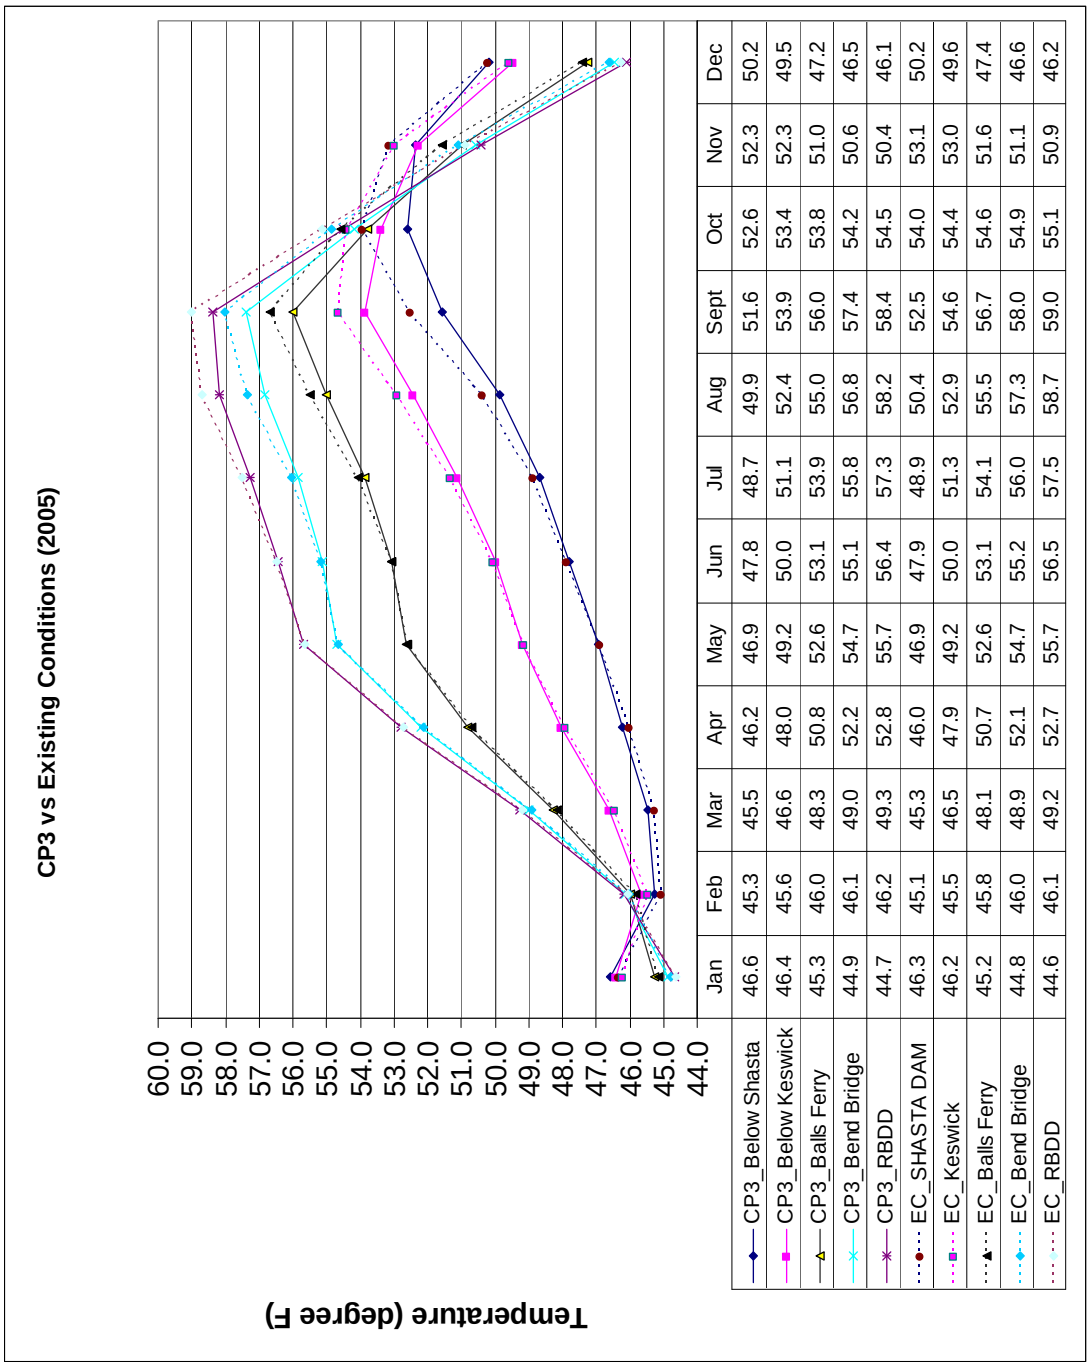
Years with the highest mortality were the same for all the Comprehensive Plans and were 1937, 1957, 1973, 1982, 1994, and 1997. All water-year types were covered. Two years were preceded by a wet water year, one preceded by an above-normal water year, and two by a below-normal water year (Attachments 10C and 11C).

When the spawning population equaled the AFRP goal, late fall-run Chinook salmon mortality caused by operations-related activities was slightly less under CP3 than under No-Action Alternative (Attachment 12B). Under CP3, mortality caused by operations-related activities would decrease from non-operations related mortality by 29 percent. Under CP3, the greatest mortality to late fall-run Chinook salmon occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because late fall-run Chinook salmon have, overall, a reduced mortality, late fall-run Chinook salmon would benefit from actions taken in CP3. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-13 (CP3): Changes in Flow and Water Temperatures in the Upper Sacramento River Resulting from Project Operation—Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass CP3 operation would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be less than significant.

This impact would be similar to Impact Aqua-13 (CP1). The impact could be greater because of the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise.

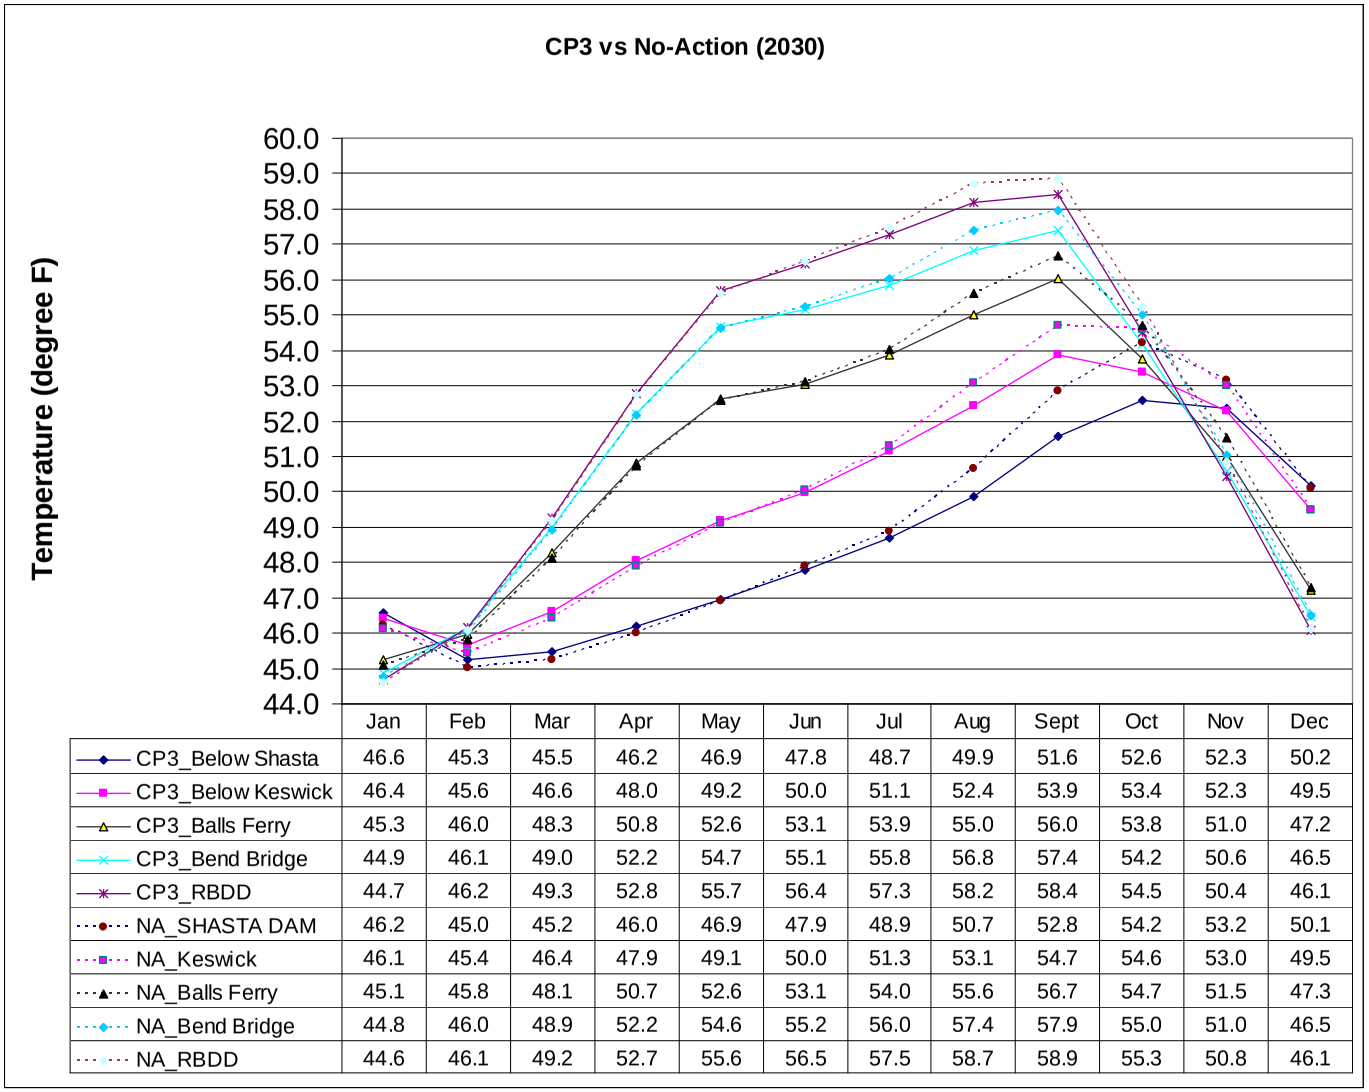


Flow-Related Effects Similar to CP1, monthly mean flows at all model locations (i.e., below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBDD) within the upper Sacramento River under CP3 would be essentially equivalent to flows (less than 4 percent) under the Existing Condition and No-Action Alternative conditions simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). Potential flow-related effects on fish species of management concern in the upper Sacramento River would be minimal. All potential changes in flows and stages would diminish rapidly downstream from RBDD because of increasing effect of inflows from tributaries, and of diversions and flood bypasses.

There would be no discernable flow-related effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River related to changes in monthly mean flows under CP3, relative

to the Existing Condition and No-Action Alternative. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Flow-related effects on these fish species would be less than significant.

Water Temperature-Related Effects Similar to CP1, monthly mean water temperatures at all model locations (i.e., below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBDD) within the upper Sacramento River under CP3 would be the same or fractionally lower than those under the Existing Condition and No-Action Alternative simulated for all months (Figures 11-23 and 11-24) (see also the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). As discussed above, the modeling simulations may not fully account for real-time management of the cold-water pool and TCD (through the SRTTG) to achieve maximum cold-water benefits. Therefore, the modeled changes in water temperature (i.e., small benefits) are likely conservative and understated to some degree. Nevertheless, potential water temperature-related effects on fish species of management concern in the upper Sacramento River from CP3 would be minimal. During most years, annual releases from Shasta Dam would be unchanged. On average, the greatest cooling effect (less than 1°F) occurs during critical years and during the late summer (i.e., July to September), because of the increased cold-water pool volume within Shasta Lake, even following an extended dry period. All potential changes in flows and stages would diminish downstream from RBDD because of the increasing effect of inflows from tributaries, and of diversions and flood bypasses.



There would be very small water temperature–related effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River related to slightly cooler monthly mean water temperatures under CP3, relative to the Existing Condition and No-Action Alternative. Mean monthly water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River. Water temperature-related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-24. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area (No-Action Alternative)

Impact Aqua-14 (CP3): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows CP3 operations could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

This impact would be similar to Impact Aqua-14 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and flows) to be stored behind the raised dam. Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and associated stage elevation of water surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flow, with relatively large flows providing the energy required to mobilize sediment from the river bed, produce meander migration, increase stage elevation, and create seasonally inundated floodplains. Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

CP3 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

These effects would likely occur along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. These impacts would be potentially significant within the primary study area. Mitigation for this impact is proposed in Section 11.3.4.

Lower Sacramento River and Delta

Impact Aqua-15 (CP3): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern CP3 operation would result in no discernable change in mean monthly flow or water temperature conditions in the lower Sacramento River; however, predicted

changes in flow in the Feather River, American River, and Trinity River could result in an adverse effect on Chinook salmon, steelhead, coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass if they were to occur. This impact would be potentially significant.

This impact would be similar to Impact Aqua-15 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and increased cold-water pool) to be stored behind the raised dam.

Similar to CP1, monthly mean flows at model locations (i.e., Verona, Freeport) within the lower Sacramento River under CP3 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative conditions simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). All potential changes in flows diminished rapidly downstream from RBDD because of the increasing effect of inflows from tributaries, and of diversions and flood bypasses. Potential flow-related effects on fish species of management concern in the lower Sacramento River from this alternative would be minimal. Differences in mean monthly flow are generally small (less than 2 percent) and within the existing range of variability. All potential changes in water temperatures in the lower Sacramento River due to small changes in releases would diminish rapidly downstream because of increasing effect of inflows, atmospheric influences, and groundwater. Therefore, flow- and temperature-related impacts on fish species in the lower Sacramento River would be less than significant.

Also similar to CP1, monthly mean flows at all model locations within the lower Feather River, the American River, and Trinity River under CP2 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative simulated for most months; however, there are several months within the modeling record showed substantial changes (based on model simulations) to flows in tributaries (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete CalSim-II modeling results). All potential changes in flows could be diminished in these areas per existing operational rules and because of operation of upstream reservoirs (i.e., Lake Oroville, Folsom Lake, and Trinity Lake) and increasing effects of inflows from tributaries and of diversions and flood bypasses. Nevertheless, based on predicted changes in flow and associated flow-habitat relationships, potential flow-related impacts to species of management concern in the American, Feather, and Trinity rivers could occur and would be a potentially significant impact.

Monthly mean flows at all model locations within the lower Feather River (i.e., below Thermalito Afterbay) and the American River (i.e., near the H Street Bridge in Sacramento) under CP1 would also be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action

Alternative simulated for all months. All potential changes in flows were diminished in these areas because of operation of upstream CVP and SWP reservoirs (i.e., Lake Oroville and Folsom Lake) and increasing effect of inflows from tributaries, and of diversions and flood bypasses. Potential flow-related effects on fish species of management concern in the Feather River and American River from this alternative would be minimal and within the range of existing variability.

All potential changes in water temperatures in the lower Sacramento River and primary tributaries (i.e., Feather River and American River) due to altered releases from reservoirs diminished downstream from RBDD because of increasing effect of inflows, and atmospheric and groundwater influences.

As under CP1, effects of altered flow regimes resulting from implementation of CP3 are unlikely to extend into the lower Sacramento River and Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the SWP and the CVP). The guidelines for this management, which are described in the CVP/SWP OCAP, have been designed to maintain standards for flow to the lower Sacramento River and Delta. CVP and SWP operations must be consistent with OCAP to allow coverage by OCAP permits and BOs. Thus, under CP3, this project is not anticipated to cause an alteration in flow to the Delta nor cause an alteration to water temperatures in the lower Sacramento River and primary tributaries within the extended study area sufficient to cause discernable effects on Chinook salmon, steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass, relative to the Existing Condition and No-Action Alternative. Functional flows for fish migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow- and temperature-related effects on these fish species would be less than significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-16 (CP3): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the lower Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

This impact would be similar to Impact Aqua-16 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and flows) to be stored behind the raised dam. Sediment transport, deposition, and

scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and associated stage elevation of water surface also provide a backwater effect on the lowermost segment of tributaries, which the reduces potential for downcutting. These processes are regulated by the magnitude and frequency of flow, with relatively large floods providing the energy required to mobilize sediment from the river bed, produce meander migration, increase stage elevation, create seasonally inundated floodplains, and inundate floodplain bypasses. Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains.

CP3 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from the operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These effects would likely occur along upper reaches of the lower Sacramento River. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. These impacts would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-17 (CP3): Effects to Delta Fishery Habitat Resulting from Changes to Delta Outflow Based on the results of hydrologic modeling comparing Delta outflow under CP3 relative to the Existing Condition and No-Action Alternative, CP3 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta.

Results of the comparison of Delta outflows under CP3 compared with the Existing Condition and No-Action Alternative are summarized by month and water-year type in Table 11-30. The comparison includes the estimated average monthly outflow, the average monthly flow under CP3, and the percentage change between base flows and CP3 operations. Results of the analysis (Table 11-30) showed that Delta outflows were observed to be slightly lower under many of the CP3 operations as well as slightly higher than basis-of-comparison conditions depending on month and water-year type. However, none of the changes were larger than 5 percent. Based on the results of this comparison, it was concluded that CP3 would have a less than significant impact on Delta fisheries and hydrologic transport processed within the Bay-Delta as a consequence of changes in Delta outflow under existing conditions. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-18 (CP3): Effects to Delta Fishery Habitat Resulting from Changes to Delta Inflow Changes in upstream reservoir storage have the potential to affect Delta inflow. Delta inflow may affect hydrologic conditions within Delta channels, hydraulic residence times, salinity gradients, and the transport and movement of various life stages of fish, invertebrates, phytoplankton, and nutrients into and through the Delta. Delta inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources. Based on the results of hydrologic modeling comparing Delta inflow under CP3 to Existing

Condition and No-Action Alternative, CP3 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta.

Results of the comparison of Delta inflows are summarized by month and water-year type in Table 11-31. The comparison includes the estimated average monthly inflow under the basis-of-comparison conditions, the average monthly flow under CP3, and the percentage change between base flows and CP3 operations. Delta inflows were observed to be slightly lower under many of the CP3 operations and slightly higher than basis-of-comparison conditions depending on month and water-year type. None of the comparisons exceeded 5 percent difference between the No-Action Alternative, Existing Condition and CP3. Based on the results of this comparison, it was concluded that CP3 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta as a consequence of changes in Delta inflow. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP3): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow Project operation would result in a variable response in Sacramento River flow, resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water-year type. This impact would be less than significant.

Results of hydrologic modeling, by month and year type, comparing basis-of-comparison Sacramento River flow, are presented in Table 11-32. Results of these analyses show a variable response in Sacramento River flow with CP3 operations resulting in both increases and decreases in river flow above basis-of-comparison conditions, depending on month and water year. All differences in Sacramento River flow between the No-Action Alternative, Existing Condition and CP3 operations were less than 5 percent. Based on these results, it was concluded that the effect of CP3 on fish habitat and transport mechanisms within the lower Sacramento River and Delta would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP3): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis CP3 operations would result in no discernable change in San Joaquin River flows at Vernalis, and therefore no effects on fish habitat or transport mechanisms within the lower San Joaquin River and Delta compared with the Existing Condition and No-Action Alternative. This impact would be less than significant.

Results of the comparative analysis of model results, by month and water-year type, for basis-of-comparison conditions and CP3 for San Joaquin River flow are summarized in Table 11-33. Results of these analyses show that CP3 would have no effect on seasonal flows under existing conditions within the San Joaquin River. Similarly, modeling results showed that CP3 would have no effect on flows or fish habitat compared with the No-Action Alternative. Based on these results, it was concluded that CP3 would have no effect on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP3): Reduction in Low Salinity Habitat Conditions Resulting from an Upstream Shift in X2 *Location* CP3 operation would result in less than 0.5 km movement upstream or downstream from the X2 location. This impact would be less than significant.

The 1 km X2 criterion was applied to a comparison of hydrologic model results for basis-of-comparison conditions and CP3, by month and water-year type, for the months from February through May. Results of the comparisons are summarized in Table 11-34. These results showed that changes in X2 location under CP3 were less than 1 km (all were less than 0.4 km) with both variable upstream and downstream movement of the X2 location depending on month and water-year type. These results are consistent with model results for Delta outflow that showed a less than significant change in flows.

Results of a comparative analysis of changes in X2 location between the basis-of-comparison and CP3, assuming future operating conditions, are also summarized in Table 11-34. Results of these comparisons showed very little difference (less than 0.2 km) in the X2 location between CP3 and the No-Action Alternative. Based on these results, it was concluded that CP3 would have a less than significant effect on low salinity habitat conditions within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP3): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in Old and Middle Rivers Project operation would result in an increase of reverse flows in Old and Middle rivers. The increase in reverse flows would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses. This impact would be potentially significant.

Results of the analysis showed several occurrences when reverse flows within Old and Middle rivers were greater than basis-of-comparison conditions by more than 5 percent. These events occurred typically in dry and critical water years, which would be expected as a result of greater export operations under CP3. During February (Table 11-35), operations under CP3 resulted in an increase in reverse flow of greater than 5 percent during critical years. Based on results of the delta smelt analysis of the relationship between reverse flows and delta smelt salvage, the increase from approximately 4,300 cfs under the basis-of-comparison in a critical water year to approximately 4,700 cfs would not be expected to result in a significant increase in adverse effects to delta smelt. Juvenile Chinook salmon and steelhead are migrating through the Delta during February, and an increase in average monthly reverse flows of 300 to 400 cfs would be expected to increase the potential risk of increased mortality.

However given the tidal volumes and hydrodynamics of the Old and Middle rivers region, it is not expected that the change in reverse flows in February in a critical year would result in a detectable change in fish survival. The majority of juvenile Chinook salmon emigrating from the San Joaquin River typically migrate downstream later in dry years and would not be expected to occur in high numbers within Old and Middle rivers in February.

The increase in reverse flows estimated to occur under CP3 in critical and dry years in June, and under critical, dry, and below-normal years in July, exceeded 5 percent compared with the Existing Condition. The increased reverse flows in June of critical and dry years occur at a time of year when water temperatures in the Delta are elevated and juvenile Chinook salmon or steelhead would not be expected to occur in the area. Juvenile delta smelt may occur in the area in June; however, a change in Old and Middle river flows of approximately 100 to 200 cfs may result in a small increase in their vulnerability to CVP and SWP salvage, but this increase is expected to be less than significant. As water temperatures increase in the Delta during June and July, the majority of delta smelt are located farther downstream in Suisun Bay where temperatures are more suitable. The increase in reverse flows estimated from the modeling in June of a critical year and in July of below-normal, dry, and critical years, would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses as a result of increased reverse flows. The increased reverse flows in low-flow years would be expected to result in a low, but potentially significant, increase in mortality for resident warm-water fish inhabiting the south Delta.

Results of the comparison of Old and Middle rivers reverse flows are summarized in Table 11-35. Results of the analysis show that in the majority of years and months, reverse flows under CP3 did not exceed basis-of-comparison conditions by more than 5 percent. CP3 exceeded basis-of-comparison conditions during February of a critical year by approximately 700 cfs. The increase in reverse flows would be expected, particularly in a critical year, to contribute to an increase in the potential for losses of adult delta smelt and other species, which is considered to be potentially significant. During June in a critical water year, under CP3 the magnitude of reverse flows was reduced more than 5 percent but would be expected to contribute to a less than significant biological benefit based on both the low reverse flow under the basis-of-comparison and under CP3. An increase in reverse flow above the basis-of-comparison of approximately 300 to 600 cfs during dry years in July would be expected to contribute to an increase in the risk of losses to resident warm-water fish species. Increased reverse flows in July would not be expected to adversely affect delta or longfin smelt, juvenile Chinook salmon, or steelhead based on their seasonal migration patterns and geographic distribution. The potential increase in losses during February and July under CP3 is considered to be potentially significant. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

Impact Aqua-23 (CP3): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP3 operations may result in an increase in CVP and SWP exports, which is assumed to result in a direct proportional increase in the risk of fish being entrained and salvaged at the facilities. This is a considered a less than significant impact to Chinook salmon, steelhead, and longfin smelt. This is considered a potentially significant impact to delta smelt, striped bass, and splittail. Future operations of the SWP and CVP export facilities would continue to be managed and regulated in accordance with incidental take limits established for each of the protected fish by USFWS, NMFS, and DFG.

Results of the entrainment loss modeling at the CVP and SWP export facilities are presented in Table 11-36 for CP3. The initial modeling was conducted using average fish densities developed from past fish salvage monitoring at the SWP and CVP export facilities. Average monthly water exports were used in the analysis based on hydrologic simulation modeling. The indices of the potential risk of entrainment for some species, such as Chinook salmon, were not estimated separately for each species (e.g., winter-run Chinook) in these initial analyses. If the proposed project is developed in the future a more detailed species-specific analysis of potential changes in fish salvage losses, in addition to an assessment of the population-level effects on each species, would be required for use as a basis for developing a biological assessment and Section 7 BOs and incidental take permits for project operations. These indices were calculated for wet, above-normal, below-normal, dry, and critical water-year types, and for an average across all years (no water-year type specified).

The total numbers of fish lost annually, by species, are presented in Attachment 13. The difference between the non-operations related and operations related fish mortality is represented as the entrainment index, shown in the tables, to represent the effect of project operations on each fish species at the CVP and SWP facilities.

CP = Comprehensive Plan
D = dry
W = wet

Results of the entrainment risk calculations for delta smelt showed a change of less than 1 percent in wet, above-normal, and below-normal water years and an increase in risk ranging from approximately 1 to 4 percent during dry and critical water years under CP3 relative to the Existing Condition (Table 11-36). The risk of increased losses of delta smelt under CP3 compared to the No-Action Alternative (Table 11-36) was greatest in the dry years. Although the incremental change in the risk of delta smelt losses resulting from CVP and SWP export operations is small, delta smelt population abundance is currently at such critically low levels that even a small increase in the risk of losses is considered to be potentially significant. The increase in risk is also expected to contribute to cumulative factors affecting the survival of delta smelt.

The estimated change in the risk of losses for salmon follows a pattern similar to that described for delta smelt (Table 11-36). Overall, CP3 would result in a small increase in the risk of losses. The loss index for salmon also showed increased risk in wet, below-normal, dry, and critical years relative to the No-Action Alternative. Given the numbers of juvenile Chinook salmon produced each year in the Central Valley, the relatively small incremental increase in the risk of entrainment/salvage at the CVP and SWP export facilities is considered to be a less than significant direct effect but would contribute incrementally to the overall cumulative factors affecting juvenile Chinook salmon survival within the Delta, and population dynamics of the stocks.

The change in the risk of longfin smelt entrainment/salvage under CP3 compared to the No-Action Alternative and to the Existing Condition shows small positive and negative changes depending on water-year type and alternative (Table 11-36). These small changes in the risk of entrainment are considered to be less than significant.

The change in the risk to steelhead of entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-36, respectively. The small positive and negative changes in risk under wet, above-normal, below-normal, and dry water years are considered to be less than significant. The increase in risk of steelhead losses in critical water years are considered to be less than significant based on the abundance of juvenile steelhead migrating through the Delta, but would contribute directly to cumulative factors affecting the survival and population dynamics of Central Valley steelhead. The predicted increase in potential entrainment risk for steelhead under critically dry water years represents an initial estimate of the change (percentage) between the proposed project operations and the existing conditions and no-project alternatives and does not allow the predicted losses to be evaluated at the population-level. As noted above, more detailed modeling and analysis of potential steelhead losses would be required as part of preparing a project-specific analysis of entrainment losses for use in the Section 7 biological assessment and BOs for future project operations and incidental take of steelhead. As part of this more detailed analysis additional actions may be identified to further reduce and avoid potential adverse effects to steelhead.

The change in risk to juvenile striped bass for entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-36. The change in risk in wet, above-normal, and below-normal water years are considered to be less than significant based on the abundance of striped bass, but would contribute to the cumulative factors affecting striped bass survival and population dynamics in the Delta. The losses of juvenile striped bass increased substantially under dry and critical water years, which would be expected with an increase in exports during the summer months. The risk of increased losses ranged from 3.8 to 7.6 percent (approximately 30,000 to 60,000 fish) under CP3, compared to the Existing Condition, which is considered to be potentially significant. The increased losses under CP3, particularly in drier water years when juvenile striped bass production is lower, would be expected to contribute to the cumulative effects of factors affecting juvenile striped bass survival in the Delta.

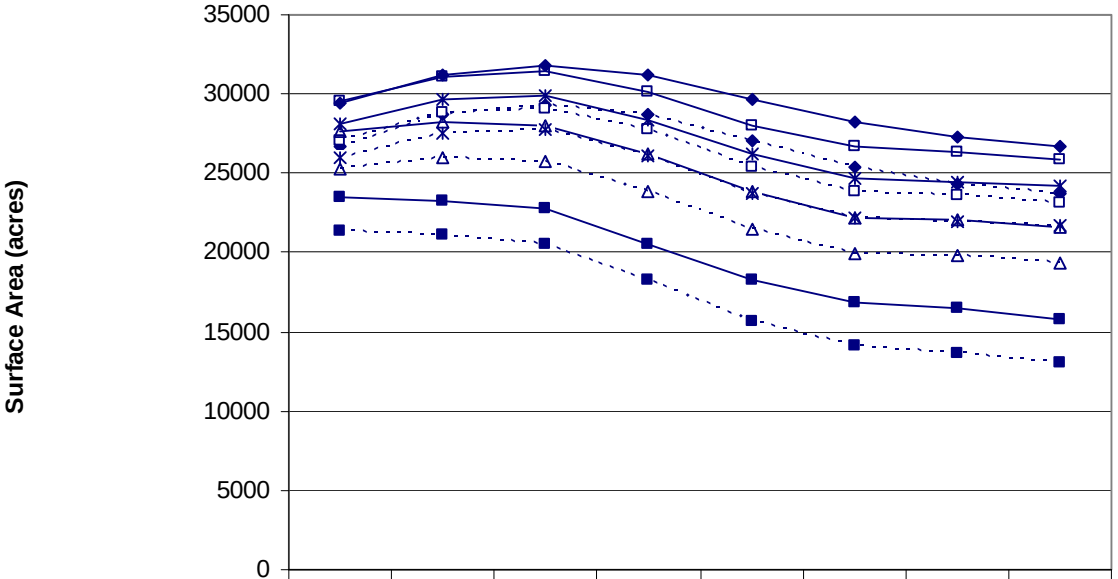
Results of the risk estimates for juvenile splittail losses under CP3 compared with the No-Action Alternative and Existing Condition show a pattern similar to other species (Table 11-36). The increased risk index was 1.3 percent or less in wet, above-normal, and below-normal water years, and was considered to be a less than significant affect. The loss index increased during dry and critically dry water years, with the greatest increase for CP3. Higher risk of entrainment/salvage losses in drier water years has a potentially greater effect of abundance of juvenile splittail since reproductive success and overall juvenile abundance is typically lower within the Delta in dry years. The increased risk of losses in drier years was considered to be potentially significant. The increased losses would also contribute to cumulative factors affecting survival of juvenile splittail within the Delta.

Impact Aqua-23 (CP1) is considered to be less than significant for Chinook salmon, steelhead, and longfin smelt, but potentially significant for delta smelt, striped bass, and splittail. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

CVP/SWP Service Areas

Impact Aqua-24 (CP3): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes. Project implementation would result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects in tributaries and reservoirs (e.g., New Melones and San Luis) with CVP and SWP dams are expected to be less than impacts on the lower Sacramento River. The change in hydrology could affect aquatic habitats that provide habitat for the fish community. These changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-24 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for additional water volume (and flows) to be stored behind the raised dam. However, these changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. The effects from CP3 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and resulting flows downstream from those reservoirs, would be small and well within the range of variability that commonly occurs in these reservoirs and downstream. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

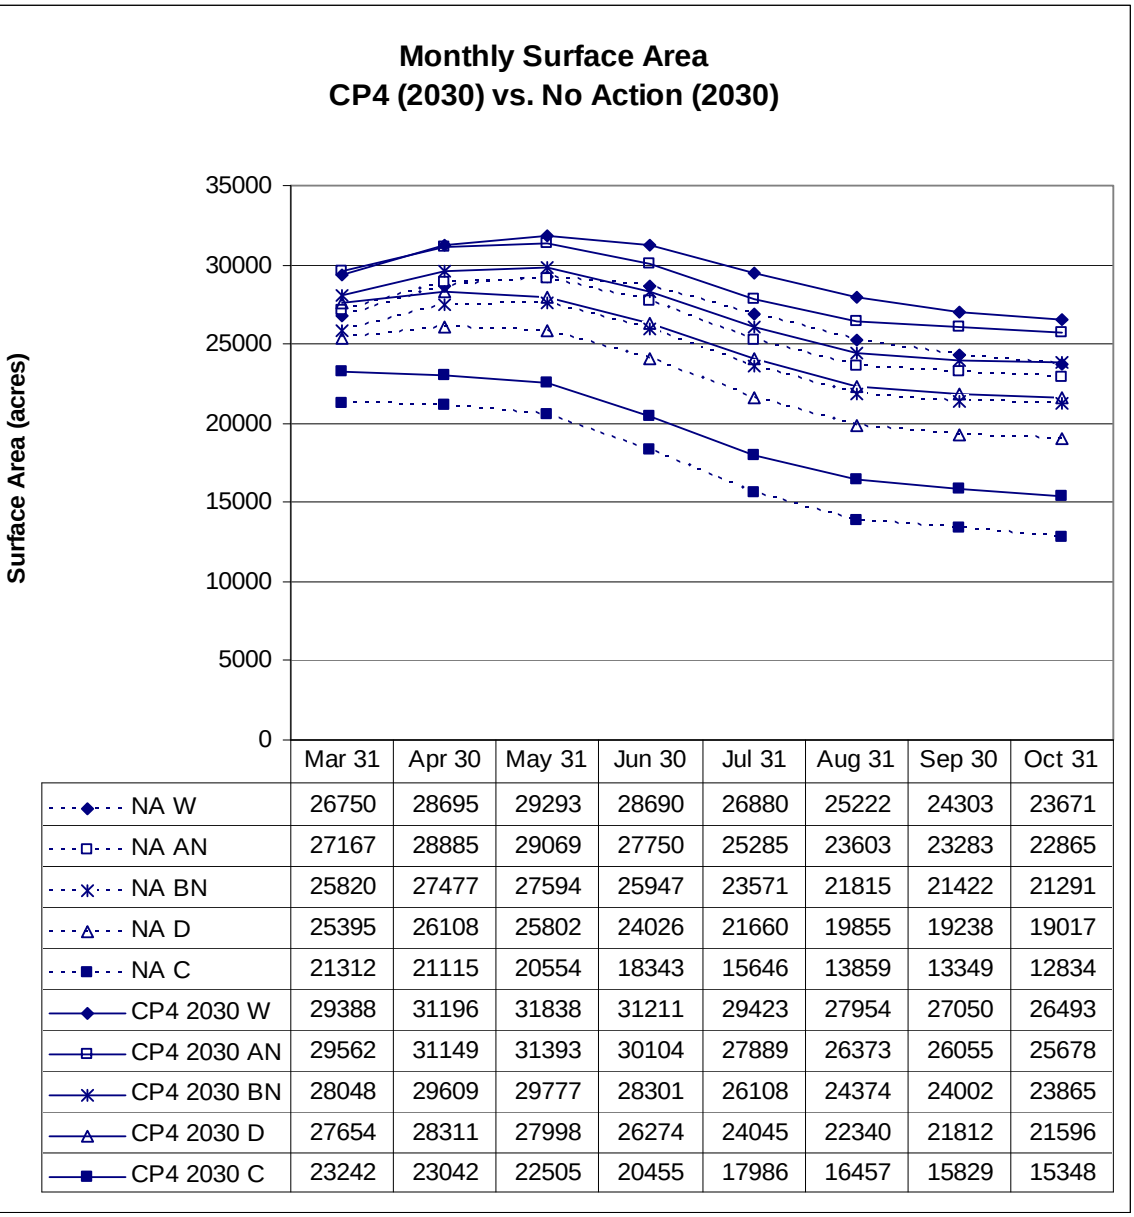


CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

The primary function of CP4 is to address survival of anadromous fish, while still improving water supply reliability. It focuses on increasing the volume of cold water available to the TCD through reservoir reoperations, and on raising Shasta Dam by 18.5 feet. CP4 also includes a 10-year spawning gravel augmentation program as an additional environmental commitment. As with CP3 and the common features above, this raise would increase the full pool by 20.5 feet and enlarge total reservoir storage space by 634,000 acre-feet. This additional storage space would expand Shasta Lake's cold-water supply available to the TCD by 378,000 acre-feet, a feature that would help reduce water temperatures in the upper Sacramento River.

Shasta Lake and Vicinity

Impact Aqua-1 (CP4): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP4, project operations would contribute to an increase in the surface area and WSEL of Shasta Lake, which would in turn increase the area and productivity of nearshore, warm-water habitat. CP2 operations would also result in reduced monthly fluctuations in WSEL, which would contribute to increased reproductive success, young-of-the-year production, and the juvenile growth rate of warm-water fish species. Similar to CP-1 the value of existing structural habitat improvements would be diminished to varying degrees, large areas of the shoreline would not be cleared, and the vegetation along these sections will be inundated periodically. In the short term, this vegetation will provide warm-water lacustrine habitat, with decay expected to occur over several decades. This impact would be less than significant.



This impact would be similar to Impact Aqua-1 (CP1, CP2, and CP3), but the surface area would be larger under the 18.5-foot dam raise than under CP1 and CP2. CalSim-II modeling shows that the surface area of Shasta Lake would be larger under CP4 for both a 2005 and 2030 water supply demand than under the Existing Condition or the No-Action Alternative in all five water-year types (Figures 11-25 and 11-26).

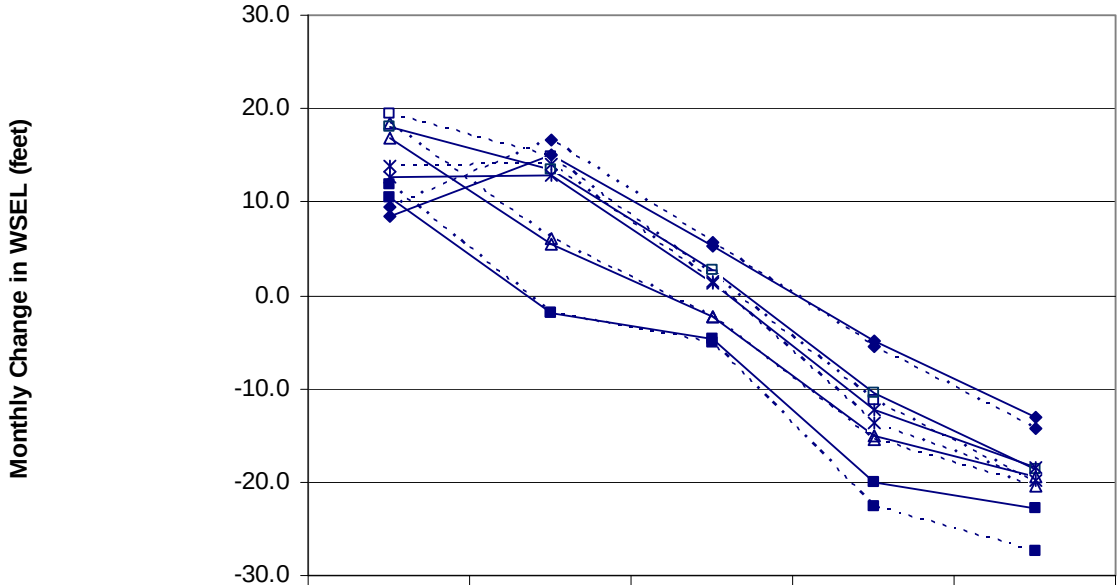
Figure 11-26. Monthly Surface Area for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP4 vs. No-Action Alternative

Monthly WSEL fluctuations were compared to projections for water supply demand. For CP4, with a 2005 water supply demand, 20 percent of monthly changes in projected WSELs (i.e., 5 of the 25 total projections made for the 5 months from March through July for all five water-year types) showed increased monthly WSEL fluctuations relative to the Existing Condition and 80 percent showed reduced monthly WSEL fluctuations (Figure 11-27). For CP3, with a projected 2030 water supply demand, 36 percent of monthly changes in projected WSELs showed increased WSEL fluctuations relative to the No-Action Alternative and 64 percent showed reduced monthly WSEL fluctuations (Figure 11-28). Under CP4, none of the changes in monthly WSEL fluctuation are different enough from the Existing Condition to warrant the investigation of daily WSEL fluctuation.

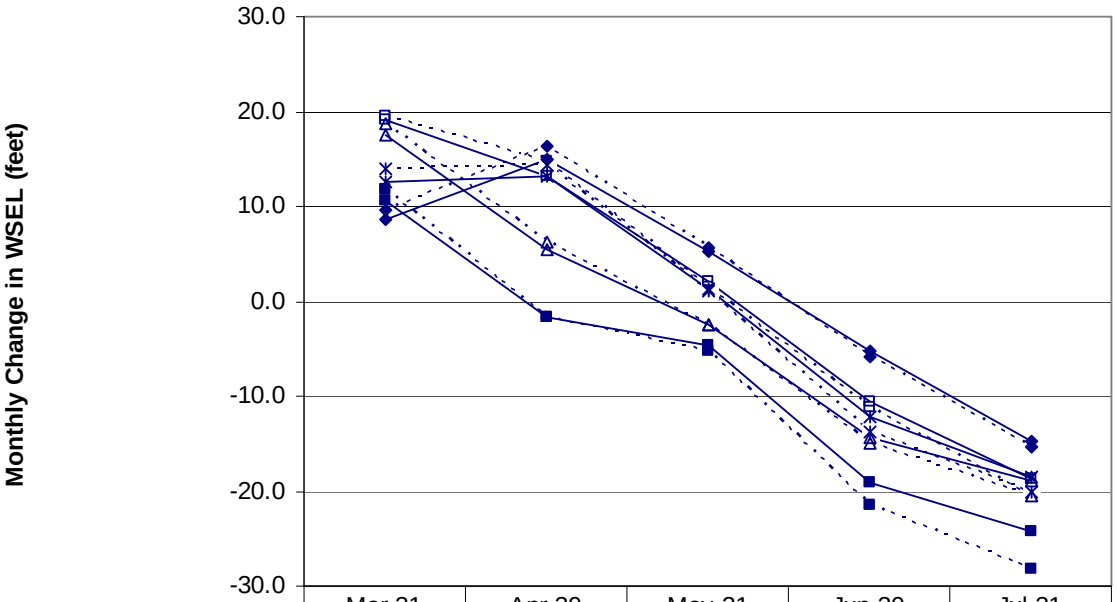


Increases in the overall surface area and WSEL under CP4 would increase the area of available warm-water habitat and stimulate biological productivity, including fish production, of the entire lake for a period of time, possibly for several decades. Furthermore, reductions in the magnitude of monthly WSEL fluctuations could contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of warm-water fish species. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-2 (CP4): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction This impact would be similar to CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed

Impact Aqua-3 (CP4): Effects on Cold-Water Habitat in Shasta Lake
Operations-related changes in the ratio of cold-water storage to surface area would affect the availability of suitable cold-water fisheries habitat in Shasta Lake, including rainbow trout. This impact would be beneficial.

This impact would be similar to Impact Aqua-3 (CP1, CP2, and CP3) but would be of lower magnitude than Aqua-1 (CP3) owing to its focus on increasing the volume of cold-water available to the TCD to benefit anadromous fish downstream from Shasta Dam.



CalSim-II modeling shows that under CP4, with a 2030 water supply demand, the ratio of cold-water storage to surface area is higher than under the No-Action Alternative in all water years and during all months modeled. The greatest projected increases over the No-Action Alternative occurred between June 30 and August 31, which is the critical holding and rearing period for cold-water fishes in reservoirs, and are greatest during critical water years (Figure 11-29). Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-29. Monthly Cold-water Storage to Surface Area Ratio for Each Water-Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP4 vs. Existing Condition

Impact Aqua-4 (CP4): Effects on Special-Status Aquatic Mollusks Under CP4, habitat for special-status mollusks could be inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could also adversely affect special-status aquatic mollusks that could occupy habitat in or near Shasta Lake and its tributaries. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-5 (CP4): Effects on Special-Status Fish Species That Occupy Habitat Provided by Shasta Lake and Its Tributaries The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat under CP4 could affect one species designated as sensitive by the USFS, the hardhead. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP4): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP4, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,090-foot contour, the maximum inundation level under this alternative. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. However, based on digital topographic data and stream channel data generated from field inventories, there do not appear to be any substantial barriers between the 1,070-foot and 1,090-foot contours that would be inundated under this alternative. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP4): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake CP4 would result in additional periodic inundation of potentially suitable spawning and rearing habitat for adfluvial salmonids in the Sacramento River, McCloud River, Pit River, Big Backbone Creek, and Squaw Creek upstream from Shasta Lake. A total of 11 miles of low-gradient reaches that could potentially provide some spawning and rearing habitat for adfluvial salmonids would be affected by CP4, which is only about 2.8 percent of the low-gradient habitat upstream from Shasta Lake. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-8 (CP4): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP4 would result in periodic inundation of the lower reaches of high-gradient, non-fish-bearing tributaries to Shasta Lake. About 24 miles of non-fish-bearing tributary habitat would be affected by CP4, which is only about 1 percent of the lengths of non-fish-bearing tributaries upstream from Shasta Lake. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This

impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP4): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP4. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to RBDD)

Impact Aqua-10 (CP4): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Construction activities have the potential to increase sediments and turbidity, and release and exposure of contaminants. With environmental commitments in place, this would be a less than significant impact.

This impact would be similar to Impact Aqua-10 (CP1). The impact could be greater because of the increased activity associated with an 18.5-foot dam raise compared to a 6.5-foot dam raise. Additionally, CP4 also includes a 10-year gravel augmentation program as an additional environmental commitment. The placement of gravel along the Sacramento River channel and bank on an annual basis would result in an additional source of fine sediment being released and exposed to the river and aquatic communities. However, the gravel augmentation activities would only occur during pre-specified in-water work windows, which would minimize the potential for impacts associated with this activity.

Lastly, CP4 also includes riparian, floodplain, and side channel habitat restoration in the upper Sacramento River at Reading Island. The Reading Island riparian, floodplain, and side channel restoration could result in additional disturbed surfaces, but most of this construction is expected to occur away from the wetted channel, and all disturbed areas would be revegetated.

However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed. *Impact Aqua-11 (CP4): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities* Construction-related activities have the potential to result in the release and exposure of contaminants, resulting in adverse effects on aquatic habitats, the aquatic food web, and fish populations, including special-status species, within the primary study area downstream from project construction activities. This impact would be less than significant with all environmental commitments in place.

This impact would be similar to Impact Aqua-11 (CP1). The impact could be greater because of the increased activity associated with an 18.5-foot raise compared to a 6.5-foot raise. Additionally, as discussed above, CP4 also includes a 10-year gravel augmentation program and restoration of riparian,

floodplain, and side channel habitat as additional environmental commitments. Both of these construction activities could result in additional sources of equipment-related contaminants potentially being released and exposed to the river and aquatic communities. However, additional environmental commitments that call for in-water work windows and specific best management practices (BMP) would minimize and/or avoid the potential for impacts associated with this activity.

However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed *Impact Aqua-12 (CP4): Improved Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon* Project operation would result in improved flow and water temperature conditions in the upper Sacramento River for fish species of management concern. This impact would be beneficial.

Winter-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average winter-run production for the 82-year period was greater under CP4 conditions relative to the No-Action Alternative and Existing Condition (Attachments 1A and 2A). The maximum increase in production relative to the No-Action Alternative was 233 percent, while the largest decrease in production under CP4 relative to the No-Action Alternative was less than 5 percent (Attachment 1A). The maximum increase in production relative to the Existing Condition was 233 percent in 1934 for CP4, while the largest decrease in production relative to the Existing Condition was 5 percent CP4 in 1976 (Attachment 2A).

All years with the lowest production over the simulation period show the largest increase in production under CP4 conditions.

Under CP4, critical water years 1924, 1931, 1933, 1934, 1977, 1988, and 1992, and dry water year 1932 had increases in production compared to the No-Action Alternative, ranging from 7 percent to 233 percent. No water years had a decrease in production compared with the No-Action Alternative greater than 5 percent.

Under CP4, critical water years 1924, 1931, 1933, 1934, 1977, 1988, 1992 and 1994 had substantial increases in production compared to the Existing Condition, ranging from 5 percent to 233 percent. Three dry (1932, 1944, and 1947) water years had increases over the Existing Condition ranging from 4 to 10 percent. No water years had a decrease in production greater than 5 percent relative to the Existing Condition.

When the spawning population equaled AFRP goal, the overall average winter-run Chinook salmon production was similar for CP4 relative to the No-Action Alternative (Attachment 3A). The maximum increase in production relative to

the No-Action Alternative was 166 percent for CP4. The largest decrease in production relative to the No-Action Alternative was 15 percent for CP4. In all years, the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP4.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to winter-run Chinook salmon under CP4 occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-4 displays the overall mortalities for each Comprehensive Plan that were caused by nonoperational factors versus those caused by the operations (i.e., water temperature and flow) (Attachments 2B and 3B). Mortalities caused by the project decrease as the proposed dam height increases from 6.5 to 18.5 feet.

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, fry were the primary life stage affected, but operations-related activities had a greater effect on eggs than on presmolts and no effect on immature smolts. The same trends for each Comprehensive Plan were observed, with the bulk of the mortality affecting the fry and egg incubation life stages, and both water temperature and flow causing the mortality (Table 11-5).

In critical water years, mortality under CP4 conditions was dominated by forced movement of fry, then by superimposition and mortality to eggs due to unsuitable water temperatures. Attachments 1C and 2C contain tables of mortality to winter-run sorted by water-year type, and Table 11-6 outlines the ranks classified under each Comprehensive Plan for each water-year type.

In dry water years, mortality to fry when moving to new habitats was the primary cause of operations-related mortalities for CP4, followed by mortality to eggs due to redd superimposition. Third was the mortality to eggs due to redd scouring and/or dewatering, followed by mortality to presmolts while moving to new habitats.

Below-normal, above-normal, and wet water years also had the greatest number of winter-run Chinook salmon perish as fry caused by forced movement to habitat downstream, followed by mortality to eggs due to redd superimposition, then the loss of eggs from unsuitable water temperatures, and forced movement of presmolts to downstream habitats.

Under CP4, years with the highest mortality were 1924, 1932, 1934, 1963, 1970 and 1982, and included two critical water years, one dry water year, and three wet water years. These years were preceded by two critical, one dry, two below-normal, and one wet water year. Years with the lowest mortality varied between all water-year types. Years in which the project had the greatest

impact on winter-run were also the years in which the lowest production occurred (Attachments 1C and 2C).

When the spawning population equaled the AFRP goal, winter-run Chinook salmon mortality caused by the operations-related activities decreased under CP4 compared to No-Action Alternative conditions. Under CP4, mortality caused by operations-related activities would decrease from non-operations related mortality by more than 12 percent. Under CP4, the greatest mortality to winter-run Chinook salmon occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives (Attachment 3B).

Because winter-run Chinook salmon have, overall, a reduced mortality, winter-run Chinook salmon would benefit from water temperature and flow conditions under in CP4. Additionally, winter-run Chinook salmon will likely benefit from the 10-year gravel augmentation program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average spring-run Chinook salmon production increased for the 82-year period under CP4 compared to the No-Action Alternative and the Existing Condition (Attachments 4A and 5A). The maximum increase in production relative to the No-Action Alternative was 5,321 percent for CP4. The largest decrease in production relative to the No-Action Alternative was 9 percent for CP4 (Attachment 4A). The maximum increase in production relative to the Existing Condition was 5,586 percent for CP4. The largest decrease in production relative to the Existing Condition was 9 percent for CP4 (Attachment 5A).

Under CP4, critical water years 1924, 1931, 1933, 1934, 1977, 1988, 1991, 1992, and 1994, dry water years 1925, 1926 and 1932, below-normal water years 1935 and 1959, and above-normal water year 2000, had increases in production compared to the No-Action Alternative, ranging from 6 to 5,321 percent. In 1955 (dry water year, 1923 (below-normal water year) and 1969 and 1997 (wet water years), production decreased between 6 and 10 percent.

Under CP4, critical water years 1924, 1931, 1933, 1934, 1977, 1988, 1991, 1992, 1994, and 2001 had increases in production compared to the Existing Condition, ranging from 11 to 5,586 percent. Dry water years 1932 and 2002 resulted in substantial increases over the Existing Condition ranging between 8 and 3,081 percent. Two below-normal water years (1935 and 1959), and one above-normal water year (2000) had substantial increases relative to the Existing Condition, from 9 to 23 percent. One above-normal water years (1978), and two wet water years (1969, 1997) had decreases in production relative to the Existing Condition ranging from 5 to 9 percent.

The overall average spring-run Chinook salmon production was slightly higher for CP4 relative to the No-Action Alternative (Attachment 6A). The maximum increase in production relative to the No-Action Alternative was 10,446 percent for CP4. The largest decrease in production relative to the No-Action Alternative was 5 percent for CP4. Years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP4.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to spring-run Chinook salmon under CP4 occurred to the eggs, followed by presmolts, then fry. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-7 displays the overall mortalities for each Comprehensive Plan that were caused by nonoperational factors versus those caused by the operations (i.e., water temperature and flow) (Attachments 4B and 5B). Mortalities caused by the project decrease as the proposed dam height increases from 6.5 to 18.5 feet (Tables 11-7 and 11-8).

When removing nonoperations-related mortality, leaving mortality due to operations-related activities, only eggs and fry were affected (Table 11-8).

Critical water years under all Comprehensive Plans follow the same trends, with mortality to eggs due to unsuitable water temperatures as the primary cause of operations-related mortalities, followed by mortality to prespawned eggs and during incubation caused by dewatering the redds, then mortality to fry from forced movement to downstream habitats. Attachments 4C and 5C contains tables of mortality to spring-run Chinook salmon sorted by water-year type, and Table 11-9 outlines the rankings classified under each Comprehensive Plan for each water-year type.

In dry, below-normal and above-normal water years, all Comprehensive Plans were dominated by egg temperature mortality, followed by mortality resulting from redd dewatering. Mortality to prespawned eggs occurred in only two dry years but no below-normal water years. Mortality to fry from forced movement was relatively low in only several more years (Table 11-9).

In wet water years, the primary cause of mortality to spring-run Chinook salmon were to eggs due to redd dewatering and/or scouring, followed by mortality to eggs due to unsuitable water temperatures, then to fry resulting from forced movement and prespawn mortality (Table 11-9).

Years with the highest operations-related mortality were the same for all the Comprehensive Plans: 1924, 1931, 1932, 1933, 1934, 1977, and 1992. Except for 1932 (a dry water year), each of these years was a critical water-year type and was preceded by either a below, dry, or (predominantly) a critical water year. However, years with the lowest mortality varied between all water-year

types. Years in which the project had the greatest impact on spring-run Chinook salmon were also the years in which the lowest production occurred, with nearly all of the mortality occurring in the egg incubation life stage (Attachments 4C and 5C).

When the spawning population equaled AFRP goals, spring-run Chinook salmon mortality caused by the operations-related activities decreased under CP4 compared to No-Action Alternative conditions. Under CP4, mortality caused by operations-related activities would decrease from non-operations related mortality by over 43 percent. Under CP4, the greatest mortality to spring-run occurs to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives (Attachment 6B).

Because spring-run Chinook salmon have, overall, a reduced mortality, spring-run Chinook salmon would benefit from actions taken in CP4. Additionally, spring-run Chinook salmon will benefit from the 10-year gravel augmentation program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average fall-run Chinook salmon production increased for the 82-year period compared with the No-Action Alternative and Existing Condition (Attachments 7A and 8A). The maximum increase in production relative to the No-Action Alternative was 350 percent. The largest decrease in production relative to the No-Action Alternative was 9 percent for CP4 (Attachment 7A). The maximum increase in production relative to the Existing Condition was 607 percent in 1934. The largest decrease in production relative to the Existing Condition was 11 percent for CP4 in 1969 (Attachment 8A).

In critical, dry, and below-normal water years, when production was lowest over the simulation period, the increase in production resulting from operations-related activities was greatest. In above-normal and wet water years, however, the lowest production years typically had a slight decrease in production under CP1 conditions relative to the No-Action Alternative.

Under CP4, critical water years 1924, 1931, 1933, 1934, 1977, 1992, and 1994, dry water year 1932, and below-normal water years 1937 and 1945 had increases in production relative to the No-Action Alternative, ranging from 6 to 351 percent. A wet water year (1999) had a production decrease of approximately 10 percent.

Under CP4, six critical water years (1924, 1931, 1933, 1934, 1977, 1992) had increases in production relative to the Existing Condition, ranging from 10 to 607 percent. Two dry water years, 1932 and 1955, had a 16 and 5 percent

increase in production compared to the Existing Condition, respectively. Two below-normal water years, 1937 and 1945, had an increase in production relative to the Existing Condition of 9 and 7 percent, respectively. One dry water year (1985), one above-normal water year (1957) and two wet water years (1969 and 1999), resulted in a decrease in production relative to the Existing Condition, ranging from 5 to 11 percent.

When the spawning population equaled the AFRP goal, overall average fall-run Chinook salmon production was similar for CP4 relative to the No-Action Alternative (Attachment 9A). The maximum increase in production relative to the No-Action Alternative was 310 percent for CP4. The largest decrease in production relative to the No-Action Alternative was 9 percent for CP4. In critical, dry, and below-normal water years, years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP4. In above-normal and wet water years, however, the lowest production years typically remained similar or slightly decreased in production under CP4 conditions relative to the No-Action Alternative.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to fall-run Chinook salmon occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-10 displays the overall mortalities for each alternative that were caused by nonoperational factors versus those caused by operations (i.e., water temperature and flow) (Attachments 7B and 8B).

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, egg incubation was still the primary life stage affected, but operations-related activities had a greater effect on fry than on presmolts and an even lesser effect on immature smolts. The same trends for each Comprehensive Plan were observed, with the bulk of the mortality affecting the egg incubation life stage, with flow triggering more of the mortality (Table 11-11).

In all water-year types, under all Comprehensive Plans, the greatest portion of mortality occurred to fry caused by forced movement to downstream habitats. Prespawn, incubation, and superimposition mortality were greater than mortality to eggs caused by unsuitable water temperatures and presmolt habitat movement.

In critical water years, all Comprehensive Plans showed the same general trend in mortality factors. Mortality to fry due to forced movement downstream was the primary cause of operations-related mortalities for the No-Action Alternative and CP4, followed by mortality to eggs prior to spawning, and then to eggs from redd dewatering or scouring. Least affected were presmolts and then immature smolts by both water temperatures and forced movement.

Attachments 7C and 8C contain tables of mortality to fall-run Chinook salmon sorted by water-year type, and Table 11-12 outlines the rankings classified under each Comprehensive Plan for each water-year type.

As with critical water years, dry water years were dominated by mortality to fry due to forced movement downstream, followed by redd dewatering or scouring and redd superimposition. Additional mortality occurred to fall-run Chinook salmon presmolts and immature smolts from both forced movement and unsuitable water temperatures (Table 11-12).

Below-normal and above-normal water years were relatively similar for all Comprehensive Plans. The mortality factors were dominated by mortality to fry due to forced movement downstream, followed by redd superimposition, dewatering, or scouring. Mortality to presmolts caused by forced downstream movement was a greater factor affecting fall-run populations than was egg mortality caused by unsuitable water temperatures or to immature smolts and fry due to unsuitable water temperatures (Table 11-12).

As with the water-year types discussed above, under wet water year conditions, the majority of the mortality also occurred to fry due to forced downstream movement, followed by redd superimposition, and redd dewatering or scouring. Mortality to presmolts and immature smolts from downstream movement had the lowest mortality rates resulting from operations-related activities. Least affected were eggs due to unsuitable water temperatures, both pre- and post-spawn.

Under conditions created by CP4 compared with the No-Action Alternative, the years with the highest mortality tended to shift to all wet water years – 1956, 1958, 1970, 1978, and 1984 – which were preceded by wet, above-normal and dry water years (Attachment 7C).

Under conditions created by CP4 compared with the Existing Condition, the years with the highest mortality rates were 1955, 1957, 1969, 1973, 1981,1983, and 1996 (Attachment 8C).

When the spawning population equaled the AFRP goal, fall-run Chinook salmon mortality caused by operations-related activities decreased under CP4 compared to No-Action Alternative conditions (Attachment 9B). Under CP4, mortality caused by operations-related activities would decrease from non-operations related mortality by over 17 percent. Under CP4, the greatest mortality to fall-run occurred to the egg incubation life stage, followed by fry, then presmolts, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives.

Because fall-run Chinook salmon have, overall, a reduced mortality, fall-run Chinook salmon would benefit from actions taken in CP4. Additionally, fall-run Chinook salmon will benefit from the 10-year gravel augmentation

program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon

Production

Based on the 1999 through 2006 population average, overall average late fall-run Chinook salmon production for the 82-year period under CP4 conditions was slightly greater than the No-Action Alternative and the Existing Condition (Attachments 10A and 11A). The maximum increase in production relative to the No-Action Alternative was 27 percent, while the largest decrease in production relative to the No-Action Alternative was 6 percent for CP4 (Attachment 10A). The maximum increase in production relative to the Existing Condition was 28 percent, while the largest decrease in production relative to the Existing Condition was 7 percent for CP4 (Attachment 11A).

Under CP4, critical water years 1924, 1929, 1931, 1933, 1976, and 1991, dry water years 1930 and 1932, and below-normal water year 1923 had increases in production compared to the No-Action Alternative, ranging from 6 to 28 percent. No water years had a decrease greater than 5 percent.

Under CP4, five critical water years (1931, 1933, 1976, 1988, and 1991) had substantial increases in production compared to the Existing Condition, ranging from 5 to 28 percent. Five dry water years (1926, 1930, 1932, 1939, and 1985), and one below-normal water year (1923), had increases in production relative to the Existing Condition, ranging from 5 to 19 percent. One wet water year (1969) and one dry water year (1949) had a decrease in production over the Existing Condition by 5 percent to 7 percent.

When the spawning population equaled the AFRP goal, overall average late fall-run Chinook salmon production was similar for CP4 relative to the No-Action Alternative (Attachment 12A). The maximum increase in production relative to the No-Action Alternative was 28 percent for CP4. The largest decrease in production relative to the No-Action Alternative was 3 percent for CP4. In critical, dry, and below-normal water years, years with the lowest production under the No-Action Alternative typically had the greatest percent increase in production under CP4. In above-normal and wet water years, however, the lowest production years typically remained similar to, or had a slight decrease in production under CP4 conditions relative to the No-Action Alternative.

Mortality

Based on the 1999 through 2006 population average, the greatest mortality to late fall-run Chinook salmon under CP4 occurred to the egg incubation life stage, followed by fry, then presmolts, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-13 displays the overall mortalities for each Comprehensive Plan that was caused by nonoperational

factors versus those caused by the operations (i.e., water temperature and flow) (Attachments 10B and 11B). Mortalities caused by the project decreased for all Comprehensive Plans relative to the No-Action Alternative.

When removing nonoperations-related mortality, allowing comparison of mortality for operations-related activities only, fry became the primary life stage affected, and operations-related activities had a greater effect on eggs than on presmolts and even less effect on immature smolts. Most of the mortality occurred as a result of flow conditions rather than water temperature (Table 11-14).

Under all Comprehensive Plans, mortality to fry resulting from unsuitable water temperatures only occurred at low levels to late fall-run Chinook salmon during critical, dry, and below-normal water years. In all water-year types, under all Comprehensive Plans, mortality to fry during forced movement to downstream habitats was the primary cause of operations-related mortality.

In critical, dry and below-normal water years, the causes of operations-related mortality followed similar trends for all Comprehensive Plans, with a few exceptions. In general, the effects of flow (and density) had the greatest effect on mortality. Forced movement of fry resulted in the greatest mortality, followed by flow effects on eggs via scouring, dewatering, or superimposition. Next affected were presmolts and immature smolts, by unsuitable water temperatures, and lastly temperature effects on eggs and flow effects on presmolts and immature smolts and fry (Table 11-15).

Wet and above-normal water years were overall similar to critical, dry, and below-normal water years except that mortality to fry due to unsuitable water temperatures disappeared and CP4 in wet years had no mortality due to redd scouring and/or dewatering.

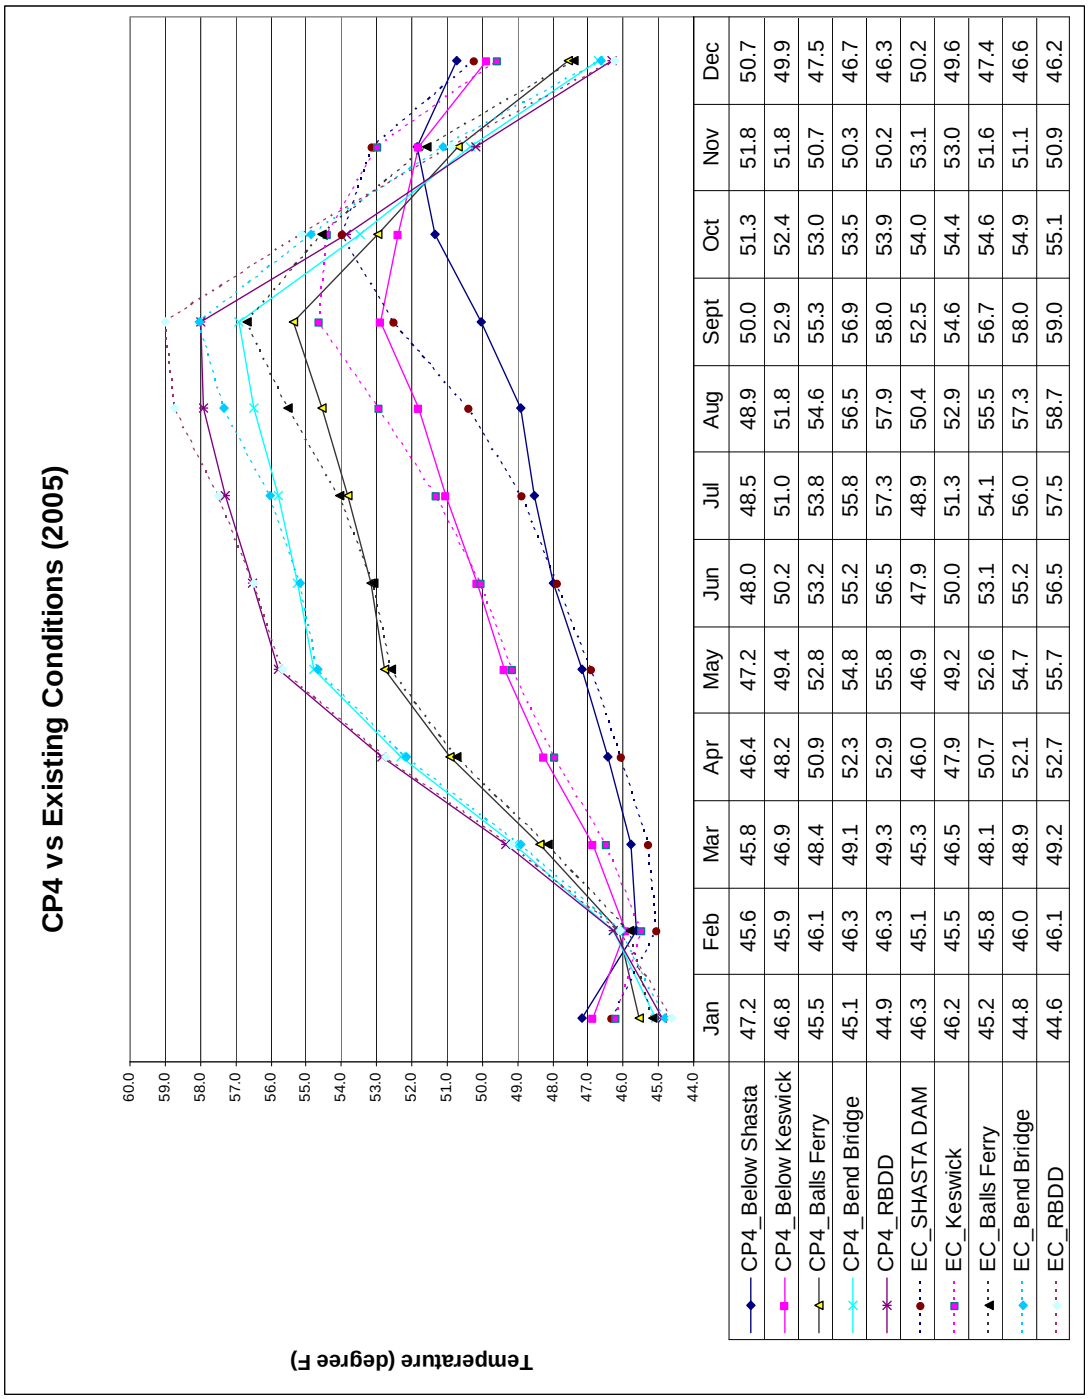
Years with the highest mortality were the same for CP4 and the No-Action Alternative and the Existing Condition: 1937, 1957, 1982, 1985, 1994 and 1997. All water-year types were covered. Three of these with the highest mortality years were preceded by a wet water year, one preceded by an above-normal water year, and at least one below-normal water year (Attachments 10C and 11C).

When the spawning population equaled the AFRP goal, late fall-run Chinook salmon mortality caused by operations-related activities was slightly less under CP4 than under No-Action Alternative conditions. Under CP4, mortality caused by operations-related activities would decrease from non-operations related mortality by over 28 percent. Under CP4, the greatest mortality to late fall-run Chinook salmon occurred to the egg incubation life stage, followed by presmolts, then fry, and lastly to immature smolts. Nonoperational conditions were the primary causes of mortality for all life stages under all alternatives (Attachment 12B).

Because late fall-run Chinook salmon have, overall, a reduced mortality, late fall-run Chinook salmon would benefit from actions taken in CP4. Additionally, late fall-run Chinook salmon will benefit from the 10-year gravel augmentation program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-13 (CP4): Changes in Flow and Water Temperatures in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass CP4 operations would result in slightly improved flow and, sometimes, improved water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass, particularly in critical water years. Overall, potential flow changes resulting from the implementation of CP4 would not be of sufficient frequency or magnitude to beneficially or adversely affect steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass, in the upper Sacramento River. However, potential water temperature changes (reductions) resulting from the implementation of CP4 would result in beneficial impacts on steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass in the upper Sacramento River especially during critical water years. Flow- and water temperature-related effects on these fish species would be less than significant (flow) and beneficial (water temperature), relative to the Existing Condition and No-Action Alternative. The benefits of the water temperature decrease outweigh the minimal effects of flow changes. Therefore, this impact would be beneficial.

This impact would be similar to Impact Aqua-13 (CP1); however, the impact could be greater (beneficial) during certain years because of the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise and the additional volume of cold-water that would be available for anadromous fish.

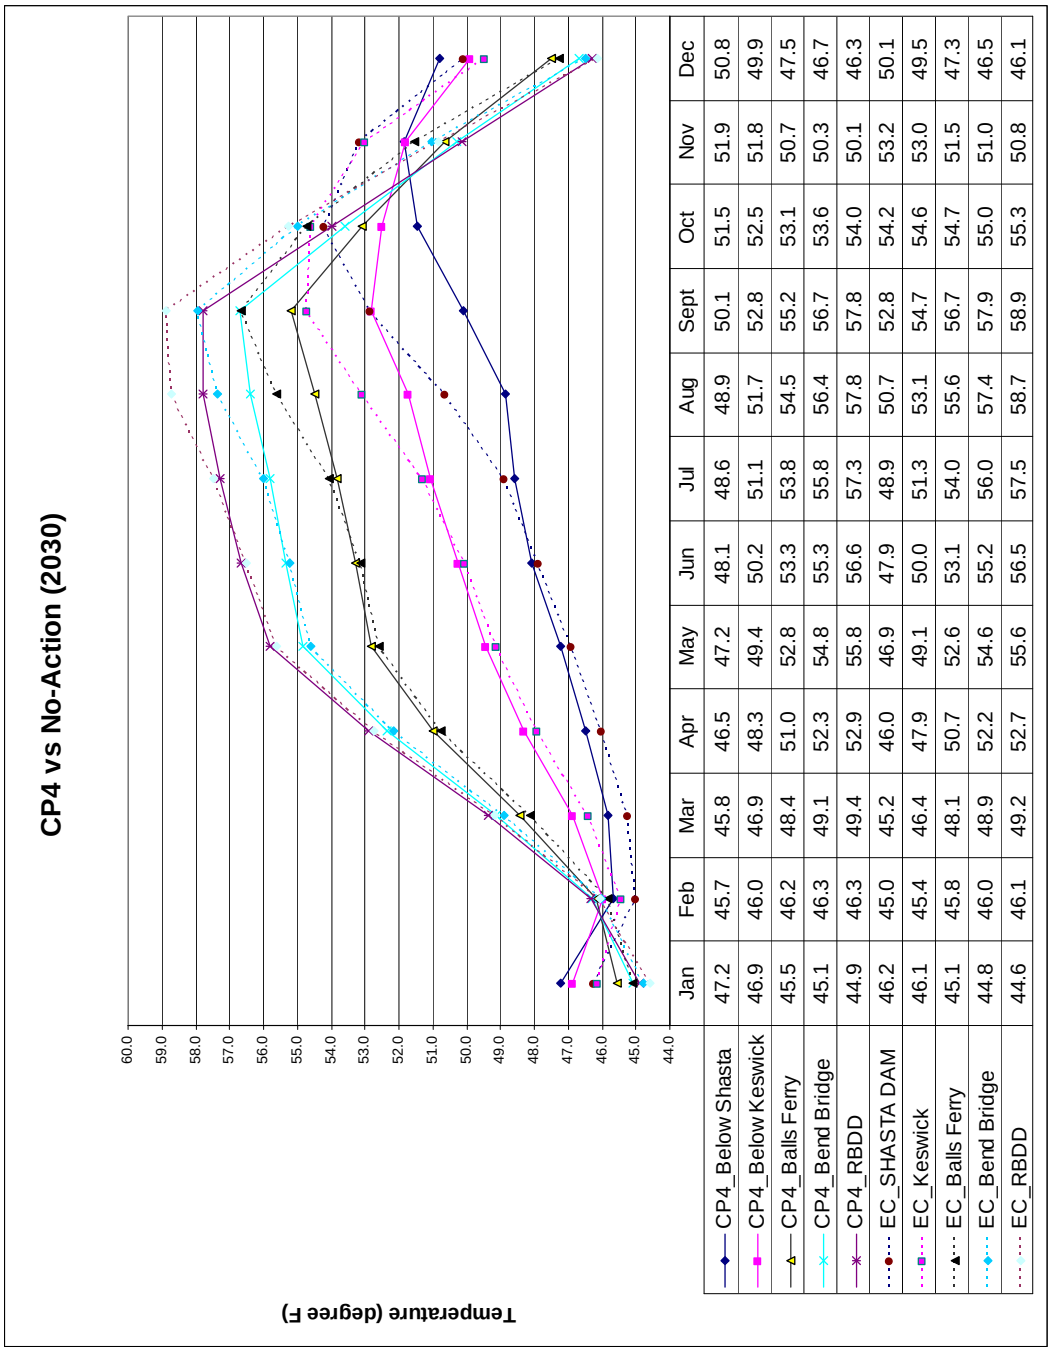


Flow-Related Effects Similar to CP1, monthly mean flows at all model locations (i.e., below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBDD) within the upper Sacramento River under CP4 would be similar to flows (less than 4 percent) under the Existing Condition and No-Action Alternative simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). Potential flow-related effects on fish species of management concern in the upper Sacramento River from this alternative would be minimal. All potential changes in flows and stages would diminish rapidly downstream from RBDD because of the increasing effect of inflows from tributaries, and of diversions and flood bypasses.

There would be no discernable flow-related effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River related to changes in monthly mean flows under CP4, relative

to the Existing Condition and No-Action Alternative. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Flow-related effects on these fish species would be less than significant.

Water Temperature-Related Effects Similar to CP1, monthly mean water temperatures at all model locations (i.e., below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBDD) within the upper Sacramento River under CP4 would be slightly less than those under the Existing Condition and No-Action Alternative conditions simulated for all months (Figures 11-30 and 11-31) (see also the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). As discussed above, modeling simulations may not fully account for real-time management of the cold-water pool and TCD (through the SRTTG) to achieve maximum cold-water benefits. Therefore, the modeled changes in water temperature (i.e., small benefits) are likely conservative and understated to some varying degree. During most years, flow releases from Shasta Dam would be unchanged. On average, the greatest cooling effect (more than a 4°F reduction) occurred during critical years and during the late summer (i.e., July through September) (Figures 11-32 and 11-33), because of the increased cold-water pool volume within Shasta Lake, even following an extended dry period. All potential changes in flows and stages would diminish rapidly downstream from RBDD because of the increasing effect of inflows from tributaries, and of diversions and flood bypasses.



There would be water temperature-related effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River related to cooler monthly mean water temperatures under CP4, relative to the Existing Condition and No-Action Alternative. Mean monthly water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River, and would actually create more suitable conditions. Water temperature-related effects on these fish species would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-33. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area for Critical Years (No-Action Alternative)

Impact Aqua-14 (CP4): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows CP4 operations could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

This impact would be similar to Impact Aqua-14 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for additional water volume (and flows) to be stored behind the raised dam. Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and associated stage elevation of water surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flow, with relatively large floods providing the energy required to mobilize sediment from the river bed, produce meander migration, increase stage elevation, and create seasonally inundated floodplains. CP4 operations could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

CP4 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from the operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

These effects would likely occur along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. As discussed above, CP4 also includes a 10-year gravel augmentation program and the restoration of riparian, floodplain, and side channel habitat at Reading Island as additional environmental commitments. The placement of gravel along the Sacramento River channel and bank on an annual basis and restoration of riparian, floodplain, and side channel habitat at Reading Island would result in ecological process (e.g., sediment transport and deposition, floodplain inundation) benefits that would partially offset the impacts described above. Nevertheless, reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. These impacts would be potentially significant within the primary study area. Mitigation for this impact is proposed in Section 11.3.4.

Lower Sacramento River and Delta

Impact Aqua-15 (CP4): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern Project operation would result in no discernable change in mean monthly flow or water temperature conditions in the lower Sacramento River; however, predicted changes in flow in the Feather River, American River, and Trinity River could result in an adverse effect on Chinook salmon, steelhead, coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass if they were to occur. This impact would be potentially significant.

This impact would be similar to Impact Aqua-15 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for additional water volume (and increased cold-water pool) to be stored behind the raised dam.

Similar to CP1, monthly mean flows at model locations (i.e., Verona, Freeport) within the lower Sacramento River under CP4 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). All potential changes in flows diminish rapidly downstream from RBDD because of the increasing effect of inflows from tributaries and of diversions and flood bypasses. Potential flow-related effects on fish species of management concern in the lower Sacramento River from this alternative would be minimal. Differences in mean monthly flow are generally small (less than 2 percent) and within the existing range of variability. All potential changes in water temperatures in the lower Sacramento River due to small changes in releases would diminish rapidly downstream because of the increasing effects of inflows, atmospheric influences, and groundwater. Therefore, flow- and temperature-related impacts on fish species in the lower Sacramento River would be less than significant.

Also similar to CP1, monthly mean flows at all model locations within the lower Feather River, the American River, and Trinity River under CP4 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative simulated for most months. However, there were several months within the modeling record that showed substantial changes (based on model simulations) to flows in tributaries (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete CalSim-II modeling results). All potential changes in flows could be diminished in these areas per existing operational rules and because of operation of upstream reservoirs (i.e., Lake Oroville, Folsom Lake, and Trinity Lake), and increasing effects of inflows from tributaries, and of diversions and flood bypasses. Nevertheless, based on predicted changes in flow and associated flow-habitat relationships, potential flow-related impacts on species of

management concern in the American, Feather, and Trinity rivers could occur and would be a potentially significant impact.

Monthly mean flows at all model locations within the lower Feather River (i.e., below Thermalito Afterbay) and the American River (i.e., near the H Street Bridge in Sacramento) under CP4 would also be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative simulated for all months. All potential changes in flows were diminished in these areas because of operation of upstream CVP and SWP reservoirs (i.e., Lake Oroville and Folsom Lake), and the increasing effect of inflows from tributaries, and of diversions and flood bypasses. Potential flow-related effects on fish species of management concern in the Feather River and American River from this alternative would be minimal and within the range of existing variability.

All potential changes in water temperatures in the lower Sacramento River and primary tributaries (i.e., Feather and American rivers) due to altered releases from reservoirs diminished downstream from RBDD because of increasing effect of inflows, and atmospheric and groundwater influences.

As under CP1, effects of altered flow regimes resulting from implementation of CP4 are unlikely to extend into the lower Sacramento River and Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the SWP and the CVP). The guidelines for this management, which are described in the CVP/SWP OCAP, have been designed to maintain standards for flow to the lower Sacramento River and Delta. CVP and SWP operations must be consistent with the OCAP to allow coverage by the OCAP permits and BOs. Thus, under CP4, this project is not anticipated to cause an alteration in flow to the Delta nor cause an alteration to water temperatures in the lower Sacramento River and primary tributaries within the extended study area sufficient to cause discernable effects on Chinook salmon steelhead, green sturgeon, Sacramento splittail, American Shad, or striped bass relative to the Existing Condition and No-Action Alternative. Functional flows for fish migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow- and temperature-related effects on these fish species would be less than significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-16 (CP4): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows CP4 operations could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the

lower Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

This impact would be similar to Impact Aqua-16 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for additional water volume (and flows) to be stored behind the raised dam. Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and associated stage elevation of water surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flow, with relatively large floods providing the energy required to mobilize sediment from the bed, produce meander migration, increase stage elevation, create seasonally inundated floodplains, and inundate floodplain bypasses. Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

CP4 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from the operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These effects would likely occur along the upper reaches of the lower Sacramento River. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. These impacts would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-17 (CP4): Effects to Delta Fishery Habitat Resulting from Changes to Delta Outflow Delta outflow conditions under CP4 would be the same as those under CP1. Therefore, CP4 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-18 (CP4): Effects to Delta Fishery Habitat Resulting from Changes to Delta Inflow Changes in upstream reservoir storage have the potential to affect Delta inflow. Delta inflow may affect hydrologic conditions within Delta channels, hydraulic residence times, salinity gradients, and the transport and movement of various life stages of fish, invertebrates, phytoplankton, and nutrients into and through the Delta. Delta inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources. Delta inflow conditions under CP4 would be the same as those under CP1; therefore, CP4 would have a less than significant effect on Delta fisheries and hydrologic

transport processed within the Bay-Delta compared with the Existing Condition and No-Action Alternative. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP4): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow CP4 operations would be the same as those under CP1 and would result in a variable response in Sacramento River flow, in turn, resulting in both increases and decreases in river flow above the Existing Condition and No-Action Alternative depending on month and water-year type. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP4): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis CP4 operation would be the same as under CP1 and would result in no discernable change in San Joaquin River flows at Vernalis. Therefore, CP4 would have no effect on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta relative to either the No-Action Alternative of Existing Condition. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP4): Reduction in Low Salinity Habitat Conditions Resulting from an Upstream Shift in X2 Location CP4 operations, the same as CP1 operations, would result in a less than 0.5 km movement upstream or downstream from the X2 location. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP4): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in Old and Middle Rivers CP4 operations, the same as CP1 operations, would result in an increase of reverse flows in Old and Middle rivers. The increase in reverse flows would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses. This impact would be potentially significant. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

Impact Aqua-23 (CP4): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP4 operations, which are the same as CP1 operations, may result in an increase of CVP and SWP exports, which is assumed to result in a direct proportional increase or decrease in the risk of fish being entrained and salvaged at the facilities. This is considered a less than significant impact to Chinook salmon, steelhead, and longfin smelt. This is considered a potentially significant impact to delta smelt, striped bass, and splittail. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

CVP/SWP Service Areas

Impact Aqua-24 (CP4): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes CP4 implementation could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects in tributaries and reservoirs (e.g., New Melones and San Luis) with CVP and SWP dams are expected to be less than impacts on the lower Sacramento River. The change in hydrology could affect aquatic habitats that provide habitat for the fish community. These changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-33 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and flows) to be stored behind the raised dam. However, these changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. The effects from CP4 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and resulting downstream flows, would be small and well within the range of variability that commonly occurs in these reservoirs and downstream flows. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 focuses primarily on increased water supply reliability, Shasta Lake-area environmental resources, and increased recreation opportunities. Major components of this plan include the following:

- Raising Shasta Dam and appurtenant facilities by 18.5 feet.
- Constructing additional resident fish habitat in Shasta Lake and along the lower reaches of the Sacramento River, McCloud River, and Squaw Creek.
- Constructing shoreline fish habitat around Shasta Lake.
- Improving operation and enhancing recreation facilities at various locations around Shasta Lake.
- Enlarging the Shasta Lake cold-water pool.
- Modifying the TCD.
- Increasing conservation storage.

- Reducing demand.
- Modifying flood operations.
- Increasing public safety at Shasta Dam.
- Modifying hydropower facilities.

The additional storage created by the 18.5-foot dam raise would be used primarily to increase water supply reliability, while also improving the ability to meet temperature objectives for winter-run Chinook salmon during drought years. The capacity of the reservoir would increase by 634,000 acre-feet to a total of 5.19 million acre-feet, and the existing TCD would be extended to achieve efficient use of the expanded reservoir.

CP5 includes restoring resident fish habitat in Shasta Lake and fisheries and riparian habitat at several locations along the lower reaches of the upper Sacramento River, McCloud River, and Squaw Creek. Specific locations and total area of restoration in the Shasta Lake area will be the subject of future studies.

Shasta Lake and Vicinity

Impact Aqua-1 (CP5): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP5, this impact would be similar to CP3. Its impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-2 (CP5): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction This impact would be similar to CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-3 (CP5): Effects on Cold-Water Habitat in Shasta Lake Under CP5, operations-related changes in the ratio of the volume of cold-water storage to surface area would increase the availability of suitable habitat for cold-water fish in Shasta Lake, including rainbow trout. This impact would be beneficial.

This impact would be similar to CP3 and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-4 (CP5): Effects on Special-Status Aquatic Mollusks Under CP5, habitat for special-status mollusks could be inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could also adversely affect special-status aquatic mollusks that could occupy habitat in or near Shasta Lake and its tributaries. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be potentially significant.

This impact would be similar to CP3 and would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-5 (CP5): Effects on Special-Status Fish Species That Occupy Habitat Provided by Shasta Lake and its Tributaries The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat under CP5 could affect one species designated as sensitive by the USFS, the hardhead. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be less than significant.

This impact would be similar to Impact Aqua-5 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP5): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP5, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,090-foot contour, the maximum inundation level under this alternative. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. However, based on digital topographic data and stream channel data generated from field inventories, it appears no substantial barriers between the 1,070-foot and 1,090-foot contours would be inundated under this alternative. This impact would be less than significant.

This impact would be similar to Impact Aqua-6 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP5): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake CP5 would result in additional periodic inundation of potentially suitable spawning and rearing habitat for adfluvial salmonids in low-gradient tributaries to Shasta Lake. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. A total of 11 miles of low-gradient reaches that could potentially provide some spawning and rearing habitat for adfluvial salmonids would be affected by CP5, which is only about 2.8 percent of the low-gradient habitat upstream from Shasta Lake. This impact would be less than significant.

This impact would be similar to CP3 and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-8 (CP5): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP5 would result in periodic inundation of the lower reaches of high-gradient, non-fish-bearing tributaries to Shasta Lake. About 24 miles of non-fish-bearing tributary habitat would be affected by CP5, which is only about 1 percent of the total length of non-fish-bearing tributaries

upstream from Shasta Lake. Tributary investigations are ongoing and will provide additional information and analysis for inclusion in the FEIS. This impact would be less than significant.

This impact would be similar to Impact Aqua-8 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP5): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP5. There would be no impact.

This impact would be similar to Impact Aqua-9 (CP1), and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to RBDD)
Impact Aqua-10 (CP5): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Construction activities have the potential to increase sediments and turbidity, and release and exposure of contaminants. With environmental commitments in place, this would be a less than significant impact

This impact would be similar to Impact Aqua-10 (CP1). The impact could be greater because of the increased activity associated with an 18.5-foot dam raise compared to a 6.5-foot dam raise. Similar to CP4, CP5 also includes a 10-year gravel augmentation program as an additional environmental commitment. The placement of gravel along the Sacramento River channel and bank on an annual basis would result in an additional source of fine sediment being released and exposed to the river and aquatic communities. However, the gravel augmentation activities would only occur during pre-specified in-water work windows, which would minimize the potential for impacts associated with this activity.

Also similar to CP4, CP5 also includes a riparian, floodplain, and side channel habitat restoration in the upper Sacramento River at Reading Island. The Reading Island riparian, floodplain, and side channel restoration could result in additional disturbed surfaces, but most of this construction is expected to occur away from the wetted channel, and all disturbed areas would be revegetated.

However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed. *Impact Aqua-11 (CP5): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities* Construction-related activities have the potential to result in the release and exposure of contaminants, resulting in adverse effects on aquatic habitats, the aquatic food web, and fish populations, including special-status species, within the primary

study area downstream from project construction activities. This impact would be less than significant with all environmental commitments in place.

This impact would be similar to Impact Aqua-11 (CP1). The impact could be greater because of the increased activity associated with an 18.5-foot raise compared to a 6.5-foot raise. Similar to CP4, CP5 also includes the implementation of the gravel augmentation program and restoration of riparian, floodplain, and side channel habitat at Reading Island. However, the environmental commitments for all action would result in less than significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-12 (CP5): Improved Flow and Water Temperature in the Upper Sacramento River Resulting From Project Operation – Chinook Salmon Project operation would result in improved flow and water temperature conditions in the upper Sacramento River for fish species of management concern. This impact would be beneficial.

Winter-Run Chinook Salmon Impacts and benefits under CP5 to winter-run Chinook salmon are the same as those identified under CP3. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon Impacts and benefits under CP5 to spring-run Chinook salmon are the same as those identified under CP3. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon Impacts and benefits under CP5 to fall-run Chinook salmon are the same as those identified under CP3. Mitigation for this impact is not needed, and thus not proposed.

Late Fall–Run Chinook Salmon Impacts and benefits under CP5 to late fall-run Chinook salmon are the same as those identified under CP3. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-13 (CP5): Changes in Flow and Water Temperatures in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass Project operation would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be less than significant.

This impact would be the same as Impact Aqua-13 (CP3). Flow- and water temperature-related effects on these fish species would be less than significant, relative to the Existing Condition and No-Action Alternative. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-14 (CP5): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

This impact would be similar to Impact Aqua-14 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and flows) to be stored behind the raised dam. Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and associated stage elevation of water surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flow, with relatively large floods providing the energy required to mobilize sediment from the river bed, produce meander migration, increase stage elevation, and create seasonally inundated floodplains. Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

CP5 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

These effects would likely occur along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. As discussed above, CP5 also includes a 10-year gravel augmentation program and the restoration of riparian, floodplain, and side channel habitat at Reading Island as additional environmental commitments. The placement of gravel along the Sacramento River channel and bank on an annual basis and restoration of riparian, floodplain, and side channel habitat at Reading Island would result in ecological process (e.g., sediment transport and deposition, floodplain inundation) benefits that would partially offset the impacts described above. Nevertheless, reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. These impacts would be potentially significant within the primary study area. Mitigation for this impact is proposed in Section 11.3.4.

Lower Sacramento River and Tributaries, Delta, and Trinity River
Impact Aqua-15 (CP5): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern Project operation would result in no discernable change in mean monthly flow or water temperature conditions in the lower Sacramento River; however, predicted changes in flow in the Feather River, American River, and Trinity River could result in an adverse effect on Chinook salmon, steelhead, Coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass if they were to occur. This impact would be potentially significant.

This impact would be similar to Impact Aqua-15 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and increased cold-water pool) to be stored behind the raised dam.

Similar to CP1, monthly mean flows at model locations (i.e., Verona, Freeport) within the lower Sacramento River under CP5 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative conditions simulated for all months (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete modeling results). All potential changes in flows diminish rapidly downstream from RBDD because of increasing effects of inflows from tributaries and of diversions and flood bypasses. Potential flow-related effects on fish species of management concern in the lower Sacramento River from this alternative would be minimal. Differences in mean monthly flow were generally small (less than 2 percent) and within the existing range of variability. All potential changes in water temperatures in the lower Sacramento River due to small changes in releases would diminish rapidly downstream because of increasing effects of inflows, atmospheric influences, and groundwater. Therefore, flow- and temperature-related impacts on fish species in the lower Sacramento River would be less than significant.

Also similar to CP1, monthly mean flows at all model locations within the lower Feather River, the American River, and Trinity River under CP2 would be essentially equivalent (less than 2 percent difference) to flows under the Existing Condition and No-Action Alternative simulated for most months. However, several months within the modeling record showed substantial changes (based on model simulations) to flows in tributaries (see the *Hydrology, Hydraulics, and Water Management Technical Report* for complete CalSim-II modeling results). All potential changes in flows could be diminished in these areas per existing operational rules, and because of operation of upstream reservoirs (i.e., Lake Oroville, Folsom Lake, and Trinity Lake), and increasing effects of inflows from tributaries and of diversions and flood bypasses. Nevertheless, based on predicted changes in flow and associated flow-habitat relationships, potential flow-related impacts on species of management concern in the American, Feather, and Trinity rivers could occur and would be a

potentially significant impact. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-16 (CP5): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains, all of which are processes necessary for the maintenance of important aquatic habitat functions and values for the fish and macroinvertebrate community. A reduction in these ecologically important geomorphic processes and related aquatic habitat functions and values in the lower Sacramento River and lowermost (confluence) areas of tributaries would be a potentially significant impact.

This impact would be similar to Impact Aqua-16 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and flows) to be stored behind the raised dam. Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and associated stage elevation of water surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flow, with relatively large floods providing the energy required to mobilize sediment from the bed, produce meander migration, increase stage elevation, create seasonally inundated floodplains, and inundate floodplain bypasses. Project operation could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

CP5 would lead to a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These effects would likely occur along the upper reaches of the lower Sacramento River. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. These impacts would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4.

Impact Aqua-17 (CP5): Effects to Delta Fishery Habitat Resulting from Changes to Delta Outflow Delta outflow conditions under CP5 would be identical to those under CP3. Therefore, CP5 would have a less than significant

effect on Delta fisheries and hydrologic transport processed within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-18 (CP5): Effects to Delta Fishery Habitat Resulting from Changes to Delta Inflow Changes in upstream reservoir storage have the potential to affect Delta inflow. Delta inflow may affect hydrologic conditions within Delta channels, hydraulic residence times, salinity gradients, and the transport and movement of various life stages of fish, invertebrates, phytoplankton, and nutrients into and through the Delta. Delta inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources. Delta inflow conditions under CP5 would be the same as those under CP3; therefore, CP5 would have a less than significant effect on Delta fisheries and hydrologic transport processed within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19(CP5): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow CP5 operations would be the same as those under CP3 and would result in a variable response in Sacramento River flow, resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water year. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP5): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis CP5 operation would be the same as under CP3 and result in no discernable change in San Joaquin River flows at Vernalis; and therefore CP5 would have no effect on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta compared with both the No-Action Alternative and Existing Condition. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP5): Reduction in Low Salinity Habitat Conditions Resulting from an Upstream Shift in X2 Location CP5 operation would be the same as under CP3 and result in a less than 0.5 km movement upstream or downstream from the X2 location. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP5): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in Old and Middle Rivers CP5 operations would be the same as under CP3 and would result in an increase of reverse flows in Old and Middle rivers. The increase in reverse flows would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses. This impact would be potentially significant. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

Impact Aqua-23 (CP5): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP5 operations, which are the same as CP3 operations, may result in an increase of CVP and SWP exports, which is assumed to result in a direct proportional increase or decrease in the risk of fish being entrained and salvaged at the facilities. This is considered a less than significant impact to Chinook salmon, steelhead, and longfin smelt. This is considered a potentially significant impact to delta smelt, striped bass, and splittail. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs.

CVP/SWP Service Areas

Impact Aqua-24 (CP5): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes Project implementation could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects in tributaries and reservoirs (e.g., New Melones and San Luis) from CVP and SWP dams are expected to be less than impacts on the lower Sacramento River. The change in hydrology could affect aquatic habitats that provide habitat for the fish community. These changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-24 (CP1). The impact could be greater because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow additional water volume (and flows) to be stored behind the raised dam. However, these changes are unlikely to result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. The effects from CP4 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and the resulting downstream flows, would be small and well within the range of variability that commonly occurs in these reservoirs and downstream flows. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

11.3.4 Mitigation Measures

Table 11-7 presents a summary of mitigation measures for fisheries and aquatic ecosystems.

No-Action Alternative

Under the No-Action Alternative, no action would be taken, including implementation of mitigation measures; rather, existing conditions would continue to change into the future.

Table 11-37. Summary of Mitigation Measures for Fisheries and Aquatic Ecosystems

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Aqua-1: Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations	LOS before Mitigation	PS	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	PS	LTS	LTS	LTS	LTS	LTS

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Aqua-1 (CP1), through Aqua-13 (CP1), or Aqua-17 through Aqua-21 (CP1). No mitigation is proposed for Impacts Aqua-22 (CP1) or Aqua-22 (CP1). Mitigation measures are provided below for other impacts of CP1 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP1): Implement Mitigation Measure Geo-2 (CP1) This mitigation measure is the same as Mitigation Measure Geo-2 (CP1) described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The loss of riparian habitat provided by springs, seeps and streams will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the study sub-area. Examples of techniques that may be used include channel and bank stabilization, channel re-direction, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Aqua-2 (CP1) to a less than significant level.

Mitigation Measure Aqua-14 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is the same as Mitigation Measure Bot-7 (CP1), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-14 (CP1) to a less than significant level.

Mitigation Measure Aqua-15 (CP1): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP1) to a less than significant level.

Mitigation Measure Aqua-16 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities
Implementation of mitigation measure Bot-7 (CP1) would reduce Impact Aqua-16 (CP1) to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Aqua-1 (CP2) through Aqua-13 (CP2), or Aqua-17 through Aqua-21 (CP2). No mitigation is proposed for Aqua-22 (CP2) or Aqua-23 (CP2). Mitigation measures are provided below for other impacts of CP2 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP2): Implement Mitigation Measure Geo-2 (CP2): Replace Lost Ecological Functions of aquatic Habitats by Restoring Existing Degraded aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Geo-2 (CP2) described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The loss of riparian habitat provided by springs, seeps and streams will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the study sub-area. Examples of techniques that may be used include channel and bank stabilization, channel re-direction, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Aqua-2 (CP2) to a less than significant level.

Mitigation Measure Aqua-14 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP2), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-14 (CP2) to a less than significant level.

Mitigation Measure Aqua-15 (CP2): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP2) to a less than significant level.

Mitigation Measure Aqua-16 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP2), described in Chapter

12, "Botanical Resources and Wetlands." Implementation of this measure would reduce Impact Aqua-16 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impacts Aqua-1 (CP3) through Aqua-13 (CP3), or Aqua-17 through Aqua-21 (CP3). No mitigation is proposed for Aqua-22 (CP3) or Aqua-23 (CP3). Mitigation measures are provided below for other impacts of CP3 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP3): Implement Mitigation Measure Geo-2 (CP3) : Replace Lost Ecological Functions of aquatic Habitats by Restoring Existing Degraded aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Geo-2 (CP3) described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The loss of riparian habitat provided by springs, seeps and streams will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the study sub-area. Examples of techniques that may be used include channel and bank stabilization, channel re-direction, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Aqua-2 (CP3) to a less than significant level.

Mitigation Measure Aqua-14 (CP3): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-14 (CP3) to a less than significant level.

Mitigation Measure Aqua-15 (CP3): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP3) to a less than significant level.

Mitigation Measure Aqua-16 (CP3): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This

measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this measure would reduce Impact Aqua-16 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts Aqua-1 (CP4) through Aqua-13 (CP4), or Aqua-17 through Aqua-21 (CP4). No mitigation is proposed for Aqua-22 (CP4) or Aqua-23 (CP4). Mitigation measures are provided below for other impacts of CP4 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP4): Implement Mitigation Measure Geo-2 (CP4) : Replace Lost Ecological Functions of aquatic Habitats by Restoring Existing Degraded aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Geo-2 (CP3) described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The loss of riparian habitat provided by springs, seeps and streams will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the study sub-area. Examples of techniques that may be used include channel and bank stabilization, channel re-direction, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Aqua-2 (CP4) to a less than significant level.

Mitigation Measure Aqua-14 (CP4): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP1), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-14 (CP4) to a less than significant level.

Mitigation Measure Aqua-15 (CP4): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP4) to a less than significant level.

Mitigation Measure Aqua-16 (CP4): Implement Mitigation Measure Bot-7: Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a

Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP1), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this measure would reduce Impact Aqua-16 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts Aqua-1 (CP5) through Aqua-13 (CP5), or Aqua-17 through Aqua-21 (CP5). No mitigation is proposed for Impacts Aqua-22 (CP5) or Aqua-23 (CP5). Mitigation measures are provided below for the other impacts of CP5 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP5): Implement Mitigation Measure Geo-2 (CP5) : Replace Lost Ecological Functions of aquatic Habitats by Restoring Existing Degraded aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Geo-2 (CP3) described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The loss of riparian habitat provided by springs, seeps and streams will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the study sub-area. Examples of techniques that may be used include channel and bank stabilization, channel re-direction, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Aqua-2 (CP5) to a less than significant level.

Mitigation Measure Aqua-14 (CP5): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-14 (CP5) to a less than significant level.

Mitigation Measure Aqua-15 (CP5): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP5) to a less than significant level.

Mitigation Measure Aqua-16 (CP5): Implement Mitigation Measure Bot-7 (CP3): Implement Mitigation Measure Bot-7: Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this measure would reduce Impact Aqua-16 (CP5) to a less than significant level.

11.3.5 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," discusses overall cumulative impacts of the project alternatives and the No-Action Alternative, including the relationship to CALFED Programmatic Cumulative Impacts Analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria.

As described in Section 11.3, "Affected Environment," aquatic habitats within the primary and extended study areas historically contained large populations of anadromous and other native fish species. Water supply projects, urban development, and flood control modifications have resulted in altered and degraded habitat conditions and reduced this historical fishery throughout. The combined effects of past and present projects have resulted in a significant adverse cumulative impact on fisheries and aquatic ecosystems in the primary and extended study areas.

Many of the reasonably foreseeable future projects identified would involve changes to SWP and CVP water operations that would in turn be anticipated to affect fisheries and aquatic ecosystems. While some of these changes could result in beneficial effects compared to current conditions, aquatic habitat and fisheries resources would remain limited.

The effects of climate change on operations at Shasta Lake could potentially result in changes to water temperature, flow, and ultimately, fish populations. As described in the Climate Change Projection Appendix, climate change could result in increased inflows to Shasta Lake and higher reservoir releases in the future due to an increase in winter and early spring inflow into the lake from high-intensity storm events. The change in reservoir releases could be necessary to manage flood events resulting from these potentially larger storms. Climate change could also result in reduced-end-of September carryover storage volumes, resulting in lower lake levels for a portion of the year, and a smaller cold-water pool resulting in warmer water temperature and reduced water quality within Shasta Reservoir. Most importantly, it is expected that climate change will result in increased water temperatures downstream from Shasta Dam, particularly in summer months, and more frequent wet and drought (particularly extended drought) years. The increased water temperatures, and

greater inter-annual precipitation variability will compound the threats to fish (especially anadromous fish) in the Sacramento River. Winter-run Chinook salmon are particularly vulnerable to climate warming, prolonged droughts, and other catastrophic environmental events because they have only one remaining population that spawns during the summer months, when water temperature increases are expected to be the largest (NMFS 2009). Additionally, ocean productivity is expected to decline from altered upwelling cycles. This could reduce the available food resources for ocean-rearing salmonids and sturgeon, impacting fish survival.

The following analysis evaluates the potential cumulative impacts on fisheries and aquatic ecosystems when considering the project alternatives in combination with other past, present, and reasonably foreseeable future projects.

CP1– 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As described in Section 11.3, without mitigation, CP1 could cause potentially significant effects on vegetation and habitats and special-status species in the primary and extended study areas. These effects would be caused by the loss or degradation of aquatic habitats in the primary study area, or by alteration of the flow regime of the upper Sacramento River and associated geomorphic processes in the primary and extended study areas.

Given the scale and duration of the project construction activities associated with CP1, the contribution to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP1 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the RWQCB. The SWPPP would require implementation of extensive BMPs during project construction as well as post-construction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the proposed project's contribution to cumulative construction-related impacts to a less than significant level.

Given major past alterations to the Sacramento River aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP1 would be cumulatively considerable. With implementation of Mitigation Measures Aqua-14 (CP1) and Aqua-16 (CP1), adverse effects from CP1 would be reduced and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP1 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and

summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for winter-run Chinook spawning. Under CP1, potential impacts to fish would be beneficial.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The cumulative effects of CP2 are similar to those of CP1, but greater in magnitude because CP2 would require additional construction and would result in the potential for increased alteration of flows associated with increased storage volume.

Given the scale and duration of the project construction activities associated with CP2, the contribution to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP2 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the RWQCB. The SWPPP would require implementation of extensive BMPs during project construction as well as post-construction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the proposed project's contribution to cumulative construction-related impacts to a less than significant level.

Given major past alterations to the Sacramento River aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP2 would be cumulatively considerable. With implementation of Mitigation Measures Aqua-14 (CP2) and Aqua-16 (CP2), adverse effects from CP2 would be reduced and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP2 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for winter-run Chinook spawning. Under CP2, potential impacts to fish would be beneficial.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

The cumulative effects of CP3 are similar to those of CP1 and CP2, but greater in magnitude because CP3 would require additional construction and would result in the potential for increased alteration of flows associated with increased storage volume.

Given the scale and duration of the project construction activities associated with CP3, the contribution to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP3 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the RWQCB. The SWPPP would require implementation of extensive BMPs during project construction as well as post-construction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the proposed project's contribution to cumulative construction-related impacts to a less than significant level.

Given major past alterations to the Sacramento River aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP3 would be cumulatively considerable. With implementation of Mitigation Measures Aqua-14 (CP3) and Aqua-16 (CP3), adverse effects from CP3 would be reduced and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP3 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for winter-run Chinook spawning. Under CP3, potential impacts to fish would be beneficial.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

The cumulative effects of CP4 are similar to those of CP1, CP2 and CP3, but greater in magnitude because CP3 would require additional construction and would result in the potential for increased alteration of flows associated with increased storage volume. Some of these impacts would be partially offset with the implementation of the gravel augmentation program, floodplain and riparian restoration at Reading Island, and cold-water supply for anadromous fish management.

Given the scale and duration of the project construction activities associated with CP4, the contribution to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP4 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the RWQCB. The SWPPP would require implementation of extensive BMPs during project construction as well as post-construction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways.

Implementation of these measures would reduce the proposed project's contribution to cumulative construction-related impacts to a less than significant level.

Given major past alterations to the Sacramento River aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP4 would be cumul--14 (CP4) and Aqua-16 (CP4), adverse effects from CP4 would be reduced and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP4 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for winter-run Chinook spawning. Under CP4, potential impacts to fish would be beneficial.

CP5 – 18.5-Foot Dam Raise, Combination Plan

The cumulative effects of CP5 are similar to those of CP1, CP2 and CP3, but greater in magnitude because CP3 would require additional construction and would result in the potential for increased alteration of flows associated with increased storage volume. Some of these impacts would be partially offset with the implementation of the gravel augmentation program, floodplain and riparian restoration at Reading Island.

Given the scale and duration of the project construction activities associated with CP5, the contribution to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP5 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the RWQCB. The SWPPP would require implementation of extensive BMPs during project construction as well as post-construction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the proposed project's contribution to cumulative construction-related impacts to a less than significant level.

Given major past alterations to the Sacramento River aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP5 would be cumulatively considerable. With implementation of Mitigation Measures Aqua-14 (CP5) and Aqua-16 (CP5), adverse effects from CP5 would be reduced and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP5 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for winter-run Chinook spawning. Under CP5, potential impacts to fish would be beneficial.

Chapter 12
Botanical Resources and Wetlands

12.1 Affected Environment

This section describes the affected environment related to botanical resources for the dam and reservoir modifications proposed under the SLWRI. For a more in-depth description, see the *Botanical Resources and Wetlands Technical Report*.

The botanical resources and wetlands setting for the Shasta Lake and vicinity portion of the primary study area consists of the impoundment area (five arms and the Main Body of Shasta Lake, as described below) and the relocation areas (Figure 12-1).

Reclamation established project boundaries for focused surveys in the areas that would be subject to inundation under the various enlargement scenarios. The lower boundary corresponds to the current full-pool elevation defined by Reclamation (1,070-foot mean sea level contour line). The upper boundary was established using the 1,090-foot mean sea level contour line around the entire lake. This area is referred to as the "impoundment area" (Figure 12-1).

Areas subject to physical disturbance as an indirect result of the proposed project (i.e., areas proposed as relocation sites for roadways, bridges, utilities, and campgrounds that would be inundated after the enlargement of Shasta Dam as well as proposed dike locations) were incorporated into the Shasta Lake and vicinity portion of the primary study area. These locations are hereafter referred to as "relocation areas" (Figure 12-1).

To examine the biological resources along riverine reaches that would be subject to inundation if Shasta Dam were enlarged, reaches of 11 streams and rivers that are tributary to Shasta Lake were also incorporated into the Shasta Lake and vicinity portion of the primary study area. These streams were selected by Reclamation in conjunction with USFS as an initial sampling of streams representative of riverine and riparian habitats. Subsequently, botany studies have been expanded into select areas of the impoundment area and within all of the relocation areas.

For the purposes of this investigation, approximate acreages for vegetation types and waters of the United States are reported by arm of the lake. For a relocation area that falls between two arms, the area is included with the arm that has the most acreage of the vegetation type or water of the United States.

Vegetation communities and special-status plant species in the extended study area are discussed in less detail. The extended study area includes the Sacramento River basin from Red Bluff Diversion Dam (RBDD) south to the Delta. It also includes the San Francisco Bay/Sacramento–San Joaquin River Delta (Bay-Delta) area and portions of the American River basin, San Joaquin River basin, and the water service areas of the CVP and the SWP.

Descriptions of biological resources were derived primarily from the following sources:

- Shasta Lake Water Resources Investigation Mission Statement Milestone Report (Reclamation 2003)
- Shasta Lake Water Resources Investigation Initial Alternatives Information Report (Reclamation 2004)
- Chapter 3, "Biological Environment," in the Draft Shasta Lake Water Resources Investigation Plan Formulation Report (Reclamation 2007)
- USFWS Endangered Species Lists
- The California Natural Diversity Database (CNDDB)
- The California Native Plant Society (CNPS) online inventory

Several attachments to the *Botanical Resources and Wetlands Technical Report* provide detailed lists and descriptions of special-status species present in the primary and extended study areas:

- Attachment 1, "Lists of All Special-Status Plant Species Known from or Potentially Present in the Primary and Extended Study Areas"
- Attachment 2, "List of Plant Species Observed in the Shasta Lake and Vicinity Portion of the Primary Study Area"
- Attachment 3, "Special-Status Plant Species Known to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area"
- Attachment 4, "List of All Sensitive Plant Species in the Extended Study Area Reported to the CNDDB"
- Attachment 5, "Known Weed Source Locations, Potential Mode of Spread, and Risk of Spread"

12.1.1 Vegetation Communities

Shasta Lake and Vicinity

North State Resources, Inc. (NSR) conducted extensive mapping to characterize the plant communities in the Shasta Lake and vicinity portion of the primary study area. The study area for botanical resources in the Shasta Lake and vicinity portion of the primary study area corresponds to the area that would be subject to inundation under the five action alternatives and areas where infrastructure would be removed, modified, or relocated (Figure 12-1). The vegetation mapping followed the technical approach described in *A Manual of California Vegetation* (Sawyer and Keeler-Wolf 1995) (MCV), using the vegetation alliance classification system described in *A Manual of California Vegetation, Second Edition* (Sawyer et al. 2009).

MCV represents the most recent effort to provide a common and accepted vegetation classification system for use throughout California. It classifies vegetation into a set of plant alliances, provisional alliances, special stands, or semi-natural stands. In this system, the plant species dominance or importance in the layer (i.e., tree, shrub, and ground) with the greatest amount of cover determines the vegetation alliance classification. The same approach used to describe and classify MCV types was applied when other vegetation types not described in the current MCV were encountered and determined to be significant vegetative components.

The vegetation mapping used recent 1:2,400-scale color aerial photography provided by Reclamation. All vegetation mapping was performed in the field by ground truthing the study area from boat, vehicle, and/or on foot. MCV plant alliances were identified and delineated onto the aerial photographs. The delineated boundaries were digitized and generated in ArcGIS/ArcInfo software for display and data query purposes.

The Shasta Lake and vicinity area is characterized by a variety of vegetation types typical of transitional mixed woodland and low-elevation forest habitats. MCV plant series types in this portion of the primary study area are birch-leaf mountain mahogany chaparral, black willow thicket, blue oak woodland, Brewer's oak scrub, buck brush chaparral, California annual grassland, California black oak forest, California ash chaparral, California buckeye groves, California yerba santa scrub, canyon live oak forest, deer brush chaparral, Fremont cottonwood forest, ghost pine woodland, Himalayan blackberry brambles, interior live oak chaparral, interior live oak woodland, knobcone pine forest, mixed willow, Oregon ash groves, Oregon white oak woodland, pale spike rush marshes, ponderosa pine–Douglas fir forest, ponderosa pine forest, red osier thickets, sandbar willow thickets, spicebush thickets, valley oak woodland, white alder groves, and white leaf manzanita chaparral. Vegetation in each of these series varies, with dramatic changes often occurring in relation to aspect, slope, geologic substrate, or juxtaposition with other habitats.

The acreage of MCV types found in the impoundment area along the Main Body and the five arms of Shasta Lake is shown in Table 12-1, and the acreage of MCV types found in the relocation areas along the Main Body and the five arms of Shasta Lake is shown in Table 12-2. The locations of each type are depicted on Figures 12-2a through 12-2f. General descriptions of each type are provided below.

Barren Barren habitat consists mainly of nonvegetated man-made features. Barren habitat is scattered throughout the Shasta Lake and vicinity portion of the primary study area, including boat ramps, parking lots, and roads. Other barren habitats are a large gravel plain feature at the confluence of Butcher Creek and Shasta Lake (Main Body) and a sealed riprap feature adjacent to Interstate 5 near the upper Sacramento Arm and Shasta Lake confluence. Vegetation is usually not present, although sparse opportunistic grasses/forbs or weedy species may occur.

Birch-Leaf Mountain-Mahogany Chaparral Birch-leaf mountain-mahogany chaparral is a relatively common associate species in many chaparral and woodland plant series types. As a plant series, birch-leaf mountain-mahogany occurs in the Shasta Lake and vicinity portion of the primary study area along the upper McCloud and Sacramento arms. These sites are located on floodplain terraces and are characterized as moderate to dense chaparral stands dominated by birch-leaf mountain-mahogany (*Cercocarpus betuloides*), with occasional buck brush (*Ceanothus cuneatus*), poison oak (*Toxicodendron diversilobum*), western redbud (*Cercis occidentalis*), yerba santa (*Eriodictyon californicum*), and Brewer oak (*Q. garryana* var. b*reweri*).

Black Willow Thicket Although commonly associated with willow and other riparian plant series types, black willow thicket is uncommon in the Shasta Lake and vicinity portion of the primary study area. This plant series is dominated by black willow (*Salix gooddingii*), with spicebush (*Calycanthus occidentalis*), rushes (*Juncus* spp.), and California grape (*Vitis californica*). It occurs at only two locations in the Shasta Lake and vicinity portion of the primary study area, one along the Sacramento Arm and the other in the Jones Valley area (Pit Arm).

Blue Oak Woodland The blue oak plant series occurs mainly as small inclusions within other more prevalent plant series types; however, moderate-sized stands also occur. This plant series occurs at scattered locations along the Main Body, McCloud Arm, and Pit Arm and is characterized by open to moderate woodlands dominated by blue oak (*Quercus douglasii*). Associated tree species include occasional interior live oak (*Q. wislizenii* var. *wislizenii*) and gray pine (*Pinus sabiniana*). The shrub layer is open or absent, and a moderate to dense forb layer dominates the understory.

Brewer Oak Scrub The Brewer oak plant series consists of moderate to very dense stands of Brewer oak, the shrub form of Oregon white oak (*Q. garryana* var. *garryana*). This plant series type is widespread throughout the Shasta Lake and vicinity portion of the primary study area. Brewer oak stands are often nearly pure; occasionally, however, shrub species such as poison oak, white leaf manzanita, yerba santa, buck brush, bush poppy (*Dendromecon rigida*), Fremont's silktassel (*Garrya fremontii*), deer brush (*Ceanothus integerrimus*), skunkbrush (*Rhus trilobata*), and snowdrop bush (*Styrax officinalis*) occur in association with Brewer oak.

Buck Brush Chaparral Buck brush chaparral occurs at scattered locations throughout the Shasta Lake and vicinity portion of the primary study area. This plant series is dominated by moderate to dense stands of buck brush. Associated species include white leaf manzanita, poison oak, western redbud, yerba santa, Brewer oak, birch-leaf mountain-mahogany, and coffeeberry (*Rhamnus* sp.).

California Annual Grassland California annual grassland is uncommon in the Shasta Lake and vicinity portion of the primary study area, occurring only as small inclusions in other more prevalent plant series types or in areas subjected to previous disturbance. Dominant species include wild oat (*Avena fatua*), cheatgrass (*Bromus tectorum*), ripgut (*B. diandrus*), yellow star-thistle (*Centaurea solstitialis*), squirreltail (*Elymus elymoides*), and European hairgrass (*Aira caryophyllea*).

California Ash Chaparral California ash is a relatively common associate species in many chaparral and woodland plant series types. As a plant series, California ash chaparral occurs in the Shasta Lake and vicinity portion of the primary study area at several locations along the McCloud Arm. This plant series is characterized as a moderate to dense chaparral stand dominated by birch-leaf mountain-mahogany, with occasional buck brush, poison oak, western redbud, yerba santa, and Brewer oak.

California Black Oak The black oak series is characterized by moderate to dense stands of California black oak (*Quercus kelloggii*). This plant series is relatively common throughout the Shasta Lake and vicinity portion of the primary study area. Understory associates include white leaf manzanita (*Arctostaphylos viscida*), poison oak, snowdrop bush (*Styrax officinalis*), and buck brush. The ground layer is open to dense and is dominated by various grasses and forbs.

California Buckeye Groves Although a common associate in many plant series types in the Shasta Lake and vicinity portion of the primary study area, California buckeye groves are uncommon as a plant series type. This plant series is dominated by California buckeye (*Aesculus californica*). Associated species include poison oak, Brewer oak, buck brush, and various grasses and forbs. It occurs at only several scattered locations in the Sacramento Arm, McCloud Arm, and Pit Arm.

California Yerba Santa Scrub California yerba santa scrub is a relatively common associate species in many chaparral and woodland plant series types. California yerba santa is a pioneer species that readily responds to various disturbances and wildfire. As a plant series, California yerba santa scrub occurs in the Shasta Lake and vicinity portion of the primary study area at two general locations subject to recent wildfire: the Dry Creek area (Main Body) and the Jones Valley area (Pit Arm). This plant series is characterized as moderate to dense chaparral stands dominated by California yerba santa, with occasional

shrub interior live oak, shrub canyon live oak, buck brush, poison oak, western redbud, and Brewer oak.

Canyon Live Oak Forest The canyon live oak plant series is characterized by moderate to dense stands of canyon live oak (*Quercus chrysolepis*). This plant series is relatively common throughout the Shasta Lake and vicinity portion of the primary study area. Associated tree species include occasional California black oak. Understory associates include white leaf manzanita and poison oak. The ground layer is open to moderate and is dominated by various grasses and forbs.

Deer Brush Chaparral Deer brush chaparral is a relatively common associate in chaparral and forest plant series types in the Shasta Lake and vicinity portion of the primary study area; however, deer brush is uncommon in the study area as a plant series type. This plant series is dominated by deer brush. It occurs at several scattered locations along the Main Body, McCloud Arm, and Pit Arm.

Fremont Cottonwood Forest In the Shasta Lake and vicinity portion of the primary study area, Fremont cottonwood forest is an uncommon plant series type that occurs as single stands of trees along small portions of the upper Sacramento Arm and the Pit Arm. The dominant species is Fremont cottonwood (*Populus fremontii*).

Ghost (Gray) Pine The ghost pine plant series occurs in all parts of the Shasta Lake and vicinity portion of the primary study area except along the Big Backbone Arm. This plant series type is characterized by open to moderate stands of gray pine. Associated species include blue oak, canyon live oak, interior live oak, and California black oak. Shrub species are moderate to dense and include white leaf manzanita, western redbud, buck brush, Brewer oak, poison oak, and yerba santa.

Himalayan Blackberry Brambles Himalayan blackberry (*Rubus discolor*) is a common associate in many riparian plant series and in various other plant series with mesic microhabitats and/or previous disturbance. As a plant series, Himalayan blackberry brambles occur in portions of the Dry Creek (Main Body) and Jones Valley (Pit Arm) areas recently disturbed by wildfire. This plant series occurs in and along drainage and stream features and is characterized as dense thickets of Himalayan blackberry. Associated species include spicebush, willow, and rushes.

Interior Live Oak Chaparral In the Shasta Lake and vicinity portion of the primary study area, the interior live oak chaparral plant series is relatively uncommon, occurring mainly along the Sacramento Arm. However, this plant series also occurs at scattered locations along the Main Body, the McCloud Arm, and the Pit Arm. This plant series is dominated by moderate to dense stands of the shrub form of interior live oak. Associated species include Brewer oak, white leaf manzanita, poison oak, and buck brush.

Interior Live Oak Woodland The interior live oak woodland plant series is uncommon in the Shasta Lake and vicinity portion of the primary study area. It occurs in several small areas along the Sacramento Arm, the Pit Arm, the McCloud Arm, and the Main Body.

Knobcone Pine Forest The knobcone pine forest plant series consists of open to dense knobcone pine (*Pinus contorta*) stands. This plant series is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. Knobcone pine forest often occurs at locations characterized by disturbances, including historic mining activities and past or recent wildfires. Dominant species include knobcone pine, with occasional canyon live oak, California black oak, ponderosa pine (*Pinus ponderosa*), and gray pine. The shrub layer is moderate to dense and is dominated by white leaf manzanita and poison oak. The ground layer varies and is dominated by various grasses and forbs.

Lacustrine Lacustrine habitat consists of the area regularly inundated by Shasta Lake (i.e., areas at and below the 1,070-foot elevation). Most of this area is barren of vegetation and is characterized as exposed soil and/or rock. Portions of the lacustrine habitat do support vegetation, including woody riparian species such as black willow, button willow (*Cephalanthus occidentalis*), Fremont cottonwood, and various grasses and forbs, during draw-down periods.

Mixed Willow Mixed willow is the most common willow plant series type in the Shasta Lake and vicinity portion of the primary study area and occurs throughout the entire area. Dominant species include red willow (*Salix laevigata*), black willow, shining willow (*S. lasiandra*), arroyo willow (*S. lasiolepis*), and narrowleaf willow (*S. exigua*).

Oregon Ash Groves Oregon ash groves are an uncommon plant series type in the Shasta Lake and vicinity portion of the primary study area. This type occurs along the upper McCloud Arm and is dominated by open to moderate stands of Oregon ash (*Fraxinus latifolia*) with willow, California grape, mock orange, brickellbush (*Brickellia* sp.), and poison oak.

Oregon White Oak Woodland The Oregon white oak woodland plant series is uncommon in the Shasta Lake and vicinity portion of the primary study area and occurs as small inclusions in other more prevalent plant series types. This plant series is characterized by open to moderate woodlands dominated by Oregon white oak. Associated tree species include occasional canyon live oak, blue oak, and California black oak. The shrub layer is open or absent, and a moderate to dense forb layer dominates the understory.

Pale Spike Rush Marshes Pale spike rush is an uncommon plant series in the Shasta Lake and vicinity portion of the primary study area; it is known to occur only in a portion of one relocation area near Lakehead (Sacramento Arm). This plant series is characterized as a seasonal wetland dominated by a complex of

annual and perennial upland and wetland plant species. Dominant species include pale spike rush (*Eleocharis macrostachya*), jointed coyote-thistle (*Eryngium articulatum*), pennyroyal (*Mentha pulegium*), panic grass (*Panicum acuminatum*), iris-leaf rush (*Juncus xiphioides*), sedges (*Carex* spp.), rushes, poison oak, white leaf manzanita, western choke-cherry (*Prunus virginiana*), interior rose (*Rosa woodsii*), and Himalayan blackberry.

Ponderosa Pine–Douglas-Fir Ponderosa pine-Douglas-fir is the second-most-common conifer plant series type in the Shasta Lake and vicinity portion of the primary study area, occurring everywhere except along the Big Backbone Arm. This plant series is characterized by open to dense conifer stands dominated by Douglas-fir (*Pseudotsuga menziesii*) and ponderosa pine. Associated species include occasional sugar pine (*P. lambertiana*), incense cedar (*Calocedrus decurrens*), canyon live oak, and California black oak. Associated understory species vary and include Pacific dogwood (*Cornus nuttallii*), mock orange (*Philadelphus lewisii*), poison oak, snowdrop bush, and white leaf manzanita. The ground layer is open to moderate and is dominated by various grasses and forbs.

Ponderosa Pine Ponderosa pine is the most common conifer plant series type in the Shasta Lake and vicinity portion of the primary study area and is scattered throughout all portions of the area. This plant series is characterized by open to dense conifer stands dominated by ponderosa pine. Associated species include occasional Douglas-fir, sugar pine, incense cedar, canyon live oak, and California black oak. Associated understory species vary and include redbud, buck brush, mock orange, poison oak, snowdrop bush, and white leaf manzanita. The ground layer is open to moderate and is dominated by various grasses and forbs.

Red Osier Thickets Red osier is a common associate in many riparian plant series types in the Shasta Lake and vicinity portion of the primary study area. As a plant series, red osier thickets are an uncommon plant series type. In the vicinity of Shasta Lake, red osier thickets are found along the upper McCloud Arm. Dominant species include red osier (*Cornus stolonifera*), brown dogwood (*C. glabrata*), mock orange, spicebush, and California grape.

Riverine Riverine habitat includes the free-flowing portions of the larger Shasta Lake tributaries occurring in the Shasta Lake and vicinity portion of the primary study area. The riverine habitat is highly variable and ranges from moderate, low-gradient to steep, well-confined stream reaches.

Sandbar Willow Thickets Sandbar willow thicket is an uncommon plant series that occurs at one location each along the McCloud Arm and the Squaw Creek Arm. Dominant species include narrowleaf willow, with occasional red willow, black willow, shining willow, and arroyo willow.

Spicebush Thickets Spicebush is a common associate in many riparian plant series types in the Shasta Lake and vicinity portion of the primary study area. As a plant series, spicebush thickets are an uncommon plant series type. This plant series occurs at several locations along the McCloud Arm. Dominant species include spicebush, red osier, mock orange, and California grape.

Urban Urban habitat consists of various man-made features scattered throughout the Shasta Lake and vicinity portion of the primary study area, including resorts and a portion of the visitor center complex at Shasta Dam. These features are typically a combination of various buildings, pavement areas with manicured landscaping, and lawns.

Valley Oak Woodland Valley oak woodland is an uncommon plant series and occurs at two small locations in the Lakehead area (Sacramento Arm). Dominant species include valley oak (*Quercus lobata*) with white leaf manzanita, redbud, poison oak, and various grasses and forbs.

White Alder Groves The white alder plant series occurs in the riparian vegetation found in drainages throughout the Shasta Lake and vicinity portion of the primary study area. This plant series is characterized as narrow bands of vegetation occurring in and along the margins of rivers, streams, or other drainages. Dominant species include white alder (*Alnus rhombifolia*) with occasional Oregon ash, red osier, big-leaf maple (*Acer macrophyllum*), narrowleaf willow, red willow, shining willow, and arroyo willow. Associated shrubs include spicebush, mock orange, California blackberry (*Rubus ursinus*), mugwort (*Artemisia douglasiana*), ninebark (*Physocarpus capitatus*), and western azalea (*Rhododendron occidentale*). Common lianas include California grape, pipevine (*Aristolochia californica*), greenbriar (*Smilax californica*), and virgin's bower (*Clematis ligusticifolia*). The ground layer is open to dense and is dominated by sedges with various grasses and forbs.

White Leaf Manzanita Chaparral White leaf manzanita is the most common chaparral plant series type in the Shasta Lake and vicinity portion of the primary study area and is scattered throughout all portions of the area. The dominant species is white leaf manzanita. Associated species include occasional common manzanita (*A. manzanita*), western redbud, buck brush, deer brush, poison oak, birch-leaf mountain-mahogany, interior live oak (shrub form), Fremont's silktassel, bush poppy, yerba santa, and Brewer's oak.

Upper Sacramento River (Shasta Dam to Red Bluff)

The plant communities present in the primary study area between Shasta Dam and RBDD are grouped into common and sensitive communities as described below, and the relevant aspects of their ecology are discussed in detail in the *Botanical Resources and Wetlands Technical Report*, and summarized below for sensitive communities. These descriptions are generally applicable to the extended study area as well. (Plant community names and descriptions used in

this section are based primarily on the Preliminary Descriptions of the Terrestrial Natural Communities of California (Holland 1986).)

Common plant communities present within the primary study area include annual grassland, chaparral, and agricultural lands. The upper banks along steep-sided, bedrock constrained segments of the Sacramento River and its tributaries are characterized primarily by upland communities including blue oak woodland, foothill pine-oak woodland, and chaparral. These segments occur primarily between Shasta Dam and Redding.

Sensitive plant communities include those that are of special concern to resource agencies or are afforded specific consideration through CEQA, Section 1602 of the California Fish and Game Code, Section 404 of the Federal Clean Water Act (CWA), and the State's Porter-Cologne Water Quality Control Act, as discussed under "Regulatory Framework."

Oak Woodlands Oak woodlands present in the study area include blue oak woodland, blue oak savanna, foothill pine-oak woodland, and valley oak woodland. The oaks that dominate the tree layer of oak savannas and woodlands are long-lived trees that are resilient to damage; their stems often survive fire, and when their stems are killed by fire or are cut down, basal sprouts often grow into new stems. (Valley oak also tolerates inundation during winter before it has leafed out.) Nonetheless, there are concerns regarding the status and ongoing trends of tree mortality and recruitment in tree canopies of blue oak- and valley oak-dominated savannas and woodlands (Tyler et al. 2006).

Riparian Communities California's riparian communities have experienced the most extensive reductions in their acreage, and in the Sacramento Valley more than 90 percent of riparian vegetation has been converted to agriculture or development, and the remainder substantially altered by dams, diversions, gravel mining, grazing practices, and invasive species (Hunter et al. 1999).

In the primary study area, much of the Sacramento River from Shasta Dam to Redding is deeply entrenched in bedrock, which precludes development of extensive areas of riparian vegetation. The river corridor between Redding and Red Bluff, however, still maintains extensive areas of riparian vegetation.

Riparian communities present within the floodplain of the Sacramento River, within the study area, include blackberry scrub, Great Valley willow scrub, Great Valley cottonwood riparian forest, Great Valley mixed riparian forest, and Great Valley valley oak riparian forest. Willow and blackberry scrub and cottonwood- and willow-dominated riparian communities are present along active channels and on the lower flood terraces whereas valley oak–dominated communities occur on higher flood terraces.

More than 15 native species of deciduous trees and shrubs occur in the riparian forests, woodlands, and scrubs of the Central Valley and the Delta (Conard et al.

1977, Vaghti and Greco 2007). Flow regime, disturbance, and species attributes determine the species composition and physical structure of this woody vegetation. Although flow regime influences the dispersal, establishment, growth, and survival of all the woody riparian species, Fremont's cottonwood (*Populus fremontii*) and the willow species (*Salix* sp.) particularly depend on specific hydrologic events for their recruitment. During seed release, flows must be high enough to disperse seed to surfaces where scouring by subsequent flows does not occur, yet not so high that seedlings desiccate after flows recede, and flows must recede gradually to enable germination and seedling establishment while the substrate is still moist (Mahoney and Rood 1998).

Fremont's cottonwood and willow species are rapidly growing, shade intolerant and relatively short-lived (Burns and Honkala 1990, Vaghti and Greco 2007). Within 10 to 20 years, initially shrubby thickets have reached 10-40 feet in height. Other species, such as Oregon ash (*Fraxinus latifolia*) and valley oak (*Quercus lobata*), establish concurrently or subsequent to the willows and cottonwood, grow more slowly but are more tolerant of shade, and are longer-lived (Burns and Honkala 1990; Tu 2000). In the absence of frequent disturbance, these species enter the canopy, particularly after 50 years, as mortality of willows and cottonwood frees space. Conversely, frequent disturbance prevents the transition to mature mixed riparian or valley oak forests.

The operation of Shasta Dam has limited the frequency, magnitude, and duration of intermediate and larger flows during fall and winter, since the dam's construction, and flow volumes have been greater during the growing season. The operation of Shasta Dam also produces increasing flow volumes during the period of cottonwood seed dispersal (rather than flow volume decreasing during this period), largely precluding establishment of cottonwoods (and to a lesser extent willows) throughout much of the riparian zone (Roberts et al. 2002). The combined effect of these changes in flow regime has been a decrease in early- and mid-successional communities along the Sacramento River that is still ongoing (Fremier 2003).

Wetland Communities *S*imilar to riparian communities, much of the wetland habitat that once occurred in the Sacramento River Valley has been eliminated as a consequence of land use conversion to agriculture and urbanization. It is estimated that nearly 1.5 million acres of wetlands once occurred in the Central Valley. Today, approximately 123,000 acres remain. Wetland communities that are likely to occur in the primary study area between Shasta Dam and RBDD include freshwater marsh, freshwater seep, northern hardpan vernal pools, northern volcanic mudflow vernal pools, and other seasonal wetlands.

Freshwater marshes are herbaceous wetland plant communities that occur along rivers and lakes and are characterized by dense cover of perennial, emergent plant species. Marshes are typically perennial wetlands, but may dry out for short periods of time. In marsh vegetation, vegetation structure and species

richness are strongly influenced by disturbance, changes in water levels, and the range of elevations present at a site (Keddy 2000). Disturbances, and water level drawdowns that expose previously submerged surfaces, provide opportunities for species to establish, which creates diversity in species composition and vegetation structure. With increasing depth of water, the growth of marsh plants is reduced, and thus this vegetation type is typically restricted to shallow water.

Freshwater seep is a wetland plant community characterized by dense cover of perennial herb species usually dominated by rushes, sedges, and grasses. Freshwater seep communities occur on sites with permanently moist or wet soils resulting from daylighting groundwater.

Vernal pools are seasonal wetlands that fill during winter rains and dry up in spring. They occur in undulating or mima mound (i.e., mound-intermound) topography where the soil or underlying rock has layers that are relatively impermeable to water. Vernal pools may be isolated from one another, but more often they are interconnected by swales or ephemeral drainages in vernal pool complexes that may extend for hundreds of acres. Vernal pool complexes generally include water features. The two predominant types of vernal pool communities in the study area are northern hardpan vernal pools and northern volcanic mudflow vernal pools.

Pool size and the depth, duration, and seasonal timing of ponding are important factors that influence the composition and diversity of plant and animal species in vernal pools (Solomeshch et al. 2007). Consequently, the vegetation of vernal pools can vary substantially from year to year in response to interannual fluctuations in climate.

Management activities such as grazing and burning also influence species composition and diversity. In fact, recent research indicates that the abundance of nonnative grasses, grazing practices, and hydrology are strongly interrelated and can substantially affect the plant communities of vernal pools (Robins and Vollmar 2002; Pyke 2004; Marty 2005).

Seasonal wetlands are ephemeral wetlands that pond or remain flooded for long periods during a portion of the year, generally the rainy winter season, then dry up, typically in spring. They often occur in shallow depressions on flood terraces that are occasionally to infrequently flooded. Seasonal wetlands are herbaceous communities typically characterized by species adapted for growth in both wet and dry conditions, and may contain considerable cover of upland species as well. Seasonal wetlands differ from vernal pools in that they do not have a restrictive hardpan layer and are usually dominated by nonnative plant species, especially nonnative grasses.

Lower Sacramento River and Delta A large number of natural plant communities occur in the extended study area, and some are described in this section and the “CVP/SWP Service Areas” section, or in the *Botanical*

Resources and Wetlands Technical Report. The other natural plant communities are described in the following sections, and in Mayer and Laudenslayer 1988, Sawyer and Keeler-Wolf 1995, and CALFED 2000a. In addition to natural plant communities, plant communities of agricultural and urban areas occupy extensive portions of the extended study area.

The lower Sacramento River can be subdivided into distinct reaches that differ in topography, hydrology, and geomorphology; and thus, in vegetation and associated habitat functions.

Red Bluff Diversion Dam to Colusa In this reach, the Sacramento River is classified as a meandering river, where relatively stable, straight sections alternate with more sinuous, dynamic sections (Resources Agency 2003). The channel remains active and has the potential to migrate in times of high water. Point bars, islands, high and low terraces, instream woody cover, early-successional riparian plant growth, and other evidence of river meander and erosion are common in this reach. Major physiographic features include floodplains, basins, terraces, active and remnant channels, and oxbow sloughs. These features sustain a diverse array of riparian plant communities.

Colusa to the Delta The general character of the Sacramento River changes quite drastically downstream from Colusa from a dynamic and active meandering channel to a confined, narrow channel restricted from migration. Surrounding agricultural lands encroach directly adjacent to the levees, which have cut the river off from most of its riparian corridor, especially on the eastern side of the river. Most of the levees in this reach are lined with riprap, allowing the river no erodible substrate and limiting the extent of riparian vegetation.

Primary Tributaries to the Lower Sacramento River The primary tributaries of the lower Sacramento River are the Feather River, American River, and the Sacramento River floodplain bypasses. The aquatic ecosystem in the lower Feather River, down to the confluence with the Sacramento River at Verona, is influenced by DWR's Oroville Facilities. The upper extent is fairly confined by levees as the river flows through the city of Oroville. Downstream from Oroville, the Feather River is fairly active and meanders its way south to Marysville. However, this stretch is bordered by active farmland, which confines the river into an incised channel in certain stretches and limits the width of riparian woodland. Some of this adjacent farmland is in the process of being restored to floodplain habitat with the relocation of levees to become setback levees.

The lower American River (below Folsom and Nimbus Dams) is fairly low gradient. Most of the lower American River is surrounded by the American River Parkway, which preserves the surrounding riparian zone. The river channel does not migrate to a large degree because it has become deeply incised, leaving tall cliffs and bluffs adjacent to the river.

Multiple water diversion structures in the lower Sacramento River move floodwaters into floodplain bypass areas during high-flow events. These floodplain bypass areas – the Butte Basin, Sutter Bypass, and Yolo Bypass – provide broad, inundated floodplain habitat during wet years. Unlike other Sacramento River and Delta habitats, floodplains and floodplain bypasses are seasonally dewatered (as high flows recede). Their predominant communities include grassland, seasonal wetlands, and agricultural vegetation.

Sacramento–San Joaquin River Delta The Delta comprises an area of approximately 750,000 acres divided into a number of islands by hundreds of miles of waterways. Before reclamation, the Delta was inundated each year by winter and spring runoff, which changed channel geometry in response to flood conditions and tidal influence. Consequently, there were extensive areas of marsh in the Delta.

Nearly all of the Delta's marshland has since been reclaimed by agriculture, peat production, and urban and industrial uses. More than 1,000 miles of levees protect this reclaimed land (CALFED 2000b). However, some small islands remain in a quasinatural state, as do some other areas with aquatic and wetland communities (e.g., "flooded islands" that were once reclaimed land, but have been abandoned after levee failures). The species composition and ecology of these riparian, marsh, and aquatic plant communities differ from the composition and ecology of communities in the upper and lower Sacramento River portions of the study area and are described below.

Along the lower Sacramento River and in the Delta, riparian vegetation is characterized by narrow linear strips of trees and shrubs, in single- to multiple-story canopies. Tree canopies may be continuous or discontinuous, or absent altogether (as in riparian scrubs). These patches of riparian vegetation may be on or at the toe of levees (particularly in the Delta). Riparian communities in this region include cottonwood-willow woodland, Valley oak riparian woodland, riparian scrub, and willow scrub. These communities are described below.

The dynamics of riparian communities along the lower Sacramento River and in the Delta are similar to those described for riparian communities along the upper Sacramento River. However, along the Sacramento River south of Colusa, in the flood bypasses, and in the Delta, the disturbances that remove riparian vegetation, or create newly exposed surfaces where riparian vegetation can establish, differ somewhat from those along the upper Sacramento River. In these downstream areas, disturbances related to meander migration are more limited, and anthropogenic (human-caused) disturbances, such as levee maintenance and trampling, are greater than those upstream. This is because of the close proximity to levees, extensive placement of bank protection, and greater human population.

In addition to the wetland communities described for the upper Sacramento River, the Delta has tidal freshwater and brackish-water emergent marshes that like nontidal marshes are dominated by clonal perennial plants. This community occurs on instream islands and along mostly unleveed, tidally influenced waterways. In addition to the environmental factors affecting nontidal marshes, the species composition of tidal marshes in the Delta is also affected by regional salinity gradients.

The Delta also supports extensive areas of aquatic vegetation. These communities consists of submerged plants generally rooted in the substrate, whose stems may partially extend above the water surface (e.g., during flowering) and floating plants that are generally not rooted in the substrate. The availability of light (which decreases with depth), turbidity, and shade cast by overtopping vegetation can restrict submerged plants to relatively shallow areas. In the Delta (which has turbid waters), most submerged vegetation appears to be restricted to areas less than 5 to 10 feet deep. The velocity of flows may contribute to this depth restriction.

CVP/SWP Service Areas Although agricultural and urban land uses have substantially reduced the area and connectivity of natural vegetation, the service areas still contain a large diversity of both lowland and upland plant communities, including many sensitive plant communities (see the *Botanical Resources and Wetlands Technical Report*). The most dramatic difference between historical and existing conditions is the fragmentation of what were once large contiguous blocks of habitat. Significant changes to the natural landscape in the region occurred in the late 1800s and early 1900s with land conversions to agriculture. However, in southern California, that pattern shifted dramatically compared to the pattern in the Central Valley, as urban growth in the region that started in the 1900s began to convert large areas of agricultural lands and of remaining natural vegetation to developed land uses.

12.1.2 Special-Status Species

Special-status species addressed in this section include plants that are legally protected or are otherwise considered sensitive by Federal, State, or local resource conservation agencies and organizations. These include species that are State listed and/or Federally listed as rare, threatened, or endangered; those considered as candidates or proposed for listing as threatened or endangered; species identified by DFG as Species of Special Concern or USFS as sensitive, endemic, or needing additional survey or management actions; and plants considered jointly by DFG and CNPS to be rare, threatened, or endangered; and species afforded protection under local planning documents, including the CALFED Bay-Delta Program's (CALFED) Multi-Species Conservation Strategy (MSCS).

Shasta Lake and Vicinity

Within the Shasta Lake and vicinity portion of the primary study area are a wide variety of vegetative communities and habitat components that support a large

diversity of plant species. To aid in determining the potential impacts of the project, a list of potential plant species of concern was developed.

For the purposes of this evaluation, botanical species of concern are plants, lichen, and fungi that fall into any of the following categories:

- Designated as rare or listed as threatened or endangered by the State or Federal government
- Proposed for designation as rare or listing as threatened or endangered by the State or Federal government
- Candidate species for State or Federal listing as threatened or endangered
- Ranked as California Rare Plant Rank (CRPR) 1B, 2, 3, or 4 (formerly CNPS List 1A, 1B, 2, 3, or 4)
- Considered sensitive or endemic by USFS
- Considered a survey and manage species by USFS or U.S. Bureau of Land Management (BLM)
- Designated as an MSCS covered species by CALFED

Potentially occurring plant species of concern were determined by performing several database searches, reviewing USFWS and DFG special-status species lists for Shasta County, reviewing other appropriate literature, discussions with resource agency personnel, and professional experience in the region. Additionally, results from the various vegetation habitat mapping efforts, botanical surveys, and wildlife surveys conducted in the area by NSR since 2002 were used in developing the list of species of concern.

Table 12-3 summarizes special-status plant species identified as having a potential to occur in the Shasta Lake and vicinity portion of the primary study area.

Table 12-3. Plant Species of Concern with Potential to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area

Common Name	Scientific Name	Status[1]
Shasta ageratina	Ageratina shastensis	CRPR 1B.2, USFS E
Bent-flowered fiddleneck	Amsinckia lunaris	CRPR 1B.2, BLMS
Mallory's manzanita	Arctostaphylos malloryi	CRPR 4.3
Shasta County arnica	Arnica venosa	CRPR 4.2, USFS E
Depauperate milk-vetch	Astragalus pauperculus	CRPR 4.3
Moonwort, grape-fern	Botrychium subgenus Botrychium	USFS S, S&M
Yellow-twist horsehair	Bryoria tortuosa	BLMS
Green bug moss	Buxbaumia viridis	USFS S, BLMS, S&M
Callahan's mariposa lily	Calochortus syntrophus	CRPR 1B.1
Butte County morning-glory	Calystegia atriplicifolia ssp. buttensis	CRPR 4.2
Castle Crags harebell	Campanula shetleri	CRPR 1B.3, USFS S, BLMS
Buxbaum's sedge	Carex buxbaumii	CRPR 4.2
Bristly sedge	Carex comosa	CRPR 2.1, MSCS r
Fox sedge	Carex vulpinoidea	CRPR 2.2
Shasta clarkia	Clarkia borealis ssp. arida	CRPR 1B.1, MSCS m, BLMS
Northern clarkia	Clarkia borealis ssp. borealis	CRPR 1B.3, BLMS
Silky cryptantha	Cryptantha crinita	CRPR 1B.2, MSCS m, BLMS
California lady's-slipper	Cypripedium californicum	CRPR 4.2
Clustered lady's-slipper	Cypripedium fasciculatum	CRPR 4.2, USFS S, BLMS, S&M
Mountain lady's-slipper	Cypripedium montanum	CRPR 4.2, USFS S, BLMS, S&M
Four-angled spike rush	Eleocharis quadrangulata	CRPR, MSCS m
Butte County fritillary	Fritillaria eastwoodiae	CRPR 3.2, USFS S
Dubious pea	Lathyrus sulphureus var. argillaceus	CRPR 3
Broad-lobed linanthus	Leptosiphon latisectus	CRPR 4.3
Cantelow's lewisia	Lewisia cantelovii	CRPR 1B.2, USFS S, BLMS
Howell's lewisia	Lewisia cotyledon var. howellii	CRPR 3.2
Bellinger's meadowfoam	Limnanthes floccosa ssp. bellingeriana	CRPR 1B.2, MSCS m, BLMS
Awl-leaved navarretia	Navarretia subuligera	CRPR 4.3
Shasta snow-wreath	Neviusia cliftonii	CRPR 1B.2, USFS S, MSCS m, BLMS
Thread-leaved beardtongue	Penstemon filiformis	CRPR 1B.3, MSCS m, USFS S, BLMS
Narrow-petaled rein orchid	Piperia leptopetala	CRPR 4.3
Bidwell's knotweed	Polygonum bidwelliae	CRPR 4.3
Eel-grass pondweed	Potamogeton zosteriformis	CRPR 2.2, MSCS m
Pacific fuzzwort	Ptilidium californicum	USFS S, BLMS, S&M
Brownish beaked-rush	Rhynchospora capitellata	CRPR 2.2
Sanford's arrowhead	Sagittaria sanfordii	CRPR 1B.2, MSCS m, BLMS
Marsh skullcap	Scutellaria galericulata	CRPR 2.2, MSCS m
Canyon Creek stonecrop	Sedum obtusatum ssp. paradisum	CRPR 1B.3, USFS S, BLMS
English Peak greenbriar	Smilax jamesii	CRPR 1B.3, USFS S, MSCS m, BLMS
Obtuse starwort	Stellaria obtusa	CRPR 4.3
Slender false lupine	Thermopsis gracilis var. gracilis	CRPR 4.3
Shasta huckleberry	Vaccinium sp., undescribed	Genetically distinct from coastal and Sierra Nevada populations; may warrant taxonomic consideration.
Oval-leaved viburnum	Viburnum ellipticum	CRPR 2.3

Table 12-3. Plant Species of Concern with Potential to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Notes:

[1] Status Codes

CRPR 1B = Plants rare, threatened, or endangered in California and elsewhere

CRPR 2 = Plants rare, threatened, or endangered in California but more common elsewhere

CRPR 3 = Plants for which more information is need—a review list

CRPR 4 = Plants of limited distribution—a watch list

CRPR Threat Ranks

0.1 = Seriously threatened in California

0.2 = Fairly threatened in California

0.3 = Not very threatened in California

Multi Species Conservation Strategy (MSCS) covered species

R = Recovery. Recover species' populations within the MSCS focus area to levels that ensure the species' long-term survival in nature.

r = Contribute to recovery. Implement some of the actions deemed necessary to recover species' populations within the MSCS focus area.

m = Maintain. Ensure that any adverse effects on the species that could be associated with implementation of CALFED actions will be fully offset through implementation of actions beneficial to the species (CALFED 2000c).

Key:

BLMS = BLM sensitive

CRPR = California Rare Plant Rank

USFS = U.S. Forest Service

USFS E = USFS Endemic Species

USFS S = USFS Sensitive Species

S&M = Survey and Manage Species

MSCS = Multi Species Conservation Strategy

The CNDDB was reviewed for records of special-status plant species in or near the Shasta Lake and vicinity portion of the primary study area. The CNDDB is a database consisting of historical observations of special-status plant species, wildlife species, and natural communities. The CNDDB is limited to reported sightings and is not a comprehensive list of special-status species that may occur in a particular area.

A search of the CNPS Electronic Inventory was also conducted. The Electronic Inventory allows users to query the database using a set of variable search criteria. The result of the search is a list of potentially occurring special-status plant species. The criteria used for the query included all CRPR 1A, 1B, 2, 3, and 4 plants (formerly CNPS) occurring in Shasta County in closed-cone coniferous forest, chaparral, cismontane woodland, lower montane coniferous forest, marshes and swamps, pebble plain, valley and foothill grasslands, riparian forest, riparian woodland, and riparian scrub habitats between the elevations of approximately 900 feet and 2,500 feet.

Botanical Surveys Because botanical studies are ongoing, detailed technical memoranda describing methods, results, and conclusions will be provided in the Final Environmental Impact Statement (FEIS).

NSR conducted several botanical surveys for special-status plant species in the Shasta Lake and vicinity portion of the primary study area. Botanical surveys were conducted in 2002, 2003, 2004, 2009, and 2010. A list of species observed during the surveys is provided as Attachment 2. Hickman (1993) was used as the standard reference for taxonomic nomenclature and identification. Special-status plant species detected during the surveys are discussed in more detail in Attachment 3.

The first botanical surveys were performed during 2002 along the Big Backbone and Squaw Creek arms. The surveys were conducted in accordance with the technical methods prescribed by Nelson (1994). In 2003, botanical surveys were conducted along 11 selected riverine reaches: Little Backbone Creek, Sugarloaf Creek, upper Sacramento River, middle Salt Creek, Salt Creek, Nosoni Creek, Dekkas Creek, Campbell Creek, Flat Creek, Ripgut Creek, and Potem Creek. The surveys were conducted in accordance with the technical methods prescribed by Nelson (1994). In 2004, botanical surveys were conducted at a series of randomly and nonrandomly selected locations. Nonrandomly selected sites were located throughout the Shasta Lake and vicinity portion of the primary study area (not including relocation areas) based on 2002 and 2003 survey results. Sites were selected based on the presence of unique habitat and ecological attributes, such as recently burned areas, unique geologic substrates, late-seral forests, and relatively rare plant series. Nonrandomly selected sites varied in size and often included several plant series types. Randomly selected sites were selected throughout the area using plant series polygons developed from previously completed vegetation mapping. Using geographic information systems, individual vegetation polygons were assigned a unique number, and 100 numbers (i.e., vegetation polygons) were then randomly selected.

Based on previous surveys resulting in discoveries of Shasta snow-wreath (*Neviusia cliftonii*) and Shasta huckleberry (*Vaccinium* sp. undescribed), specific surveys for these species were conducted in 2009 and 2010. These surveys were designed to identify potential habitat for and locate populations of these species outside of the proposed project area. Pedestrian surveys were conducted to search the focus areas identified. Using methods described in Lindstrand and Nelson (2006), potential survey areas were identified using soil and geologic information at known sites and choosing areas with those same characteristics. In addition, survey sites were identified using intuitive techniques, such as selecting areas with vegetative cover types similar to those of known populations and areas near known populations (regardless of vegetative cover).

To address potential project impacts and evaluate potential mitigation measures, a genetic study of the Shasta snow-wreath was conducted in 2009 and 2010. The goal of the genetic study was to determine (1) whether all Shasta snow-wreath populations are genetically identical and (2) whether there are several homogeneous population clusters or whether some other pattern is present.

Twenty-one of the 23 known Shasta snow-wreath sites were included in the study. The genetic study determined that the species is characterized by low genetic diversity and high levels of genetic differentiation (National Forest Genetics Laboratory 2010). No strong patterns were found between the Shasta snow-wreath populations and several physical and geographic variables, including soil, geology, population size, and geographic location. Although high levels of genetic differentiation and no strong population patterns are present, the genetic study found three general population clusters, providing insight and basic species information for potential mitigation planning.

Concurrently with the Shasta snow-wreath genetic study, a genetic study was conducted in 2009 and 2010 to determine whether the huckleberry is different genetically from red huckleberry and, if so, to determine if it warrants recognition as a new taxon. The genetic study determined that the species is genetically distinct from other huckleberry populations (National Forest Genetics Laboratory 2010). Based on the results of the genetic studies combined with phenotypic characteristics, this species warrants recognition as a new taxon. The Shasta huckleberry appears to be an uncommon and geographically restricted species.

In 2010, botanical surveys were conducted in all relocation areas including the dam footprint. The surveys were conducted in accordance with the technical methods prescribed by Nelson (1994).

Shasta County arnica (*Arnica venosa*), Northern clarkia (*Clarkia borealis* ssp. *borealis*), Butte County fritillary (*Fritillaria eastwoodiae*), Cantelow's lewisia (*Lewisia cantelovii*), Shasta snow-wreath, slender false lupine (*Thermopsis gracilis* var. *gracilis*), Shasta huckleberry, and oval-leaved viburnum (*Viburnum ellipticum*) were special-status plant species found both incidentally and during the surveys efforts.

One population of Shasta County arnica was found in ponderosa pine habitat south of Bridge Bay Resort along the Main Body and one population was found near the privately owned cabins on National Forest System lands in the Salt Creek inlet on the Sacramento Arm. Additionally, the USFS has located a population along the Sacramento Arm north of Slaughterhouse Island during surveys conducted in 2010 (Figures 12-3a and 12-3c).

One population of northern clarkia was found in hardwood-conifer/chaparral habitat near Bailey Cove on the McCloud Arm, and another population was found in hardwood-conifer/chaparral habitat in Sugarloaf Cove west of Beehive Point on the Sacramento Arm. Locations of northern clarkia found incidentally and during the surveys are shown on Figures 12-3c through 12-3d.

Surveys conducted by the USFS in 2010 located five populations of Butte County fritillary; two populations along Flat Creek and three populations along Ripgut Creek on the Pit Arm (Figure 12-3f).

One population of Cantelow's lewisia was discovered on a rock outcrop on the right bank of the upper Sacramento River near the Shasta Lake/upper Sacramento River transition zone. Additionally, the USFS has located three populations along Sacramento Arm near Elmore Mountain during surveys conducted in 2010 (Figures 12-3c).

Shasta snow-wreath is currently known from 23 locations, most of which occur at or near the periphery of Shasta Lake. Ten Shasta snow-wreath populations occur in habitats associated with limestone formations, and 13 occur in other habitat types. Most populations are associated with stream drainages or the lower portions of upland slopes. Of these, 13 Shasta snow-wreath populations were discovered during the botanical surveys along the McCloud Arm (south of Shasta Caverns and Keluche Creek), Pit Arm (Brock Creek, Ripgut Creek, Flat Creek, Stein Creek, and west of Stein Creek), and the Main Body (Blue Ridge east, Blue Ridge west, Blue Ridge middle, Cove Creek, south of Cove Creek, and Jones Valley). Locations of Shasta snow-wreath found incidentally and during the surveys are shown on Figures 12-3a through 12-f.

Slender false lupine populations were discovered in all portions of the primary study area, generally on low-gradient slopes. Locations of slender false lupine found during the surveys and incidentally are shown on Figures 12-3a through 12-3f.

Shasta huckleberry is currently known from 12 locations in the upper Spring Creek, Dry Fork, (little) Squaw Creek, Shoemaker Gulch, and Little Backbone Creek drainages, and from the vicinity of Bully Hill. All locations occur in the area historically known as the Copper Belt of Shasta County in the immediate vicinity of historic copper mining activities. Shasta huckleberry occurs at four locations in the SLWRI project area: (little) Squaw Creek, Shoemaker Gulch, Little Backbone Creek, and Horse Creek near Bully Hill. Locations of Shasta huckleberry found incidentally and during the surveys are shown on Figures 12-3a through 12-3f.

Two oval-leaved viburnum populations were found during the surveys. One population was found in a forested upland slope west of Pine Point Campground along the McCloud Arm and a second population was found in chaparral habitat at Jones Valley along the Pit Arm near the Clikapudi Trail. Locations of oval-leaved viburnum found incidentally and during the surveys are shown on Figures 12-3d and 12-3f.

Upper Sacramento River (Shasta Dam to Red Bluff)

Based on review of CNDDB and CNPS database searches, a USFWS list of species that could be potentially affected in this portion of the primary study area, and previously prepared biological reports for the area, 25 special-status plant species were identified as possibly occurring in the primary study area between Shasta Dam and RBDD, and thus their potential to occur in this portion of the study area was evaluated further. These special-status plant species, along with the legal status, habitat, and potential for occurrence of each species, are provided in Table 12-4.

Sixteen of the special-status plant species listed in Table 12-4 have the potential to occur within habitat present along the Sacramento River between Shasta Dam and RBDD. Many of these species, such as Bogg's Lake hedge hyssop (*Gratiola heterosepala*; State endangered, MSCS m, CNPS 1B), Ahart's dwarf rush (*Juncus leiospermus* var. *ahartii*; MSCS m, CNPS 1B), Ahart's paronychia (*Paronychia ahartii*; MSCS m, CNPS 1B), dwarf downingia (*Downingia pusilla*; CNPS 2), Greene's legenere (*Legenere limosa*; MSCS m, CNPS 1B), Henderson's bent grass (*Agrostis hendersonii*; MSCS m, CNPS 3), Red Bluff dwarf rush (*Juncus leiospermus* var. *leiospermus*; CNPS 1B), and slender Orcutt grass (*Orcuttia tenuis*; Federal endangered, state endangered, MSCS m, CNPS 1B), typically occur in vernal pools, which are generally not present within the active floodplain of regulated rivers in the extended study area. Other special-status plants, however, could occur in the extended study area in the freshwater marshes, swamps, and riparian woodlands that are found along the river corridor. These species include fox sedge (*Carex vulpinoidea*; CNPS 2), rose mallow (*Hibiscus lasiocarpus*; MSCS m, CNPS 2), and silky cryptantha (*Cryptantha crinita*; USFS SM, CNPS 1B). The remaining five species may occur in annual grassland, chaparral, cismontane woodland, and lower montane coniferous forest vegetation communities along the river corridor, including adobe-lily (*Fritillaria pluriflora*; MSCS m, CNPS 1B), Butte County fritillary (*Fritillaria eastwoodiae*; USFS S, CNPS 3), dubious pea (*Lathyrus sulphureus* var. *agillaceous*; CNPS 3), mountain lady's slipper (*Cypripedium fasciculatum*; USFS SM, CNPS 4), and oval-leaved viburnum (*Viburnum ellipticum*; CNPS 2).

Of the special-status species that could occur along the upper Sacramento River, four are known to occur along the edge of the Sacramento River channel, or along a Sacramento River tributary within 0.2 mile of the river proper, and their establishment and reproduction could potentially be affected by changes in flow regime: fox sedge, silky cryptantha, rose mallow, and Ahart's paronychia (CNDDB 2007, University of California 2011).

Table 12-4. Special-Status Plant Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Diversion Dam

Species	Legal Status[1]					Habitat and Blooming Period	Potential for Occurrence
	USFWS	DFG	MSCS	USFS	CNPS		
Shasta ageratina *Ageratina shastensis*		–		E	4	Rocky carbonate outcrops in chaparral and lower montane coniferous forest; 1,300 – 5,900 feet elevation. Blooms June – October.	Could occur near Shasta Dam if suitable outcrops are present. Potential is low because most of the study area is below species' known elevation range.
Henderson's bent grass *Agrostis hendersonii*	–	–	m	–	3	Mesic sites in valley and foothill grassland, vernal pools; 230 – 1,000 feet elevation. Blooms April – May.	Could occur along the Sacramento River if suitable vernally mesic habitat is present.
Shasta County arnica *Arnica venosa*	–	–	–	E	4	Cismontane woodlands and lower montane coniferous forests, often in disturbed areas and roadcuts; 1,300 – 4,900 feet elevation. Blooms May – July.	Could occur along the Sacramento River and tributaries within the study area. Potential is low because most of the study area is below species' known elevation range.
Fox sedge *Carex vulpinoidea*	–	–	–	–	2	Freshwater marshes and swamps and riparian woodland; 100 – 4,000 feet elevation. Blooms May – June.	Could occur in suitable habitat along the Sacramento River.
Silky cryptantha *Cryptantha crinita*	–	–	m	–	1B	Gravelly streambeds within cismontane woodland, lower montane coniferous forest, riparian forest, riparian woodland, valley and foothill grassland; 275 – 4,000 feet elevation. Blooms April – May.	Could occur along the Sacramento River and tributaries within the study area.
Clustered lady's slipper *Cypripedium fasciculatum*	–	–	–	SM	4	Lower montane coniferous forest, North Coast coniferous forest; often in serpentinite seeps or on streambanks; 300 – 8,000 feet elevation. Blooms March – July.	Unlikely; no coniferous forest known in the study area.
Mountain lady's slipper *Cypripedium montanum*	–	–	–	SM	4	Broadleaved upland forest, cismontane woodland, lower montane coniferous forest, North Coast coniferous forest; 500 – 7,000 feet elevation. Blooms March – July.	Could occur at Shasta Dam or along the Sacramento River and tributaries.
Dwarf downingia *Downingia pusilla*	–	–	–	–	2	Mesic sites in valley and foothill grassland, vernal pools. Blooms March – May.	Could occur along the Sacramento River if suitable vernally mesic habitat is present.

Table 12-4. Special-Status Plant Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Diversion Dam (contd.)

Species	Legal Status[1]					Habitat and Blooming Period	Potential for Occurrence
	USFWS	DFG	MSCS	USFS	CNPS		
Butte County fritillary *Fritillaria eastwoodiae*	–	–	–	S	3	Openings and sometime serpentine areas in chaparral, cismontane woodland, and lower montane coniferous forest; 160 – 4,900 feet elevation. Blooms March – June.	Could occur along the Sacramento River and tributaries within the study area.
Adobe-lily *Fritillaria pluriflora*	–	–	m	–	1B	Chaparral, cismontane woodland, valley and foothill grassland; often in adobe soils; 200 – 2,300 feet elevation. Blooms February – April.	Could occur at Shasta Dam and along the Sacramento River.
Bogg's Lake hedge hyssop *Gratiola heterosepala*	–	E	m	–	1B	Marshes and swamps, vernal pools; 30 – 8,000 feet elevation. Blooms April – August.	Could occur along the Sacramento River and tributaries.
Rose mallow *Hibiscus lasiocarpus*	–	–	m	–	2	Freshwater marshes and swamps.	Could occur along the Sacramento River and tributaries.
Ahart's dwarf rush *Juncus leiospermus* var. *ahartii*	–	–	m	–	1B	Mesic sites in valley and foothill grassland; 100 – 300 feet elevation. Blooms March – May.	Could occur along the Sacramento River if suitable vernally mesic habitat is present. Shasta Dam is higher than species' known elevation range.
Red Bluff dwarf rush *Juncus leiospermus* var. *leiospermus*	–	–	–	–	1B	Vernally mesic sites in chaparral, cismontane woodland, meadows and seeps, valley and foothill grassland, vernal pools; 100 –3,350 feet elevation. Blooms March – May.	Could occur at Shasta Dam or along the Sacramento River if suitable vernally mesic habitat is present.
Dubious pea *Lathyrus sulphureus* var. *argillaceous*	–	–	–	–	3	Cismontane woodland, lower montane coniferous forest, upper montane coniferous forest; 500 – 1,000 feet elevation. Blooms in April.	Could occur at Shasta Dam and along the Sacramento River.
Greene's legenere *Legenere limosa*	–	–	m	–	1B	Vernal pools; 1 – 3,000 feet elevation. Blooms April – June.	Could occur along Sacramento River if suitable vernal pool habitat is present.

Table 12-4. Special-Status Plant Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Diversion Dam (contd.)

Species	Legal Status[1]					Habitat and Blooming Period	Potential for Occurrence
	USFWS	DFG	MSCS	USFS	CNPS		
Cantelow's lewisia *Lewisia cantelovii*	–	–	–	S	1B	Mesic granitic sites within broadleaved upland forest, chaparral, cismontane woodland, and lower montane coniferous forest; 1,250 – 4,500 feet. Sometimes in serpentinite seeps. Blooms May – October.	Could occur in the Shasta Dam area. The remainder of the study area is below species' known elevation range.
Bellinger's meadowfoam *Limnanthes floccosa* ssp. *bellingeriana*	–	–	m	–	1B	Mesic sites in cismontane woodland, meadows and seeps; 950 – 3,600 feet elevation. Blooms April – June.	Could occur at Shasta Dam. Potential along Sacramento River is low because majority of study area is below species known elevation range.
Shasta snow wreath *Neviusia cliftonii*	–	–	m	S	1B	Carbonate substrates in lower montane coniferous forest and riparian woodland; 1,000 – 1,600 feet elevation. Blooms May – June.	Could occur in Shasta Dam area. Unlikely to occur along Sacramento River because study area is lower than species known elevation range.
Slender orcutt grass *Orcuttia tenuis*	E	E	m	–	1B	Vernal pools; 100 – 6,000 feet elevation. Blooms May – October.	Could occur along the Sacramento River if suitable vernal pool habitat is present. Federally designated critical habitat for this species occurs east of the Sacramento River, east of Cottonwood (Units 3A and 3B) and northeast of Anderson (Units 2C and 2D).
Ahart's paronychia *Paronychia ahartii*	–	–	m	–	1B	Cismontane woodland, valley and foothill grassland, vernal pools; 100 – 1,700 feet elevation. Blooms March – June.	Could occur at Shasta Dam and along the Sacramento River.
Pacific fuzzwort *Ptilidium californicum*	–	–	–	SM	–	An epiphytic on bark at the base of standing mature to old-growth trees or recently fallen logs; rarely on other organic substrates such as decaying logs and stumps, or humus covering boulders; 1,275 – 5,725 feet elevation.	Could occur along the Sacramento River and tributaries within the study area. Potential is low because most of the study area is below species' known elevation range.

Table 12-4. Special-Status Plant Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Diversion Dam (contd.)

Species	Legal Status[1]					Habitat and Blooming Period	Potential for Occurrence
	USFWS	DFG	MSCS	USFS	CNPS		
Canyon Creek stonecrop *Sedum paradisum*	–	–	–	S	1B	Granitic, rocky areas in broadleafed upland forest, chaparral, lower montane coniferous forest, subalpine coniferous forest; 980 – 6,100 feet elevation. Blooms May – June.	Could occur along the Sacramento River and tributaries within the study area. Potential is low because most of the study area is below species' known elevation range.
English Peak greenbriar *Smilax jamesii*	–	–	m	S	1B	Found along streambanks and lake margins in broadleafed upland forest, lower montane, upper montane, and north coast coniferous forests, and marshes and swamps; 1,600 – 8,200 feet elevation. Blooms May – July, rarely through August.	Could occur along the Sacramento River and tributaries within the study area. Potential is low because most of the study area is below species' known elevation range.
Oval-leaved viburnum *Viburnum ellipticum*	–	–	–	–	2	Chaparral, cismontane woodland, lower montane coniferous forest; 800 – 4,600 feet elevation. Blooms May – June.	Could occur at Shasta Dam and along the Sacramento River.

Lower Sacramento River and Delta

Most of the special-status plant species listed in Table 12-4 have the potential to occur within the extended study area (lower Sacramento River and Delta and CVP/SWP service areas). Numerous additional special-status plant species could occur in the extended study area. Attachment 4 of the *Botanical Resources and Wetlands Technical Report* contains comprehensive lists of all sensitive plant species in the extended study area that have been reported to the

CNDDB, or that otherwise have the potential to occur in the extended study area.

A number of special-status plant species could be affected in the lower Sacramento River and Delta by changes in hydrology (CALFED 2000c). These include species associated with vernal pool, riparian, marsh, and aquatic plant communities; and several other species with restricted distributions on or near channel banks, active floodplains, flood bypasses, and Delta waterways. These assemblages of special-status species are described below.

Species of Vernal Pool Communities In addition to species that are potentially present in the primary study area (Table 12-4), special-status plant species that may be associated with vernal pools along the lower Sacramento River and in the Delta region include alkali milk-vetch (*Astragalus tener* var. *tener*; MSCS r, CNPS 1B), brittlescale (*Atriplex depressa*; MSCS m, CNPS 1B), Hoover's spurge (*Chamaesyce hooveri*; Federal threatened, MSCS m, CNPS 1B), Contra Costa goldfields (*Lasthenia conjugens*; Federal endangered, MSCS m, CNPS 1B), hairy orcutt grass (*Orcuttia pilosa*; Federal endangered, MSCS m, CNPS 1B), slender Orcutt grass (*Orcuttia tenuis*; Federal threatened, MSCS m, CNPS 1B), bearded popcornflower (*Plagoibothrys hystriculus*; CNPS 1B), Delta woolly-marbles (*Psilocarphus brevissimus* var. *multiflorus*; CNPS 4), Crampton's tuctoria (*Tuctoria mucronata*; Federal and State endangered, MSCS r, CNPS 1B), and Greene's tuctoria (*Tuctoria greenei*; Federal endangered, MSCS m, CNPS 1B). The primary threats affecting most of these species at multiple locations are habitat loss because of development, nonnative species, and incompatible grazing practices. Additional threats affecting some of these species at one or more location include game management practices (e.g., inundation of land for waterfowl during the growing season), off-road vehicle use and trampling, incompatible agricultural practices, and hydrological alterations.

Species of Riparian and Marsh Communities In addition to species considered potentially present in the primary study area (Table 12-4 of the *Botanical Resources and Wetlands Technical Report*), special-status plant species associated with riparian and marsh communities along the lower Sacramento River or in the Delta region include bristly sedge (*Carex comosa*; MSCS r, CNPS 2), Suisun thistle (*Cirsium hydrophilum* var. *hydrophilum*; Federal endangered, MSCS R, CNPS 1B), Soft bird's-beak (*Cordylanthus mollis* ssp. *mollis*; Federal endangered, State rare, MSCS R, CNPS 1B), Delta button-celery (*Eryngium racemosum*; MSCS r, CNPS 1B), Northern California black walnut (*Juglans hindsii*; MSCS r, CNPS 1B), Delta tule pea (*Lathyrus jepsonii* var. *jepsonii*; MSCS r, CNPS 1B), Mason's lilaeopsis (*Lilaeopsis masonii*; MSCS R, CNPS 1B), Delta mudwort (*Limosella subulata*; MSCS r, CNPS 2), Sanford's arrowhead (*Sagittaria sanfordii*; MSCS m, CNPS 1B), Marsh skullcap (*Scutellaria galericulata*; MSCS m, CNPS 2), blue skullcap (*Scutellaria lateriflora*; MSCS m, CNPS 2), and Suisun Marsh aster (*Symphytotrichum lentum*; CNPS 1B) (CNDDB 2007, CNPS 2011). The

primary threats affecting these species are habitat loss, competition from nonnative species, and alterations to hydrology (including trenching and diking). Additional threats include grazing and trampling, installation of riprap, and anthropogenic disturbances (e.g., off-road vehicles; road, utility, and levee maintenance).

Species of Aquatic Communities Eel-grass pondweed (P*otamogeton zosteriformis*; MSCS m, CNPS 2), a submerged aquatic plant of assorted freshwater habitats is rare in California but more common elsewhere (CNPS 2011). Overall, the distribution, abundance, and threats affecting this species in California are not well known.

CVP/SWP Service Areas

Special-status plants are not likely to occur in a substantial portion of the CVP and SWP service areas because the agricultural and urban land uses tend to preclude suitable habitat for most native species. Although agricultural and developed land uses account for most of the CVP and SWP service areas, a portion of these areas still remains in natural vegetation, Because of the large size of the CVP and SWP service areas, this natural vegetation is distributed over a wide range of climate and soils, and is varied in structure and species composition. Consequently, a large number of special-status plant species has the potential to occur in the natural vegetation that remains within the CVP and SWP service areas. (See the *Botanical Resources and Wetlands Technical Report*.)

12.1.3 Invasive Species

Shasta Lake and Vicinity

Nonnative plant species introduced to the region by early settlers are of concern in the Shasta Lake and vicinity portion of the study area. When plants that evolved in one region of the globe are moved by humans to another region, a few flourish, crowding out native vegetation and wildlife that feed on the native species. Some invasive plants can even change ecosystem processes such as hydrology, fire regimes, and soil chemistry. These invasive plants have a competitive advantage because they are no longer controlled by their natural predators and can quickly spread. In California, approximately 3 percent of the plant species growing in the wild are considered invasive, but they inhabit a much greater proportion of the landscape (Cal-IPC 2007).

Plant pests are defined by law, regulation, and technical organizations, and are regulated by many different bodies, including the California Department of Food and Agriculture (CDFA), U.S. Department of Agriculture, and the California Invasive Plant Council (Cal-IPC). CDFA uses an action-oriented pest-rating system. The low rating assigned to a pest by CDFA does not necessarily mean that the pest is not a problem; rather, the rating system is meant to prioritize response by CDFA and county agricultural commissioners. Plants on CDFA's highest priority "A" list are defined as plants "of known

economic importance subject to state-county enforced action involving eradication, quarantine regulation, containment, rejection or other holding action."

Cal-IPC has developed a list of plant pests specific to California wildlands. The Cal-IPC list is based on information submitted by land managers, botanists, and researchers throughout the state and on published sources. To determine plant pests potentially occurring in the Shasta Lake and vicinity portion of the primary study area, this list was reviewed and local agencies (BLM, USFS, California Department of Transportation, and Shasta County Department of Agriculture) were contacted to gather knowledge of known weed locations (Table 12-5). Incidental observations of noxious weeds by NSR biologists and botanists were also recorded. Attachment 5 describes each weed source location, the potential mode of spread, and the risk of spread at each of the known sites.

Management actions have been required to prevent the loss of habitat caused by some of the more invasive exotic species that outcompete native vegetation. However, these management actions have been limited and have been confined primarily to areas adjacent to campgrounds and USFS facilities.

Table 12-5. Nonnative Plant Species Known to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area

Common Name	Scientific Name	Cal-IPC Rating[1]	CDFA Ranking[2]	Habitat
Tree of heaven	Ailanthus altissima	Moderate	None	Grassland, oak woodland, riparian
Slender wild oats	Avena barbata	Moderate	None	Coastal scrub, grassland, oak woodland, forest
Common wild oats	Avena fatua	Moderate	None	Coastal scrub, grassland, oak woodland, forest
Rattlesnake grass	Briza maxima	Limited	None	Grassland
Ripgut brome	Bromus diandrus	Moderate	None	Dunes, scrub, grassland, woodland, forest
Soft brome	Bromus hordeaceus	Limited	None	Grassland, sage brush, serpentine soils
Red brome	Bromus madritensis ssp. rubens	High	None	Interior scrub, woodlands, grassland
Cheatgrass	Bromus tectorum	High	None	Interior scrub, woodlands, grassland
Lenspod whitetip	Cardaria chalapensis	Moderate-ALERT	B	Central Valley wetlands
Italian thistle	Carduus pycnocephalus	Moderate	None	Forest, scrub, grasslands, woodlands.

Table 12-5. Nonnative Plant Species Known to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Cal-IPC Rating[1]	CDFA Ranking[2]	Habitat
White knapweed	Centaurea diffusa	Moderate	A	Great Basin scrub, coastal prairie
Spotted knapweed	Centaurea maculosa	High	A	Riparian, grassland, wet meadows, forests
Yellow star-thistle	Centaurea solstitialis	High	C	Grassland, woodlands, occasionally riparian
Squarrose knapweed	Centaurea virgata var. squarrosa	Moderate	A	Scrub, grassland, pinyon-juniper woodland
Rush skeleton weed	Chondrilla juncea	Moderate	A	Grassland
Canada thistle	Cirsium arvense	Moderate	B	Grassland, riparian areas, forests
Bull thistle	Cirsium vulgare	Moderate	None	Riparian areas, marshes, meadows
Field bindweed	Convolvulus arvensis	Evaluated, not listed	C	Agricultural weed
Bermuda grass	Cynodon dactylon	Moderate	C	Riparian scrub, common landscape weed
Scotch broom	Cystis scoparius	High	C	Coastal scrub, oak woodland
Longbeak stork's bill	Erodium botrys	Evaluated, not listed	None	Many upland habitats
Redstem stork's bill	Erodium cicutarium	Limited	None	Many upland habitats
Leafy spurge	Euphorbia esula	High-ALERT	A	Forests, woodlands, juniper forests
Fig	Ficus carica	Moderate	None	Riparian woodland
Fennel	Foeniculum vulgare	High	None	Grassland, scrub
French broom	Genista mospessulana	High	C	Coastal scrub, oak woodland, grassland
English ivy	Hedera helix	High	None	Coastal forest, riparian areas
Mediterranean barley, foxtail	Hordeum marinum, H. murinum	Moderate	None	Grassland
Common St. John's wort	Hypericum perforatum	Moderate	C	Many habitats, disturbed
Dyer's woad, Marlahan mustard	Isatis tinctoria	Moderate	B	Great Basin scrub and grassland
Dalmation toadflax	Linaria dalmatica	Moderate	A	Grassland, forest clearings
Italian ryegrass	Lolium multiflorum	Moderate	None	Grassland, oak woodlands, pinyon-juniper woodland
Oleander	Nerium oleander	Evaluated, not listed	None	Riparian areas
Pokeweed	Phytolacca americana	None	None	Riparian forest, riparian woodland

Table 12-5. Nonnative Plant Species Known to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Cal-IPC Rating[1]	CDFA Ranking[2]	Habitat
Black locust	Robinia pseudoacacia	Limited	None	Riparian areas, canyons
Himalayan blackberry	Rubus discolor	High	None	Riparian areas, marshes, oak woodlands
Cutleaf blackberry	Rubus laciniatus	None	None	Riparian areas, marshes, oak woodlands
Curly dock	Rumex crispus	Limited	None	Grassland, vernal pools, meadows, riparian
Tansy ragwort	Senecio jacobaea	Limited	B	Grassland, riparian
Johnsongrass	Sorghum halepense	None	C	Disturbed sites, moist places
Spanish broom	Spartium junceum	High	None	Coastal scrub, grassland, wetlands, oak woodland, forests
Medusa-head	Taeniatherum caput-medusae	High	C	Grassland, scrub, woodland
Spreading hedgeparsley	Torilis arvensis	Moderate	None	Widespread
Common mullein	Verbascum thapsus	Limited	None	Meadows, riparian, sagebrush, pinyon-juniper woodland
Periwinkle	Vinca major	Moderate	None	Riparian, oak woodlands, coastal scrub
Rat-tail fescue	Vulpia myuros	Moderate	None	Coastal sage scrub, chaparral

Notes:

[1] Cal-IPC Inventory Categories:

- High — Severe ecological impacts on physical processes, plant and animal communities, and vegetation structure. Reproductive biology and other attributes are conducive to moderate to high rates of dispersal and establishment. Widely distributed ecologically.
- Moderate — Substantial and apparent ecological impacts on physical processes, plant and animal communities, and vegetation structure. Reproductive biology and other attributes are conducive to moderate to high rates of dispersal, although generally dependent on ecological disturbance. Ecological amplitude and distribution may range from limited to widespread.
- Limited — Invasive but ecological impacts are minor. Reproductive biology and other attributes result in moderate rates of invasiveness. Ecological amplitude and distribution are generally limited, but may be locally persistent and problematic (Cal-IPC 2007).

[2] CDFA Pest Ratings of Noxious Weed Species and Noxious Weed Seed

A – Eradication, containment, rejection, or other holding action at the state-county level.

B – Intensive control or eradication, where feasible, at the county level.

C – Control or eradication as local conditions warrant, at the county level.

Q – Rating as "A" is pending at the state or county level.

Key:

Cal-IPC = California Invasive Plant Council

CDFA = California Department of Food and Agriculture

Upper Sacramento River (Shasta Dam to Red Bluff) and Lower Sacramento River and Delta

A number of nonnative species have been introduced and become abundant in the riparian areas and marshes (fresh emergent wetlands) of the Sacramento Valley and Delta (Hunter et al. 2003). Several of these invasive nonnatives, including red sesbania (*Sesbania punicea*), Himalayan blackberry (*Rubus discolor*), giant reed (*Arundo donax*), and perennial pepperweed (*Lepidium latifolium*), form dense, monotypic stands that preclude the establishment of native species (Bossard et al. 2000). In general, these species displace native plants, reduce biodiversity, alter river flows, and reduce wildlife habitat values. Table 12-6 lists the most problematic of those species in Sacramento Valley and Delta riparian areas and marshes—invasive species rated "high" by Cal-IPC; these species have severe ecological impacts on physical processes, plant and animal communities, and vegetation structure (Cal-IPC 2006).

Table 12-6. Cal-IPC High-Rated Invasive Plants of Sacramento Valley and Delta Riparian and Marsh Habitats

Scientific Name Common Name	Cal-IPC Rating	Primary Riparian/ Marsh Habitat(s)	Plant Type
Arundo donax Giant Reed	H	Riparian Forest/Scrub	Perennial Grass
Cortaderia selloana Pampas Grass	H	Riparian Scrub	Perennial Grass
Foeniculum vulgare Fennel	H	Riparian Scrub	Perennial Herb
Lepidium latifolium Perennial Pepperweed	H	Tidal and Nontidal Marsh, Riparian Scrub	Perennial Herb
Lythrum salicaria Purple Loosestrife	H	Tidal And Nontidal Marsh	Perennial Herb
Rubus armeniacus (= R. discolor) Himalayan Blackberry	H	Riparian Forest and Scrub, Nontidal Marsh	Vine
Sesbania punicea Red Sesbania	H, A	Riparian Forest and Scrub	Tree
Tamarix chinensis, T. gallica, T. parviflora, T. ramosissima Chinese Tamarisk, French Tamarisk, Small Flower Tamarisk, Salt Cedar	H	Riparian Forest and Scrub	Tree, Shrub

Source: Cal-IPC 2006

Notes:

Cal-IPC Inventory Ratings:

A = Alert – Plants with the potential to spread explosively; infestations currently small and localized.

H = High – These species have severe ecological impacts on physical processes, plant and animal communities, and vegetation structure. Their reproductive biology and other attributes are conducive to moderate to high rates of dispersal and establishment. Most are widely distributed ecologically.

12.1.4 Waters of the United States, Including Wetlands, in Shasta Lake and Vicinity

NSR delineated waters of the United States (wetlands and other waters under Federal jurisdiction) in the impoundment area around the perimeter of Shasta Lake, and on public lands in the relocation areas. Cumulatively, 29,992 acres of Federal jurisdictional waters of the United States occur along the impoundment area, including Shasta Lake at full pool. Wetlands, totaling 25 acres, consist of fresh emergent/riparian wetland, intermittent swale, riparian wetland, seasonal wetland, seep/spring wetland, and vegetated ditch. Other waters, totaling 29,967 acres consist of ephemeral, intermittent, and perennial streams, roadside ditches, seep/spring other waters and lacustrine. Some demolition and construction activities associated with the impoundment area and relocation areas will extend into Shasta Lake below the existing full pool elevation. Therefore, the acreage of the surface of Shasta Lake has been included with the acreage of waters of the United States for the impoundment area. Acreage totals for relocation areas will be provided in the FEIS.

The delineation was conducted in accordance with the routine onsite method identified in the *Corps of Engineers Wetlands Delineation Manual* (Environmental Laboratory 1987) (Corps Manual) and the *Interim Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region* (USACE 2006) (Arid West Manual). Each on site wetland determination was based on field observations of soil, vegetation, and hydrologic characteristics. Delineation of "other waters" was based on the presence of an ordinary high-water mark (OHWM) and whether the feature is tributary to waters of the United States. Data points were characterized and documented for 10 percent of all feature types along the perimeter of Shasta Lake. In each relocation area, at least one pair of data points was recorded for each feature type. Soil pits were dug to a depth sufficient to document the presence or confirm the absence of hydric soil or hydrology indicators. Indicator status of wetland plants was determined using the *National List of Plant Species That Occur in Wetlands: California Region 0* (Reed 1988). Positive indicators of hydric soils were observed in the field in accordance with the criteria outlined in *Field Indicators of Hydric Soils in the United States* (NRCS 2006). The hydric status of each soil map unit located in the study area was reviewed using the *Web Soil Survey* (Soil Survey Staff 2010). Indicators of depth and duration of soil saturation, ponding, and drainage patterns and the OHWM were observed in the field. The boundaries of each wetland feature and the three-parameter data points were mapped using rectified color aerial photography. A Trimble Pathfinder Pro XH Global Positioning System capable of sub-foot accuracy was primarily used to delineate features in the relocation areas.

The fieldwork for the impoundment area was conducted in 2004, 2006, and 2010. Along the McCloud Arm, the impoundment area extends beyond the McCloud River Bridge. Fieldwork will be completed in this area during the spring/summer of 2011. The fieldwork in the relocation areas was completed in

early January 2011 and is currently being processed. These data will be provided in the FEIS.

Main Body

The wetland delineation of the impoundment area along the Main Body was conducted from January to April 2010. Delineated waters of the United States consisted of wetlands (seep/spring and riparian wetland, and vegetated ditch) and other waters (ephemeral, intermittent, and perennial streams, seep/spring other waters, and roadside ditch). Table 12-7 specifies the acres of each of the types of jurisdictional waters that occur in the impoundment area.

Table 12-7. Jurisdictional Waters in the Impoundment Area

Jurisdictional Water Type	Area (Acres)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Wetlands						
Fresh emergent/ riparian wetland	0.00	0.00	3.14	0.00	0.00	0.00

Note:
* Acreage values are approximate

Big Backbone Arm

The wetland delineation along the Big Backbone Arm was conducted during November 2006. Delineated waters of the United States consisted of wetlands

(seep/spring and riparian wetlands) and other waters (ephemeral, intermittent, and perennial streams). Table 12-7 specifies the acres of each of the types of jurisdictional waters occurring along the Big Backbone Arm.

Sacramento Arm

The wetland delineation along the Sacramento Arm was conducted primarily from September through early December 2010 and intermittently in March, April, and June 2010. Delineated waters of the United States consisted of wetlands (seep/spring, riparian, seasonal, and riparian/fresh emergent wetlands) and other waters (ephemeral, intermittent, and perennial streams, seep/spring other waters, and roadside ditch). Table 12-7 specifies the acres of each of the types of jurisdictional waters occurring along the Sacramento Arm.

McCloud Arm

The wetland delineation along the McCloud Arm was conducted primarily during December 2009 and then intermittently in April, June, and November 2010. Delineated waters of the United States consisted of wetlands (seep/spring and riparian wetlands, and vegetated ditch) and other waters (ephemeral, intermittent, and perennial streams, and seep/spring other waters). Table 12-7 specifies the acres of each of the types of jurisdictional waters occurring along the McCloud Arm.

Squaw Creek Arm

The wetland delineation along the Squaw Creek Arm was conducted from late August through September 2004. Delineated waters of the United States include wetlands (seep/spring, riparian wetlands, and seasonal wet meadow) and other waters (ephemeral, intermittent, perennial streams, and seep/spring other waters). Table 12-7 specifies the acres of each of the types of jurisdictional waters occurring along the Squaw Creek Arm.

Pit Arm

The wetland delineation along the Pit Arm was conducted from late November 2006 through April 2007. Delineated waters of the United States consisted of wetlands (riparian, seep/spring, seasonal wetlands, and intermittent swale) and other waters (ephemeral, intermittent, and perennial streams). Table 12-7 specifies the acres of each of the types of jurisdictional waters occurring along the Pit Arm.

Characterization of Features

Wetlands mapped in the Shasta Lake and vicinity portion of the primary study area include fresh emergent/riparian wetland, intermittent swale, riparian wetland, seasonal wetland, seep/spring wetland, and vegetated ditch. The jurisdictional limit of each feature was delineated where all three wetland parameters (wetland vegetation, soils, and hydrology) were met.

One fresh emergent riparian wetland occurs along the Sacramento Arm at the confluence of Salt Creek and Shasta Lake. The Interstate 5 crossing coupled

with USFS attempts to develop the area for recreation has impounded the flows of Salt Creek, resulting in the development of fresh emergent riparian wetlands. Depending on water depths, wooded riparian areas and fresh emergent vegetation have established throughout the feature.

Dominant overstory species include Goodding's black willow (OBL[1]), arroyo willow (FACW), red willow (assume FACW), and shining willow (OBL). Fresh emergent species include pennyroyal (*Mentha pulegium*–OBL), willow dock (*Rumex salicifolius*–OBL), and broadleaf cattail (*Typha latifolia*). Inundation was observed during the field visit on December 16, 2010. Wetland hydrology and hydric soil criteria were met through evidence of frequent flooding, including sediment deposits, watermarks, drift lines, and drainage patterns.

Intermittent swales occur along the Big Backbone and Pit arms. Intermittent swales are characterized as linear, or somewhat linear, drainage features lacking evidence of scour, but where wetland plant species have established as a result of soil saturation. Typical species occurring in this feature include monkey flower (*Mimulus guttatus*–OBL), spiny fruit buttercup (*Ranunculus muricatus*–FACW), slender rush (*Juncus tenuis*–FACW), and centaury (*Centaurium venustum*–NL).

Riparian wetlands generally occur as "stringers," or narrow features found only immediately adjacent to intermittent or perennial streams throughout the primary study area. Typical species found in riparian wetlands in the study area include arroyo willow (FACW), Goodding's black willow (OBL), white alder (FACW), Oregon ash (FACW), Indian rhubarb (*Darmera peltata*-NL), mugwort (*Artemesia douglasiana*-FACW), California wild grape (FACW), and Himalayan blackberry (FACW). Wetland hydrology and hydric soil criteria are met through evidence of frequent flooding, including sediment deposits, watermarks, drift lines, and drainage patterns.

The seasonal wetlands occurring along the Sacramento, Squaw Creek, and Pit arms are influenced by adjacent water features or are depressions that frequently pond. Plant species found in these features include slender rush (FACW), sword leaf rush (*Juncus ensifolius*–FACW), monkey flower (OBL), yampah (*Perideridia californica*–FACW), annual checker bloom (*Sidalcea calycosa*–OBL), little quaking grass (*Briza minor*–FACW), California oatgrass (*Danthonia californica*–FACW), and spiny fruit buttercup (FACW). Wetland hydrology and soils criteria are met through evidence of long-duration saturation, including saturation in the upper 12 inches, aquic moisture regime, and drainage patterns.

[1] OBL = Obligate Wetland Plants—Estimated probability of occurring in wetland >99 percent.
FACW = Facultative Wetland Plants—Estimated probability of occurring in wetland >67 percent to 99 percent.
FAC = Facultative Plants—Estimated probability of occurring in wetland 33 percent to 67 percent.
FACU = Facultative Upland Plants—Estimated probability of occurring in wetland 1 percent to <33 percent.
UPL = Obligate Upland Plants—Estimated probability of occurring in wetland <1 percent.
NI = No Indicator—Plants for which insufficient information was available to determine an indicator status.
NL = Not listed—Plants not listed in Reed 1988.

Seep/spring wetlands are found throughout the primary study area; they form when groundwater flows out of the ground where the aquifer meets the ground surface. Hydrophytic vegetation colonizes the area where water is provided by the seep/spring. Typical species in these features include white alder (FACW), chain fern (*Woodwardia fimbriata*–FACW), goat's beard (*Aruncus dioicus*–FACW), Indian rhubarb (NL), monkey flower (*Mimulus guttatus*–OBL), horsetail (*Equisetum arvense* –FAC), red stem dogwood (*Cornus stolonifera*–FACW), spicebush (NL), Himalayan blackberry (FACW), and western azalea (FAC). The criteria for wetland hydrology and soils are met through evidence of long-duration saturation, including inundation, saturation in the upper 12 inches, watermarks, and drainage patterns.

There are few vegetated ditches in the Shasta Lake and vicinity area; they occur only along the Main Body and the McCloud Arm, and in relocation areas. Vegetated ditches are ditches that have been excavated to drain adjacent uplands, parking areas, roads, or railways. Because the gradients of these features are so slight, pooling and/or saturation occurs, allowing hydrophytic vegetation to colonize. Dominant plant species include nutsedge (*Cyperus eragrostis*-FACW), seep monkey flower (OBL), broadlead cattail, and rush (*Juncus* sp.-assume FACW). Wetland hydrology criteria were met through the observation of surface water on March 19, 2010, and a thin muck surface indicating long-duration inundation. Hydric soil criteria were met through the observation of inundation and 1 centimeter of muck, indicating long-duration saturation. Other waters of the United States mapped in the Shasta Lake and vicinity portion of the primary study area include seep/spring other waters and ephemeral, intermittent, and perennial streams. The jurisdictional limit of each feature was delineated at the OHWM.

Ephemeral streams are characterized by indicators of scour and deposition, minor drift lines, and sediment deposits, but they lack a groundwater component that contributes to their flow. Hydrology is provided by sheet flow. The poorly defined hydrology indicators, proximity to the headwaters, and the small size of the ephemeral drainages indicate short duration of flow lacking a groundwater component.

Intermittent streams are the most abundant jurisdictional feature along the three arms. Intermittent streams range from small, poorly defined tributaries to larger, well-defined streams that flow into the summer. Like ephemeral streams, intermittent streams flow seasonally, but, in addition to precipitation and sheet flow from adjacent slopes, groundwater extends the duration of flow. Intermittent streams were identified as exhibiting the defined characteristics of a stream, generally a bed and bank and scour and depositions. Other characteristics, such as algae growth or hydrophytic vegetation in or adjacent to the stream, indicate inundation for a longer duration. Substrates observed were primarily cobble. Hydrology and hydric soil criteria are met through evidence of frequent flooding, including water marks, algal matting, drift lines, and sediment deposits.

Perennial streams exhibit the same characteristics as intermittent streams, but tend to be larger and to have a consistent source of groundwater. The substrate consists of boulders, bedrock, cobble, sand, and gravel. Riparian features often occur within the OHWM, but evident riparian "stringers" were delineated as wetlands. Hydrology and hydric soil criteria are met through evidence of frequent flooding, including water marks, algal matting, drift lines, and sediment deposits.

Roadside ditches are found along the Sacramento Arm near roadways and railroad tracks. These features have been excavated solely to drain uplands. Boundaries were established at the OHWM as indicated by sediment and drift deposits.

Seep/spring other waters are found along the Main Body, the Sacramento Arm, and the McCloud Arm. They form when groundwater flows out of the ground where the aquifer meets the ground surface. Hydrophytic vegetation is lacking. A channel may form, but in most cases water does not have the velocity to scour a bed and bank. Duff and organic soil substrates absorb the water and slow water movement downslope.

12.2 Regulatory Framework

Biological resources in California are protected and/or regulated by a variety of Federal and State laws and policies. In addition, in many parts of California, there are local or regional habitat and species conservation planning efforts in which a project applicant may participate. Key regulatory and conservation planning issues applicable to the project and alternatives under consideration are discussed below.

12.2.1 Federal

Endangered Species Act

Pursuant to the Federal Endangered Species Act (ESA), USFWS and NMFS have authority over projects that may result in "take" of a Federally listed species. In general, ESA Section 7 prohibits persons (including private parties) from "taking" listed endangered or threatened fish and wildlife species on private property, and from "taking" listed endangered or threatened plant species in areas under Federal jurisdiction or in violation of State law (16 U.S. Code (USC) 1532, 50 Code of Federal Regulations (CFR) 17.3). Under the ESA, the definition of "take" is to "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct" as part of an intentional or negligent act or omission. The term "harm" includes acts that result in death or injury to wildlife. Such acts may include significant habitat modification or degradation if it results in death or injury to wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. Section 7(a) of the ESA, as amended, requires Federal

agencies to evaluate their actions with respect to any species that is proposed for listing or is listed as endangered or threatened. Section 7(a)(2) requires Federal agencies to ensure that activities they authorize, fund, or carry out are not likely to jeopardize the continued existence of a listed species or to destroy or adversely modify its critical habitat. If a Federal action may affect a listed species or its critical habitat, the responsible Federal agency must enter into formal consultation with USFWS.

As defined in the ESA, critical habitat is a specific geographic area that is essential for the conservation of a threatened or endangered species and that may require special management and protection. It may include an area that is not currently occupied by the species but that will be needed for its recovery. Critical habitats are designated to ensure that actions authorized by Federal agencies will not destroy or adversely modify critical habitat, thereby protecting areas necessary for the conservation of the species.

Clean Water Act

The objective of the CWA is to restore and maintain the chemical, physical, and biological integrity of the nation's waters. USACE regulates discharges of fill or dredged materials into waters of the United States under Section 404 of the CWA (33 USC 1251–1376). Waters of the United States include lakes, rivers, streams, and their tributaries and adjacent wetlands. Wetlands are defined under Section 404 as areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support (and that do support under normal circumstances) a prevalence of vegetation typically adapted for life in saturated soil conditions (33 CFR 328.3, 40 CFR 230.3). Activities that require a permit under Section 404 include, but are not limited to, placing fill or riprap, grading, mechanized land clearing, and dredging. Any activity that results in the deposit of dredged or fill material below the ordinary high-water mark of waters of the Unites States or within a jurisdictional wetland usually requires a Section 404 permit, even if the area is dry at the time the activity takes place. To comply with the Section 404 policy that there be no net loss of wetlands, the project cannot affect the total acreage of wetlands within the project boundary.

Section 401 Water Quality Certification

Under Section 401 of the CWA, an applicant for a Section 404 permit must obtain a certificate from the appropriate State agency stating that the intended dredging or filling activity is consistent with the State's water quality standards and criteria. In California, the authority to grant water quality certification is delegated by the State Water Resources Control Board to the nine Regional Water Quality Control Boards (RWQCB).

Rivers and Harbors Act

USACE regulates the construction of structures in, over, or under; excavation of material from; or deposition of material into "navigable waters of the United States" under Section 10 of the Federal Rivers and Harbors Act (33 USC 401 et

seq.). Navigable waters of the United States are defined as those waters subject to the ebb and flow of the tide shoreward to the mean high-water mark or those that are currently used, have been used in the past, or may be susceptible to use to transport interstate or foreign commerce. A letter of permission or permit from USACE is required before any work may be completed within navigable waters. Projects are permitted under either individual or general (i.e., nationwide) permits. The specific applicability of the permit types is determined by USACE on a case-by-case basis. Based on a preliminary conversation with the USACE (San Francisco District, Eureka Field Office), the project is expected to be permitted under Nationwide Permit Number 27.

U.S. Forest Service Sensitive Species

The National Forest Management Act requires USFS to "provide for a diversity of plant and animal communities" (16 USC 1604(g)(3)(B)) as part of its multiple-use mandate. USFS must maintain "viable populations of existing native and desired nonnative species in the planning area" (36 CFR 219.19). The Sensitive Species program is designed to meet this mandate and to demonstrate USFS's commitment to maintaining biodiversity on National Forest System lands. The program is a proactive approach to conserving species to prevent a trend toward listing under the ESA and to ensure the continued existence of viable, well-distributed populations. A "Sensitive Species" is any species of plant or animal that has been recognized by the Regional Forester to need special management to prevent the species from becoming threatened or endangered.

Shasta-Trinity National Forest Land and Resource Management Plan

The *Shasta-Trinity National Forest Land and Resource Management Plan* (STNF LRMP) contains forest goals, standards, and guidelines designed to guide the management of the Shasta-Trinity National Forest. The following goals, standards, and guidelines related to botanical resource issues associated with the study area were excerpted from the STNF LRMP (USFS 1995a).

U.S. Forest Service Survey and Manage

Standards and Guidelines In 1994, the BLM and USFS adopted standards and guidelines developed as part of the *Northwest Forest Plan*. These standards and guidelines address management of habitat for late-successional and old-growth forest related species within the range of the northern spotted owl. The *Northwest Forest Plan* was designed to address human and environmental needs served by the Federal forests of the western part of the Pacific Northwest and Northern California. The development of the *Northwest Forest Plan* was triggered in the early 1990s by the listing of the northern spotted owl and marbled murrelet as threatened under the ESA.

To mitigate potential impacts on plant and wildlife species that have the potential to occur within the range of the northern spotted owl, surveys are required for species thought to be rare, or whose status is unknown because of a lack of information. These species became known as the Survey and Manage

species. The *Northwest Forest Plan* has gone through several revisions since its implementation in 1994, including the elimination of the Survey and Manage Mitigation Measure Standards and Guidelines in 2004. However, these guidelines were reinstated in January 2006 as the result of a court order.

Biological Diversity

Goals (LRMP, p. 4-4) Integrate multiple resource management on a landscape level to provide and maintain diversity and quality of habitats that support viable populations of plants, fish, and wildlife.

Standards and Guidelines (LRMP, p. 4-14)

- Natural Openings – Management of natural openings will be determined at the project level consistent with desired future conditions.

- Snags – Over time, provide the necessary number of replacement snags to meet density requirements as prescribed for each land allocation and/or management prescription. Live, green culls and trees exhibiting decadence and/or active wildlife use are preferred.

- Hardwood – Apply the following standards in existing hardwood types:

  – Manage hardwood types for sustainability.

  – Conversion to conifers will only take place to meet desired future ecosystem conditions.

  – Where hardwoods occur naturally within existing conifer types on suitable timber lands, manage for a desired future condition for hardwoods as identified during ecosystem analysis consistent with management prescription standards and guidelines. Retain groups of hardwoods over single trees.

Threatened, Endangered, and Sensitive Species (Plants and Animals)

Goals (LRMP, p. 4-5)

Monitor and protect habitat for Federally listed threatened and endangered and candidate species. Assist in recovery efforts for threatened and endangered species. Cooperate with the State to meet objectives for state listed species.

Manage habitat for sensitive plants and animals in a manner that will prevent any species from becoming a candidate for threatened and endangered status.

Botany (Sensitive and Endemic Plants)

Standards and Guidelines (LRMP, pp. 4-14 through 4-16)

Map, record, and protect essential habitat for known and newly discovered sensitive and endemic plant species until conservation strategies are developed.

Analyze the potential effects of all ground-disturbing projects on sensitive and endemic plants and their habitat. Mitigate project effects to avoid a decline in species viability at the Forest level.

Monitor the effects of management activities on sensitive and endemic plants. If monitoring results show a decline in species viability, alter management strategy.

Provide reports of sensitive plant populations to the DFG annually.

Coordinate sensitive plant inventory and protection efforts with the DFG, the USFWS, the Nature Conservancy, the California Native Plant Society, and other concerned agencies, organizations, and adjacent landowners.

Protect type localities of sensitive and endemic plants for their scientific value.

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

A portion of the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area is included in the Shasta Lake and vicinity portion of the primary study area. The Management Guide for the Whiskeytown-Shasta-Trinity National Recreation Area, including the Shasta Unit, contains management strategies intended to achieve or maintain a desired condition. These strategies take into account opportunities, management recommendations for specific projects, and mitigation measures needed to achieve specific goals. The following strategies related to botanical and wetland resource issues associated with the Shasta Lake and vicinity portion of the primary study area were excerpted from the Management Guide (USFS 1996).

Vegetation (Management Guide, pp. IV-18 through IV-19)

- Prescribed burning, fuel break construction, and other forms of vegetation manipulation will be used to reduce fire hazards and improve forest health.

- Hazard trees in traditionally high-use recreation areas which pose safety hazards to people or property will be identified and removed.

- Recreation sites will be inventoried and vegetative management plans will be developed to ensure healthy and safe vegetation complexes are maintained over time.

- Protect known populations of Threatened and Endangered Species plant species and their habitat and implement mitigation measures if necessary to maintain or enhance their continued viability. Conservation strategies for Threatened and Endangered Species plant species will be utilized as they are developed.

- Implement management practices which promote restoration of native plant diversity.

- Implement a program to restore native vegetation to highly disturbed or degraded areas using native plants. Local in-kind, on-site seed or other propagation sources will be used in order to maintain genetic integrity.

- Chaparral and woodland habitat management will occur to meet wildlife objectives.

- Interpretive materials will address the need to conserve rare plant communities in accordance with the National Recreation Area Interpretive Plan.

- Rare plants in or near camping areas will be monitored on a regular basis.

- Diversity of native species will be emphasized. Eradication program will be implemented for nonnative, introduced species in areas where healthy, botanically diverse plant communities are necessary to meet ecosystem management objectives.

- Native plants from local gene pools will be utilized when landscaping campgrounds, interpretive facilities, etc.

- Partnerships will be utilized to assist with collection of seed, propagation of seeds/propagules, and planting.

U.S. Forest Service Noxious Weed Management Policy 2081

USFS Manual Policy 2080, Noxious Weed Management (USFS 1995b), includes a policy statement requiring a risk assessment for noxious weeds for every project. Specifically, the manual states:

> *2081.03. When any ground disturbing action or activity is proposed, determine the risk of introducing or spreading noxious weeds associated with the proposed action.*
>
> - *For projects having moderate to high risk of introducing or spreading noxious weeds, the project decision*

document must identify noxious weed control measures that must be undertaken during project implementation.

- *Use contract and permit clauses to prevent the introduction or spread of noxious weeds by contractors and permittees. For example, where determined to be appropriate, use clauses requiring contractors or permittees to clean their equipment prior to entering National Forest System lands.*

2081.2. Determine the factors which favor the establishment and spread of noxious weeds and design management practices or prescriptions to reduce the risk of infestation or spread of noxious weeds.

Where funds and other resources do not permit undertaking all desired measures, address and schedule noxious weed prevention and control in the following order:

- *First Priority: Prevent the introduction of new invaders,*
- *Second Priority: Conduct early treatment of new infestations, and*
- *Third Priority: Contain and control established infestations.*

Executive Order 11990: Protection of Wetlands

Executive Order 11990 established the protection of wetlands and riparian systems as the official policy of the Federal government. It requires all Federal agencies to consider wetland protection as an important part of their policies and take action to minimize the destruction, loss, or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands.

Executive Order 11312: Invasive Species

Executive Order 11312 directs all Federal agencies to prevent and control introductions of invasive nonnative species in a cost-effective and environmentally sound manner to minimize their economic, ecological, and human health impacts. Executive Order 11312 established a national Invasive Species Council made up of Federal agencies and departments and a supporting Invasive Species Advisory Committee composed of State, local, and private entities. The Invasive Species Council and Advisory Committee oversee and facilitate implementation of the Executive Order, including preparation of a National Invasive Species Management Plan.

12.2.2 State

California Endangered Species Act

Under the California Endangered Species Act (CESA), DFG has the responsibility for maintaining a list of endangered and threatened species (California Fish and Game Code, Section 2070). DFG also maintains a list of "candidate species," which are species for which DFG has issued a formal notice that they are under review for addition to the list of endangered or threatened species. Pursuant to the requirements of CESA, an agency reviewing a proposed project within its jurisdiction must determine whether any State-listed endangered or threatened species may be present in the project study area and, if so, whether the proposed project would have a potentially significant impact on any of these species. In addition, DFG encourages informal consultation on any proposed project that may affect a species that is a candidate for state listing.

Project-related impacts on species listed as endangered or threatened under the CESA would be considered significant. "Take" of protected species incidental to otherwise lawful management activities may be authorized under Section 2081 of the California Fish and Game Code. Under the CESA, "take" is defined as an activity that would directly or indirectly kill an individual of a species, but the definition does not include "harm" or "harass," as the Federal act does. Therefore, the threshold for take may be higher under CESA than under ESA because habitat modification is not necessarily considered take under CESA.

Authorization from DFG would be in the form of an incidental take permit or as a consistency determination (Section 2080.1[a] of the Fish and Game Code). Section 2080.1[a] of the Fish and Game Code authorizes DFG to accept a Federal biological opinion as the take authorization for a state-listed species when a species is listed under both the ESA and the CESA.

California Native Plant Protection Act

The Native Plant Protection Act (NPAA) (California Fish and Game Code Sections 1900-1913) prohibits the taking, possessing, or sale within the state of any plants with a State designation of rare, threatened, or endangered, as defined by DFG. The NPPA's definition of "endangered" and "rare" closely parallel the CESA definitions of "endangered" and "threatened" plant species.

Section 1602 of the California Fish and Game Code—Streambed Alteration

Diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by DFG, pursuant to Section 1602 of the California Fish and Game Code. The regulatory definition of stream is a body of water that flows at least periodically or intermittently through a bed or channel that has banks and supports wildlife, fish, or other aquatic life. This includes watercourses that have a surface or subsurface flow that supports or has

supported riparian vegetation. DFG's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife. A DFG streambed alteration agreement must be obtained for a project that would result in an impact on a river, stream, or lake.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act requires that each of the nine RWQCBs prepare and periodically update basin plans for water quality control. Each basin plan sets forth water quality standards for surface water and groundwater and actions to control nonpoint and point sources of pollution to achieve and maintain these standards. Basin plans offer an opportunity to protect wetlands through the establishment of water quality objectives. The RWQCB's jurisdiction includes Federally protected waters as well as areas that meet the definition of "waters of the state." Waters of the state is defined as any surface water or groundwater, including saline waters, within the boundaries of the state. The RWQCB has the discretion to take jurisdiction over areas not Federally protected under Section 401 provided they meet the definition of waters of the state. Mitigation requiring no net loss of wetlands functions and values of waters of the state is typically required by the RWQCB.

California Department of Fish and Game Species Designations

DFG maintains an informal list of species called "species of special concern." These are broadly defined as plant and wildlife species that are of concern to DFG because of population declines and restricted distributions, and/or because they are associated with habitats that are declining in California. These species are inventoried in the CNDDB regardless of their legal status. Impacts on species of special concern may be considered significant.

California Department of Fish and Game/California Native Plant Society Plant Species Designations

CNPS is a statewide nonprofit organization that seeks to increase understanding of California's native flora and to preserve this rich resource for future generations. DFG and CNPS assign rare plant ranks through the collaborative efforts of the Rare Plant Status Review Group composed of over 300 botanical experts from government, academia, non-government organizations, and the private sector and managed jointly by DFG and CNPS. California native plants meeting the rarity or endangerment criteria are assigned a CRPR. These plants were formerly referred to as CNPS listed species; however, as of March 2010, DFG has adopted the name CRPR for the rarity and endangerment categories to eliminate the false impression that these assignments are the exclusive work of CNPS and that CNPS has had undue influence over the regulatory process. CRPR 1 and 2 species generally qualify as endangered, rare, or threatened within the definition of State CEQA Guidelines CCR Section 15380. In general, CRPR 3 and 4 species do not meet the definition of endangered, rare, or threatened pursuant to CEQA Section 15380; however, these species may be evaluated by the lead agency on a case-by-case basis to determine significance criteria under CEQA.

12.2.3 Local

Shasta, Tehama, Glenn, Sutter, Sacramento, and Yolo counties and the Cities of Redding, Colusa, and Sacramento have established codes and policies that address protection of natural resources, including vegetation, sensitive species, and trees, and are applicable to the project.

Shasta County's general plan emphasizes that the maintenance and enhancement of quality fish and wildlife habitat is critical to the recreation and tourism industry, and acknowledges that any adverse and prolonged decline of these resources could result in negative impacts on an otherwise vibrant industry. The general plan identifies efforts to protect and restore these habitats to sustain the long-term viability of the tourism and recreation industry (Shasta County 2004).

The City of Redding's general plan strives to strike a balance between development and conservation by implementing several measures such as creek-corridor protection, sensitive hillside development, habitat protection, and protection of prominent ridge lines that provide a backdrop to the city (City of Redding 2000).

Tehama County's general plan (Tehama County 2009) update provides an overarching guide to future development and establishes goals, policies, and implementation measures designed to address potential changes in county land use and development. The general plan identifies the importance of retaining agriculture as one of the primary uses of land in Tehama County.

Glenn County's general plan provides a comprehensive plan for growth and development in Glenn County for the next 20 years (2007 to 2027). This plan recognizes that public lands purchased for wildlife preservation generate economic activity as scientists and members of the public come to view and study remnant ecosystems (Glenn County 1993).

The City of Colusa's general plan seeks to promote its natural resources through increased awareness and improved public access (City of Colusa 2007).

Sutter County's general plan contains policies that generally address preservation of natural vegetation, including wetlands. It requires that new development mitigate the loss of Federally protected wetlands to achieve "no net loss," but it does not include any other specific requirements.

Sacramento County's general plan contains policies that promote protection of marsh and riparian areas, including specification of setbacks and "no net loss" of riparian woodland or marsh acreage (Sacramento County 1993). It also addresses the need to conserve vernal pools and ephemeral wetlands to ensure no net loss of vernal pool acreage. Several policies specifically promote protection of native oak trees, and, in some areas of the county, seek to ensure

that there is no net loss of canopy area. The general plan for the County of Sacramento is currently under revision.

The City of Sacramento Municipal Code addresses the protection of trees within the city boundaries, including general protection of all trees on city property and specific protection of heritage trees.

Yolo County's general plan aims to provide an active and productive buffer of farmland and open space separating the Bay Area from Sacramento, and integrating green spaces into its communities.

12.2.4 Federal, State, and Local Programs and Projects

California Bay-Delta Authority

The California Bay-Delta Authority was established as a State agency in 2003 to oversee implementation of CALFED for the 25 Federal and State agencies working cooperatively to improve the quality and reliability of California's water supplies while restoring the Bay-Delta ecosystem. The CALFED Ecosystem Restoration Program has provided a funding source for projects that include those involving acquisition of lands within the Sacramento River Conservation Area, initial baseline monitoring and preliminary restoration planning, and preparation of long-term habitat restoration management and monitoring plans.

Cantara Trustee Council

The Cantara Trustee Council administers a grant program that has provided funding for numerous environmental restoration projects in the primary study area, including programs in the Fall River watershed, Sulphur Creek, the upper Sacramento River, Middle Creek, lower Clear Creek, Battle Creek, Salt Creek, and Olney Creek. The Cantara Trustee Council is a potential local sponsor for future restoration actions in the primary study area. The Cantara Trustee Council includes representatives from DFG, USFWS, the Central Valley Regional Water Quality Control Board, California Sportfishing Protection Alliance, and Shasta Cascade Wonderland Association.

Resource Conservation Districts

There are numerous resource conservation districts (RCD) within the study area. Once known as soil conservation districts, RCDs were established under California law with a primary purpose to implement local conservation measures. Although RCDs are locally governed agencies with locally appointed, independent boards of directors, they often have close ties to county agencies and the National Resources Conservation Service. RCDs are empowered to conserve resources within their districts by implementing projects on public and private lands and to educate landowners and the public about resource conservation. They are often involved in the formation and coordination of watershed working groups and other conservation alliances. In the Shasta Lake and upper Sacramento River vicinity, districts include the

Western Shasta County RCD and the Tehama County RCD. To the east are the Fall River and Pit River RCDs, and to the west and north are the Trinity County and Shasta Valley RCDs.

Riparian Habitat Joint Venture

The Riparian Habitat Joint Venture (RHJV) was initiated in 1994 and includes signatories from 18 Federal, State, and private agencies. The RHJV promotes conservation and the restoration of riparian habitat to support native bird populations through three goals:

- Promote an understanding of the issues affecting riparian habitat through data collection and analysis.
- Double riparian habitat in California by funding and promoting on-the-ground conservation projects.
- Guide land managers and organizations to prioritize conservation actions.

RHJV conservation and action plans are documented in the Riparian Bird Conservation Plan (RHJV 2004). The conservation plan targets 14 "indicator" species of riparian-associated birds and provides recommendations for habitat protection, restoration, management, monitoring, and policy. The report notes habitat loss and degradation as one of the most important factors causing the decline of riparian birds in California. The RHJV has participated in monitoring efforts within the Sacramento National Wildlife Refuge Complex and other conservation areas. The RHJV's conservation plan identifies lower Clear Creek as a prime breeding area for yellow warblers and song sparrows, advocating a continuous riparian corridor along lower Clear Creek. Other recommendations of the conservation plan apply to the North Delta Offstream Storage Investigation study area in general.

Sacramento River Conservation Area Program

Senate Bill 1086 called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance both fisheries and riparian habitat. The Sacramento River Conservation Area Program has an overall goal of preserving remaining riparian habitat and reestablishing a continuous riparian ecosystem along the Sacramento River between Redding and Chico, and reestablishing riparian vegetation along the river from Chico to Verona. The program is to be accomplished through an incentive-based, voluntary river management plan. The *Upper Sacramento River Fisheries and Riparian Habitat Management Plan*, January 1989 (Resources Agency 1989), identifies specific actions to help restore the Sacramento River fishery and riparian habitat between the Feather River and Keswick Dam. The *Sacramento River Conservation Area Forum Handbook* (Resources Agency 2003) is a guide to implementing the program. The Keswick Dam-to-Red Bluff portion of the conservation area includes areas within the 100-year floodplain, existing

riparian bottomlands, and areas of contiguous valley oak woodland, totaling approximately 22,000 acres. The 1989 fisheries restoration plan recommended several actions specific to the study area:

- Fish passage improvements at RBDD (under way; project final Environmental Impact Statement (EIS)/Environmental Impact Report released May 2008)
- Modification of the Spring Creek Tunnel intake for temperature control (completed)
- Spawning gravel replacement program (ongoing)
- Development of side-channel spawning areas, such as those at Turtle Bay in Redding (ongoing)
- Structural modifications to the Anderson-Cottonwood Irrigation District Dam to eliminate short-term flow fluctuations (completed)
- Maintaining instream flows through coordinated operation of water facilities (ongoing)
- Improvements at the Coleman National Fish Hatchery (partially complete)
- Measures to reduce acute toxicity caused by acid mine drainage and heavy metals (ongoing)
- Various fisheries improvements on Clear Creek (partially complete)
- Flow increases, fish screens, and revised gravel removal practices on Battle Creek (beginning summer 2006)
- Control of gravel mining, improvements of spawning areas, improvements of land management practices in the watershed, and protection and restoration of riparian vegetation along Cottonwood Creek

Sacramento River National Wildlife Refuge

The Sacramento River National Wildlife Refuge (SRNWR) is composed of many units between the cities of Red Bluff and Princeton. The SRNWR along the middle Sacramento River is part of the Sacramento National Wildlife Refuge Complex, consisting of five refuges and three wildlife management areas within the Sacramento Valley. Reaches and subreaches of the river are delineated based generally on transitions in fluvial geomorphic riverine conditions, although county boundaries were considered as well. The middle Sacramento River region between Red Bluff and Colusa includes three units

within the Chico Landing Subreach that contain restoration project sites addressed in the *Sacramento River–Chico Landing Subreach Habitat Restoration Draft Environmental Impact Report* (CBDA 2005). In addition, three areas proposed for restoration in this area occur within the larger SRNWR units that were evaluated in the *Environmental Assessment for Proposed Restoration Activities on the Sacramento River National Wildlife Refuge* (USFWS 2001; CBDA 2005).

In June 2005, USFWS issued the *Sacramento River National Wildlife Refuge Draft Comprehensive Conservation Plan and Environmental Assessment and Finding of No Significant Impact* (USFWS 2005) to serve as an integrated management plan for land that it acquires and manages for inclusion in the SRNWR. The SRNWR final comprehensive conservation plan includes goals, objectives, and strategies to guide management of lands within the SRNWR. It also includes assessments of and establishes parameters for "compatible uses," which are uses that are considered compatible with the primary purposes for which the area was established. Riparian habitat restoration projects are being implemented under cooperative agreements between USFWS and other entities such as The Nature Conservancy (TNC) in accordance with the SRNWR final comprehensive conservation plan.

Sacramento River Preservation Trust

The Sacramento River Preservation Trust is a private, nonprofit organization active in environmental education and advocacy to preserve the natural environmental values of the Sacramento River. The trust has participated in various conservation and land acquisition projects, including securing lands for the SRNWR. The group is pursuing designation of a portion of the Sacramento River between Redding and Red Bluff as a national conservation area.

Sacramento River Watershed Program

The Sacramento River Watershed Program is an effort to bring stakeholders together to share information and work together to address water quality and other water-related issues within the Sacramento River watershed. The group is funded congressionally through the U.S. Environmental Protection Agency. The program's primary goal is "to ensure that current and potential uses of Sacramento River watershed resources are sustained, restored, and where possible, enhanced while promoting the long-term social and economic vitality of the region." The Sacramento River Watershed Program manages grants for the Sacramento River Toxic Pollutants Control Program; performs extensive water quality monitoring, data collection, and data management for the watershed; and is instrumental in the study and monitoring of toxic pollutants. Although the program does not implement restoration projects, it is a potential partner for coordinating research and monitoring through consensus-based collaborative partnerships and promoting mutual education among the stakeholders of the Sacramento River watershed.

Sacramento Watersheds Action Group

The Sacramento Watersheds Action Group is a nonprofit corporation that secures funding for, designs, and implements projects that provide watershed restoration, streambank and slope stabilization, erosion control, watershed analysis, and road removal. Sacramento Watersheds Action Group has successfully worked with local groups, agencies, and organizations to fund and complete restoration projects on the Sacramento River and tributaries downstream from Keswick Dam. Their projects include development of the *Sulphur Creek Watershed Analysis and Action Plan*, the Whiskeytown Lake Shoreline Erosion Control Project, the Sulphur Creek Crossing Restoration Project, and the Lower Sulphur Creek Realignment and Riparian Habitat Enhancement Project. Sacramento Watersheds Action Group is a potential local sponsor for watershed restoration actions in the study area.

Shasta Land Trust

The Shasta Land Trust is a regional, nonprofit organization dedicated to conserving open space, wildlife habitat, and agricultural land. The trust works with public agencies and private landowners and is funded primarily through membership dues and donations. It employs various voluntary programs to protect and conserve valuable lands using conservation easements, land donations, and property acquisitions. The trust is a potential local partner for restoration activities in the Shasta Dam-to-Red Bluff area.

The Nature Conservancy

TNC is a private, nonprofit organization involved in environmental restoration and conservation throughout the United States and the world. TNC approaches environmental restoration primarily through strategic land acquisition from willing sellers and obtaining conservation easements. Some of the lands are retained by TNC for active restoration, research, or monitoring activities, while others are turned over to government agencies such as USFWS or DFG for long-term management. Lower in the Sacramento River basin, TNC has been instrumental in acquiring and restoring lands in the SRNWR and managing several properties along the Sacramento River. It also has pursued conservation easements on various properties at tributary confluences, including Cottonwood and Battle creeks.

The Trust for Public Land

The Trust for Public Land is a national, nonprofit organization involved in preserving lands with natural, historic, cultural, or recreational value, primarily through conservation real estate. The trust's Western Rivers Program has been involved in conservation efforts along the Sacramento River between Redding and Red Bluff (the BLM's Sacramento River Bend Management Area), Battle Creek, Paynes Creek, Inks Creek, and Fenwood Ranch in Shasta County. The group promotes public ownership of conservation lands to ensure public access and enjoyment.

12.3 Environmental Consequences and Mitigation Measures

This section describes the methods of environmental evaluation, assumptions, and specific criteria used to determine significance for each resource area, then discusses effects of the project and proposes mitigation where necessary.

12.3.1 Methods and Assumptions

The following sections describe the methods, processes, procedures, and assumptions used to formulate and conduct the environmental impact analysis. Data for the following analysis were taken from the use of modeling, existing reports on local and site-specific biology, and on site assessments during field reviews.

CalSim Modeling

The CalSim-II computer model was used to aid in the evaluation of potential impacts of the project alternatives on water-related resources, including riparian habitats along the upper and lower Sacramento River and in the Delta. This computer modeling used historical data on California hydrology to represent the variety of weather and hydrologic patterns, including wet periods and droughts, under which water storage and conveyance facilities would be operated. Two scenarios (base cases) of demands for, and storage and conveyance of, water were used in model runs: 2005 facilities and demands ("existing conditions") and forecasted 2030 demands and reasonably foreseeable projects and facilities ("future conditions"). A model run was conducted for each of these base cases combined with each alternative, so that the effects of the No-Action Alternative and other alternatives could be evaluated relative to both existing and future conditions. CalSim-II is a useful tool for this type of comparative analysis where the model is run twice, once to represent a base condition (no action) and a second time with a specific change (action) to assess the change in the outcome due to the input change.

The hydrologic analysis conducted for this EIS used the Common Assumptions Common Modeling Package Version 8D CalSim-II models, which are the best available hydrological modeling tools, to approximate system-wide changes in storage, flow, salinity, and reservoir system reoperation associated with the SLWRI alternatives. The historical flow record of October 1921 to September 2003, adjusted for the influences of land use changes and upstream flow regulation, is used to represent the possible range of water supply conditions. Major Central Valley rivers, reservoirs, and CVP/SWP facilities are represented by a network of arcs and nodes. CalSim-II uses a mass balance approach to route water through this network. Simulated flows are mean flows for the month; reservoir storage volumes correspond to end-of-month storage. A more detailed description of the CalSim-II model, the modeling methodology used to evaluate this project, and key assumptions are provided in the Modeling Appendix. Summaries of the analysis and modeling results are provided in Chapter 6, "Hydrology, Hydraulics, and Water Management."

Vegetation and Habitat Types

The effects of construction-related activities are evaluated in the sections addressing Shasta Lake and its vicinity. Besides construction-related activities, the project could potentially affect vegetation and habitat types through any of the following impact mechanisms:

- Increased inundated width of the river during the active growing season
- Reduced frequency and/or magnitude of peak flows
- Altered geomorphic processes (e.g., meander, channel avulsion) along rivers
- Altered availability of groundwater
- Altered rates of stage decline during seed dispersal or germination-establishment

For each vegetation type, environmental effects potentially resulting from each of these impact mechanisms were assessed. This assessment was based on a review of the results of CalSim simulations of mean monthly flows, aerial photographs, background information on the upper Sacramento River and adjacent uplands, and scientific literature on the ecology of each vegetation type. Results of hydraulic modeling of the project's potential effects on peak flows and analyses of the project's potential effects on geomorphic processes along the Sacramento River were not available to support this analysis.

In addition to these impact mechanisms, increased water supplies or increased supply reliability also could reduce a limitation on urban growth and development or on other activities that could affect vegetation in the primary and extended study areas, resulting in potentially significant impacts. The effects of this growth would be analyzed in general plan environmental impact reports and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these impacts would be the responsibility of these local jurisdictions, and not Reclamation. The expected increase in water yield relative to the entire CVP would be small, however, and assuming that this new yield could be provided to any number of geographic areas within the CVP service area (and in part would substitute for ongoing groundwater pumping), the project's impact on urban growth and development that could affect vegetation would be minor.

Similarly, projects potentially affecting streambeds, wetlands, and listed species would require permits from the DFG, USACE, and USFWS, respectively; it is anticipated that impacts on these resources would be avoided, minimized, and/or mitigated during those agency consultations.

Because the extent, location, and timing of induced growth are currently highly uncertain, and in the future the impacts of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects, growth-inducing effects on vegetation and habitat types are not discussed further in this section. However, additional discussion of growth-inducing effects specific to the alternatives is provided in the EIS.

For the purposes of this impact analysis on the loss of general habitats in the Shasta Lake and vicinity portion of the primary study area, California Wildlife Habitat Relationship (CWHR) types will be used to describe habitats for special-status plants affected. Table 12-8 lists the cross references between MCV and CWHR habitat types.

Special-Status Species

The project could affect special-status plant species through the same impact mechanisms potentially affecting vegetation and habitat types, and also by altering the structure and species composition of vegetative communities, particularly within river corridors.

Potential impacts resulting from these impact mechanisms were assessed for special-status plant species that may occur in the project area. This assessment was based on the potential impacts on vegetation and habitat types for each alternative, and available information on the distribution, ecology, and reproductive biology of each special-status species.

Assumptions

The following assumptions have been made for the purposes of the impact analysis:

- Activity areas (construction areas for infrastructure and relocation areas) would be completely cleared.
- Mechanized equipment would be used for discrete areas where total clearing would occur.
- All trees would be removed along other areas of the lake, including those that could be considered a hazard in coves used by houseboats for moorage; other vegetation would be left.

Trees would be removed using helicopters and barges.

Table 12-8. Cross Reference of MCV Vegetation Types and CWHR Habitat Types

MCV Type	CWHR Type
Barren	Barren
Birch-leaf mountain-mahogany chaparral	Mixed chaparral
Black willow thicket	Montane riparian
Blue oak woodland	Blue oak woodland
Brewer oak scrub	Mixed chaparral
Buck brush chaparral	Mixed chaparral
California annual grassland	Annual grassland
California ash chaparral	Mixed chaparral
California black oak forest	Montane hardwood
California buckeye groves	Mixed chaparral
California yerba santa scrub	Mixed chaparral
Canyon live oak forest	Montane hardwood
Deer brush chaparral	Mixed chaparral
Douglas-fir	Douglas-fir
Fremont cottonwood	Montane riparian
Ghost pine woodland	Montane hardwood–conifer, Blue oak–foothill pine
Himalayan blackberry brambles	Montane riparian
Interior live oak chaparral	Mixed chaparral
Interior live oak woodland	Montane hardwood
Knobcone pine forest	Closed-cone pine–cypress
Lacustrine	Lacustrine
Mixed willow	Montane riparian
Oregon ash groves	Montane riparian
Oregon white oak woodland	Montane hardwood
Ponderosa pine–Douglas-fir forest	Montane hardwood–conifer
Ponderosa pine forest	Ponderosa pine
Red osier thickets	Montane riparian
Riverine	Riverine
Sandbar willow thickets	Montane riparian
Spicebush thickets	Montane riparian
Valley oak woodland	Montane hardwood
Urban	Urban
White alder groves	Montane riparian
White leaf manzanita chaparral	Mixed chaparral

12.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an environmental impact statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

Vegetation and Habitat Types

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on vegetation and habitat types would be significant if project implementation would do any of the following:

- Result in a substantial adverse effect on any riparian vegetation or habitat, oak woodlands or savannas, or other sensitive natural community identified in local or regional plans, policies, regulations, or by DFG or USFWS
- Conflict with a local policy or ordinance that protects vegetation resources, such as a tree preservation policy or ordinance
- Conflict with or violate the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, State, or Federal habitat conservation plan relating to the protection of plant resources
- Result in the potential for spread of nonnative and invasive plant species

Special-Status Species

Impacts of an alternative on special-status species would be significant if project implementation would do any of the following:

- Result in a substantial adverse effect, either directly or through habitat modifications, on any plant species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by DFG or USFWS

- Have the potential to substantially reduce the number or restrict the range of an endangered or threatened plant species or a plant species that is a candidate for State listing or proposed for Federal listing as endangered or threatened

- Have the potential for substantial reductions in the habitat of an endangered or threatened plant species or a plant species that is a candidate for State listing or proposed for Federal listing as endangered or threatened

- Substantially reduce the number or restrict the range of an endangered, rare, or threatened species, cause a native plant population to drop below self-sustaining levels, or threaten to eliminate a plant community

- Have the potential to cause a native plant population to drop below self-sustaining levels

Wetlands

Impacts of an alternative on wetlands would be significant if project implementation would do any of the following:

- Have a substantial adverse effect on Federally protected wetlands as defined by Section 404 of the CWA (including, but not limited to, marsh, vernal pool, etc.) through direct removal, filling, hydrological interruption, or other means

- Conflict with any State or local policies or ordinances protecting wetland and/or riparian resources

- Conflict with or violate the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, State, or Federal habitat conservation plan relating to the protection of wetland resources

Shasta-Trinity National Forest Land and Resource Management Plan

In addition to the above significance criteria, the *Shasta-Trinity National Forest Land and Resource Management Plan* (USFS 1995a) contains forest goals, standards, and guidelines designed to guide the management of the biological resources within the Shasta-Trinity National Forest, located in the Shasta Lake and vicinity portion of the primary study area. To comply with NEPA, this assessment of impacts evaluates the project's compliance with the STNF LRMP forest goals, standards, and guidelines listed in the "Regulatory Framework" section listed above. Mitigation measures are provided (as needed) to move project actions toward compliance with the STNF LRMP.

12.3.3 Topics Eliminated from Further Consideration

No topics related to botanical resources that are included in the significance criteria listed above were eliminated from further consideration. All relevant topics are analyzed below.

12.3.4 Direct and Indirect Effects

This section identifies how specific vegetation types could be affected by the project. The project could affect vegetation by doing any of the following:

- Causing construction-related effects at Shasta Dam and around Shasta Lake
- Altering flow regimes downstream from Shasta Lake and downstream from other reservoirs with altered operations
- Increasing water supply reliability that, in turn, could contribute to growth or changes in agricultural land uses in the CVP and SWP service areas

By altering storage and reservoir operations, the project would change flow regimes in downstream waterways. In turn, these alterations to the flow regime could affect vegetation, particularly riparian and wetland vegetation along several waterways.

No-Action Alternative

Under the No-Action Alternative, Reclamation would not pursue an action to enlarge Shasta Dam. No new facilities would be constructed at Shasta Dam; thus there would be no construction-related impacts. In addition, there would be no changes in releases from Shasta Dam or other CVP reservoirs as a result of a Shasta Dam enlargement.

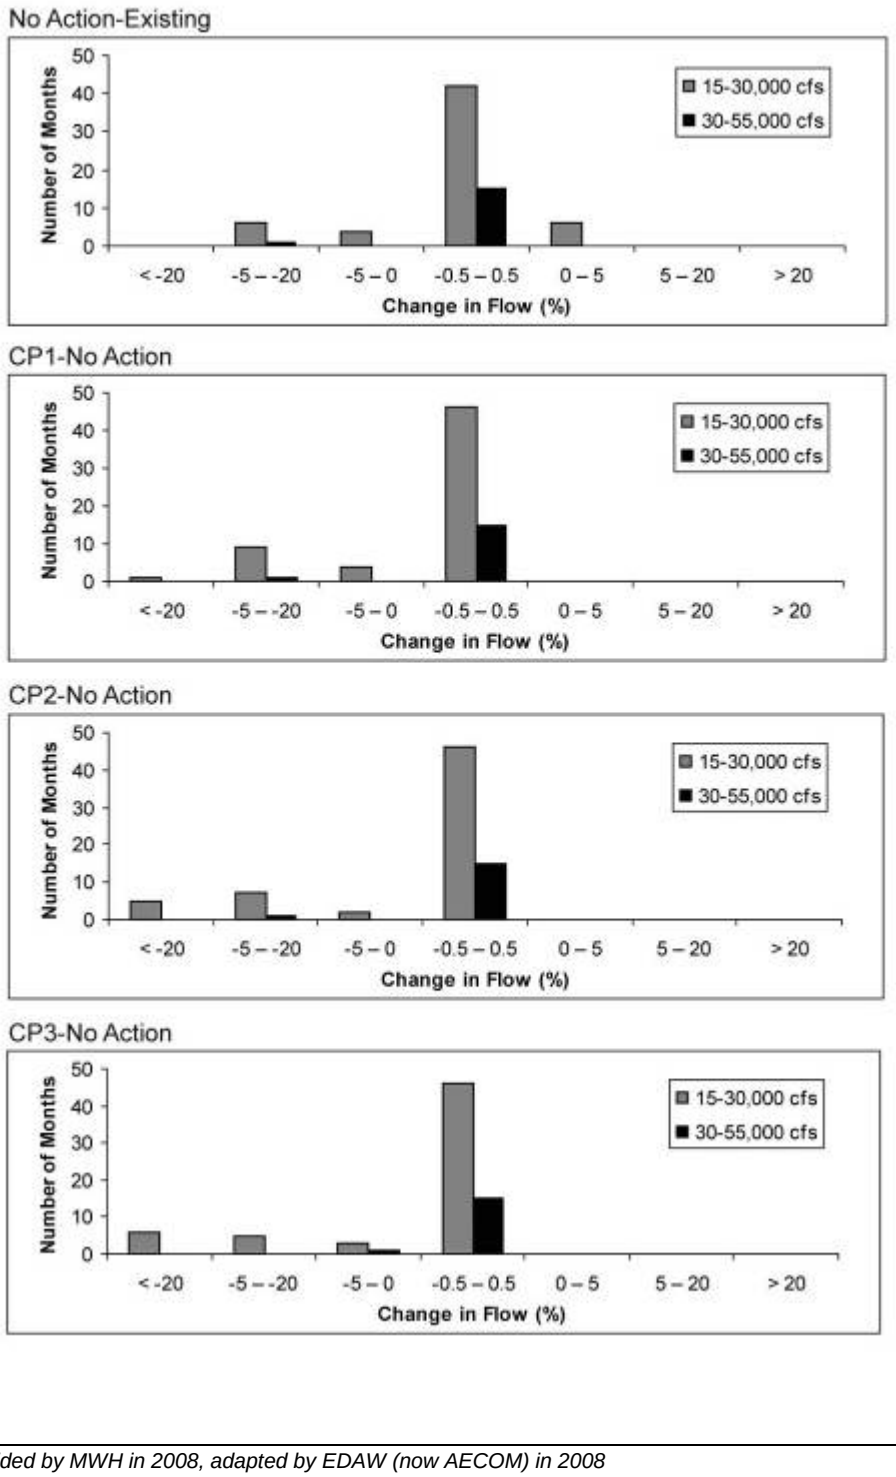
Shasta Lake and Vicinity

Impact Bot-1 (No-Action): Loss of Federally or State Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-2 (No-Action): Loss of MSCS Covered Species Species covered by the MSCS would not be lost as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-3 (No-Action): Loss of USFS sensitive, BLM sensitive, or CRPR Species USFS sensitive, BLM sensitive or CRPR listed species would not be lost as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

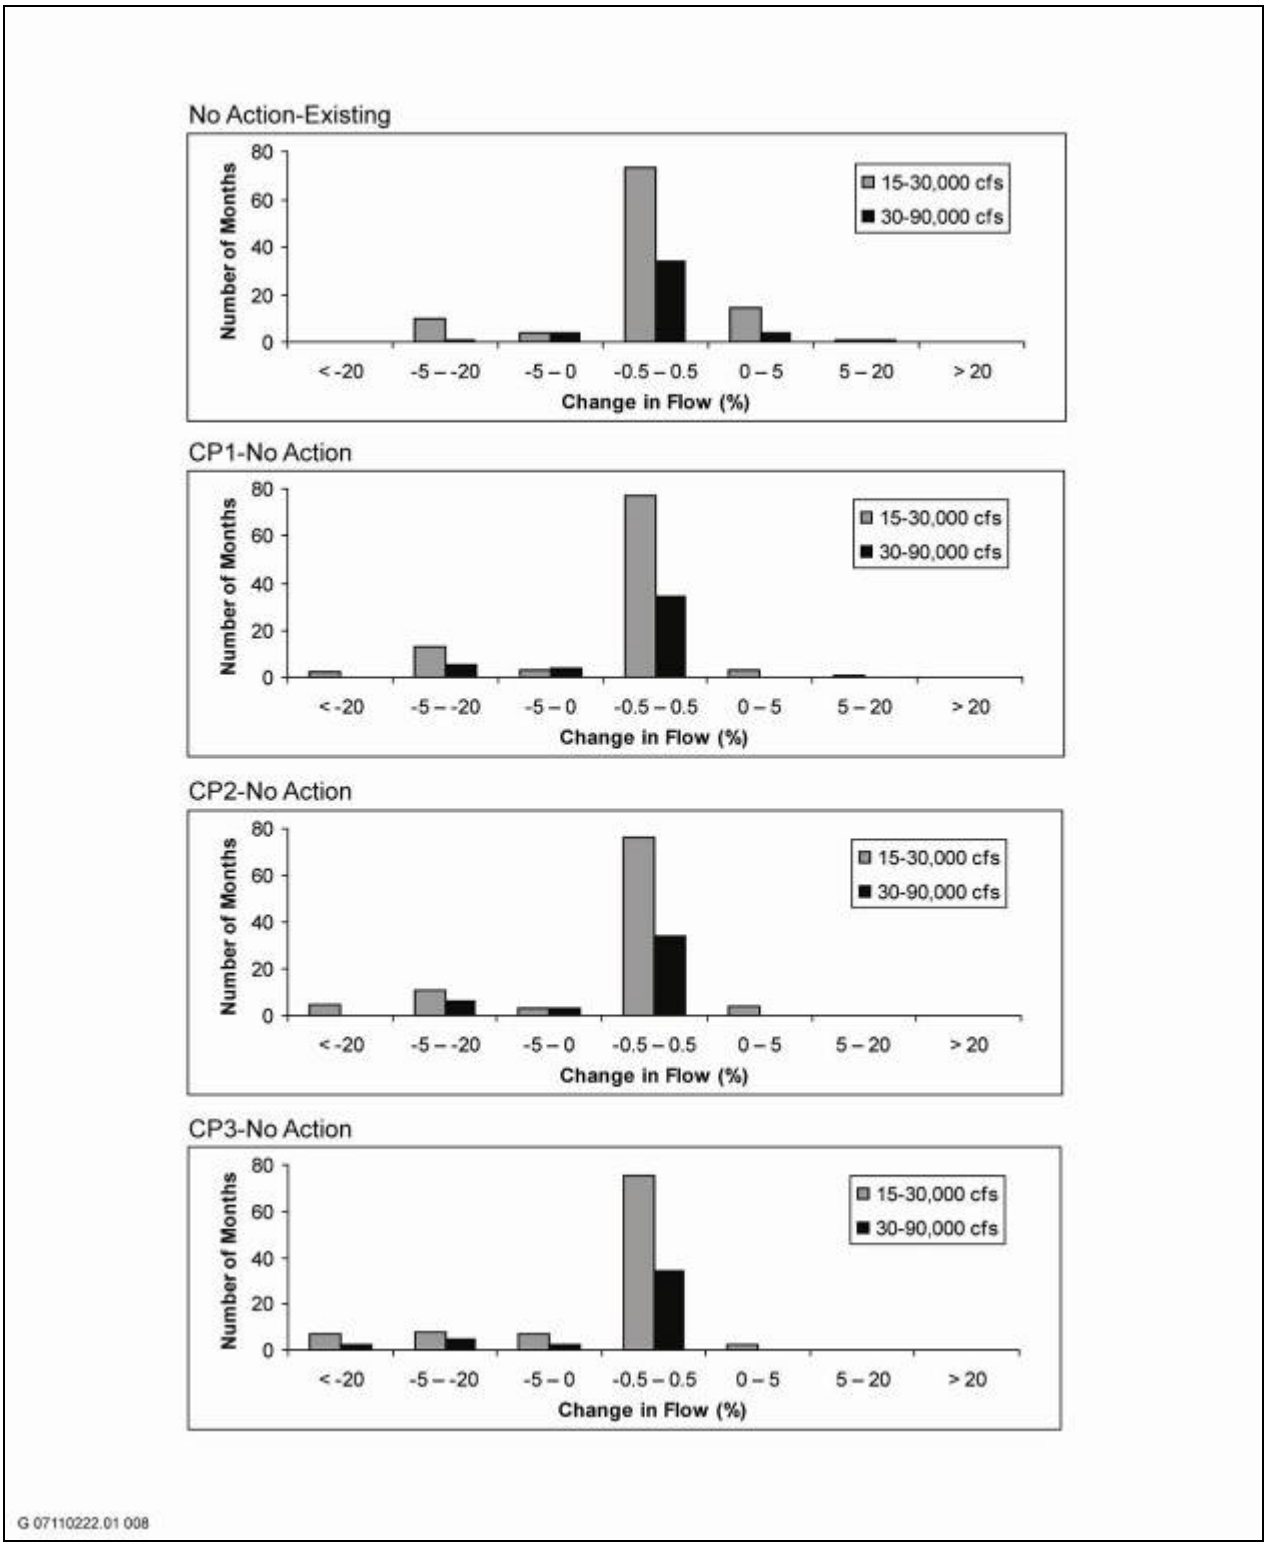
Impact Bot-4 (No-Action): Loss of Jurisdictional Waters Waters of the United States would not be lost as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.



Impact Bot-5 (No-Action): Loss of General Vegetation Habitats General vegetation habitats would not be lost as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-6 (No-Action): Spread of Noxious and Invasive Weeds Noxious and invasive weeds would not be spread as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative..

Upper Sacramento River (Shasta Dam to Red Bluff)



Impact Bot-7 (No-Action): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with the No-Action Alternative could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities along the upper Sacramento River, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants would be small, and beneficial effects are also anticipated to result from other management and restoration actions. Thus, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. As a consequence of these actions, the flow regime of the upper Sacramento River would change between 2005 and 2030. The CalSim-II modeling results that simulate these changes are provided in the *Hydrology, Hydraulics, and Water Management Technical Report* and the simulated discharges below Keswick Dam and above Red Bluff are summarized on Figures 12-5 and 12-6, respectively. Overall, these modeling results suggest there would be only a very small decrease in flows of 15,000 to 55,000 cubic feet per second (cfs). Flows of this magnitude strongly affect bank erosion and meander migration, and are related to other geomorphic processes affecting the extent of different riparian communities. These relationships are described in greater detail under CP1.

Source: Data provided by MWH in 2008, adapted by EDAW (now AECOM) in 2008

Figure 12-5. Simulated Changes in Larger Mean Monthly Flows of the Sacramento River Below Keswick Dam

Source: Data provided by MWH in 2008, adapted by EDAW (now AECOM) in 2008

Figure 12-6. Simulated Changes in Larger Mean Monthly Flows of the Sacramento River Above Red Bluff

This change might not be sufficient to cause significant effects on riparian and wetland communities, or on associated special-status species.

In addition to causing small changes in flow regime, the No-Action Alternative would continue to alter the structure and species composition of riparian and wetland vegetation resulting from continued operation of Shasta Dam. Before the construction of Shasta Dam, river flow and stage would decrease gradually during the period of cottonwood and willow seed dispersal. In many years, this flow pattern would facilitate establishment of these early-successional species along the Sacramento River throughout the primary study area.

Operation of Shasta Dam has increased flow volumes from mid-spring to early summer. Consequently, in most years, operation of the dam precludes or substantially reduces opportunities for establishment of cottonwoods and opportunities for willow establishment. As a result of this (and other alterations to the flow regime of the Sacramento River), the structure and species composition of riparian vegetation has been changing within the primary study area (Fremier 2003, Roberts et al. 2002). The extent of early-successional riparian communities (e.g., cottonwood forest) has been decreasing while the extent of mid-successional communities (e.g., mixed riparian forest) has been increasing. Such changes would continue under the No-Action Alternative for several decades, but would diminish with time.

However, under the No-Action Alternative a number of management and restoration plans and programs would be implemented. These actions are described in Section 12.2, “Regulatory Setting,” of this EIS. These actions would cause beneficial effects that would likely be of similar magnitude as the anticipated adverse effects of small changes in flow regime and of continued effects from past actions, and thus would largely offset those adverse effects.

For the reasons described above, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-8 (No-Action): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management
Numerous local and regional plans promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Expected future effects of the No-Action Alternative on riparian communities have largely been considered in the existing plans. The No-Action Alternative would not conflict with approved local or regional plans. This impact would be less than significant**.**

Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River in the primary study area. These plans, which are discussed in more detail in the “Regulatory Setting” section of this EIS, include the Sacramento River Conservation Area Program, which promotes the conservation and the

restoration of riparian habitat. Under the No-Action Alternative, adverse effects would result from the continued consequences of past actions (e.g., construction of Shasta Dam and the introduction of nonnative species) and from the effects of reasonably foreseeable actions. Most adverse effects that are the continued consequences of past actions have been considered in the development of existing local and regional plans. In addition, foreseeable water resources and levee actions are expected to be consistent with local and regional plans, and anticipated adverse effects are likely to be fully mitigated and not conflict with a local or regional plan. Therefore, the No-Action Alternative would not conflict with approved local or regional plans with objectives of riparian habitat protection or watershed management. This impact would be less than significant**.** Mitigation is not required for the No-Action Alternative.

Impact Bot-9 (No-Action): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for vernal pool species in the upper Sacramento River area is not expected to be adversely affected. This impact would be less than significant.

Designated critical habitat for four vernal pool special-status plant species exists in the upper Sacramento River portion of the primary study area: slender orcutt grass, Hoover's spurge, hairy orcutt grass, and Greene's tuctoria. Critical habitat for these species in the primary study area is confined to vernal pool communities (USFWS 2006). Vernal pools are generally not present within the active floodplain. However, if vernal pool habitats for these special-status species are present in the active floodplain of the upper Sacramento River, they could be affected by the small reduction in the frequency and magnitude of overbank flows. It is not known if this would be an adverse or beneficial effect. Because this effect of the No-Action Alternative is somewhat speculative and not necessarily adverse, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-10 (No-Action): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Although Shasta Dam would not be altered, water storage, conveyance, and deliveries to water districts would likely increase because of reasonably foreseeable projects. However, environmental regulations would continue to provide protection for botanical resources, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Therefore, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable projects that would occur with or without enlarging Shasta Dam. Consequently, deliveries to water districts along the upper Sacramento River in the primary study area would likely increase between now and 2030, and this could reduce a limitation on urban growth and development. However, environmental regulations would continue to protect wetlands, riparian

habitats, other sensitive botanical communities, and special-status plant species, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Furthermore, CVP water delivered in this area would primarily be for agricultural purposes, and agricultural acreages are not expected to expand. For the reasons described above, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

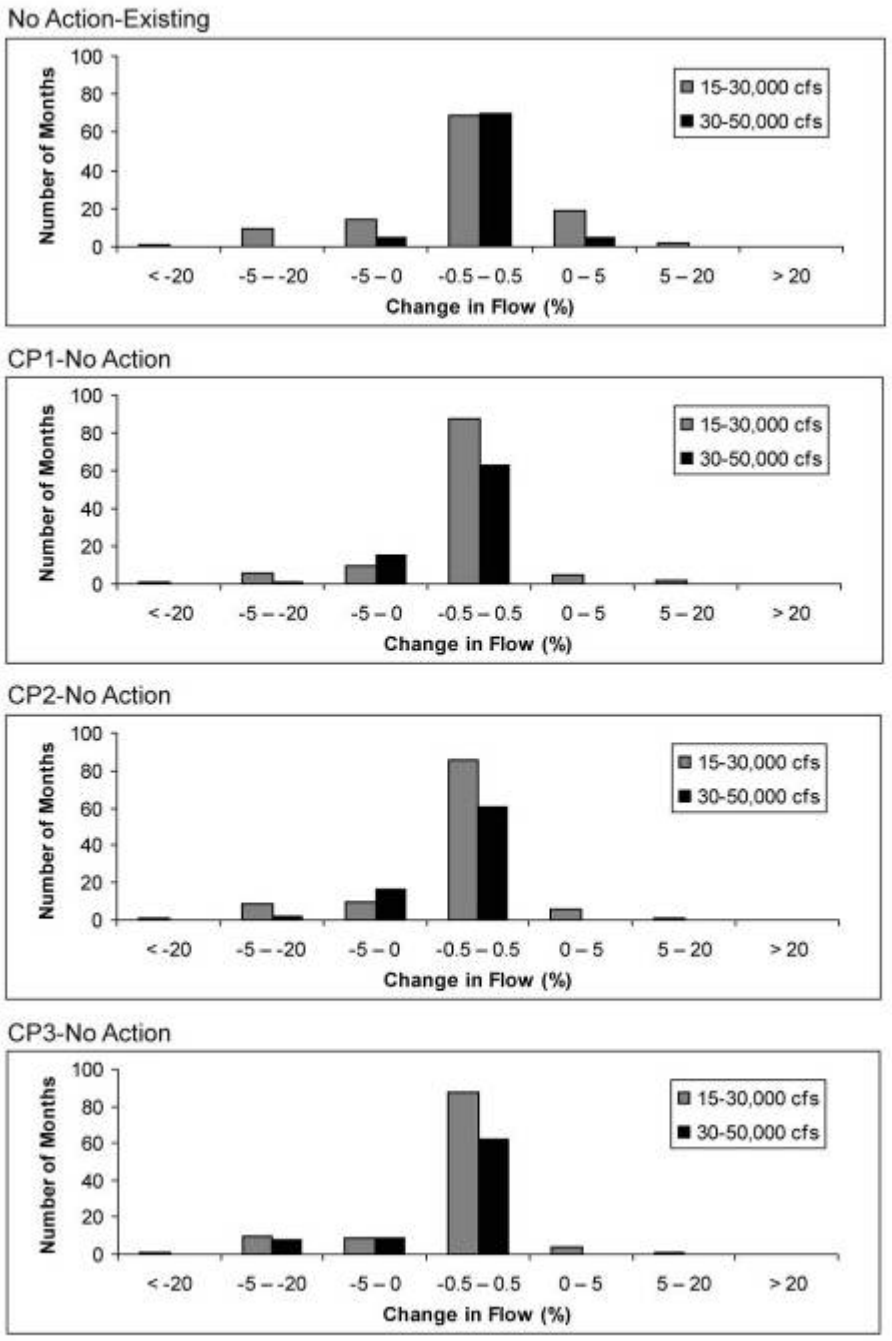
Lower Sacramento River and Delta

Impact Bot-11 (No-Action): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or the Reading Island Restoration Plan, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under the No-Action Alternative. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-12 (No-Action): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under the No-Action Alternative. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-13 (No-Action): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under the No-Action Alternative. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

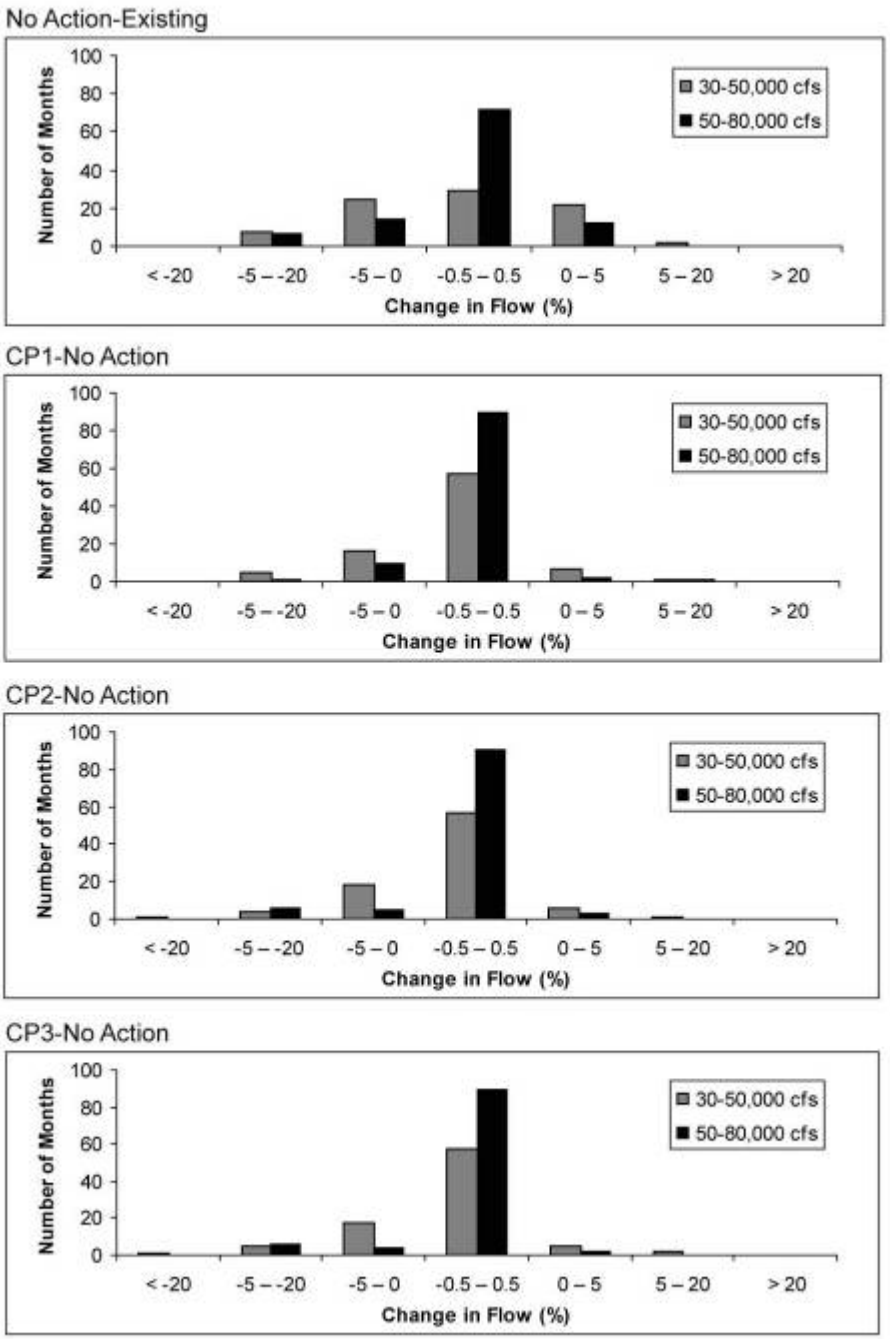
Impact Bot-14 (No-Action): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimeson the Lower Sacramento River Altered flow regimes associated with the No-Action Alternative could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities along the lower Sacramento River and in the Delta, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants would be small, and beneficial effects are also anticipated to result from



management and restoration actions. Thus, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. As a consequence of these actions, the flow regime of the lower Sacramento River could change between 2005 and 2030. The CalSim-II modeling results that simulate these changes are provided in the *Hydrology, Hydraulics, and Water Management Technical Report* and the larger simulated discharges above Red Bluff and at Wilkins Slough and Freeport are summarized on Figures 12-6, 12-7, and 12-8, respectively. (These locations are shown on Figure 12-9.) Overall, these modeling results suggest only a very small decrease in flows greater than 15,000 cfs along the uppermost portion of the lower Sacramento River. This change might not be sufficient to cause significant effects on riparian and wetland communities, or on associated special-status species.

However, besides causing additional, very small changes in flow regime, the No-Action Alternative would continue to alter the structure and species composition of riparian and wetland vegetation along the lower Sacramento River resulting from the continued operation of Shasta Dam. Before the construction of Shasta Dam, flow volume would decrease gradually during the period of cottonwood and willow seed dispersal. In many years, this flow pattern would facilitate establishment of these early- successional species along the Sacramento River throughout the extended study area. As described for the upper Sacramento River above, along the lower Sacramento River, the extent of early-successional riparian communities would continue decreasing while the extent of mid-successional communities would continue increasing under the No-Action Alternative.



However, under the No-Action Alternative, a number of management and restoration plans and programs carried out by a large number of agencies would be implemented. These actions are described in the “Regulatory Setting” section of this EIS. These actions would cause beneficial effects that would likely be of similar magnitude as the anticipated adverse effects of small changes in flow regime and of continued effects from past actions, and thus would largely offset those adverse effects.

For the reasons described above, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-15 (No-Action): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River and in the Delta. In the development of regional and local plans, most on-going adverse effects of past actions were considered, but not all effects of reasonably forseeable actions. Unmitigated effects from these actions could be sufficient to conflict with these plans. Therefore, the No-Action Alternative could conflict with approved local or regional plans. This impact would be potentially significant.

There are adopted local and regional plans that address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River and in the Delta in the extended study area. These plans, which are discussed in more detail in the "Regulatory Framework" section of this EIS, include the Sacramento River Conservation Area Program and the CALFED Ecosystem Restoration Program, both of which promote the conservation and the restoration of riparian habitat. Under the No-Action Alternative, adverse effects would result from the continued consequences of past actions (e.g., construction of Shasta Dam and the introduction of nonnative species) and from the effects of foreseeable actions. Most adverse effects that are the continued consequences of past actions have been considered in the development of existing local and regional plans. However, the adverse effects of all foreseeable water resource and levee actions were not considered in the development of local and regional plans, and these adverse effects are not likely to be completely avoided or fully mitigated. The unmitigated effects of these actions could be sufficient overall to conflict with a local or regional plan. Therefore, the No-Action Alternative could conflict with approved local or regional plans with objectives of riparian habitat protection or watershed management. This impact would be potentially significant**.** Mitigation is not required for the No-Action Alternative.

Impact Bot-16 (No-Action): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Along the Lower Sacramento River and in the Delta Although Shasta Dam would not be altered, water storage, conveyance, and deliveries to water districts would likely increase because of reasonably foreseeable actions. However, environmental regulations would continue to provide protection for botanical resources, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for site-specific projects. Therefore, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries would likely increase because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. Thus, deliveries to water districts in the extended study area along the lower Sacramento River and in the Delta would likely

increase between now and 2030, and this could reduce a limitation on urban growth and development. However, environmental regulations would continue to protect wetlands, riparian habitats, other sensitive botanical communities, and special-status plant species, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for site-specific projects. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas

Impact Bot-17 (No-Action): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with the No-Action Alternative could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities in the CVP and SWP service areas, and of habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs would be less than below Shasta Dam along the Sacramento River, and may not be sufficient to alter the distribution of plant communities, or the extent or quality of associated special-status species habitat. Therefore, this impact would be less than significant.

Altered flow regimes associated with the No-Action Alternative could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected by the altered flow regime. Effects on oak communities and upland habitats for special-status plants would be somewhat speculative and may not all be adverse; thus, on oak communities and special-status plants of upland habitats, this impact would be less than significant. Although riparian and wetland communities could be affected, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. Below CVP and SWP reservoirs, these alterations may not be sufficient to alter the extent of early-successional riparian and wetland communities, or the extent or quality of associated special-status species habitat. Therefore, this impact would be less than significant below CVP and SWP reservoirs in the extended study area. Mitigation is not required for the No-Action Alternative.

Impact Bot-18 (No-Action): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas The No-Action Alternative would not have substantial effects on riparian vegetation and habitats, and thus, would not conflict with existing local and regional plans in the CVP and SWP service areas. This impact would be less than significant.

There are adopted local and regional plans that address and promote the conservation of riparian vegetation and associated habitats along rivers below

reservoirs in the CVP and SWP service areas. However, implementation of the No-Action Alternative would not have substantial effects on riparian vegetation and habitats. Therefore, implementation of this alternative would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact in the CVP and SWP service areas would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-19 (No-Action): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Although Shasta Dam would not be altered, water storage, conveyance, and deliveries to the CVP and SWP service areas would likely increase because of reasonably foreseeable actions. However, environmental regulations would continue to protect botanical resources, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Therefore, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries to the CVP and SWP service areas would likely increase because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. Thus, CVP and SWP deliveries would likely increase between now and 2030, and this could reduce a limitation on growth. However, environmental regulations would continue to protect wetlands, riparian habitats, other sensitive botanical communities, and special-status plant species, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability while contributing to increased survival of anadromous fish, actions that are consistent with the 2000 CALFED Record of Decision (ROD) (CALFED 2000b). In addition to the features common to all comprehensive plans, CP1 consists primarily of raising Shasta Dam 6.5 feet, an elevation change that would increase the reservoir's full pool by 8.5 feet and enlarge the total storage space in the reservoir by 256,000 acre-feet. Under this plan, operational guidelines for Shasta Dam would continue unchanged, with the additional storage retained for water supply reliability and increased survival of anadromous fish.

Shasta Lake and Vicinity

Impact Bot-1 (CP1): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact on Federally listed, State-listed, or candidate plant species would occur under CP1. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP1): Loss of MSCS Covered Species Implementation of the project could result in the loss of MSCS covered species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be significant.

The only MSCS species known to occur in the project area is Shasta snow-wreath. Inundation caused by a 6.5-foot dam raise could impact all or portions of 12 (52 percent) of the Shasta snow-wreath populations found on the Sacramento River, McCloud River, and Pit River arms and the Main Body of the lake. Within its range (the Shasta Lake region), there are 23 known populations.

Portions of two Shasta snow-wreath populations are found within one relocation area at Ellery Creek. Activities to decommission the campground could impact the Shasta snow-wreath populations present.

Because complete surveys have not been conducted in the entire impoundment area, other MSCS plant species may be present. In these areas, all or portions of MSCS plant populations could be inundated. This would be a potentially significant impact.

Additional analysis of impacts will be conducted in relation to suitable habitats present in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be provided in the FEIS. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS.

This loss of MSCS covered species and their habitat would be significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-3 (CP1): Loss of USFS sensitive, BLM sensitive, or CRPR Species Implementation of the project could result in the loss of USFS sensitive, BLM sensitive, or CRPR species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

For areas where botanical surveys have been conducted, direct impacts have been determined using geographic information systems to ascertain the populations within the impoundment area, relocation areas, and construction footprints.

Based on results of surveys to date, special-status plant species known to occur in the primary study area include Shasta County arnica, northern clarkia, Butte County fritillary, Cantelow’s lewisia, Shasta snow-wreath, slender false lupine, Shasta huckleberry, and oval-leaved viburnum.

Direct impacts on Shasta snow-wreath caused by CP1 are addressed in Impact Bot-2 (CP1). As a Forest Service sensitive species, the Shasta snow-wreath is

recognized by the Forest Service to need special management to prevent the species from becoming threatened or endangered. Because the snow-wreath is a local Shasta County endemic species, the impacts are likely to result in a decline in habitat and result in a trend towards listing.

Inundation caused by a 6.5-foot dam raise and vegetation removal could impact all or portions of Shasta County arnica, northern clarkia, Butte County fritillary, Cantelow's lewisia, slender false lupine, Shasta huckleberry, and oval-leaved viburnum populations occurring in the impoundment and relocation areas. Potential populations occurring in the unsurveyed portions of the impoundment area could be flooded and would result in a potentially significant impact. Impacts on known populations are provided below.

Inundation of the impoundment area would impact all or portions of the Shasta arnica population south of Bridge Bay Resort on the Main Body of the lake and the population north of Slaughterhouse Island on the Sacramento Arm. Vegetation removal may impact the Shasta arnica population near the privately owned cabins on National Forest System lands on the Salt Creek inlet on the Sacramento Arm.

Inundation of the impoundment area and vegetation removal in the relocation areas would impact all or portions of northern clarkia populations in Bailey Cove (McCloud Arm) and in Sugarloaf Cove west of Beehive Point (Sacramento Arm).

Inundation of the impoundment area may impact all or portions of populations of Butte County fritillary located on Flat and Ripgut creeks on the Pit Arm.

Inundation of the impoundment area would impact all or portions of the Cantelow's lewisia population on a rock outcrop on the right bank of the Upper Sacramento River riverine reach near the Shasta Lake/upper Sacramento River transition zone. Inundation may also impact populations found along the Sacramento Arm near Elmore Mountain.

Inundation of the impoundment area and vegetation removal in the relocation areas would impact all or portions of slender false lupine populations throughout the impoundment area and relocation areas.

Within its range (the Shasta Lake region), there are 12 known populations Shasta huckleberry. Inundation caused by a 6.5-foot dam raise could impact portions of the 12 (100 percent) Shasta huckleberry populations on the Squaw Creek Arm and the Main Body. The populations extend beyond the project boundary at each location and no population will be completely lost as a result of CP1.

Portions of one Shasta huckleberry population occur within one relocation area at in the Bully Hill area. Construction activities in this area could impact the Shasta huckleberry population present.

Because complete surveys have not been conducted in the entire impoundment area, other of USFS sensitive, BLM sensitive, and CRPR species plant species may be present. In these areas, all or portions of USFS sensitive, BLM sensitive, and CRPR species plant populations could be inundated. This would be a potentially significant impact.

Collectively, the loss of USFS sensitive, BLM sensitive, and CRPR species and their habitat would therefore be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-4 (CP1): Loss of Jurisdictional Waters Implementation of the project may result in the loss of jurisdictional waters caused by flooding the impoundment area and discharge of fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine). Therefore, this impact would be significant.

Direct impacts would incur with the conversion of jurisdictional waters (e.g., wetlands and streams) to lacustrine with implementation of CP1. All features within the impoundment area would be converted to lacustrine. Under CP1, 11 acres of wetlands and 18 acres of other waters would be converted to lacustrine (Table 12-9). This will result in a net loss of 11 acres to wetlands and a no net loss to other waters. This is considered a significant impact.

Direct impacts on jurisdictional waters (e.g., intermittent and perennial streams) that will be filled as a result of relocation of facilities or dam construction will be determined. Additionally, some fill may be placed in the existing full pool of Shasta Lake for restoration and enhancement activities. An analysis of impacts on jurisdictional waters in the full pool, relocation areas, indirect impacts, and temporary impacts will be provided in the FEIS. Additional analysis of impacts will be conducted in relation to waters of the United States present in the Shasta Lake watershed. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-5 (CP1): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Under CP1, 1,221 acres of general vegetation habitat will be directly impacted by the inundation of the impoundment area and 3,127 acres of general vegetation habitat will be impacted by vegetation removal in the construction footprints of the relocation areas (Table 12-10 and Table 12-11). This impact is considered significant.

Note:
*Acreage values are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be provided in the FEIS. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-6 (CP1): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds as a result of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). Therefore, this impact would be potentially significant.

Noxious and invasive weeds are abundant around Shasta Lake specifically in the relocation areas. Vectors that would increase as a result of project implementation include weed seed and seed parts brought in on tools, vehicles, and workers' clothing and boots. The extent of the risk would depend on the construction methods used and site-specific actions implemented to complete the project. As access into specific project areas is improved, road construction, temporary roads, and road maintenance would increase the number of vectors in an area. As traffic along new and existing corridors increases, the risk for weed dispersal would increase. Seed mixtures and mulches may be used during erosion control efforts and revegetation of areas. These mixtures and mulches are potential vectors for noxious weed and invasive plant dispersal.

Construction of the dam would result in inundation of shoreline habitat. Depending on the extent of colonization, many populations of noxious weeds

could be inundated. However, there would be no increase in vector traffic and no soil disturbance due to inundation. Therefore, the risk of weed spread from the inundation of habitat is low.

However, vegetation removal in areas to be inundated may increase risk of weed spread. Habitat vulnerability and project-associated vectors in inundation zones would be variable, based on the extent of the vegetation removal and the location of the proposed activity. All habitats are vulnerable when canopies are opened and soil is disturbed. Increased traffic and soil disturbance coupled with an adjacent, high-ranking noxious weed may result in a moderate to high risk of weed spread.

Because of the dam expansion, other ground-disturbing projects would be implemented to relocate displaced roads, railways, utilities, homes, and recreation facilities. The potential for disturbance of noxious weeds is highly variable, based on the proposed activity and the abundance of weeds present. Depending on the location of high-ranking noxious weeds, the extent of ground-disturbing activities, and the amount of traffic entering a project site, the risk of noxious weed infestation would vary.

This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Bot-7 (CP1): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP1 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, this impact would be significant.

Potential impacts on flow and stages of the upper Sacramento River from CP1 would be small. On average, in each month, changes in mean monthly flow would be reductions or increases of several percent. Generally, these effects diminish with distance downstream because of the influence of inflows from tributaries and of diversions and flood bypasses.

In average and wet years, river flows would decrease during the November through February period of some years. This would be because of the increased storage space that could be filled in some years, usually following dry or critically dry water years. During these years, mean monthly flow November through February could be reduced by 10 percent or more.

During the June through August period of some years, flow and stage would increase. This increase would be most pronounced during some dry and critical years as more water is released from Shasta Dam for water supply reliability purposes. During May through August in different types of water years, the average changes in mean monthly flow would be reductions or increases of several percent (generally less than 2 percent), although the changes in mean monthly flow would be greater in some years. (September through October and March through April flows would be transitional and intermediate between those described for November through February and for May through August.)

Northern hardpan vernal pools and Northern volcanic mudflow vernal pools are not present at Shasta Dam and are generally not present within the active floodplain immediately adjacent to the channel of the upper Sacramento River or its tributaries in the primary study area. Therefore, northern hardpan vernal pools and associated special-status plant species would likely not be affected by the altered flows in the primary study area downstream from Shasta Dam.

The altered flow regime of the upper Sacramento River associated with implementation of CP1 could affect oak communities and upland habitat for special-status plant species by prolonging inundation and changing the availability of soil moisture. Prolonged inundation during the growing season kills most upland plants. This effect would occur during years when mean monthly stage during March – October is greater than in preceding years. Interannual fluctuations in stage during the growing season already cause upland vegetation to become removed from (or prevent its establishment within) a zone along rivers downstream from Shasta Dam. CP1 could increase the average elevation of this zone slightly (by, on average, increasing stage during the growing season of most years), but it would not increase the zone's elevational range. For some upland vegetation, greater summer flows in some years also could increase summer soil moisture, and reduced intermediate and large flows during winter in some years could reduce spring soil moisture. Because of the important influence of water availability on plant growth and survival, these changes in the availability of moisture could change the structure and species composition of oak communities or affect special-status plants of upland habitats.

These effects, however, are speculative, and may not all prove to be adverse with project implementation and operation. For example, greater summer flows in some years could increase summer soil moisture; in dry years, increased soil moisture could sustain plants that otherwise would be damaged or die. Therefore, the impact on oak communities and on upland habitat for special-status plants resulting from altered flow regimes on the upper Sacramento River within the primary study area would be less than significant.

The flow regime of a river or stream strongly influences the structure and species composition of the riparian and wetland communities associated with it.

For this reason, the altered flow regimes resulting from project implementation would affect riparian and wetland vegetation. These effects are described below.

River flows strongly affect the growth and survival of riparian plants. Riparian plants are strongly affected by the timing and duration of inundation; abrasion and burial by water-borne sediment; and by water table fluctuations (Toner and Keddy 1997; Friedman and Auble 1999; Karrenberg et al. 2002; Bagstad et al. 2005; Lite and Stromberg 2005; Williams and Cooper 2005). As a result, riparian communities often differ in structure and species composition along gradients of elevation or flooding frequency and intensity (Conard et al. 1977; Harris 1987; Toner and Keddy 1997; Bagstad et al. 2005; Vaghti and Greco 2007).

River flows not only affect the survival and growth of established riparian vegetation, but also create sites for establishment of early-successional vegetation. The geomorphic processes of channel meander migration, avulsion, and deposition of sediment on floodplains, which result primarily from intermediate and large flows, bury and uproot herbaceous vegetation and uproot or undercut trees and shrubs. These disturbances also create opportunities for early-successional vegetation to establish, including willow and cottonwood seedlings that grow to form willow scrub and Great Valley cottonwood riparian forest.

Early successional riparian communities change rapidly in structure and species composition (Tu 2000; Fremier 2003; Vaghti and Greco 2007). Over several decades, early-successional vegetation develops into mid- and late-successional vegetation with less willow and cottonwood and a greater abundance of other trees including box-elder, Oregon ash, black walnut, and valley oak (e.g., Great Valley mixed riparian forest) (Fremier 2003).

Thus, for riparian vegetation, the rates of geomorphic processes strongly affect the extent of different riparian communities; and, these rates are strongly related to flow regime. For example, bank erosion, and the average rate of meander migration are closely related to the cumulative portion of flow above a threshold volume. On portions of the Sacramento River, this threshold may be around 30,000 cfs (Larsen et al. 2006; Stillwater Sciences 2007), which is well below the bankfull discharge but well above flows during spring and summer. However, other important thresholds for bank erosion and channel avulsion along the Sacramento River have been estimated within the range from 10,000 to 80,000 cfs (Stillwater Sciences 2007). (For additional discussion of the relationship of geomorphic processes to flow along the Sacramento River, see the *Fisheries and Aquatic Ecosystem Technical Report*.)

Flow regimes during the period of seed dispersal also strongly influence establishment of seedlings of riparian trees and shrubs, particularly willows and cottonwoods. In general, seeds of riparian plants can only successfully germinate and establish on exposed surfaces; prolonged inundation of a surface

during the growing season prevents establishment. Willows and cottonwoods have very small, short-lived seed and are shade-intolerant plants; thus, their seeds must disperse to exposed, moist surfaces that are largely free of vegetation. Such surfaces are often created by channel migration, avulsion, and sediment deposition during larger winter and spring flows. They are then exposed by declining flows during the seed dispersal period of willow and cottonwood species. These seed dispersal periods are staggered across spring and summer; for example, March through April for arroyo willow, April–June for cottonwood, and May through August for black willow. Once willow and cottonwood seeds germinate, slowly declining flows are necessary to maintain their roots in contact with saturated soils, which in turn is necessary for establishment. Rapidly declining flows (i.e., those greater than 1 to 1.5 inches per day) result in desiccation and mortality of seedlings (Mahoney and Rood 1998; Stillwater Sciences 2007). Conversely, flows that increase during the growing season bury, uproot, or scour many seedlings.

Consequently, reductions in the magnitude, duration, and frequency of intermediate and large flows could reduce opportunities for cottonwood and willow species to establish and thus limit the extent of early and mid-successional riparian communities. The absence of slowly declining spring flows also would reduce cottonwood establishment.

The operation of Shasta Dam has limited the frequency, magnitude, and duration of intermediate and larger flows during fall and winter, since the dam's construction, and flow volumes have been greater during the growing season. The operation of Shasta Dam also produces increasing flow volumes during the period of cottonwood seed dispersal (rather than flow volume decreasing during this period), largely precluding establishment of cottonwoods (and to a lesser extent willows) throughout much of the riparian zone (Roberts et al. 2002). The combined effect of these changes in flow regime has been a decrease in early- and mid-successional communities along the Sacramento River that is still ongoing (Fremier 2003).

CP1 would lead to a further reduction in the magnitude, duration, and frequency of intermediate and large flows, but it would not alter the general annual pattern of flows increasing during the cottonwood seed dispersal period. However, CP1's effects on larger flows could further reduce the frequency or extent of suitable conditions for cottonwoods to establish from seed. Overall, the project would increase the existing, ongoing impacts on riparian vegetation resulting from the operation of Shasta Dam. This could reduce the area of riparian vegetation slightly, and reduce the proportion of riparian vegetation that is in early- and mid-successional stages (e.g., willow- and cottonwood-dominated communities) while increasing the extent of mid-successional communities (e.g., mixed riparian forest). This would be an exacerbation of an ongoing transition (which is described under Impact Bot-7 (No-Action)).

These effects would likely occur along the upper Sacramento River throughout the primary study area. Reductions in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian corridor along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. These effects on larger flows downstream from Keswick Dam and above Red Bluff are shown on Figures 12-5 and 12-6, respectively. On average, mean monthly flows greater than 15,000 cfs would be reduced only slightly; however, this average reduction reflects a combination of many months with little change in flow and other months with larger changes. For example, at Red Bluff, 142 months had mean monthly flows greater than 15,000 cfs. On average, CP1 would result in a reduction in these flows of less than 2 percent; but in 16 (11 percent) of these months, flows would be reduced by more than 5 percent versus only 1 month with a simulated increase of greater than 5 percent.

Although the establishment of most wetland plants is less strongly influenced by specific attributes of the flow regime than willows and cottonwoods, flow regime still plays an important role in wetland communities. In general, wetland communities on floodplains are strongly influenced by timing and duration of inundation, scour and deposition of sediment, and fluctuations in water table elevations within and among years (Keddy 2000; Leyer 2005; van Eck et al. 2006). Changes in flow during some years would change the extent of some wetland communities (e.g., seeps, seasonal wetlands) during that year and/or subsequent years, and thus the average extent of those communities. Overall, wetland communities could experience effects similar to those described for riparian communities.

For the reasons outlined above, and because riparian and wetland communities are sensitive natural communities, this impact would be significant. Mitigation for this impact is proposed in Section 12.3.5.

Eleven special-status plant species could occur in riparian or wetland habitats in the primary study area (including mesic upland-associated species; Table 12-4). Of these, within the primary study area and nearby counties (Butte and Glenn), four are known to occur along the edge of the Sacramento River channel, or along a Sacramento River tributary within 0.2 mile of the river proper, and their establishment and reproduction could potentially be affected by changes in flow regime: fox sedge (CNPS list 2), silky cryptantha (CNPS list 1B), rose mallow (CNPS list 2), and Ahart's paronychia (CNPS list 1B) (CNDDB 2007; University of California 2011). Because altered flow regimes associated with the project could modify habitat for these special-status species, this impact would be significant.

Impact Bot-8 (CP1): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management
Numerous local and regional plans promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because

CP1 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant**.**

Local and regional plans addressing riparian habitats in the primary study area are discussed in more detail in the "Regulatory Setting" section of this EIS and include the RHJV and the Sacramento River Conservation Area Program, both of which promote the conservation and the restoration of riparian habitat. As described for Impact Bot-7 (CP1), implementation of this alternative could cause substantial adverse effects on riparian and wetland communities by altering the flow regime of the upper Sacramento River and could, therefore, conflict with existing local and regional plans that aim to conserve riparian habitats. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-9 (CP1): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, such critical habitat is not expected to be adversely affected by CP1. This impact would be less than significant.

Critical habitat for four special-status species – slender orcutt grass, Hoover's spurge, hairy orcutt grass, and Greene's tuctoria – exists within the primary study area. Critical habitat for these species in the primary study areas is confined to vernal pool communities (USFWS 2006). Vernal pools are generally not present within the active floodplain. However, if vernal pool habitats for these special-status species are present in the active floodplain of the upper Sacramento River, they could be affected by the small reduction in the frequency and magnitude of overbank flows. It is not known if this would be an adverse or beneficial effect. Because this effect of CP1 is somewhat speculative and not necessarily adverse, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP1): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementing CP1 could increase water yield for water districts in the primary study area along the upper Sacramento River. This increase in water yield could reduce a limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

Along the upper Sacramento River, the CVP and SWP service areas contain wetland, riparian, oak, and other sensitive plant communities, and a large number of special-status plant species (Attachment 4). Increased water supplies

or increased supply reliability could reduce a limitation on urban growth and development or on other activities that could affect sensitive plant communities or special-status plants in the primary and extended study areas, potentially resulting in significant effects.

The expected increase in water yield relative to the entire CVP and SWP service areas would be small (i.e., less than 1 percent), however, and this new yield would be provided to a number of geographic areas within the CVP and SWP service areas. (In the portions of the CVP service area in the upper Sacramento River region, total agricultural water supplies would increase in some years but by less than 1 percent.) Also, a substantial portion of this water would substitute for groundwater pumping, allow for changes in agricultural irrigation practices, or return idle cropland to production. Consequently, this alternative's effect on growth that could affect vegetation would be minor.

Furthermore, the effects of this growth would be analyzed in general plan Environmental Impact Reports and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these effects would be the responsibility of these local jurisdictions, and not of Reclamation. Similarly, projects potentially affecting riparian and wetland habitats and listed species would require permits from DFG, USACE, and USFWS; it is anticipated that effects on these resources would be avoided, minimized, and/or mitigated during those agency consultations.

The extent of induced growth that could affect botanical resources would likely be minor, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP1): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or the Reading Island Restoration Plan, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-12 (CP1): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-13 (CP1):Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Bot-14 (CP1): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with project implementation under CP1 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and loss of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River, but these effects are unlikely to extend to the Delta; thus, this impact would be significant on the lower Sacramento River, and less than significant in the Delta.

This impact would be similar to Impact Bot-7 (CP1) for the upper Sacramento River, but alteration of the Sacramento River's flow regime would be attenuated in the lower river by the effects of inflows from tributaries and of diversions and flood bypasses. Measurable effects on riparian and wetland plant communities are unlikely to extend as far downstream as the Delta, in part because releases from Shasta Dam account for a smaller fraction of total flow with increasing distance downstream as tributaries cumulatively add to the Sacramento River's flow.

Nonetheless, significant impacts on riparian and wetland communities, and associated special-status plants, would be caused on the lower Sacramento River, particularly near the upper Sacramento River. South of RBDD, the portion of the Sacramento River's total annual flow that is accounted for by flows greater than 30,000 cfs would still be reduced, and also the frequency of flows greater than 60,000 to 80,000 cfs (i.e., roughly the size of the current 1.5- to 2-year events) would be reduced. For Red Bluff, Wilkins Slough, and Freeport, these changes are summarized on Figures 12-6, 12-7, and 12-8, respectively. (These three locations are shown on Figure 12-9.) As described for Impact Bot-7 (CP1) (and in the *Fisheries and Aquatic Ecosystem Technical Report*), flows above about 30,000 cfs and 1.5- to 2-year events cause substantial changes in riparian ecosystems. These changes indicate that although they would be small, the alterations to the lower Sacramento River's flow regime could be sufficient to cause significant impacts in the Red Bluff-to-Chico Landing reach. This reach is immediately downstream from the primary

study area but upstream from the flood bypasses and the Feather and American rivers, which substantially attenuate the effects of flows released from Shasta Dam. This reach is mostly unleveed and has few other constraints to channel movement, river meander, and flooding; consequently, it has an extensive acreage of early-, mid-, and late-successional riparian communities (Resources Agency 2003).

Effects are unlikely to extend to the Delta because the flood bypasses and the Feather and American rivers attenuate the effects of flows released from Shasta Dam. In addition, much of the Sacramento River's length south of Colusa, and almost all Delta sloughs, are leveed (often close to the channel), restricting channel movement, river meander and flooding. Further; the acreage of early-, mid-, and late-successional riparian communities is much less extensive along the Sacramento River south of Colusa and in the Delta.

Effects of flow alterations are also unlikely to extend to the Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the CVP and SWP). The guidelines for this management, which are described in the CVP Operations Criteria and Plan, have been designed to maintain standards for Delta inflow. CVP and SWP operations must be consistent with the Operations Criteria and Plan to allow coverage by the Operations Criteria and Plan biological opinion. Thus, implementation of CP1 is not anticipated to alter Sacramento River flows to the Delta sufficiently to alter the dynamics or structure of vegetation in the Delta. Thus, impacts on the Delta portion of the extended study area would be less than significant.

This impact would be significant along the lower Sacramento River and less than significant in the Delta. Mitigation for this impact along the lower Sacramento River is proposed in Section 12.3.5.

Impact Bot-15 (CP1): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. Because CP1 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact on the lower Sacramento River would be potentially significant**.**

Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River and in the Delta. These plans, which are discussed in more detail in the "Regulatory Framework" of this EIS, include the Riparian Habitat Joint Venture and the Sacramento River Conservation Area Program, both of which promote the conservation and the restoration of riparian habitat. As described for Impact Bot-14 (CP1), implementation of this alternative could cause substantial adverse effects on riparian and wetland communities along a portion of the lower

Sacramento River by altering its flow regime, but such effects would not occur in the Delta. Because the project has the potential to result in substantial adverse effects on riparian communities, it could conflict with existing local and regional plans. Therefore, on the lower Sacramento River, this impact would be potentially significant, but in the Delta this impact would be less than significant. Mitigation for this impact on the lower Sacramento River is proposed in Section 12.3.5.

Impact Bot-16 (CP1): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Along the Lower Sacramento River and in the Delta Implementation of CP1 could increase water yield for water districts in the extended study area along the lower Sacramento River. This increase in water yield could reduce a limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1) for the upper Sacramento River, but the increased water yield available along the lower Sacramento River would differ from that along the upper Sacramento River. However, this impact would also be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP1): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with project implementation under CP1 could alter the structure and species composition or cause the loss of sensitive plant communities and of habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to alter the extent of early successional riparian and wetland communities or of associated habitat for special-status species. Therefore, this impact would be less than significant below CVP and SWP reservoirs in the extended study area.

This impact would be similar to Impact Bot-7 (CP1) for the upper Sacramento River. However, flow changes below CVP and SWP reservoirs are anticipated to be smaller than along the Sacramento River. These alterations may not be sufficient to alter the extent of early successional riparian and wetland communities or of associated habitat for special-status species. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP1): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementing CP1 would not cause a significant impact on riparian vegetation and habitats. Therefore, CP1 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact in the CVP and SWP service areas would be less than significant.

Local and regional plans address and promote the conservation of riparian vegetation and associated habitats in the CVP and SWP service areas. (These plans are discussed in more detail in the "Regulatory Setting" section of this EIS.) However, as described for Impact Bot-17 (CP1), implementation of CP1 would not cause significant impacts on riparian and wetland communities in the CVP and SWP service areas. Therefore, CP1 would not conflict with existing local and regional plans. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP1): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP1 could increase water yield for water districts in the CVP and SWP service areas. This increase in water yield could reduce a limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1) for the upper Sacramento River, but the increased water yield available in the CVP and SWP service areas would differ from that along the upper Sacramento River. However, this impact would also be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Like CP1, this comprehensive plan focuses on enlarging Shasta Dam and Shasta Lake consistent with the goals of the 2000 CALFED ROD (CALFED 2000b), and was formulated for the primary purposes of increasing water supply reliability and survival of anadromous fish. In addition to the features common to all comprehensive plans, CP2 consists of raising Shasta Dam 12.5 feet, an elevation change that would increase the reservoir's full pool by 14.5 feet and enlarge the total storage space in the reservoir by 443,000 acre-feet. This alternative would help reduce future shortages by increasing water supply reliability in drought and average years. The increased cold-water pool also

would contribute to improved seasonal water temperatures for anadromous fish on the upper Sacramento River.

Shasta Lake and Vicinity

Impact Bot-1 (CP2): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact on Federally listed, State-listed, or candidate plant species would occur under CP2. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP2): Loss of MSCS Covered Species Implementation of the project could result in the loss of MSCS covered species because of inundation, vegetation removal, or construction activities. Therefore, this impact would be significant.

Impacts related to dam construction and vegetation clearing within the relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam could result in the loss of more individual plants. Therefore, this impact would be significant.

Additional analysis of impacts will be conducted in relation to suitable habitats in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be provided in the FEIS. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-3 (CP2): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species Implementation of the project could result in the loss of USFS sensitive, BLM sensitive, or CRPR species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Impacts related to dam construction and vegetation clearing within the relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam could result in the loss of more individual plants and their suitable habitat. Therefore, this impact would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be provided in the FEIS. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-4 (CP2): Loss of Jurisdictional Waters Implementation of the project may result in the loss of jurisdictional waters caused by flooding the impoundment area and discharge of fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine). Therefore, this impact would be significant.

Direct impacts would incur with the conversion of jurisdictional waters (e.g., wetlands and streams) to lacustrine with implementation of CP2. All features within the impoundment area would be converted to lacustrine. Under CP2, 15 acres of wetlands and 25 acres of other waters would be converted to lacustrine (Table 12-12). This will result in a net loss of 15 acres to wetlands and a no net loss to other waters. This is considered a significant impact.

Table 12-12. Impacts to Jurisdictional Waters (Acres*) in the Impoundment Area (12.5-Foot Dam Raise)

Jurisdictional Water Type	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Wetlands						
Fresh emergent/ riparian wetland	0.00	0.00	3.13	0.00	0.00	0.00
Intermittent swale	0.00	0.001	0.00	0.00	0.00	0.03
Riparian wetland	0.79	0.66	4.40	2.79	0.67	0.69
Seasonal wetland	0.00	0.00	0.14	0.00	0.08	0.02
Seep/spring wetland	0.57	0.17	0.59	0.21	0.07	0.34
Vegetated ditch	0.08	0.00	0	0.01	0.00	0.00
Total Wetlands	1.44	0.84	8.26	3.01	0.82	1.08
Other Waters of the United States						
Ephemeral stream	0.19	0.01	0.37	0.17	0.09	0.08
Intermittent stream	1.00	0.15	1.34	0.61	0.55	1.70
Perennial stream	1.14	1.32	6.57	7.55	1.52	0.88
Roadside ditch	0.00	0.00	0.01	0.00	0.00	0.00
Seep/spring other waters	0.02	0.00	0.001	0.01	0.00	0.00
Total Other Waters	2.39	1.48	8.29	8.34	2.16	2.66
Total Waters of the U.S.	3.83	2.32	16.55	11.35	2.98	3.74

Note:
*Acreage values are approximate.

Direct impacts on jurisdictional waters (e.g., intermittent and perennial streams) that will be filled as a result of relocation of facilities or dam construction will be determined. Additionally, some fill may be placed in the existing full pool of Shasta Lake for restoration and enhancement activities. An analysis of impacts

on jurisdictional waters in the full pool, relocation areas, indirect impacts, and temporary impacts will be provided in the FEIS. Additional analysis of impacts will be conducted in relation to waters of the United States present in the Shasta Lake watershed. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-5 (CP2): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Under CP2, a total of 1,715 acres of general vegetation habitats will be directly impacted by the inundation of the impoundment area (Table 12-13).

Table 12-13. Impacts to CWHR Habitats (Acres*) in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (Acres*)					
	Main Body	Big Backbone Creek	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Annual grassland	0.36	0	1.53	0.53	0	0
Barren	0.77	0	0.36	0.00	0	0.00
Blue oak – foothill pine	7.05	0	0	0	2.46	5.27
Blue oak woodland	0	0	0	0	0	1.65
Closed-cone pine – cypress	24.40	0	8.95	14.89	32.72	262.31
Douglas-fir	0	0	0	0.06	0	0
Mixed chaparral	20.58	9.56	112.76	10.97	7.35	40.11
Montane hardwood	53.30	25.75	120.48	45.31	13.31	1.77
Montane hardwood – conifer	48.77	0.70	99.06	97.70	78.41	7.73
Montane riparian	2.72	3.23	20.57	6.12	1.00	1.19

Riverine	0	0.42	4.02	4.51	0.84	0
Urban	16.65	0	1.63	6.42	0	1.24
Total	326.64	61.20	492.71	301.28	171.18	362.19

Note:
*Acreage values are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be provided in the FEIS. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional

discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-6 (CP2): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds as a result of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). Therefore, this impact would be potentially significant.

Impacts resulting from the spread of noxious weeds under CP2 are anticipated to be similar to, but greater than, those described for CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Bot-7 (CP2): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP2 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. For example, greater summer flows in some years could increase summer soil moisture, especially during some dry and critical years as more water is released from Shasta Dam for water supply reliability purposes. This increased soil moisture in dry years could reduce losses of upland vegetation during drought years. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, this impact would be significant.

This impact would be similar to Impact Bot-7 (CP1). The extent of the impact under CP2 would be greater than that under CP1, but less than that under CP3, which would entail more substantial alterations of flow regimes. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative below Keswick Dam and above Red Bluff are summarized on Figures 12-5 and 12-6, respectively.) This impact would be significant for riparian and wetland plant communities and associated special-status plants. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-8 (CP2): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management
Numerous local and regional plans promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP2 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Bot-8 (CP1). The extent of the impact under CP2 would be greater than that under CP1 but less than that under CP3, and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-9 (CP2): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, critical habitat for vernal pool species is not expected to be adversely affected by CP2 because vernal pools are generally not present within the active floodplain. For this reason, this impact would be less than significant.

This impact would be similar to Impact Bot-9 (CP1). The extent of the impact under CP2 would be greater than that under CP1 but less than that under CP3, and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP2): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementation of CP2 could increase water yield for water districts in the primary study area along the upper Sacramento River. This increase in water yield could reduce a limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1). In the portions of the CVP service area in the upper Sacramento River region, total agricultural water supplies would increase in some years by up to 1 percent. The extent of the impact under CP2 would be greater than that under CP1 but less than that under CP3, which would entail more substantial alterations of flow regimes. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP2): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or the Reading Island Restoration Plan, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-12 (CP2): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp,

or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-13 (CP2):Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Bot-14 (CP2): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower sacramento River Altered flow regimes associated with project implementation under CP2 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River, but these effects are unlikely to extend to the Delta; thus, for riparian and wetland communities and special-status plants, this impact would be significant on the lower Sacramento River, and less than significant in the Delta.

This impact would be similar to Impact Bot-14 (CP1). The extent of the impact under CP2 would be greater than that under CP1, but less than that under CP3, which would entail more substantial alterations of flow regimes. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative above Red Bluff and at Wilkins Slough and Freeport are summarized on Figures 12-6, 12-7, and 12-8, respectively.) This impact would be significant on the lower Sacramento River for riparian and wetland plant communities and associated special-status plant species. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-15 (CP2): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. Because CP2 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact on the lower Sacramento River would be potentially significant.

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-16 (CP2): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Along the Lower Sacramento River and in the Delta Implementation of CP2 could increase water yield for water districts in the extended study area along the lower Sacramento River. This increase in water yield could reduce a limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-16 (CP1). The extent of the impact under CP2 would be greater than that under CP1 but less than that under CP3, which would result in greater increases in water yield. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP2): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with project implementation under CP2 could alter the structure and species composition or cause the loss of sensitive plant communities and of habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to affect the extent of early-successional riparian and wetland communities or of associated habitats for special-status plant species. Therefore, this impact would be less than significant below CVP and SWP reservoirs in the extended study area.

This impact would be similar to Impact Bot-17 (CP1). The extent of the impact under CP2 would be greater than that under CP1 but less than that under CP3, which would entail more substantial alterations of flow regimes. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP2): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of CP2 would not cause a significant impact on riparian vegetation and habitats.

Therefore, CP2 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact in the CVP and SWP service areas would be less than significant.

This impact would be to the same as Impact Bot-18 (CP1). The extent of the impact under CP2 would be greater than that under CP1 but less than that under CP3, and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP2): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP2 could increase water yield to water districts in the CVP and SWP service areas. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-19 (CP1). The extent of the impact under CP2 would be greater than that under CP1 but less than that under CP3, which would result in greater increases in water yield. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

CP3 is similar to CP1 and CP2. It focuses on the greatest practical enlargement of Shasta Dam and Shasta Lake consistent with the goals of the 2000 CALFED ROD (CALFED 2000b), and was formulated for the primary purposes of increasing water supply reliability and survival of anadromous fish. In addition to the features common to all comprehensive plans, CP3 consists of raising Shasta Dam 18.5 feet, an elevation change that would increase the reservoir's full pool by 20.5 feet and enlarge the reservoir's total storage space by 634,000 acre-feet to 5.19 million acre-feet.

The botany and wetland impact analysis for CP1 assumes maximum vegetation clearing within the relocation areas. Therefore, vegetation clearing impacts within the relocation areas would be identical for CP1 through CP5.

Shasta Lake and Vicinity

Impact Bot-1 (CP3): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact on Federally listed, State-listed, or candidate plant species would occur under CP3. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP3): Loss of MSCS Covered Species Implementation of the project could result in the loss of MSCS covered species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be significant.

Impacts related to dam construction and vegetation clearing within the relocation areas would be similar to CP1. However, inundation caused by a 18.5-foot raise of Shasta Dam could result in the loss of more individual plants. This impact would be significant.

Additional analysis of impacts will be conducted in relation to suitable habitats in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be provided in the FEIS. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-3 (CP3): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species Implementation of the project could result in the loss of USFS sensitive, BLM sensitive, or CRPR species because of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Impacts related to dam construction and vegetation clearing within the relocation areas would be similar to CP1. However, inundation caused by a 18.5-foot raise of Shasta Dam could result in the loss of more individual plants. This impact would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be provided in the FEIS. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-4 (CP3): Loss of Jurisdictional Waters Implementation of the project may result in the loss of jurisdictional waters caused by flooding the impoundment area and discharge of fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine). Therefore, this impact would be significant.

Direct impacts would incur with the conversion of jurisdictional waters (e.g., wetlands and streams) to lacustrine with implementation of CP3. All features within the impoundment area would be converted to lacustrine. Under CP3, 25 acres of wetlands and 47 acres of other waters would be converted to lacustrine

(Table 12-14). This will result in a net loss of 25 acres to wetlands and a no net loss to other waters. This is considered a significant impact.

Table 12-14. Impacts to Jurisdictional Waters (Acres*) in the Impoundment Area (18.5-Foot Dam Raise)

Jurisdictional Water Type	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Wetlands						
Fresh emergent/ riparian wetland	0.00	0.00	3.14	0.00	0.00	0.00
Intermittent swale	0.00	0.002	0.00	0.00	0.00	0.04
Riparian wetland	1.16	1.71	5.42	8.26	1.48	0.82
Seasonal wetland	0.00	0.00	0.18	0.00	0.14	0.02
Seep/spring wetland	0.77	0.23	0.80	0.31	0.13	0.41
Vegetated ditch	0.13	0.00	0.00	0.02	0.00	0.00
Total Wetlands	2.06	1.94	9.54	8.59	1.75	1.29
Other Waters of the United States						
Ephemeral stream	0.28	0.02	0.54	0.26	0.12	0.13
Intermittent stream	1.42	0.25	2.06	0.94	0.84	2.61
Perennial stream	1.53	3.00	8.67	20.27	2.29	1.46
Roadside ditch	0.00	0.00	0.02	0.00	0.00	0.00
Seep/spring other waters	0.03	0.00	0.001	0.01	0.00	0.00
Total Other Waters	3.26	3.27	11.29	21.48	3.25	4.20
Total	5.32	5.21	20.83	30.07	5.00	5.49

Note:
*Acreage values are approximate.

Direct impacts on jurisdictional waters (e.g., intermittent and perennial streams) that will be filled as a result of relocation of facilities or dam construction will be determined. Additionally, some fill may be placed in the existing full pool of Shasta Lake for restoration and enhancement activities. An analysis of impacts on jurisdictional waters in the full pool, relocation areas, indirect impacts, and temporary impacts will be provided in the FEIS. Additional analysis of impacts will be conducted in relation to waters of the United States present in the Shasta Lake watershed. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-5 (CP3): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Under CP3, 2,472 acres of general vegetation habitats will be directly impacted by the inundation of the impoundment area (Table 12-15).

Table 12-15. Impacts to CWHR Habitats (Acres*) in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (Acres*)					
	Main Body	Big Backbone Creek	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Annual grassland	0.44	0	3.10	0.70	0	0
Barren	1.05	0.00	0.55	0.00	0.00	0.00
Blue oak – foothill pine	10.36	0	0	0	4.29	1.94
Blue oak woodland	0	0	0	0	0	6.81
Closed-cone pine – cypress	32.68	0	12.95	20.79	44.72	373.48
Douglas-fir	0	0	0	0.36	0	0
Mixed chaparral	29.19	13.64	161.04	15.06	10.35	59.50
Montane hardwood	73.49	38.76	171.01	66.06	19.43	2.49
Montane hardwood – conifer	70.68	0.99	150.42	140.93	111.63	10.55
Montane riparian	4.16	6.67	26.16	13.91	1.53	1.57
Ponderosa pine	215.11	30.72	188.19	161.74	49.56	57.50
Riverine	0	0.88	5.24	15.43	1.41	0
Urban	21.95	0	1.95	7.96	0	1.92
Total	459.11	91.67	720.06	442.93	242.92	515.77

Note:
*Acreage values are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be provided in the FEIS. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-6 (CP3): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds because of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). Therefore, this impact would be potentially significant.

Impacts resulting from the spread of noxious weeds under CP3 are anticipated to be similar to, but greater than, those described for CP1. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Bot-7 (CP3): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP3 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities

and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, this impact would be significant.

This impact would be similar to Impact Bot-7 (CP1). The extent of the impact would be greater under CP3 than under CP1 and CP2 because it would entail more substantial alterations of flow regimes. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative below Keswick Dam and above Red Bluff are summarized on Figures 12-5 and 12-6, respectively.) This impact would be significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-8 (CP3): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management
Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP3 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Bot-8 (CP1). The extent of the impact would be greater under CP3 than under CP1 and CP2 because it would result in a greater increase in water yield. This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-9 (CP3): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, such critical habitat is not expected to be adversely affected by CP3. For this reason, this impact would be less than significant.

This impact would be similar to Impact Bot-9 (CP1). The extent of the impact would be greater under CP3 than under CP1 and CP2 because it would result in a greater increase in water yield. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP3): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementation of CP3 could increase water yield for water districts in the primary study area along the upper Sacramento River. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1). In the portions of the CVP service area in the upper Sacramento River region, total agricultural water supplies would increase in some years by up to 2 percent. The extent of the impact would be greater under CP3 than under CP1 and CP2 because it would result in a greater increase in water yield. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP3): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or the Reading Island Restoration Plan, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-12 (CP3): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-13 (CP3):Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area The proposed gravel augmentation program and Reading Island restoration and construction activities would not be implemented under CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Bot-14 (CP3): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with project implementation under CP3 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River, but these effects are unlikely to extend to the Delta; thus, for riparian and wetland communities and special-status plants, this impact would be significant on the lower Sacramento River, and less than significant in the Delta.

This impact would be similar to Impact Bot-14 (CP1). The extent of the impact would be greater under CP3 than under CP1 and CP2 because it would entail more substantial alterations of flow regimes. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative above Red Bluff and at Wilkins Slough and Freeport are summarized on Figures 12-6, 12-7, and 12-8, respectively.) This impact would be significant on the lower Sacramento River and less than significant in the Delta. Mitigation for this impact on the lower Sacramento River is proposed in Section 12.3.5.

Impact Bot-15 (CP3): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River in the extended study area. Because CP3 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact on the lower Sacramento River would be potentially significant.

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-16 (CP3): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Along the Lower Sacramento River and in the Delta Implementation of CP3 could increase water for water districts in the extended study area along the lower Sacramento River. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-16 (CP1). The extent of the impact under CP2 would be similar to that under CP1 but less than that under CP3, which would result in a greater increase in water yield. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP3): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with project implementation under CP3 could alter the structure and species composition or cause the loss of sensitive plant communities and of habitat for special-status plant species. However, alteration of flow regimes

below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to alter the extent of early-successional riparian and wetland communities or associated habitats for special-status plant species. Therefore, this impact would be less than significant below CVP and SWP reservoirs in the extended study area.

This impact would be similar to Impact Bot-17 (CP1). The extent of the impact would be greater under CP3 than under CP1 and CP2. Nonetheless, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP3): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of CP3 would not cause a significant impact on riparian vegetation and habitats. Therefore, CP3 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact in the CVP and SWP service areas would be less than significant.

This impact would be the same as Impact Bot-18 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP3): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP3 could increase water yield to water districts in the extended study area in the CVP and SWP service areas. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-19 (CP1). The extent of the impact under CP2 would be similar to that under CP1 but less than that under CP3, which would result in a greater increase in water yield. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

The primary function of CP4 is to address the survival of anadromous fish while still improving water supply reliability. It focuses on increasing the volume of cold water available to the temperature control device through reservoir

reoperations, and on raising Shasta Dam by 18.5 feet. As with CP3 and the common features above, this raise would increase the full pool by 20.5 feet and enlarge total reservoir storage space by 634,000 acre-feet. This additional storage space would expand Shasta Lake's cold-water supply available to the temperature control device by 378,000 acre-feet.

In addition to the activities common to CP1 – CP3, CP4 includes augmenting locations along the Upper Sacramento River segment of the study area with gravel to increase spawning habitat for anadromous fish. Gravel placement would occur at one or more sites per year over a 10-year period and would be accomplished by one of three methods; lateral berms, talus cone, direct placement in river; as appropriate depending on specific conditions, including geomorphology, of the augmentation site. To the extent available, existing river access points would be used to deliver gravel to the river; however, temporary new access roads would be needed in some cases, mostly adjacent to the river.

In addition, under CP4, riparian, floodplain, and side channel habitat restoration would be constructed at Reading Island to restore habitat for anadromous salmonids in the Anderson Creek Slough. This Reading Island project could involve some vegetation clearing.

The botany and wetland impact analysis for CP1 assumes maximum vegetation clearing within the relocation areas. Therefore, vegetation clearing impacts within the relocation areas would be identical for CP1 thorugh CP5. However, greater vegetation clearing would result under CP4 as a result of clearing to access gravel augmentation sites and to allow gravel to fall easily into the river from adjacent banks or terraces.

Shasta Lake and Vicinity

Impact Bot-1 (CP4): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact on Federally listed, State-listed, or candidate plant species would occur under CP4. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP4): Loss of MSCS Covered Species Implementation of the project could result in the loss of MSCS covered species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be significant.

This impact would be similar to Impact Bot-2 (CP3) and would be significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-3 (CP4): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species Implementation of the project could result in the loss of USFS sensitive, BLM sensitive, or CRPR species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Bot-3 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-4 (CP4): Loss of Jurisdictional Waters Implementation of the project may result in the loss of jurisdictional waters because of flooding the impoundment area and fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine). Therefore, this impact would be significant.

This impact would be similar to Impact Bot-4 (CP3) and would be significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-5 (CP4): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities.

This impact would be similar to Impact Bot-5 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-6 (CP4): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds as a result of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). This impact would be potentially significant.

Impacts resulting from the spread of noxious weeds under CP4 are anticipated to be similar to those described for CP3. This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Bot-7 (CP4): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP4 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, for riparian and wetland communities and special-status plants, this impact would be significant.

This impact would be the same as Impact Bot-7 (CP1) and would be significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-8 (CP4): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management

Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP4 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant**.**

This impact would be the same as Impact Bot-8 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-9 (CP4): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, such critical habitat is not expected to be adversely affected by CP4. This impact would be less than significant.

This impact would be the same as Impact Bot-9 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP4): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementation of CP4 could increase water yield for water districts in the primary study area along the upper Sacramento River. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be the same as Impact Bot-10 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP4): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or the Reading Island Restoration Plan, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area Implementing the gravel augmentation program could result in the removal of riparian and wetland vegetation or the degradation of riparian and wetland habitats, including wetlands qualifying as waters of the United States. In addition, habitat restoration, boat ramp rehabilitation, and fishing area construction at Reading Island could remove riparian vegetation, or result in discharge of fill material into waters of the United States. This impact would be potentially significant.

A gravel augmentation program would be implemented under CP4, as described in Chapter 2, “Alternatives.” Gravel placement falls under Nationwide Permit (NWP) 27, “Aquatic Habitat Restoration, Establishment, and Enhancement.” Activities qualifying for NWPs have been determined by USACE to have no more than minimal adverse effects on the aquatic environment (72 Federal

Register 11092). Therefore, the direct placement of gravel into the Sacramento River would not be considered a significant impact on waters of the United States. There are no vernal pools or other seasonal wetlands present at any of the proposed augmentation sites. However, gravel augmentation could result in removal of riparian vegetation during construction of access routes to the gravel placement sites. To the extent feasible, existing access roads would be used, but access to some of the proposed placement sites does not currently exist. Clearing and grubbing would be needed to create access to these gravel placement sites, and in some areas, vegetation clearing along banks would be used to allow gravel to fall easily from the banks into the river. These activities could result in removal of riparian vegetation.

In addition, actions would be implemented to restore connectivity between the Sacramento River and the Reading Island side channel, to restore floodplain and riparian habitat in the Reading Island side channel, to rehabilitate the boat ramp at Reading Island, and to create a handicap fishing access area at Reading Island, as described in Chapter 2, "Alternatives."

Breaching or creating an engineered opening in the levee at Reading Island to restore flow from the Sacramento River to Anderson Slough would fall under NWP 27, "Aquatic Habitat Restoration, Establishment, and Enhancement." Rehabilitation of the existing boat ramp and construction of fishing access would also qualify for an NWP. Activities qualifying for NWPs have been determined by USACE to have no more than minimal adverse effects on the aquatic environment (72 Federal Register 11092). Therefore, these activities would not be considered to have a significant impact on waters of the United States. The Reading Island Restoration Plan would involve acquiring and revegetating floodplain terraces and adjacent riparian areas with native riparian vegetation. This is expected to provide a beneficial effect on floodplain and riparian habitat in the side channel. However, construction activities associated with restoring river connectivity, rehabilitating the boat ramp, or creating handicap fishing access could result in removal of riparian vegetation.

With implementation of the gravel augmentation program and habitat restoration, boat ramp rehabilitation, and fishing area construction at Reading Island, the impact on sensitive natural communities would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-12 (CP4): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area Vegetation removal and gravel placement could result in the loss of special-status plants if they are present, and implementing the Reading Island projects could result in the removal of riparian vegetation. This impact would be potentially significant.

Special-status plant species could be killed during vegetation clearing and grubbing or gravel placement if they are present at the gravel placement sites or areas that would be cleared for access. In addition, actions would be implemented to restore connectivity between the Sacramento River and the Reading Island side channel, to restore floodplain and riparian habitat in the Reading Island side channel, to rehabilitate the boat ramp at Reading Island, and to create a handicap fishing access area at Reading Island, as described in Chapter 2, "Alternatives." Special-status plants are not likely to be affected by rehabilitation of the boat ramp because it is an existing structure that would be accessed through existing paved surfaces. However, if special-status plant species are present on the levee or elsewhere on Reading Island, they could be killed during construction to restore connectivity between the Sacramento River and Anderson Slough or during construction of the handicap fishing access area.

Direct loss of special-status plants would be a potentially significant impact. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-13 (CP4): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area Implementing the gravel augmentation program could result in the spread of noxious and invasive weeds as a result of vegetation clearing and grubbing and an increased number of vectors. In addition, at Reading Island, actions would be implemented to restore connectivity between the Sacramento River and the Reading Island side channel, to restore floodplain and riparian habitat, to rehabilitate the boat ramp, and to create a handicap fishing access area at Reading Island. The activities at Reading Island could also result in the spread of noxious and invasive weeds as a result of vegetation clearing and grubbing and an increased number of vectors. This impact would be potentially significant.

Vegetation removal and grubbing at gravel placement sites and access routes could result in increased risk of introduction and spread of noxious and invasive weeds. The risk of introducing or spreading noxious weeds would vary depending on the proximity of existing noxious weed infestations, extent of ground-disturbing activities, and the amount of traffic entering a project site. Vectors that would increase as a result of project implementation include weed seed and seed parts brought in on tools, vehicles, and workers' clothing and boots. Vegetation clearing and construction of temporary access routes would increase the number of weed vectors in an area. As traffic along new and existing corridors increases, the risk for weed dispersal would increase. Seed mixtures and mulches may be used during erosion control efforts and revegetation of disturbed areas. These mixtures and mulches are potential vectors for noxious weed and invasive plant dispersal.

Reading Island restoration activities would include use of a mechanical harvester to remove invasive aquatic vegetation from the side channel and

Anderson Slough. This aspect of the restoration plan is expected to result in a beneficial effect by reducing the existing population of invasive aquatic plants. However, vegetation removal at the levee, boat ramp, and handicap fishing access construction sites and along 0.8 mile of the channel for conveyance could result in increased risk of introduction and spread of noxious and invasive weeds on Reading Island. The risk of introducing or spreading noxious weeds would vary depending on the proximity of existing noxious weed infestations, extent of ground-disturbing activities, and the amount of traffic entering a project site. Vectors that would increase as a result of project implementation include weed seed and seed parts brought in on tools, vehicles, and workers' clothing and boots. Vegetation clearing from the levee or for fishing access would increase the number of weed vectors in an area. As traffic along existing corridors increases, the risk for weed dispersal would increase. Seed mixtures and mulches used during erosion control efforts and revegetation of riparian areas are potential vectors for noxious weed and invasive plant dispersal.

Spread and introduction of noxious and invasive weeds would be a potentially significant impact. Mitigation for this impact is proposed in Section 12.3.5.

Lower Sacramento River and Delta

Impact Bot-14 (CP4): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with project implementation under CP4 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River, but these effects are unlikely to extend to the Delta; thus, this impact would be significant on the lower Sacramento River, and less than significant in the Delta.

This impact would be the same as Impact Bot-14 (CP1) and would be significant on the lower Sacramento River and less than significant in the Delta. Mitigation for this impact on the lower Sacramento River is proposed in Section 12.3.5.

Impact Bot-15 (CP4): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. Because CP4 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact on the lower Sacramento River would be potentially significant.

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-16 (CP4): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Along the Lower Sacrramento River and in the Delta Implementation of CP4 could increase water yield to water districts in the extended study area along the lower Sacramento River. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be the same as Impact Bot-16 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP4): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with implementation of CP4 could alter the structure and species composition or cause the loss of sensitive plant communities and of habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to alter the extent of early-successional riparian and wetland communities or associated habitats for special-status plant species. Therefore, this impact would be less than significant below CVP and SWP reservoirs in the extended study area.

This impact would be the same as Impact Bot-17 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP4): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of CP4 would not cause a significant impact on riparian vegetation and habitats. Therefore, CP4 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact in the CVP and SWP service areas would be less than significant.

This impact would be the same as Impact Bot-18 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP4): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP4 could increase water yield for water districts in the extended study area along the lower Sacramento River. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be the same as Impact Bot-19 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 would address both the primary and secondary planning objectives. In addition to the features common to all comprehensive plans, CP5 includes enlarging Shasta Dam 18.5 feet, which is consistent with the objectives of the 2000 CALFED ROD. CP5 also involves (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing either additional or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. Formulation of specific environmental restoration features and increased recreation components is included in the Draft Feasibility Report.

CP5 would also include implementing the same gravel augmentation program and the same riparian, floodplain, and side channel habitat restoration at Reading Island as described for CP4.

Shasta Lake and Vicinity

Impact Bot-1 (CP5): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact on Federally listed, State-listed, or candidate plant species would occur under CP5. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP5): Loss of MSCS Covered Species Implementation of the project could result in the loss of MSCS covered species as a result of ground-disturbing construction activities or inundation. Therefore, this impact would be significant.

This impact would be similar to Impact Bot-2 (CP3) and would therefore be significant.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the

proposed actions are developed. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-3 (CP5): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species Implementation of the project could result in the loss of USFS Sensitive, BLM Sensitive, or CRPR species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Bot-3 (CP3) and would be potentially significant.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-4 (CP5): Loss of Jurisdictional Waters Implementation of the project may result in the loss of jurisdictional waters because of flooding the impoundment area and fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine). This impact would be significant.

This impact would be similar to Impact Bot-4 (CP3) and would be significant.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-5 (CP5): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities. This impact would be potentially significant.

This impact would be similar to Impact Bot-5 (CP3) and would be potentially significant.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-6 (CP5): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds because of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). This impact would be potentially significant.

Impacts resulting from the spread of noxious weeds under CP5 are anticipated to be similar to those described for CP3. This impact would be potentially significant.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed. Mitigation for this impact is proposed in Section 12.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Bot-7 (CP5): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP5 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, this impact would be significant.

This impact would be the same as Impact Bot-7 (CP3) and would be significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-8 (CP5): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP5 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Bot-8 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-9 (CP5): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, such critical habitat is not expected to be adversely affected by CP5. This impact would be less than significant.

This impact would be the same as Impact Bot-9 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP5): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementation of CP5 could increase water yield to water districts in the primary study area along the upper Sacramento River. This increase in water yield could reduce a limitation on

growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be the same as Impact Bot-10 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP5): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or the Reading Island Restoration Plan, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area Implementing the gravel augmentation program could result in the removal of riparian and wetland vegetation or the degradation of riparian and wetland habitats, including wetlands qualifying as waters of the United States. Habitat restoration, boat ramp rehabilitation, and fishing area construction at Reading Island could remove riparian vegetation, or result in discharge of fill material into waters of the United States. This impact would be potentially significant.

This impact would be the same as Impact Bot-11 (CP4) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-12 (CP5): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area Vegetation removal and gravel placement could result in the loss of special-status plants if they are present, and implementing the Reading Island projects could result in the removal of riparian vegetation. This impact would be potentially significant.

This impact would be the same as Impact Bot-12 (CP4) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-13 (CP5): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program, Restoring Sacramento River Flow Through Anderson Slough, Rehabilitating the Reading Island Boat Ramp, or Constructing a Handicap Fishing Access Area Implementing the gravel augmentation program could result in the spread of noxious and invasive weeds as a result of vegetation clearing and grubbing and an increased number of vectors. In addition, at Reading Island, actions would be implemented to restore connectivity between the Sacramento River and the Reading Island side channel, to restore floodplain and riparian habitat, to rehabilitate the boat ramp, and to create a handicap fishing access area at Reading Island. The activities at Reading Island could also result in the spread of noxious and invasive weeds as a result of vegetation clearing and grubbing and an increased number of vectors. This impact would be potentially significant.

This impact would be the same as Impact Bot-13 (CP4) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Lower Sacramento River and Delta

Impact Bot-14 (CP5): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with project implementation under CP1 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River, but these effects are unlikely to extend to the Delta; thus, this impact would be significant on the lower Sacramento River, and less than significant in the Delta.

This impact would be the same as Impact Bot-14 (CP3) and would be significant on the lower Sacramento River and less than significant in the Delta. Mitigation for this impact on the lower Sacramento River is proposed in Section 12.3.5.

Impact Bot-15 (CP5): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. Because CP5 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact on the lower Sacramento River would be potentially significant.

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5.

Impact Bot-16 (CP5): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Along the Lower Sacramento River and in the Delta Implementation of CP5 could increase water yield for water districts in the extended study area along the lower Sacramento River. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be the same as Impact Bot-16 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP5): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with project implementation under CP5 could alter the structure and species composition or cause the loss of sensitive plant communities and of habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to alter the extent of early-successional riparian and wetland communities or associated habitats for special-status plant species. Therefore, this impact would be less than significant below CVP and SWP reservoirs in the extended study area.

This impact would be the same as Impact Bot-17 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP5): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of CP5 would not cause a significant impact on riparian vegetation and habitats. Therefore, CP5 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact in the CVP and SWP service areas would be less than significant.

This impact would be the same as Impact Bot-18 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP5): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP5 could increase water yield for water districts in the CVP and SWP service areas. This increase in water yield could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water yield for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be the same as Impact Bot-19 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

12.3.5 Mitigation Measures

Table 12-16 presents a summary of mitigation measures for botanical resources and wetlands.

Table 12-16. Summary of Mitigation Measures for Botanical Resources

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Bot-1: Loss of Federally or State Listed Plant Species	LOS before Mitigation	NI	NI	NI	NI	NI	NI
	Mitigation Measure	None required.	None needed; thus, none proposed.

Notes:
LOS = level of significance
LTS = less than significant
NA = not applicable
NI = no impact
PS = potentially significant
S = significant
SU = significant and unavoidable

No-Action Alternative

Under the No-Action Alternative, no action would be taken, including implementation of mitigation measures; rather, existing conditions would continue to change into the future. No mitigation is needed.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Bot-1 (CP1), Bot-9 (CP1), Bot-10 (CP1), Bot-11 (CP1) through Bot-13 (CP1), and Bot-16 (CP1) through Bot-19 (CP1). Mitigation is provided below for the remaining impacts of CP1 on botanical resources.

Mitigation Measure Bot-2 (CP1): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas

The following mitigation measures will reduce impacts on MSCS plants:

- When feasible in relocation areas, avoid or minimize actions that could result in harm or mortality to individuals or to the viability of populations.

- When feasible, Reclamation will relocate populations of MSCS plants that would be directly affected to suitable habitat within undisturbed portions of the Shasta Lake and vicinity portion of the primary study area.

- A mitigation and monitoring plan will be developed to monitor success of MSCS plant populations that have been relocated or revegetated. The plan will identify suitable sites for mitigation, species to be planted, and numbers and sizes of plantings. It will describe planting techniques, prescribe methods to remove existing noxious weeds, and establish reasonable performance standards and contingency measures. Further, it will establish conservation easements as appropriate. The vegetation restoration plan will be developed in consultation with the USACE, USFWS, USFS, and DFG.

- Where appropriate, MSCS covered plant species will be used for revegetation.

Implementation of this mitigation measure would reduce impacts on MSCS plant species; however, because successful relocation, transplanting, and artificial propagation of Shasta snow-wreath are unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of

mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-3 (CP1): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas The following mitigation measures will reduce impacts on USFS sensitive, BLM sensitive and CRPR plants:

When feasible in relocation areas, avoid or minimize actions that could result in harm or mortality to individuals or to the viability of populations.

- When feasible, Reclamation will relocate populations of USFS sensitive, BLM sensitive and CRPR plants that would be directly affected to suitable habitat within undisturbed portions of the Shasta Lake and vicinity portion of the primary study area.

- A mitigation and monitoring plan will be developed to monitor success of USFS sensitive, BLM sensitive, and CRPR plant populations that have been relocated or revegetated. The plan will identify suitable sites for mitigation, species to be planted, and numbers and sizes of plantings. It will describe planting techniques, prescribe methods to remove existing noxious weeds, and establish reasonable performance standards and contingency measures. Further, it will establish conservation easements as appropriate. The vegetation restoration plan will be developed in consultation with USACE, USFWS, USFS, and DFG.

- To the extent feasible, USFS sensitive, BLM sensitive, and CRPR plant species will be used for revegetation.

Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive, and CRPR plant species; however, because successful relocation and transplantation of these species are unproven, impacts would remain potentially significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-4 (CP1): Mitigate Loss of Jurisdictional Waters Specific mitigation measures have not been determined for this impact. Within relocation areas, jurisdictional waters of the United States will be avoided when feasible. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation will be provided in the FEIS. A discussion of

mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Until the details of this mitigation measure are developed, Impact Bot-4 (CP1) is considered significant and unavoidable.

Mitigation Measure Bot-5 (CP1): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of vegetation habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Potential mitigation lands containing comparable habitat in locations where these species are known to occur have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable. Until the details of this mitigation measure are developed, Impact Bot-5 (CP1) is considered significant and unavoidable.

Mitigation Measure Bot-6 (CP1): Develop a Weed Management Plan Reclamation will develop a weed management plan to avoid or minimize the potential for project-related impacts from noxious and invasive plants. This plan would include the following:

- Conduct annual weed monitoring of relocation and construction areas for three seasons after project completion.
- Design and implement appropriate USFS approved eradication methods for weed species detected.
- Treat and monitor existing source weed populations within and adjacent to construction and relocation areas.
- In relocation areas, seed disturbed soils with native grass and forb seeds to discourage occupation by noxious weeds.
- Include C Provision 6.35, Equipment Cleaning (4/04), in all contracts.

Use only weed-free road fill, gravel, mulches, and seed sources. Implementation of these measures would reduce Impact Bot-6 (CP1) to a less than significant level.

Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities Reclamation will develop and implement a riverine ecosystem mitigation and adaptive management plan to mitigate to the extent feasible any identified impacts of an altered Sacramento River flow regime on existing riparian and wetland communities, and associated instream, riparian, and wetland habitat values for aquatic and terrestrial special-status species along the Sacramento River from Shasta Dam to Colusa (River Mile 144). The plan will be consistent with and supporting implementation of the Senate Bill 1086 program, and will be developed in coordination with USFWS, the NMFS, DFG, and the Sacramento River Conservation Area Forum. The Plan will be developed before project construction. The plan is limited to the Sacramento River from Shasta Dam to Colusa (River Mile 144). The existing conditions as of 2010 are the baseline conditions.

The goals of the plan will be to result in no net reduction in the average amount of any of the following along the Sacramento River from Shasta Dam to Colusa:

- Channel migration in selected areas of natural vegetation dominated by native species
- Overbank inundation of natural vegetation dominated by native species in selected areas
- Regeneration of early-successional riparian vegetation (e.g., cottonwood regeneration) in selected areas

The riverine ecosystem mitigation plan will include all of the following elements:

- Modeling or monitoring at representative locations to quantify direct and indirect impacts resulting from adaptive management of project implementation. A method of quantifying impacts will be used that ensures repeatability.
- An evaluation of feasible modifications to the procedures for operating Shasta Dam (e.g., ramping rates) to do any of the following:
  - Reduce or eliminate adverse impacts on ecologically important bankfull and overbank flows (as feasible within existing flood reduction constraints)
  - Reduce or eliminate adverse impacts (e.g., reduction) on meander migration rates

  - Facilitate establishment of cottonwoods and early-successional vegetation at intervals sufficient to sustain cottonwoods and early-successional riparian vegetation along the Sacramento River riparian corridor and floodplain (e.g., at 5- to 15-year intervals)

  - Feasible modifications to operational procedures are those not in conflict with applicable laws, agreements, and regulations, or with the purpose of the project. Implementation of this mitigation measure cannot increase flood risk.

- A specific combination of mitigation actions will be developed and implemented to attain the plan's goals. Mitigation actions will consist of feasible modifications of dam operation procedures and/or funding of appropriate and feasible restoration actions that have been developed by Reclamation, other federal agencies, state or local governments, or private nonprofits and received applicable federal and state permits. Appropriate and feasible restoration actions do any of the following:

  - Enhance connectivity of river side channels (e.g., by modifying the elevation of secondary channels, remnant oxbows, or meander scars)

  - Expand the river meander zone at selected locations (e.g., by assisting in funding projects that meet this objective)

  - Increase floodplain connectivity (e.g., by assisting in funding projects that meet this objective)

  - Control and remove nonnative, invasive plant species from riparian areas to shift dominance to native species

  - Create riparian and wetland communities (e.g., through plantings)

  - Increase shaded riverine aquatic habitat (e.g., through plantings)

- The methods and results of an analysis demonstrating that a specified combination of mitigation actions should attain the plan's goals.

- The location of restoration actions specified in the combination of mitigation actions. Restoration actions will be performed on preserved sites and with funding for management in perpetuity. (Preserved sites include sites previously preserved by other entities.)

- Implementation mechanisms (i.e., mechanisms by which Reclamation will fund implementation) and criteria for implementing dam operation procedures that provide mitigation

- Parameters for preparation and content of restoration and management plans, or existing applicable plans.

At a minimum, mitigation in this plan will include the following:

- Feasible modifications to dam operation procedures identified as reducing adverse impacts on meander migration or ecologically important bankfull and overbank flows, or as facilitating cottonwood establishment

- Either of the following elements:

  – Provide actions or funding to increase meander migration, side-channel connectivity, or floodplain connectivity along the Sacramento River, and creation (or conversion of nonnative-dominated to native-dominated) of riparian or wetland communities

  – Provide mitigation that has been determined by USFWS, NMFS, and DFG to be of comparable or greater value and is included in the terms and conditions of permits for impacts on species listed as threatened or endangered by the State or Federal governments

Implementation of this mitigation measure would mitigate the impact of altered flow regimes on instream, riparian, and wetland communities, and thus would reduce Impact Bot-7 (CP1) to a less than significant level.

Mitigation Measure Bot-8 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP1) as described above. As described under Mitigation Measure Bot-7 (CP1), developing and implementing a riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the upper Sacramento River in the primary study area. Consequently, implementation of the previous mitigation measure would reduce Impact Bot-8 (CP1) to a less than significant level.

Mitigation Measure Bot-14 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP1) as described above. This mitigation measure involves developing and implementing of a riverine

ecosystem mitigation plan. Implementation of this mitigation measure would reduce Impact Bot-14 (CP1) to a less than significant level.

Mitigation Measure Bot-15 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP1) as described above. As described under Mitigation Measure Bot-7 (CP1), developing and implementing a riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the lower Sacramento River in the extended study area. Consequently, implementing the previous mitigation measure would reduce Impact Bot-15 (CP1) to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Bot-1 (CP2), Bot-9 (CP2), Bot-10 (CP2), Bot-11 (CP2) through Bot-13 (CP2), and Bot-16 (CP2) through Bot-19 (CP2). Mitigation is provided below for the remaining impacts of CP2 on botanical resources.

Mitigation Measure Bot-2 (CP2): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-2 (CP1). Implementation of this mitigation measure would reduce impacts on MSCS species; however, because relocation of these species is unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-3 (CP2): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive and CRPR plant species; however, because relocation of these species is unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of

mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-4 (CP2): Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-4 (CP1). Specific mitigation measures have not been determined for this impact. Within relocation areas, jurisdictional waters of the United States will be avoided when feasible. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Until the details of this mitigation measure are developed, Impact Bot-4 (CP2) is considered significant and unavoidable.

Mitigation Measure Bot-5 (CP2): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Specific mitigation measures have not been determined for this impact. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Until the details of this mitigation measure are developed, Impact Bot-5 (CP2) is considered significant and unavoidable.

Mitigation Measure Bot-6 (CP2): Develop a Weed Management Plan This mitigation measure is identical to Mitigation Measure Bot-6 (CP1). Implementation of this mitigation measure would reduce Impact Bot-6 (CP2) to a less than significant level.

Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP1), except that mitigation in the riverine ecosystem mitigation plan will include either of the following elements:

- Increased meander migration, side-channel connectivity, or floodplain connectivity along the Sacramento River, and creation (or conversion from nonnative-dominated to native-dominated) of riparian or wetland communities

- Mitigation that has been determined by USFWS, NMFS, and DFG to be of comparable or greater value and is included in the terms and

conditions of permits for impacts on species listed as threatened or endangered by the State or Federal government

Implementation of this mitigation measure would reduce Impact Bot-7 (CP2) to a less than significant level.

Mitigation Measure Bot-8 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP2) as described above. Developing and implementing this riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the upper Sacramento River in the primary study area. Implementation of this mitigation measure would reduce Impact Bot-8 (CP2) to a less than significant level.

Mitigation Measure Bot-14 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP2). This mitigation measure involves the development and implementation of a riverine ecosystem mitigation plan. Implementation of this mitigation measure would reduce Impact Bot-14 (CP2) to a less than significant level.

Mitigation Measure Bot-15 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP2) as described above. Developing and implementing this riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the lower Sacramento River in the extended study area. This mitigation measure is identical to Mitigation Measure Bot-7 (CP2). Implementation of this mitigation measure would reduce Impact Bot-15 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impacts Bot-1 (CP3), Bot-9 (CP3), Bot-10 (CP3), Bot-11 (CP3) through Bot-13 (CP3), and Bot-16 (CP3) through Bot-19 (CP3). Mitigation is provided below for the remaining impacts of CP3 on botanical resources.

Mitigation Measure Bot-2 (CP3): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-2 (CP1). Implementation of this mitigation measure would reduce impacts on MSCS species; however, because relocation of these species is unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-3 (CP3): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive and CRPR plant species; however, because relocation of these species is unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-4 (CP3): Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-4 (CP1). Specific mitigation measures have not been determined for this impact. Within relocation areas, jurisdictional waters of the United States will be avoided when feasible. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Until the details of this mitigation measure are developed, Impact Bot-4 (CP3) is considered significant and unavoidable.

Mitigation Measure Bot-5 (CP3): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Specific mitigation measures have not been determined for this impact. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be

provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Until the details of this mitigation measure are developed, Impact Bot-5 (CP3) is considered significant and unavoidable.

Mitigation Measure Bot-6 (CP3): Develop a Weed Management Plan This mitigation measure is identical to Mitigation Measure Bot-6 (CP1). Implementation of this mitigation measure would reduce Impact Bot-6 (CP3) to a less than significant level.

Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP1), except that mitigation in the riverine ecosystem mitigation plan will include either of the following elements:

- Increased meander migration, side-channel connectivity, or floodplain connectivity along the Sacramento River, and creation (or conversion from nonnative-dominated to native-dominated) of riparian or wetland communities

- Mitigation that has been determined by USFWS, NMFS, and DFG to be of comparable or greater value and is included in the terms and conditions of permits for impacts on species listed as threatened or endangered by the State or Federal government.

Implementation of this mitigation measure would reduce Impact Bot-7 (CP3) to a less than significant level.

Mitigation Measure Bot-8 (CP3): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP3) as described above. The development and implementation of this riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the upper Sacramento River in the primary study area. Implementation of this mitigation measure would reduce Impact Bot-8 (CP3) to a less than significant level.

Mitigation Measure Bot-14 (CP3): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). This mitigation measure involves the development and implementation of a riverine ecosystem mitigation plan. Implementation of this mitigation measure would reduce Impact Bot-14 (CP3) to a less than significant level.

Mitigation Measure Bot-15 (CP3): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP3) as described above. The development and implementation of this riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the lower Sacramento River in the extended study area. Implementation of this mitigation measure would reduce Impact Bot-15 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts Bot-1 (CP4), Bot-9 (CP4), Bot-10 (CP4), and Bot-16 (CP4) through Bot-19 (CP4). Mitigation is provided below for the remaining impacts of CP4 on botanical resources.

Mitigation Measure Bot-2 (CP4): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-2 (CP1). Implementation of this mitigation measure would reduce impacts on MSCS species; however, because relocation of these species is unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-3 (CP4): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive and CRPR plant species; however, because relocation of these species is unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-4 (CP4): Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-4 (CP1). Specific mitigation measures have not been determined for this impact. Within relocation areas, jurisdictional waters of the United States will be avoided when feasible. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Until the details of this mitigation measure are developed, Impact Bot-4 (CP4) is considered significant and unavoidable.

Mitigation Measure Bot-5 (CP4): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Specific mitigation measures have not been determined for this impact. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Until the details of this mitigation measure are developed, Impact Bot-5 (CP4) is considered significant and unavoidable.

Mitigation Measure Bot-6 (CP4): Develop a Weed Management Plan This mitigation measure is identical to Mitigation Measure Bot-6 (CP1). Implementation of this mitigation measure would reduce Impact Bot-6 (CP4) to a less than significant level.

Mitigation Measure Bot-7 (CP4): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Bot-7 (CP4) to a less than significant level.

Mitigation Measure Bot-8 (CP4): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Bot-8 (CP4) to a less than significant level.

Mitigation Measure Bot-11 (CP4): Revegetate Disturbed Areas, Consult with DFG Reclamation will implement the following measures to reduce and compensate for loss of sensitive natural communities:

- Before removing any vegetation at the augmentation sites and access areas, a survey will be conducted to map and classify the natural communities present in these areas, including wetland communities.

- Augmentation access will be designed to avoid disturbing wetland plant communities to the extent feasible. Removal of mature riparian vegetation and other sensitive vegetation will be minimized to the extent possible while still allowing access to gravel augmentation sites.

- DFG will be consulted with to determine if a Section 1602 streambed alteration agreement will be required for the gravel augmentation activities affecting the bed and bank of the Sacramento River and side channels.

- Staging and gravel and equipment storage will be confined to developed or disturbed areas to the extent feasible.

- A revegetation plan will be prepared to restore native vegetation in all areas cleared to implement the gravel augmentation program immediately following completion of the gravel augmentation activities at each augmentation site. The revegetation plan will include performance standards and success criteria to ensure that mitigation habitat would be successfully maintained and result in no net loss of sensitive natural communities, including riparian vegetation.

- Implement all conditions of the streambed alteration agreement to the satisfaction of DFG, subject to limitations on its authority set forth in Fish and Game Code Section 1600 et seq.

In addition, Reclamation will implement the following measures to reduce and compensate for potential loss of sensitive natural communities from the Reading Island Plan:

- A survey will be conducted before removing any vegetation at the augmentation sites and access areas, to map and classify the natural

communities present in restoration and potential construction areas at Reading Island.

- DFG will be consulted with to determine if a Section 1602 streambed alteration agreement will be required for the Reading Island restoration and construction activities affecting the bed and bank of the Sacramento River and side channel.

- Handicap fishing access will be designed to avoid disturbing sensitive plant communities to the extent feasible. A 100-foot no disturbance buffer shall be established around sensitive plant communities that are to be avoided during construction. Removal of mature riparian vegetation and other sensitive vegetation will be minimized to the extent possible.

- Staging, equipment storage, and construction access for Reading Island activities will be confined to existing roads and parking lots.

- Native riparian and other sensitive vegetation, if any, removed from the levee, boat ramp, and fishing access sites will be replaced on a no-net-loss basis. Riparian vegetation will be replaced through planting and establishment of comparable native riparian vegetation along the side channel floodplain. Other sensitive plant communities may be replaced through restoration of comparable native vegetation at other sites on Reading Island.

- Planting mix, composition, and density will be determined by a more detailed site analysis, but could include native cottonwood, willow, box elder, valley oak, western sycamore, elderberry, and a variety of understory brush species. Temporary irrigation will be provided on an as-needed basis.

Implement all conditions of the streambed alteration agreement to the satisfaction of DFG, subject to limitations on its authority set forth in Fish and Game Code Section 1600 et seq.

Implementation of this mitigation measure would reduce Impact Bot-11 (CP4) to a less than significant level.

Mitigation Measure Bot-12 (CP4): Conduct Preconstruction Surveys for Special-Status Plants and Avoid Special-Status Plant Populations During Construction Reclamation will implement the following measures to avoid impacts on special-status plants from resulting from the gravel augmentation program:

- Botanists will be hired to conduct protocol-level special-status plant surveys before commencing any construction activities that could disturb vegetation.

- All special-status plants identified within 250 feet of the proposed augmentation sites will be mapped and identified for avoidance. Access routes and gravel placement will be designed to avoid impacts on special-status plants.

- Fencing will be installed a minimum of 100 feet from special-status plants and no project activity will be permitted within the area occupied by special-status plants or the 100-foot buffer area around these plants.

- Insecticides, herbicides, fertilizers, or other chemicals that might harm special-status plants will not be used within 100 feet of the plants. Roadways and disturbed areas within 100 feet of special-status plants will be watered at least twice a day and as needed to minimize dust emissions.

In addition, Reclamation will implement the following measures to avoid impacts on special-status plants resulting from the Reading Island Plan:

- Qualified botanists will be hired to conduct protocol-level special-status plant surveys before commencing any construction activities that could disturb vegetation.

- All special-status plants identified within 250 feet of the proposed augmentation sites will be mapped and avoided to the extent feasible. It is unlikely that special-status plants are present on the levee, but if they are, it may not be possible to avoid them and still be able to breach the levee and restore connectivity to the Sacramento River. Handicap fishing access and boat ramp rehabilitation activities shall avoid special-status plants. Protective fencing will be installed around special-status plant locations and a 100-foot buffer zone during construction activities.

- Insecticides, herbicides, fertilizers, or other chemicals that might harm special-status plants will not be used within 100 feet of special-status plants. Roadways and disturbed areas within 100 feet of special-status plants will be watered at least twice a day and as needed to minimize dust emissions.

Implementation of this mitigation measure would reduce Impact Bot-12 (CP4) to a less than significant level.

Mitigation Measure Bot-13 (CP4): Implement Weed Management Measures and Revegetation Reclamation will implement the following measures to reduce the risk of introducing and spreading noxious weeds or invasive plant species during gravel augmentation or implementation of the Reading Island Plan:

- Before conducting gravel augmentation activities, invasive plant and noxious weed infestations will be identified and mapped within the augmentation sites, including vegetation clearing sites.

- Noxious weeds will be removed at the onset of construction and disposed of properly. If noxious weeds are not removed at the onset of construction, they will be fenced and avoided during construction.

- Any clothing, footwear, and equipment used during construction will be ensured free of soil, seeds, vegetative matter or other debris or potential seed-bearing material before entering the project sites or before moving from infested sites to uninfested sites.

- Mitigation Measure Bot-11 (CP4) will be implemented to restore native vegetation in all areas disturbed by gravel placement and construction of access routes immediately following completion of the gravel augmentation activities at each augmentation site.

- Only weed-free gravel, fill soil, mulch, seed mixes, and straw materials will be used during construction, implementation of BMPs, and post construction revegetation. Certified weed-free material will be used if available.

Implementation of this mitigation measure would reduce Impact Bot-13 (CP4) to a less than significant level.

Mitigation Measure Bot-14 (CP4): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Bot-14 (CP4) to a less than significant level.

Mitigation Measure Bot-15 (CP4): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Bot-15 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts Bot-1 (CP5), Bot-9 (CP5), Bot-10 (CP5), and Bot-16 (CP5) through Bot-19 (CP5). Mitigation is provided below for the remaining impacts of CP5 on botanical resources.

Mitigation Measure Bot-2 (CP5): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-2 (CP1). Implementation of this mitigation measure would reduce impacts on MSCS species; however, because relocation of these species is unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-3 (CP5): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive and CRPR plant species; however, because relocation of these species is unproven, impacts would remain significant and unavoidable.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-4 (CP5): Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-4 (CP1). Specific mitigation measures have not been determined for this impact. Within relocation areas, jurisdictional waters of the United States will be avoided when feasible. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Until the details of this mitigation measure are developed, Impact Bot-4 (CP5) is considered significant and unavoidable.

Mitigation Measure Bot-5 (CP5): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats This mitigation measure is identical

to Mitigation Measure Bot-3 (CP1). Specific mitigation measures have not been determined for this impact. Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation and at what ratios will be provided in the FEIS. A discussion of mitigation for loss of habitat through preservation and enhancement in mitigation areas will be included in the FEIS.

Mitigation Measure Bot-6 (CP5): Develop a Weed Management Plan This mitigation measure is identical to Mitigation Measure Bot-6 (CP1). Implementation of this mitigation measure would reduce Impact Bot-6 (CP5) to a less than significant level.

Mitigation Measure Bot-7 (CP5): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Bot-7 (CP5) to a less than significant level.

Mitigation Measure Bot-8 (CP5): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Bot-8 (CP5) to a less than significant level.

Mitigation Measure Bot-11 (CP5): Revegetate Disturbed Areas; Consult with DFG This mitigation measure is identical to Mitigation Measure Bot-11 (CP4). Implementation of this mitigation measure would reduce Impact Bot-11 (CP5) to a less than significant level.

Mitigation Measure Bot-12 (CP5): Conduct Preconstruction Surveys for Special-Status Plants and Avoid Special-Status Plant Populations During Construction This mitigation measure is identical to Mitigation Measure Bot-12 (CP4). Implementation of this mitigation measure would reduce Impact Bot-12 (CP5) to a less than significant level.

Mitigation Measure Bot-13 (CP5): Implement Weed Management Measures and Revegetation This mitigation measure is identical to Mitigation Measure Bot-13 (CP4). Implementation of this mitigation measure would reduce Impact Bot-13 (CP5) to a less than significant level.

Mitigation Measure Bot-14 (CP5): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This

mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Bot-14 (CP5) to a less than significant level.

Mitigation Measure Bot-15 (CP5): Implement Mitigation Measure Bot-7 (CP3): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Bot-15 (CP5) to a less than significant level.

12.3.6 Cumulative Effects

A large number of past actions have occurred in the study area. These past actions have substantially degraded botanical resources within the primary and extended study areas. This degradation is indicated by the number of species that have been listed as threatened or endangered under the CESA and Federal ESA, and by the large portion of all native plant species that are now listed by CNPS as rare, threatened, or endangered, or that are now on CNPS watch or review lists.

Past actions have caused these effects by converting habitat to developed or agricultural land uses, altering biotic interactions or physical processes, and damaging or causing mortality from human activities (e.g., vegetation removal during road, levee, or utility maintenance).

Most botanical resources in the study area have been adversely affected by most of the mechanisms described above (i.e., conversion of habitat to developed or agricultural land uses, the spread of invasive species, alteration of physical processes, and human disturbance). Overall, these botanical resources have been substantially degraded by past actions, and past actions are continuing to affect them. In particular, the geographic range and abundance (and thus the effects) of many nonnative, invasive plant species that were introduced into the study area in the past are still rapidly increasing.

The construction of Shasta Dam and the subsequent flooding of the area now known as Shasta Lake affected botanical and wildlife resources endemic to the region. For example, based on existing population locations, Shasta snow-wreath populations may have connected at the confluence of the Pit, Squaw, McCloud, and Sacramento rivers before inundation. The creation of Shasta Lake fragmented this species habitat and populations. As a result, these populations are more vulnerable to extirpation.

The effects of climate change on operations at Shasta Lake could potentially affect botanical resources both at the lake and downstream. As described in the Climate Change Projection Appendix, climate change could result in higher reservoir releases in the future because of an increase in winter and early-spring

inflow into the lake from high-intensity storm events. The change in reservoir releases could be necessary to manage for flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in flooding frequency and acreages and distribution of vegetation.

Shasta Lake and Vicinity

As described in Section 12.3, without mitigation, CP1 through CP5 could cause potentially significant effects on botanical and wetland resources in the primary and extended study areas. These effects could be caused by project construction activities; increased elevations of the water surface of Shasta Lake; and alteration of the flow regime of the Sacramento River and associated geomorphic processes, and thus of riparian vegetation. Although causing similar effects, CP1 – CP5 differ in the magnitude of their effects. At Shasta Lake and its vicinity, these potential adverse effects would be similar for all alternatives, but differ with the height of the dam raise: the effects of CP2 would be greater than CP1, but less than CP3 – CP5 (which would be identical). Along the upper Sacramento River and in the extended study area, potential adverse effects would be the result of altered flow regimes and would differ with both the height of the dam raise and operation of the dam: the effects of CP2 would be greater than CP1 and CP4 (which would be identical), but less than CP3 and CP5 (which also would have identical effects).

At Shasta Lake and vicinity, CP1 through CP5 would cause the loss of MSCS Covered Species, USFS sensitive, BLM sensitive, or CRPR Species, Jurisdictional Waters, and general habitats, and could cause the spread of noxious and invasive weeds. The mitigation measures described in Section 12.3.6 would reduce impacts on botanical and wetland resources. However, the adverse effects of CP1 through CP5 caused by construction activities and inundation would not be eliminated, with the exception of noxious and invasive weed impacts (Impact Bot-6). Because the overall effect of past actions on wetland and botanical resources has been cumulatively significant, and the likely additional effects of reasonably foreseeable future actions on these at Shasta Lake and in its vicinity, the adverse effects under CP1 through CP5 (except Impact Bot-6) would potentially be cumulatively considerable and these effects would be potentially cumulatively significant. Because mitigation measures to control the spread of weeds would effectively address the project's impact, however; CP1 through CP5 would not make a cumulatively considerable incremental contribution to an overall significant cumulative impact on plants and wetlands.

Upper Sacramento River and Extended Study Area

Along the Sacramento River and other rivers downstream from CVP and SWP reservoirs, substantial past alterations to geomorphic processes, vegetation, and associated habitats have resulted in an overall significant and substantial effect on these resources. Therefore, additional adverse effects would be cumulatively considerable. This adverse effect would be the result of the continued

consequences of past actions (e.g., construction of Shasta Dam and introduction of nonnative species), and of present and foreseeable water resource and levee actions whose adverse effects may not be fully mitigated.

Most adverse effects that are the continued consequences of past actions have been considered in the development of existing local and regional plans. Consequently, with respect to local and regional plans, there does not already exist an overall significant cumulative effect. However, the adverse effects of all present and reasonably foreseeable water resources and levee actions are not likely to be avoided or fully mitigated. The unmitigated effects of these actions could be sufficiently considerable to have a significant cumulative effect overall.

Habitat loss along the upper Sacramento River and in the extended study area has already resulted in an overall effect on sensitive communities and special-status plants that is significant and substantial. (It is the primary reason that a large number of plant species along the upper Sacramento River and in the extended study area have been listed as threatened or endangered by the State or Federal governments, or have been designated rare, threatened, or endangered by CNPS (i.e., placed on CNPS list 1B).)

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability As described in Chapter 2, "Alternatives" without mitigation, by altering the flow regime and associated geomorphic processes on the Sacramento River, CP1 could affect sensitive plant communities and special-status species (Impact Bot-7 (CP1) and Bot-14 (CP1)) and could potentially affect regional or local plans with objectives of riparian habitat protection or watershed management (Impact Bot-8 (CP1) and Bot-15 (CP1)). These effects could occur on the upper Sacramento River and portions of the lower Sacramento River. Because substantial past alterations to geomorphic processes, vegetation, and associated habitats along the Sacramento River have resulted in an overall significant cumulative effect on these resources, additional adverse effects would be cumulatively considerable. However, with the implementation of Mitigation Measure Bot-7 (CP1), adverse effects from CP1 on botanical resources along the Sacramento River would be fully mitigated. Thus, CP1 would not result in a cumulatively considerable incremental effect on these resources, and the potential to affect regional or local plans would also be eliminated. Therefore, these effects of CP1 would not be cumulatively significant.

By altering the flow regimes below CVP and SWP reservoirs in the extended study area, CP1 could possibly cause similar effects on these rivers as along the Sacramento River. (These effects were identified as Impacts Bot-17 (CP1) and Bot-18 (CP1).) However, the alteration of these flow regimes would be less extensive than along the Sacramento River. Even without mitigation, the effects of CP1 on these rivers might not be sufficient to alter the extent or species composition of sensitive communities or to alter the habitats of special-status

plant species. In addition, Mitigation Measure Aqua-15 (CP1), "Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements," would reduce these effects to a level that is unlikely to alter the extent or species composition of sensitive communities or to alter the extent or quality of habitat for special-status plant species. Therefore, these effects of CP1 would not be a cumulatively considerable incremental contribution to a significant cumulative impact.

By altering flow regimes on the upper Sacramento River, CP1 also could affect designated critical habitat for special-status species of vernal pool habitats (Impact Bot-9 (CP1)). However, vernal pool plant communities and associated special-status species likely would not be affected by any of the alternatives. Therefore, the project would not have a cumulatively considerable effect, and would not be cumulatively significant.

Along the upper Sacramento River and in the extended study area, CP1 could induce growth that results in the loss of sensitive plant communities and special-status plant species (Impacts Bot-10 (CP1), Bot-16 (CP1), and Bot-19 (CP1)). Habitat loss has resulted in an overall significant cumulative effect on sensitive communities and special-status plants that is substantial. (It is the primary reason that a large number of plant species along the upper Sacramento River and in the extended study area have been listed as threatened or endangered by the State or Federal governments, or have been designated rare, threatened or endangered by CNPS (i.e., placed on CNPS list 1B).) CP1 could induce growth-related effects because it would increase water yield to water districts, and this could reduce a limitation on growth. For example, most CVP water supports agricultural purposes, and agricultural acreages are not expected to increase substantially over time. However, some increment of the CVP water could be used for municipal and industrial contractors, such as Contra Costa Water District or Santa Clara Valley Water District. In this case, some growth-related effects could occur from development and have an incremental effect on botanical resources. Present and foreseeable future projects are also likely to add to this habitat loss. Although the future effects of any growth-related effects induced by CP1 would be analyzed and mitigated during land use planning and environmental review for site-specific development projects, it is unlikely that all effects would be avoided or fully mitigated. Therefore, CP1 would make a small incremental, but cumulatively considerable, contribution to an existing overall significant cumulative impact. This would be a cumulatively significant and unavoidable effect.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream vegetation. Potentially significant effects on vegetation and special-status species that would occur with implementation of CP1 could contribute to potentially significant affects of climate change on habitat acreages and distribution. Although mitigation measures listed above would be

implemented to reduce project-related impacts of CP1, CP1 would still make a considerable contribution to a potentially significant cumulative effect on botanical resources.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability The cumulative effects of CP2 would be similar to those of CP1, but greater in magnitude (because CP2 would entail more substantial alterations of flow regimes). Although greater in magnitude than the effects of CP1, the effects of CP2 on sensitive plant communities and special-status species along the upper Sacramento River and in the extended study area (Impacts Bot-7 (CP2), Bot-14 (CP2), and Bot-17 (CP2)), and potential effects on regional or local plans with objectives of riparian habitat protection or watershed management (Impacts Bot-8 (CP2), Bot-15 (CP2), and Bot-18 (CP2)) would not be considerable for the same reasons given for CP1. These would not be cumulatively significant effects.

Similarly, although greater in magnitude than the effects of CP1, the effects of CP2 on designated critical habitat for special-status species of vernal pool habitats (Impact Bot-9 (CP2)) would not be considerable for the same reasons given for CP1. This would not be a cumulatively significant effect.

Also similar to CP1, along the upper Sacramento River and in the extended study area, CP2 could cause growth-related effects that result in the loss of sensitive plant communities and special-status plant species (Impacts Bot-10 (CP2), Bot-16 (CP2), and Bot-19 (CP2)). However, the potential for CP2 to cause growth-related effects would be greater than for CP1. For the same reasons given for CP1, CP2 would make a small incremental, but cumulatively considerable, contribution to an existing overall significant cumulative impact. This would be a cumulatively significant and unavoidable effect.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream vegetation. Potentially significant effects on vegetation and special-status species that would occur with implementation of CP2 could contribute to potentially significant affects of climate change on habitat acreages and distribution. Although mitigation measures listed above would be implemented to reduce project-related impacts of CP2, CP2 would still make a considerable contribution to a potentially significant cumulative effect on botanical resources.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply The cumulative effects of CP3 would be similar to those of CP1 and CP2, but greater in magnitude. Although greater in magnitude than the effects of CP1 or CP2 (because CP3 would entail more substantial alterations of flow regimes), the effects of CP3 on sensitive plant communities and special-status species along the upper Sacramento River and in the extended study area (Impacts Bot-7 (CP3), Bot-14 (CP3), and Bot-17 (CP3)), and potential effects on regional or

local plans with objectives of riparian habitat protection or watershed management (Impacts Bot-8 (CP3), Bot-15 (CP3), and Bot-18 (CP3)) would not be considerable for the same reasons given for CP1. These would not be cumulatively significant effects.

Similarly, although greater in magnitude than the effects of CP1 or CP2, the effects of CP3 on designated critical habitat for special-status species of vernal pool habitats (Impact Bot-9 (CP3)) would not be considerable for the same reasons given for CP1. This would not be a cumulatively significant effect.

Also similar to CP1 and CP2, along the upper Sacramento River and in the extended study area, CP3 could cause growth-related effects that result in the loss of sensitive plant communities and special-status plant species (Impacts Bot-10 (CP3), Bot-16 (CP3), and Bot-19 (CP3)). However, the potential for CP3 to cause growth-related effects would be greater than for CP1 or CP2. For the same reasons given for CP1, CP3 would make a small incremental, but cumulatively considerable, contribution to an existing overall significant cumulative impact. This would be a cumulatively significant and unavoidable effect.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream vegetation. Potentially significant effects on vegetation and special-status species that would occur with implementation of CP3 could contribute to potentially significant affects of climate change on habitat acreages and distribution. Although mitigation measures listed above would be implemented to reduce project-related impacts of CP3, CP3 would still make a considerable contribution to a potentially significant cumulative effect on botanical resources.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability The cumulative effects of CP4 would be identical to those of CP3.

CP5 – 18.5-Foot Dam Raise, Combination Plan The cumulative effects of CP5 would be identical to those of CP3.

Chapter 13
Wildlife Resources

13.1 Affected Environment

This secetion deescribes the affected environment related to wildlife resources, including special-status species, for the dam and reservoir modifications proposed under the SLWRI. For a more in-depth description, see the *Wildlife Resources Technical Report.*

Shasta Dam and Shasta Lake are located on the upper Sacramento River in Northern California. Shasta Dam is located approximately 9 miles northwest of Redding, and the dam and entire reservoir are located in Shasta County. Elevations in the Shasta Lake vicinity portion of the primary study area range between approximately 1,070 and 1,200 feet, and the terrain is moderate to steep.

The wildlife resources setting for the Shasta Lake and vicinity portion of the primary study area consists of the impoundment area (five arms and the main body of Shasta Lake) and the relocation areas (Figure 13-1). The Shasta Lake and vicinity portion of the primary study area is composed of Shasta Dam and Shasta Lake and the lower reaches of the tributaries draining into Shasta Lake. In the initial phase of the SLWRI, 13 streams and rivers were selected to represent the diverse characteristics of the rivers and streams that flow into Shasta Lake.

Reclamation established project boundaries for focused surveys in the area that would be subject to inundation under various enlargement scenarios. The lower boundary corresponds to the current full-pool elevation defined by Reclamation (1,070-foot mean sea level (msl) contour line). The upper boundary was established using the 1,090-foot msl contour line around the entire lake. This area is hereafter referred to as the “impoundment area” (Figure 13-1).

To examine the physical and biological resources along riverine reaches that would be subject to inundation if Shasta Dam were enlarged, reaches of 11 streams and rivers that are tributary to Shasta Lake were also incorporated into the Shasta Lake and vicinity portion of the primary study area. These streams were selected by Reclamation in conjunction with USFS as an initial sampling of streams representative of riverine and riparian habitats.

Areas subject to physical disturbance as an indirect result of the proposed project (i.e., areas proposed as relocation sites for roadways, bridges, utilities,

and campgrounds that would be inundated subsequent to the enlargement of Shasta Dam as well as proposed dike locations) were incorporated into the Shasta Lake and vicinity portion of the primary study area. These locations are hereafter referred to as "relocation areas" (Figure 13-1).

For the purposes of this investigation, approximate acreages for habitat types are reported by arm of the lake. For a relocation area that falls between two arms, the area is included with the arm that has the most acreage of the vegetation type or water of the United States.

Descriptions of biological resources were derived primarily from the following sources:

- *Shasta Lake Water Resources Investigation Mission Statement Milestone Report* (Reclamation 2003)
- *Shasta Lake Water Resources Investigation Initial Alternatives Information Report* (Reclamation 2004)
- Chapter 3, "Biological Environment," in the *Draft Shasta Lake Water Resources Investigation Plan Formulation Report* (Reclamation 2007)
- USFWS Endangered Species Database (USFWS 2007a)
- The California Natural Diversity Database (CNDDB) (2011)

Several attachments to the *Wildlife Resources Technical Report* provide detailed lists and descriptions of special-status wildlife species present in the primary and extended study areas:

- Attachment 1, "Special-Status Wildlife Species Potentially Occurring in the Shasta Lake and Vicinity Portion of the Primary Study Area"
- Attachment 2, "Species Accounts for Special-Status Wildlife in the Shasta Lake and Vicinity Portion of the Primary Study Area"
- Attachment 3, "Breeding Bird Survey Results – 2007"
- Attachment 4, "Species Accounts for Special-Status Wildlife in the Primary Study Area Downstream from Shasta Dam"
- Attachment 5, "State and Federal Lists of Special-Status Wildlife Species in the Vicinity of the Primary Study Area"
- Attachment 6, "Special-Status Wildlife Species with Potential to Occur in the Primary and Extended Study Areas by Area"
- Attachment 7, "List of All Sensitive Wildlife Species in the Extended Study Area Reported to the CNDDB"

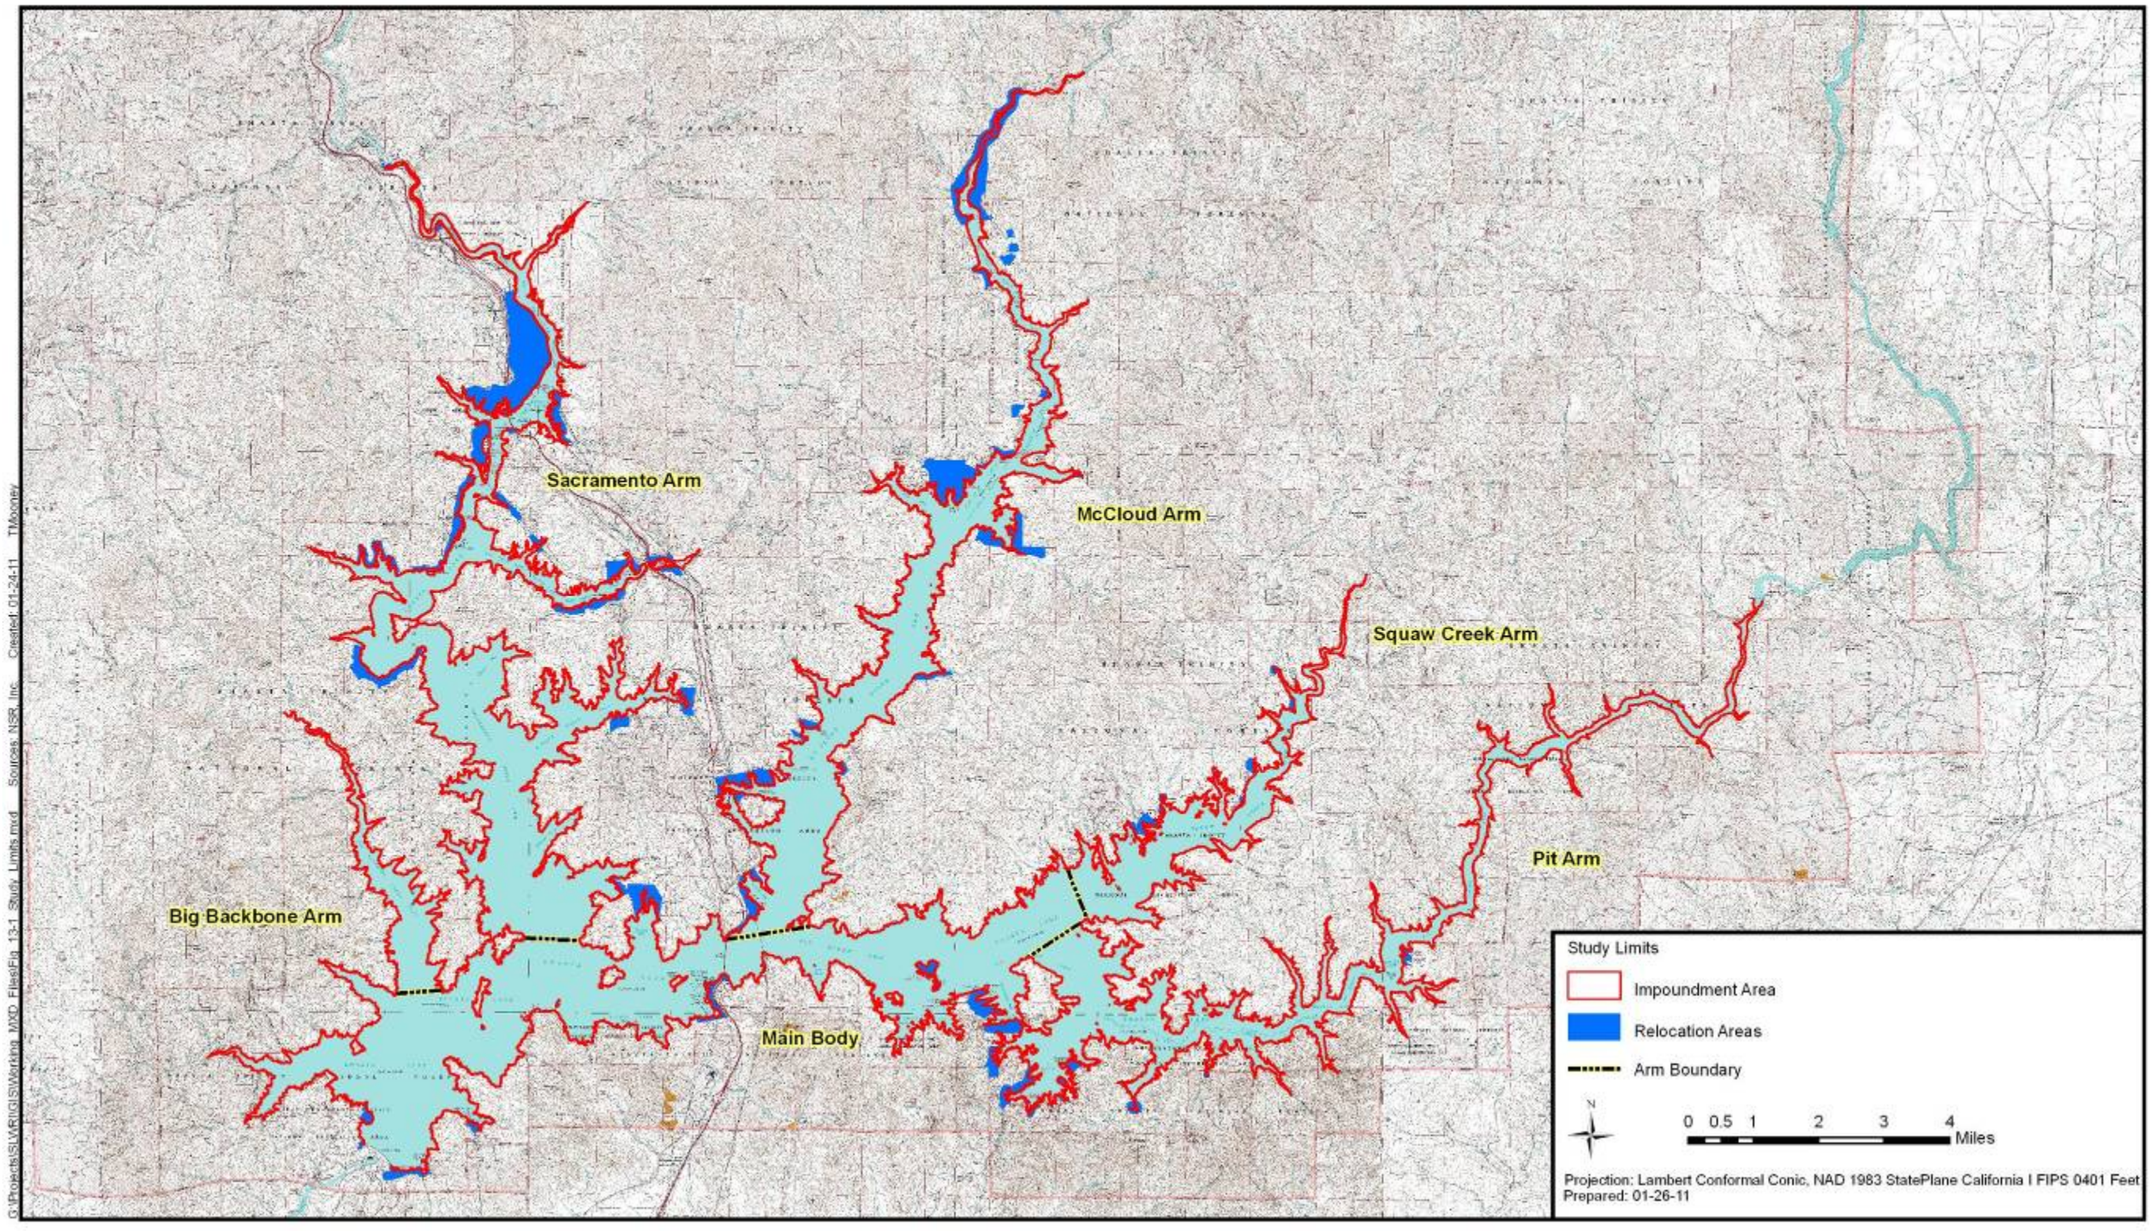

Figure 13-1. Study Limits

13.1.1 Wildlife

Shasta Lake and Vicinity

Wildlife resources described in this chapter result from the wealth and diversity of climatic and vegetative associations in and adjacent to the Shasta Lake and vicinity portion of the primary study area. Influences from the Coast Ranges, the southern Cascade Range, the northern Sierra Nevada, the Great Basin, and the Central Valley provide for a unique mix of biota. Much of this region, especially in the Central Valley, has been modified by past and present land uses.

Prior to Euro-American settlement, the area was dominated by riparian vegetation in the annual floodplains, with stands of valley oak (*Quercus lobata*) and interior live oak (*Q. wislizenii*) on higher ground. Herbaceous wetland bottoms and upland native grassland communities were common in this vegetation mosaic. The extensive oak forests and riparian/wetland habitats hosted a diverse and abundant wildlife community. Cattle grazing, deforestation of the oak woodlands, water development, flood protection, and expansion of agriculture onto the floodplains in the early to mid-1800s substantially altered the historical floodplain and channel vegetation.

Rural development, fire suppression, recreation, and wildfires have affected the population and distribution of wildlife in this area. Fire suppression, which has generally increased understory vegetation, has had mixed effects on wildlife. Bear, deer, and birds that prefer near-ground vegetation for food and cover have generally benefited, whereas birds requiring aerial foraging habitat, such as the golden eagle (*Aquila chrysaetos*), American peregrine falcon (*Falco peregrinus anatum*), and great horned owl (*Bubo virginianus*), have declined. Species that have adapted or thrived in the altered human environment include coyotes (*Canis latrans*), raccoons (*Procyon lotor*), and various other late-successional species. The quality of potential bat habitat, found primarily in the limestone formations to the north and east of Shasta Lake, has suffered from increased use by recreational rock climbers and spelunkers. Wildlife may also be affected by fragmented travel corridors in certain portions of the area that prevent species from moving between remaining suitable habitats.

Wildlife Habitats The Shasta Lake and vicinity portion of the primary study area is characterized by a variety of habitats typical of transitional mixed woodland and low-elevation forest. These habitats were mapped and classified using the *Guide to Wildlife Habitats of California* (Mayer and Laudenslayer 1988). Habitats present in the Shasta Lake and vicinity portion of the primary study area are summarized in Table 13-1 and Table 13-2. The locations of each type are depicted in Figures 13-2a through 13-2f. The wildlife species typical of each of these communities are described below.

Table 13-1. Summary of Wildlife Habitats in the Impoundment Area

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm

Annual Grassland Annual grassland is uncommon in the Shasta Lake and vicinity portion of the primary study area and occurs as small inclusions in other more prevalent plant series types or in areas subjected to previous disturbance. Dominant species include wild oat (*Avena fatua*), cheatgrass (*Bromus tectorum*), ripgut (*B. diandrus*), yellow star-thistle (*Centaurea solstitialis*), squirreltail (*Elymus elymoides*), and European hairgrass (*Aira caryophyllea*). Grassland bird species such as the mourning dove (*Zenaida macroura*), savannah sparrow (*Passerculus sandwichensis*), and white-crowned sparrow (*Zonotrichia leucophrys*), as well as rodents such as the California ground squirrel (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), and deer mouse (*Peromyscus maniculatus*), may forage on the seed crop this community provides. These species, in turn, attract predators such as the gopher snake (*Pituophis melanoleucus*), American kestrel (*Falco sparverius*), red-tailed hawk (*Buteo jamaicensis*), and coyote. Reptile species expected to inhabit this area include the western fence lizard (*Sceloporus occidentalis*), western skink (*Eumeces skiltonianus*), western rattlesnake (*Crotalus viridis*), and yellow-bellied racer (*Coluber constrictor*).

Barren Barren habitat consists mainly of nonvegetated human-made features scattered throughout the Shasta Lake and vicinity portion of the primary study area, including boat ramps, parking lots, and roads. Other barren habitats include a large gravel plain feature at the confluence of Butcher Creek and Shasta Lake (Main Body) and a sealed riprap feature adjacent to Interstate 5 near the upper Sacramento Arm and Shasta Lake confluence. Vegetation is usually not present, although sparse opportunistic grasses/forbs or weedy species may be present. Barren habitat has limited value for wildlife; however, many species in adjacent habitats may use these areas occasionally as opportunities arise, such as for feeding. Also, open nesting species such as killdeer (*Charadrius vociferus*) may use some barren surfaces for nesting.

Blue Oak Woodland Blue oak woodlands occur mainly as small inclusions within other more prevalent habitats; however, moderate-sized stands also occur. This habitat occurs at scattered locations along the Main Body, McCloud Arm, and Pit Arm. Blue oak woodland is characterized by a moderate overstory of blue oak *(Quercus douglasii)* with a dense herbaceous understory. Oak woodlands produce acorns used as forage by a variety of species, including acorn woodpeckers (*Melanerpes formicivorus*), western scrub-jays (*Aphelocoma californica*), turkey (*Meleagris gallopavo*), western gray squirrels (*Sciurus griseus*), and black-tailed deer (*Odocoileus hemonius columbianus*). Snags and live trees containing cavities provide nesting habitat for species such as the western bluebird (*Salia mexicana*), tree swallow (*Tachycineta bicolor*), American kestrel, and northern flicker (*Colaptes auratus*), as well as roost sites for bats and denning sites for mammals such as the raccoon, Virginia opossum (*Didelphis virginiana*), and gray fox (*Urocyon cinereoargenteus*). Raptors, including the red-tailed hawk and great horned owl, also nest in these woodlands. Amphibian and reptile species found here include the Pacific chorus frog (*Pseudacris regilla*), bullfrog (*Rana catesbeiana*), western fence lizard,

southern alligator lizard (*Elgaria multicarinata*), western terrestrial garter snake (*Thamnophis elegans*), common garter snake (*Thamnophis sirtalis*), and western rattlesnake.

Blue Oak – Foothill Pine Blue oak–foothill pine habitat also occurs mainly as small inclusions within other more prevalent habitats in the Shasta Lake and vicinity portion of the primary study area; however, moderate-sized stands also occur. This habitat is found in the Main Body, Squaw Creek Arm, and Pit Arm. Species composition is similar to the blue oak woodland habitat; however, gray pine and a shrub component are more common. Dominant overstory species include blue oak, California black oak *(Quercus kelloggii),* valley oak *(Quercus lobata),* interior live oak *(Quercus wislizenii),* and gray pine *(Pinus sabiniana).* Common shrubs observed in this habitat include white leaf manzanita *(Arctostaphylos viscida),* buck brush *(Ceanothus cuneatus),* poison oak *(Toxicodendron diversilobum),* coffee berry *(Rhamnus californica),* snowdrop bush *(Styrax officinalis),* wild mock orange *(Philadelphus lewisii),* deer brush *(Ceanothus integerrimus),* and California buckeye *(Aesculus californica).* Common grasses and forbs observed in this vegetation habitat include pussy ears *(Calochortus tolmiei),* Pacific hounds tongue *(Cynoglossum grande),* slender wild oat, and soaproot *(Chlorogalum pomeridianum).* Lianas of Dutchman's pipe *(Aristolochia californica)* and chaparral clematis *(Clematis lasiantha)* shroud shrubs and often grow into the tree canopy.

The blue oak–foothill pine community provides breeding habitat for a large variety of wildlife species, although no species is completely dependent on it for breeding, feeding, or cover. Many of the species found in blue oak habitat are also found here. Acorns and gray pine seeds are an important resource for many of the species using this habitat, such as the acorn woodpecker, western scrub-jay, and western gray squirrel. The newly emerged leaves of oaks in the spring support an abundance of insects that attract migrating and nesting warblers, vireos, flycatchers, and other insectivorous birds. In addition, the shrubs provide habitat for birds such as the spotted towhee (*Pipilo maculatus*), California towhee (*Pipilo crissalis*), wrentit (*Chamaea fasciata*), and blue-gray gnatcatcher (*Polioptila caerulea*). Characteristic reptiles and amphibians include western toads (*Bufo boreas*), a wide variety of snakes (common garter snakes, California whipsnakes (*Masticophis lateralis*), gopher snakes, and western rattlesnakes), western skinks, southern alligator lizards, and western fence lizards.

Closed-Cone Pine – Cypress Closed-cone pine–cypress consists of open to dense knobcone pine (*Pinus contorta*) stands. This habitat is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area and often occurs in disturbed areas, including areas of historic mining activities and past or recent wildfires. Dominant species include knobcone pine, with occasional canyon live oak (*Quercus chrysolepis*), California black oak, ponderosa pine, and gray pine. The shrub layer is moderate to dense and is dominated by white leaf manzanita and poison oak. The ground layer varies and is dominated by various grasses and forbs.

Numerous game and nongame species make use of this habitat for feeding and cover. Steller's jays (*Cyanocitta stelleri*) and western scrub-jays, downy woodpeckers (*Picoides pubescens*), and western gray squirrels extract seeds from partially opened cones. The great horned owl and red-tailed hawk are among the few species known to use this habitat for breeding.

Douglas-Fir As a habitat type, Douglas-fir is uncommon in the Shasta Lake and vicinity portion of the primary study area. This habitat type occurs in the upper portion of the McCloud Arm. Douglas-fir is characterized by moderate to dense conifer stands dominated by Douglas-fir (*Pseudotsuga menziesii*), with occasional ponderosa pine (*Pinus ponderosa*), sugar pine (*Pinus lambertiana*), incense cedar (*Calocedrus decurrens*), canyon live oak, and California black oak. Associated understory species vary and include Pacific dogwood (*Cornus nuttallii*), mock orange (*Philadelphus lewisii*), poison oak, snowdrop bush, and white leaf manzanita. The ground layer ranges from open to moderate and is dominated by various grasses and forbs. The multilayered vegetation in the Douglas-fir community supports a variety of wildlife species. A significant feature of the community is the presence of cavity-bearing trees. Mature, fire-damaged, and wind-damaged forests typically contain snags (dead trees that are still standing), which are a valuable resource for birds and mammals that prefer nest and den sites in cavities, such as the flammulated owl (*Otus flammeolus*) and northern pygmy owl (*Glaucidium gnoma*). Snags also support wood-boring insects that provide food for bark-gleaning insectivorous birds such as the brown creeper (*Certhia americana*). Other birds foraging and/or breeding in this habitat include the sharp-shinned hawk (*Accipiter striatus*), American peregrine falcon, mountain quail, western wood-pewee (*Contopus sordidulus*), and western tanager (*Piranga ludoviciana*). Mammals found in this habitat include the long-eared myotis (*Myotis evotis*), western red bat (*Lasiurus blossevillii*), northern flying squirrel (*Glaucomys sabrinus*), and bobcat (*Lynx rufus*).

Lacustrine Lacustrine habitat consists of the area regularly inundated by Shasta Lake (i.e., areas up to and below the 1,070-foot elevation). Most of this area is barren of vegetation and is characterized as exposed soil and/or rock. Portions of the lacustrine habitat do support vegetation during draw-down periods, including woody riparian species such as black willow, button willow, Fremont cottonwood, and various grasses and forbs.

Mixed Chaparral Mixed chaparral is a common habitat type and is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. This habitat often occurs on exposed slopes and/or in disturbed areas, including historic mining activities and past or recent wildfires. Mixed chaparral is typically characterized by dense shrub stands dominated by white leaf manzanita, buck brush, toyon *(Hetermeles arbutifolia),* California buckeye, Brewer's oak *(Quercus garryana* var. *breweri),* California bay *(Umbellularia californica),* interior live oak, Lemmon's ceanothus *(Ceanothus lemmonii),* birch-leaf mountain mahogany *(Cercocarpus betuloides),* holly-leaf redberry

(Rhamnus ilicifolia), yerba santa *(Eriodictyon californicum),* and poison oak. Few herbaceous plants occur in this habitat. Mixed chaparral provides habitat for a wide variety of wildlife species. It provides seeds, fruit, and protection from predators and harsh weather. In addition, it provides singing, roosting, and nesting sites for many species of birds, including the California quail (*Callipepla californica*), wrentit, and Bewick's wren (*Thryomanes bewickii*). Mammals common in this habitat include the black-tailed hare (*Lepus californicus*), gray fox, coyote, and deer mouse. Reptiles that make use of this habitat include the western fence lizard and southern alligator lizard.

Montane Hardwood Montane hardwood is a common tree habitat type and is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. The montane hardwood stands are typically characterized by moderate to dense stands of California black oak, canyon live oak, and occasional interior live oak. The understory is variable, although often sparse in the evergreen (live oak) stands because of a typically dense overstory canopy. Mast crops provided by montane hardwood forests are an important food resource for many species, including the acorn woodpecker, Steller's jay, mountain quail (*Oreortyx pictus*), western gray squirrel, and black-tailed deer. In addition, cavities in mature trees provide nesting and denning habitat for species such as the northern flicker, western screech owl (*Otus kennicottii*), American kestrel, and Virginia opossum. In moist areas, many amphibians and reptiles are found in the detrital layer, including ensatina (*Ensatina eschscholtzii*) and western skink.

Montane Hardwood – Conifer Montane hardwood–conifer is a common tree habitat type and is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. Montane hardwood–conifer is a complex forest type generally characterized by a complex of hardwood and conifer tree species. Stand composition varies, depending on numerous physical and geographic factors, and can include California black oak, canyon live oak, interior live oak, Oregon white oak (*Quercus garryana*), gray pine, ponderosa pine, Douglas-fir, sugar pine, and knobcone pine. Understory species are generally moderate to dense and include white leaf manzanita, buck brush, California buckeye, western redbud *(Cercis occidentalis),* California bay, poison oak, birch-leaf mountain mahogany, Brewer's oak, and snowdrop bush. The ground layer varies and is dominated by various grasses and forbs, including pussy ears, soaproot, Pacific hound's tongue, and slender wild oat.

The variability of the canopy cover and understory vegetation makes montane hardwood–conifer habitat suitable for numerous species of wildlife. Hollow trees and logs provide denning sites for mammals such as the coyote and gray fox, and cavities in mature trees are used by cavity-dwelling species such as the acorn woodpecker, violet-green swallow (*Tachycineta thalassina*), northern flicker, great horned owl, raccoon, and California myotis (*Myotis californicus*). In addition, raptors, such as the red-tailed hawk, construct nests in the upper canopy of mature trees. Moreover, mast crops and conifer seeds are an

important food source for many birds and mammals, including the Steller's jay, acorn woodpecker, California quail, black-tailed deer, and western gray squirrel. In moist areas, many amphibians and reptiles, including ensatina and western fence lizards, inhabit the detrital layer. Snakes, including the western rattlesnake and sharp-tailed snake (*Contia tenuis*), also are found in this habitat.

Montane Riparian Montane riparian is the dominant riparian habitat type and is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. Montane riparian habitat occurs as thin stringers and large patches along most stream corridors and is characterized as a sparse overstory of white alder (*Alnus rhombifolia*), Fremont cottonwood (*Populus fremontii*), or big leaf maple (*Acer macrophyllum*), along with a fairly dense mid-story and herbaceous layer. The mid-story is dominated by red osier dogwood (*Cornus sericea*), arroyo willow (*Salix lasiolepis*), narrow-leafed willow (*S. exigua*), red willow *(S. laevigata*), spicebush (*Calycanthus occidentalis*), mock orange, button willow (*Cephalanthus occidentalis*), American dogwood (*Cornus cericea*), California ash (*Fraxinus dipetala*), and mugwort (*Artemesia douglasiana*). Brambles of Himalayan blackberry (*Rubus discolor*) and California blackberry (*R. ursinus*) often engulf broader, low-gradient riparian areas. Lianas including California grape and greenbriar (*Smilax californica*) grow into the canopy.

Riparian habitats are among the most important wildlife habitats because of their high floristic and structural diversity, high biomass (and therefore high food abundance), and high water availability. In addition to providing breeding, foraging, and roosting habitat for a diverse array of animals, riparian habitats also provide movement corridors for some species, connecting a variety of habitats throughout the region.

The leaf litter, fallen tree branches, and logs associated with the riparian community in the study area provide cover for the western toad and Pacific chorus frog. The western fence lizard, western skink, and southern alligator lizard are also expected to occur here. Common species nesting and foraging primarily in the riparian tree canopy include the bushtit (*Psaltriparus minimus*), white-breasted nuthatch (*Sitta carolinensis*), and Nuttall's woodpecker (*Picoides nuttallii*). Other resident species, such as the spotted towhee and song sparrow (*Melospiza melodia*), nest and forage on or very close to the ground, usually in dense vegetation. A variety of mammals also inhabit riparian communities, including the deer mouse, raccoon, and Virginia opossum.

Ponderosa Pine Ponderosa pine is the most common conifer habitat type in the Shasta Lake and vicinity portion of the primary study area and is scattered throughout all portions of the area. This habitat is characterized by open to dense conifer stands dominated by ponderosa pine. Associated species include occasional Douglas-fir, sugar pine, incense cedar, canyon live oak, and California black oak. Associated understory species vary and include redbud, buck brush, mock orange, poison oak, snowdrop bush, and white leaf

manzanita. The ground layer ranges from open to moderate and is dominated by various grasses and forbs.

Ponderosa pine needles, cones, buds, pollen, twigs, seeds, and associated fungi and insects provide food for many species of birds and mammals, including the mountain quail, western gray squirrel, black-tailed deer, Allen's chipmunk (*Tamias senex*), and black bear (*Ursus americanus*). Mature trees provide nesting habitat for raptors such as the bald eagle (*Haliaeetus leucocephalus*), osprey (*Pandion haliaetus*), sharp-shinned hawk, and red-tailed hawk, and snags and hollow logs provide shelter for species such as the Virginia opossum and western spotted skunk (*Spilogale gracilis*).

Riverine Riverine habitat includes the free-flowing portions of the larger Shasta Lake tributaries in the Shasta Lake and vicinity portion of the primary study area. The riverine habitat is highly variable and ranges from moderate, low-gradient to steep, well-confined stream reaches. Most riverine habitat is dominated by run-and-riffle habitats, with bedrock, boulder, cobble, gravel, and sand substrates. The vegetation in the active stream channel is sparse, with occasional clumps of torrent sedge (*Carex nudata*) and Indian rhubarb (*Darmera peltata*).

Riverine areas provide habitat for numerous fish, including rainbow trout (*Oncorhynchus mykiss*), brown trout (*Salmo trutta*), smallmouth bass (*Micropterus dolomieu*), and riffle sculpin (*Cottus gulosus*). Aquatic wildlife species include the foothill yellow-legged frog (*Rana boylii*), aquatic garter snake (*Thamnophis atratus*), and the aquatic phase of the rough-skinned newt (*Taricha granulosa granulosa*). Birds present include the American dipper (*Cinclus mexicanus*), common merganser (*Mergus merganser*), and belted kingfisher (*Ceryle alcyon*). Many mammals in the surrounding upland habitats use the riverine areas, including raccoon, gray fox, and black-tailed deer.

Urban Urban habitat consists of various human-made features scattered throughout the Shasta Lake and vicinity portion of the primary study area, including resorts and a portion of the visitor center complex at Shasta Dam. These features are typically a combination of buildings, pavement areas with manicured landscaping, and lawns. The wildlife species most often associated with urban areas are those that are most tolerant of periodic human disturbances, including several introduced species, such as European starling (*Sturnus vulgaris*), rock dove (*Columba livia*), and house mouse (*Mus musculus*). Native species that are able to use these habitats include the western fence lizard, American robin (*Turdus migratorius*), Brewer's blackbird (*Euphagus cyanocephalus*), northern mockingbird (*Mimus polyglottos*), mourning dove, house finch (*Carpodacus mexicanus*), California ground squirrel, black-tailed hare, and striped skunk (*Mephitis mephitis*). In addition, bats that forage in nearby habitats may make use of small cavities around the eaves of structures.

Upper Sacramento River (Shasta Dam to Red Bluff)

Important wildlife habitat is found throughout the upper Sacramento River portion of the primary study area, and large contiguous blocks that contain multiple habitat types have the potential to support the highest wildlife diversity and abundance. Overall, the quantity and variety of wildlife species now inhabiting the area have been reduced since agricultural and residential development permanently removed much of the native and natural habitat. Most affected have been wildlife species associated with riparian habitats, which have declined substantially and been highly altered by land use, water resources development, and land management practices. Wildlife species associated with grassland and oak woodland habitats have also been affected by habitat loss resulting from habitat conversions to residential, commercial, and agricultural uses; cattle grazing; and other compounding factors such as lack of oak regeneration, spread of Sudden Oak Death Syndrome, and competition from invasive species. The region also supports a variety of nonnative plant and animal species, some of which are detrimental to survival of native species.

Habitats present in this portion of the primary study area are riparian woodland, riparian scrub, oak woodland, chaparral, annual grassland, agriculture, and urban. (See the Wildlife Resources Technical Report for a description of the plant and wildlife species typical of these habitats.)
Riparian habitat has been designated by DFG as a sensitive habitat in California because of its limited abundance and high value to wildlife.

Lower Sacramento River and Delta

The roughly 300 miles of the Sacramento River can be subdivided into distinct reaches. The reaches in the lower Sacramento River and Delta portion of the extended study area are discussed separately below because of differences in morphology, riparian vegetation, and habitat functions.

Sacramento River from Red Bluff Diversion Dam to the Delta Most habitat types and many of the wildlife species found in the upper Sacramento River portion of the primary study area have the potential to occur in the Central Valley portion of the extended study area, with additional species occurring in upland and foothill areas. The segment of the extended study area between Red Bluff Diversion Dam (RBDD) and the Delta includes a diverse array of wildlife habitats – floodplains, basins, terraces, active and remnant channels, and oxbow sloughs. The variety and availability of habitats along the middle Sacramento River support a wide range of wildlife species: a variety of waterfowl, raptors, and migratory and resident avian species, plus a variety of mammals, amphibians, and reptiles that inhabit both aquatic and upland habitats.

Sacramento-San Joaquin River Delta Delta wetlands are considered to be among the most productive wildlife habitats in California. These wetlands consist of permanent saline, brackish, and freshwater marshes; seasonal freshwater wetlands; open water; tidal and nontidal marshes, and emergent wetlands; and agricultural cropland (CALFED 2000a). (See the *Wildlife*

Resources Technical Report for a discussion of the plant and wildlife species typical of Delta wetlands.)

San Joaquin River Basin to the Delta Most habitat types and many of the wildlife species described above for the Sacramento River corridor have the potential to occur in the Central Valley portion of the extended study area, with additional species occurring in upland and foothill areas. The current wildlife habitat value of this area is somewhat limited by the predominance of agricultural lands, which support a relatively low diversity of wildlife species. However, the orchards, row and field crops, and fallow fields can be used by a number of common species, and fallow fields and some crops (e.g., wheat and barley) can support a variety of small mammals and provide high-quality foraging habitat for many species of raptors. More importantly, remnant native vegetation patches are likely to support a high diversity of wildlife species.

CVP/SWP Service Areas

The CVP and SWP service areas contain a large diversity of both lowland and upland habitats and species, although agricultural and urban growth has reduced the area and connectivity of important habitats that are critical to sustaining a wide variety of unique plants and animals (CALFED 2000a). The agricultural land and urban development that dominate the CVP and SWP service areas, respectively, can support many wildlife species, most of which are highly adapted to these disturbed environments.

13.1.2 Special-Status Species

Special-status species addressed in this section include animals that are legally protected or are otherwise considered sensitive by Federal, State, or local resource conservation agencies and organizations. Specifically, these include species that are Federally listed and/or State-listed as rare, threatened, or endangered; those considered as candidates or proposed for listing as threatened or endangered; species identified by DFG as fully protected or species of special concern, species identified by USFS as sensitive, or endemic; species identified by the U.S. Bureau of Land Management (BLM) as sensitive; species designated by the Northwest Forest Plan as survey and manage; other animals protected by the California Fish and Game Code; and those designated as Multi-Species Conservation Strategy (MSCS) covered species by the CALFED Bay-Delta Program (CALFED).

Shasta Lake and Vicinity

For the purposes of this evaluation, wildlife species of concern include species that are any of the following:

- Designated as threatened or endangered by the State or Federal government
- Proposed or petitioned for Federal listing as threatened or endangered

- State or Federal candidates for listing as threatened or endangered
- Identified by DFG as a species of special concern
- Considered sensitive or endemic by USFS
- Considered sensitive by BLM
- Considered survey and manage species by Northwest Forest Plan
- Designated as MSCS-covered species by CALFED

Special-status wildlife species with the potential to occur in the Shasta Lake and vicinity portion of the primary study area were determined using several database searches, review of USFWS and DFG special-status species lists for Shasta County, review of other appropriate literature, discussions with resource agency personnel, and professional experience in the area. All special-status wildlife species potentially occurring in the Shasta Lake and vicinity portion of the primary study area are discussed in Attachment 1 of the *Wildlife Resources Technical Report*, which provides a general comparison of habitat requirements for each species and the general habitats in the primary study area above Shasta Dam. For those special-status species for which generally suitable habitat was determined to be present, results from the various vegetation habitat mapping and wildlife surveys conducted in the area by North State Resources, Inc. (NSR) since 2002 were used to determine the likelihood of their presence in the primary study area above Shasta Dam (Table 13-3).

The survey and manage species include species listed in the most current survey and manage species list considered by the Northwest Forest Plan Survey and Manage Program. This list includes species from the current annual review for survey and manage species that was completed in compliance with the 2001 record of decision (ROD) for amendments to the survey and manage, protection buffer, and other mitigation measures standards and guidelines. Compliance with this ROD is conducted by completion of an annual species review and category assignment. The current survey and manage species list is from the December 2003 annual status review and includes species included in *Survey and Manage Standards and Guidelines and Category Assignment* of the 1994 ROD for the Northwest Forest Plan. For the purposes of this evaluation, survey and manage species of concern include taxa that are designated as Category A and C by the current category assignment. These categories include taxa that require what are known as predisturbance (i.e., preproject) surveys.

The CNDDB was reviewed for records of special-status plant species in or near the Shasta Lake and vicinity portion of the primary study area. The CNDDB is a database consisting of historical observations of special-status plant species, wildlife species, and natural communities. The CNDDB is limited to reported

sightings and is not a comprehensive list of special-status species that could occur in a particular area.

Table 13-3. Wildlife Species of Concern in the Shasta Lake and Vicinity Portion of the Primary Study Area

Common Name	Scientific Name	Status	Potential for Occurrence
Shasta sideband	*Monadenia troglodytes troglodytes*	FP, USFS S, S&M, MSCS m	Endemic to Shasta County. Potentially occurring in mixed conifer and woodland habitats, especially near limestone. Species occurs in limestone on the McCloud Arm from Potter Creek north.
Wintu sideband	*Monadenia troglodytes wintu*	FP, USFS S, S&M	Endemic to Shasta County. Potentially occurring in mixed conifer and woodland habitats, especially near limestone. Known to occur between the Pit and Squaw Creek arms and at Moutain Gate.
Shasta chaparral	*Trilobopsis roperi*	FP, USFS S, S&M	Endemic to Shasta County. Potentially occurring in mixed conifer and conifer/woodland habitats. Known occurrences in the Shasta Lake and vicinity portion of the study area.
Shasta hesperian	*Vespericola shasta*	FP, USFS S, S&M	Endemic to Klamath Province. Potentially occurring in mixed conifer and conifer/woodland habitats (riparian and/or riverine habitats). Only known from the southeastern Klamath Mountains region. Known occurrences in the Shasta Lake and vicinity portion of the study area.
Shasta salamander	*Hydromantes shastae*	CT, USFS S, S&M, MSCS m, BLMS	Only known from the southeastern Klamath Mountains region. Potentially occurring in mixed conifer, woodland, and chaparral habitats, especially near limestone. Known occurrences in the Shasta Lake and vicinity portion of the study area.
Tailed frog	*Ascaphus truei*	CSC	Potentially occurring in stream habitats in the Shasta Lake and vicinity portion of the study area. Known occurrences in the McCloud Arm and the upper Sacramento Arm tributaries outside the study area boundaries (DFG 2003).
California red-legged frog	*Rana draytonii*	FT, CSC, MSCS m	Requires aquatic habitat for breeding; also uses a variety of other habitat types including riparian and upland areas. A habitat assessment has been prepared to determine habitat suitability in the vicinity of Shasta Lake. Species has not been recorded in Shasta County since 1926 (University of Michigan Museum of Zoology 2009).
Foothill yellow-legged frog	*Rana boylii*	CSC, USFS S, MSCS m, BLMS	Potentially occurring in stream habitats. Known occurrences scattered throughout the Shasta Lake and vicinity portion of the primary study area.
Northwestern pond turtle	*Actinemys marmorata marmorata*	CSC, USFS S, MSCS m	Potentially occurring in stream or other wetland habitats. Adjacent upland habitats are potential nesting areas. Known occurrences scattered throughout the Shasta Lake and vicinity portion of the primary study area.
Long-eared owl	*Asio otus*	CSC, MSCS m	Potentially occurring in coniferous forest habitats.
Northern goshawk	*Accipiter gentilis*	CSC, USFS S, BLMS	Potentially occurring in mixed conifer habitats. Known to occur in the upper McCloud Arm.
Cooper's hawk	*Accipiter cooperi*	MSCS m	Potentially occurring in mixed conifer and conifer/woodland habitats.
Great blue heron	*Ardea herodias*	MSCS m	Known to breed in nearshore wooded habitat in the Turntable Bay area of Shasta Lake.

Table 13-3. Wildlife Species of Concern in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Status	Potential for Occurrence
Willow flycatcher	*Empidonax traillii*	CE, USFS S, MSCS r	Uncommon migrant in riparian habitat; unlikely to nest in the Shasta Lake and vicinity portion of the primary study area.
American peregrine falcon	*Falco peregrinus anatum*	FD, CD, CP, MSCS m	Potentially occurring in mixed conifer and conifer/woodland habitats. Nesting sites in the study area unlikely due to lack of suitable eyrie sites; however, potential eyrie sites occur adjacent to the Shasta Lake and vicinity portion of the primary study area. Known historical eyrie along the McCloud Arm, and "new" eyrie found at the Gooseneck (Sacramento Arm).
Bald eagle	*Haliaeetus leucocephalus*	FD, FB, CE, CP, USFS S, MSCS m, BLMS	Potentially occurring in riverine and lacustrine habitats. Common at Shasta Lake, and a substantial number of nests occur in the Shasta Lake and vicinity portion of the primary study area and vicinity. Shasta Lake has the highest density of breeding bald eagles in the continental United States.
Osprey	*Pandion haliaetus*	MSCS m	Potentially occurring in riverine and lacustrine habitats. Common at Shasta Lake, and many known nests occur in the Shasta Lake and vicinity portion of the primary study area and vicinity.
Northern spotted owl Critical Habitat	*Strix occidentalis caurina*	FT, MSCS m	Potentially occurring in coniferous forest habitats. The species has been recorded within 0.5 mile of the study area along the Squaw Creek Arm (DFG 2003). Critical habitat occurs in the upper portion of the Squaw Creek and Pit arms.
Vaux's swift	*Chaetura vauxi*	CSC	Potentially occurring in coniferous forest and conifer/woodland habitats. Known to occur in the Shasta Lake and vicinity portion of the study area.
Yellow warbler	*Dendroica petechia brewsteri*	CSC, MSCS r	Potentially occurring in riparian habitats. Known occurrences in and near the Shasta Lake and vicinity portion of the primary study area.
Yellow-breasted chat	*Icteria virens*	CSC, MSCS m	Potentially occurring in riparian habitats. Known occurrences in and near the Shasta Lake and vicinity portion of the primary study area.
Purple martin	*Progne subis*	CSC	Potentially occurring in conifer, woodland, and riparian habitats. Foraging habitat occurs throughout Shasta Lake and vicinity portion of the primary study area. Shasta Lake is one of the few known breeding sites in interior California.
Pallid bat	*Antrozous pallidus*	CSC, USFS S, BLMS	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the study area.
Ringtail	*Bassariscus astutus*	CP, MSCS m	Potentially occurring in mixed conifer and conifer/woodland habitats. Known occurrences in and near the Shasta Lake and vicinity portion of the primary study area.
Spotted bat	*Euderma maculatum*	CSC, BLMS	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the study area. Species has been recorded on Squaw Creek within approximately 6 miles of the Shasta Lake and vicinity portion of the primary study area (DFG 2003).

Table 13-3. Wildlife Species of Concern in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Status	Potential for Occurrence
Western mastiff bat	*Eumops perotis*	CSC, MSCS m*, BLMS *californicus subspecies only	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the Shasta Lake and vicinity portion of the primary study area.
Western red bat	*Lasiurus blossevillii*	USFS S	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the Shasta Lake and vicinity portion of the primary study area.
American marten	*Martes americana*	USFS S	Mixed evergreen forests with abundant cavities for denning and nesting and open areas for foraging.
Pacific fisher	*Martes pennanti*	FC, CSC, USFS S, BLMS	Potentially occurring in mixed conifer and conifer/woodland habitats. Known occurrences in and near the Shasta Lake and vicinity portion of the primary study area.
Long-eared myotis	*Myotis evotis*	BLMS	Potentially occurring in a wide variety of forest habitats throughout the study area.
Yuma myotis	*Myotis yumanensis*	BLMS	Potentially occurring in a wide variety of forest habitats throughout the study area.
Townsend's big-eared bat	*Plecotus townsendii*	CSC, USFS S	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the study area. The species was observed in the Shasta Lake and vicinity portion of the primary study area by NSR biologists in June 2008.

Status Definitions

BLMS = U.S. Bureau of Land Management sensitive
CD = State delisted
CE = State-listed as endangered
CP = California fully protected
CSC = California species of special concern
CT = California (State) listed as threatened
FB = Federal Bald and Golden Eagle Protection Act
FC = Federal candidate for listing
FD = Federally delisted
FP = Federally petitioned for listing
FT = Federally listed as threatened
MSCS = Multi-Species Conservation Strategy covered species
  m = Maintain. Ensure that any adverse effects on the species that could be associated with implementation of CALFED Bay-Delta Program actions will be fully offset through implementation of actions beneficial to the species.
  r = Contribute to recovery. Implement some of the actions deemed necessary to recover species' populations in the Multi-Species Conservation Strategy focus area.
S&M = Survey and manage species
USFS S = U.S. Forest Service sensitive

The life history of species known or potentially occurring in the Shasta Lake and vicinity portion of the primary study area are described in detail in Attachment 2 of the *Wildlife Resources Technical Report*. Figures 13-3a through 13-3f depict the known locations of special-status wildlife species in the primary study area above Shasta Dam located during various surveys conducted by NSR and recent USFS records. Figures 13-4a through 13-4f depict the known locations of special-status terrestrial mollusks.

Summary of Wildlife Investigations Because wildlife studies are ongoing, technical memoranda describing methods, results, and conclusions in detail will be provided in the Final Environmental Impact Statement (FEIS).

Terrestrial Mollusk Surveys (Survey and Manage) Reclamation has conducted three survey efforts for survey and manage terrestrial mollusk species in the Shasta Lake and vicinity portion of the primary study area. These include protocol-level efforts during 2002 to 2003 and 2005 along selected portions of the Shasta Lake shoreline and current protocol-level efforts initiated in 2010 at the relocation areas. Additionally, many other terrestrial mollusk locations have been found incidentally during numerous other biological survey tasks throughout the Shasta Lake and vicinity portion of the primary study area. Four survey and manage terrestrial mollusk species have been found to date: Shasta sideband (*Monadenia troglodytes troglodytes*), Wintu sideband (*Monadenia troglodytes wintu),* Shasta chaparral (*Trilobopsis roperi*), and Shasta hesperian (*Vespericola shasta*). Collectively, 29, 2, 29, and 73 locations of Shasta sideband, Wintu sideband, Shasta chaparral, and Shasta hesperian, respectively, have been found (Figures 13-4a through 13-4f).

Shasta Salamander Surveys Reclamation has conducted three survey efforts for Shasta salamander in the Shasta Lake and vicinity portion of the primary study area. These include survey efforts during 2003 and 2006 to 2007 along selected portions of the Shasta Lake shoreline and current efforts initiated in 2010 at the relocation areas. Additionally, several other Shasta salamander locations have been found incidentally during other biological survey tasks throughout the Shasta Lake and vicinity portion of the primary study area. Shasta salamanders have been found at 39 locations. These findings and other known locations show that this species occurs in all arms of Shasta Lake in both limestone and nonlimestone habitats (Figures 13-3a through 13-3f).

Bald Eagle/Osprey Surveys Reclamation mapped all known bald eagle and osprey nests in the Shasta Lake and vicinity portion of the primary study area in 2007. Additional data including diameter of nest trees, nest tree height, nest height, proximity to the high-water mark, surrounding vegetation, and shoreline erosion rating were recorded for the bald eagle nests. Twenty-eight bald eagle nests were located and 54 osprey nests were located (Figures 13-3a through 13-3f). Reclamation is currently working with USFS to update this data set, because several bald eagle nesting pairs are no longer active and/or have moved to new locations.

Neotropical Migrant Bird Surveys Reclamation conducted a breeding bird survey in the Shasta Lake and vicinity portion of the primary study area in 2007. Additionally, focused surveys for purple martins and an analysis of purple martin habitat at Shasta Lake were conducted. These surveys provided information on use of the Shasta Lake and vicinity portion of the primary study area by breeding birds, including breeding neotropical migrant species. Sixty-seven bird species were detected during these surveys, including 38 neotropical migrant species.

These surveys also provided a basic understanding of the distribution and habitat use of purple martins in the Shasta Lake and vicinity portion of the

primary study area. Purple martin monitoring has continued through 2010 and provides additional distribution and habitat use information (Figures 13-3a through 13-3f). The Shasta Lake purple martin population has remained stable and has increased slightly over the monitoring period to date. The nesting purple martin population has totaled 18, 21, 24, and 28 pairs during 2007, 2008, 2009, and 2010, respectively. Most nest sites occur in flooded snags found in the reservoir; however, recent monitoring has shown a slight increase in use of upland nest sites.

Forest Carnivore Surveys Reclamation conducted surveys for sensitive forest carnivore species (forest carnivores) in the Shasta Lake and vicinity portion of the primary study area during 2003 to 2005. The specific sensitive forest carnivore species (i.e., "target species") surveyed included the Sierra Nevada red fox (*Vulpes vulpes necator*), American marten (*Martes americana*), Pacific fisher (*Martes pennanti*), and wolverine (*Gulo gulo*). One target forest carnivore species, the Pacific fisher, was detected. Pacific fisher was detected at 13 locations scattered in all areas of the Shasta Lake and vicinity portion of the primary study area, except the McCloud Arm (Figures 13-3a through 13-3f). Additionally, the ringtail, a California fully protected species, was detected in all areas of the Shasta Lake and vicinity portion of the primary study area.

The Pacific fisher survey results provide additional information on habitat use and distribution of the species in Northern California. The survey findings represent the southeastern-most Pacific fisher occurrences in the Klamath and Sierra/Cascade regions. Additionally, these findings show Pacific fishers in areas generally (previously) not considered suitable habitat in California, including open second-growth conifer, hardwood–conifer, and hardwood habitats that have extensive chaparral components. Pacific fishers were also detected in areas that had been barren or semi-barren 50 to 60 years ago because of copper smelting and near commercial, rural residential, and industrial development areas.

California Red-Legged Frog Assessment Reclamation conducted a California red-legged frog habitat assessment in the Shasta Lake and vicinity portion of the primary study area in 2010. In consultation with USFWS, an assessment area was developed and field surveys of aquatic habitats were conducted in accordance with *Revised Guidance on Site Assessments and Field Surveys for the California Red-Legged Frog* (USFWS 2005a). The results suggest only one feature may represent potential California red-legged frog breeding habitat. A California red-legged frog habitat assessment report is currently being completed for USFWS review.

Upper Sacramento River (Shasta Dam to Red Bluff)

A list of special-status wildlife species with the potential to occur in the primary study area from Shasta Dam to RBDD (Table 13-4) was compiled based on habitat suitability and known occurrences within the area covered in the Shasta Dam, Redding, Enterprise, Cottonwood, Ball's Ferry, Bend, and Red Bluff East

U.S. Geological Survey 7.5-minute quadrangle maps (CNDDB 2007; USFWS 2007a), as well as species considered sensitive by USFS. (See the *Wildlife Resources Technical Report* for a description of the life history of special-status wildlife species known or likely to occur in the area and figures depicting the recorded locations of special-status species.)

Table 13-4. Special-Status Wildlife Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Diversion Dam

Common Name	Scientific Name	Status	Potential for Occurrence
Invertebrates			
Conservancy fairy shrimp	*Branchinecta conservatio*	FE, MSCS	Unlikely to occur. No suitable habitat is present along the river corridor.
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*	FT, MSCS	Known to occur. Elderberry shrubs are present within the riparian woodland community along the Sacramento River.
Vernal pool tadpole shrimp	*Lepidurus packardi*	FE, MSCS	Unlikely to occur. No suitable habitat is present along the river corridor.
Vernal pool fairy shrimp	*Branchinecta lynchi*	FT, MSCS	Unlikely to occur. No suitable habitat is present along the river corridor.
Amphibians			
California red-legged frog	*Rana aurora draytonii*	FT, CSC, MSCS	Unlikely to occur. No longer occurs on the floor of the Central Valley.
Foothill yellow-legged frog	*Rana boylii*	CSC, USFS S, MSCS	Unlikely to occur in the Sacramento River due to lack of suitable substrate and hydrology.
Western spadefoot toad	*Spea hammondii*	CSC, MSCS	Unlikely to occur. No suitable habitat is present along the Sacramento River corridor.
Western tailed frog	*Ascaphus truei*	CSC	Unlikely to occur in mainstem of Sacramento River where flows could be altered.
Reptiles			
Giant garter snake	*Thamnophis gigas*	FT, CT, MSCS	Unlikely to occur in the primary study area; however, known to occur in the extended study area.
Northwestern pond turtle	*Clemmys marmorata marmorata*	CSC, USFS S, MSCS	Known to occur. Suitable habitat is present in the primary study area.

Table 13-4. Special-Status Wildlife Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Diversion Dam (contd.)

Common Name	Scientific Name	Status	Potential for Occurrence
Birds			
Aleutian Canada goose	*Branta canadensis leucopareia*	FD, MSCS	Unlikely to occur within banks of the Sacramento River where flows could be altered.
American peregrine falcon (nesting)	*Falco peregrinus anatum*	CE, CP, USFS S, MSCS	Unlikely to nest in this portion of the study area; however, may forage in areas of open water with large concentrations of waterbirds.
Bald eagle (nesting and wintering)	*Haliaeetus leucocephalus*	FD, CE, CP, MSCS	Known to occur along the Sacramento River within the primary study area.
Bank swallow	*Riparia riparia*	CT, MSCS	Known to occur along the Sacramento river in the primary and extended study areas.
Black-crowned night heron (rookery)	*Nycticorax nycticorax*	BLM S, MSCS	Could nest in trees adjacent to the Sacramento River.
California gull	*Larus californicus*	MSCS	Not within breeding range. Could occur in the study area during winter or migration.
Cooper's hawk (nesting)	*Accipiter cooperii*	MSCS	Could occur. Suitable nesting and foraging habitat is present in the study area.
Double-crested cormorant (rookery)	*Phalacrocorax auritus*	MSCS	Could nest in trees adjacent to the Sacramento River.
Golden eagle	*Aquila chrysaetos*	CP, BLM S, MSCS	No suitable nesting habitat along the Sacramento River. Unlikely to forage along the river corridor.
Great blue heron (rookery)	*Ardea herodius*	MSCS	Could nest in trees adjacent to the Sacramento River.
Great egret (rookery)	*Casmerodius albus*	MSCS	Could nest in trees adjacent to the Sacramento River.
Greater sandhill crane	*Grus canadensis tabida*	CT, CP, MSCS	Unlikely to breed in the study area. Unlikely to use the Sacramento River corridor during winter or migration.
Least bittern (nesting)	*Ixobrychus exilis*	CSC, MSCS	Could nest along the Sacramento River if suitable habitat is present.
Lesser sandhill crane (wintering)	*Grus canadensis canadensis*	CSC	Does not breed in California. Unlikely to use the Sacramento River corridor during winter or migration.
Little willow flycatcher (nesting)	*Empidonax traillii brewsteri*	CE, USFS S, MSCS	Unlikely to breed in the study area due to elevation, but may use riparian woodlands during migration.
Loggerhead shrike (nesting)	*Lanius ludovidianus*	CSC	Likely to nest and forage in woodlands and scrub habitats in the study area.
Long-billed curlew	*Numenius americanus*	MSCS	Does not breed in the study area. Unlikely to use the Sacramento River corridor during winter or migration.
Long-eared owl (nesting)	*Asio otus*	CSC, MSCS	Does not nest in lowland Central Valley areas. Unlikely to forage along the Sacramento River corridor where flows would be altered.

Table 13-4. Special-Status Wildlife Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Diversion Dam (contd.)

Common Name	Scientific Name	Status	Potential for Occurrence
Mountain plover (wintering)	*Charadrius montanus*	CSC, BLM S, MSCS	Does not nest in California. Unlikely to winter along the Sacramento River where flows would be altered.
Northern goshawk (nesting)	*Accipiter gentilis*	CSC, USFS S	Unlikely to occur along the Sacramento River corridor due to lack of suitable habitat.
Northern harrier (nesting)	*Circus cyaneus*	CSC, MSCS	Likely to occur. Suitable nesting and foraging habitat is present in the study area.
Northern spotted owl (nesting)	*Strix occidentalis caurina*	FT, MSCS	Unlikely to occur along the Sacramento River corridor due to lack of suitable habitat.
Osprey (nesting)	*Pandion haliaetus*	MSCS	Known to nest along the Sacramento River within the primary study area.
Purple martin (nesting)	*Progne subis*	CSC	Could occur. Potentially suitable habitat is present along the Sacramento River corridor.
Short-eared owl (nesting)	*Asio flammeus*	CSC, MSCS	Could occur. Potentially suitable habitat is present within the primary study area.
Snowy egret (rookery)	*Egretta thula*	MSCS	Could nest in trees adjacent to the Sacramento River.
Swainson's hawk (nesting)	*Buteo swainsoni*	CT, MSCS	Could occur. Suitable nesting and foraging habitat is present in the study area.
Tricolored blackbird (nesting)	*Agelaius tricolor*	CSC, MSCS	Could occur. Potentially suitable habitat is present in the primary study area.
Western yellow-billed cuckoo (nesting)	*Coccyzus americanus occidentalis*	FC, CE, USFS S, MSCS	Likely to nest and forage in the primary study area.
Western burrowing owl (burrow sites)	*Athene cunicularia hypugea*	CSC, MSCS	Unlikely to occur along the Sacramento River corridor due to a lack of suitable nesting habitat.
White-tailed kite (nesting)	*Elanus leucurus*	CP, MSCS	Likely to occur. Suitable nesting and foraging habitat is present in the study area.
Yellow-breasted chat (nesting)	*Icteria virens*	CSC, MSCS	Likely to nest and forage in the primary study area
Yellow warbler (nesting)	*Dendroica petechia*	CSC, MSCS	Could nest and forage in the primary study area. Likely to use riparian woodlands during migration.
Mammals			
American badger	*Taxidea taxus*	CSC	Could occur along the Sacramento River corridor.
American marten	*Martes americana*	USFS S	Unlikely to occur. No suitable habitat along the Sacramento River corridor.
Pacific fisher	*Martes pennanti*	FC, USFS S	Unlikely to occur. No suitable habitat along the Sacramento River corridor.
Pallid bat	*Antrozous pallidus (roosting)*	CSC, USFS S	Could occur. Potentially suitable habitat is present in woodland in the primary study area.
Ringtail	*Bassariscus astutus*	CP, MSCS	Could occur. Potentially suitable habitat is present along the Sacramento River corridor.

Table 13-4. Special-Status Wildlife Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Diversion Dam (contd.)

Common Name	Scientific Name	Status	Potential for Occurrence
Spotted bat	*Euderma maculatum*	CSC	Unlikely to roost along the Sacramento River corridor because suitable roost sites are lacking.
Townsend's big-eared bat	*Corynorhinus townsendii townsendii (roosting)*	CSC, USFS S	Unlikely to roost along the Sacramento River corridor because suitable roost sites are lacking.
Western mastiff bat	*Eumops perotis californicus* (roosting)	CSC, MSCS	Unlikely to roost along the Sacramento River corridor because suitable roost sites are lacking.
Western red bat	*Lasiurus blossevillii*	CSC, USFS S	Could occur. Potentially suitable habitat is present in woodland in the primary study area.

Lower Sacramento River and Delta

Numerous special-status wildlife are associated with riparian, floodplain, and side channel wetland habitats along the Sacramento River and in the Delta, including those listed in Table 13-5. However, as stated above, the roughly 300 miles of the Sacramento River can be subdivided into distinct reaches. The reaches in the extended study area are discussed separately below because of differences in morphology, riparian vegetation, and habitat functions. The *Wildlife Resources Technical Report* contains a comprehensive list of all sensitive wildlife species in the extended study area that have been reported to the CNDDB.

Sacramento River from RBDD to the Delta Many of the special-status wildlife species described above for the upper Sacramento River corridor have the potential to occur in the middle and lower reaches of the Sacramento River. Wildlife species listed under the Federal Endangered Species Act (ESA) and/or California Endangered Species Act (CESA) that have potential to occur in a portion of the extended study area from RBDD to the Delta include valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*), giant garter snake (*Thamnophis gigas*), bald eagle (*Haliaeetus leucocephalus*), Swainson's hawk (*Buteo swainsoni*), western yellow-billed cuckoo (*Coccyzus americanus*

occidentalis), willow flycatcher (*Empidonax traillii*), and bank swallow (*Riparia riparia*).

Table 13-5. Sensitive Wildlife Species of Riparian and Perennial Wetland Communities Along the Sacramento River and in the Delta

Species	Status[1]	Habitat Description
Invertebrates		
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	FT	Elderberries in riparian woodlands or savanna communities.
Reptiles		
Western pond turtle *Actinemys marmorata*	CSC	Ponds, lakes, rivers, streams, creeks, marshes, and irrigation ditches with abundant vegetation and either rocky or muddy bottoms, in woodland, forest, and grassland.
Giant garter snake *Thamnophis giga*	FT CT	Marshes, sloughs, drainage canals, and irrigation ditches, especially around rice fields, and occasionally in slow-moving creeks from sea level to 400 feet. Prefers locations with vegetation close to the water for basking.
Birds		
Tricolored blackbird *Agelaius tricolor*	CSC	*Foraging:* On ground in croplands, grassy fields, flooded land, and along edges of ponds. *Nesting:* Dense cattails, tules, or thickets near fresh water.
Swainson's hawk *Buteo swainsoni*	CT	*Foraging:* Open desert, grassland, or cropland containing scattered, large trees or small groves. *Nesting:* Open riparian habitat, in scattered trees or small groves in sparsely vegetated flatlands. Usually found near water in the Central Valley.
Northern harrier *Circus cyaneus*	CSC	*Nesting:* Tall grasses and forbs in emergent wetland, along rivers or lakes, grasslands, grain fields, or on sagebrush flats several miles from water.
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	FC CE	*Nesting:* Extensive deciduous riparian thickets or forests with dense, low-level or understory foliage adjacent to slow-moving watercourses, backwaters, or seeps. Willow is almost always a dominant component of the vegetation. In the Sacramento Valley, also utilizes adjacent walnut orchards.
Yellow warbler *Dendroica petechia brewsteri*	CSC	*Nesting*: Low, open-canopy riparian deciduous woodlands with a heavy brush understory; sometimes in montane shrubbery in open conifer forests.
White-tailed kite *Elanus leucurus*	FP	*Foraging:* Undisturbed, open grasslands, meadows, farmlands, and emergent wetlands. *Nesting:* Large groves of dense, broad-leafed deciduous trees close to foraging areas.
Greater sandhill crane *Grus canadensis tabida*	CT FP	*Foraging:* Open grasslands, grain fields, and open wetlands. *Roosting:* In flocks standing in moist fields or in shallow water. *Nesting:* Open habitats with shallow lakes and fresh emergent wetlands.
Bald eagle *Haliaeetus leucocephalus*	CE FP	*Foraging:* Large bodies of water or free-flowing rivers with abundant fish and adjacent snags or other perches. *Nesting:* Large, old-growth trees or snags in remote, mixed stands near water.

Table 13-5. Sensitive Wildlife Species of Riparian and Perennial Wetland Communities Along the Sacramento River and in the Delta (contd.)

Species	Status[1]	Species
Yellow-breasted chat *Icteria virens*	CSC	*Foraging and nesting:* Riparian thickets of willow and other brushy thickets near streams or other watercourses.
California black rail *Laterallus jamaicensis coturniculus*	CT FP	*Foraging and nesting:* Tidal emergent wetlands dominated by pickleweed, in the high wetland zones near upper limit of tidal flooding, or in brackish marshes supporting bulrushes and pickleweed. In freshwater, usually found in bulrushes, cattails, and saltgrass adjacent to tidal sloughs.
Suisun song sparrow *Melospiza melodia maxillaries*	CSC	*Foraging:* The bare surface of tidally exposed mud among tules and along slough margins in brackish marshes. *Nesting:* Along edges of sloughs and bays supporting mixed stands of bulrush, cattail, and other emergent vegetation.
Bank swallow *Riparia riparia*	CT	*Foraging:* Open riparian areas, grassland, wetlands, water, and cropland. *Nesting:* Vertical banks and cliffs with fine-textured or sandy soils near streams, rivers, ponds, and lakes.
Yellow-headed blackbird *Xanthocephalus xanthocephalus*	CSC	*Foraging:* Fresh emergent wetland and sometimes along shorelines and in nearby open fields, preferably on moist ground. *Nesting:* Dense emergent wetland of cattails and tules, often along border of lake or pond.
Mammals		
Pallid bat *Antrozous pallidus*	CSC	*Foraging:* Relatively open oak woodlands, over water near riparian and upland forests and woodlands, and orchards and vineyards. *Roosting:* Rocky outcrops, cliffs, and crevices.
Western mastiff bat *Eumops perotis*	CSC	*Foraging:* Over water in broad, open areas near riparian and upland forests and woodlands. *Roosting:* Crevices in vertical cliffs, usually granite or consolidated sandstone, and in broken terrain with exposed rock faces.
Western red bat *Lasiurus blossevillii*	CSC	*Foraging:* Over water edges in open areas near riparian and upland forests and woodlands; orchards. *Roosting:* Trees along edges or in habitat mosaics in a variety of habitats and orchards.
Townsend's big-eared bat *Plecotus townsendii*	CSC	*Foraging:* Water edges in open areas near riparian and upland forests and woodlands. *Roosting:* Caves, mines, tunnels, buildings, or other human-made structures in woodlands. Prefers mesic habitats.
Salt-marsh harvest mouse *Reithrodontomys raviventris*	FE CE FP	Salt marsh dominated by pickleweed and salt grass. Generally requires nonsubmerged, salt-tolerant vegetation for escape during high tides.

Sources: CNDDB 2011

Note:

[1] Status definitions:
FC = federal candidate for listing
FE = Federally listed as endangered
FT = Federally listed as threatened
CE = California listed as endangered
CT = California listed as threatened
FP = California fully protected
CSC = California species of special concern

Sacramento–San Joaquin River Delta Many special-status species are known or are likely to occur in the Delta because of the presence of unique wetland habitats. Tidal marshes and emergent wetlands support several special-status wildlife species: California black rail (*Laterallus jamaicensis coturniculus*), California clapper rail (*Rallus longirostris obsoletus*), greater

sandhill crane (*Grus canadensis tabida*), salt marsh common yellowthroat (*Geothlypis trichas sinuosa*), salt marsh harvest mouse (*Reithrodontomys raviventris*), Suisun ornate shrew (*Sorex ornatus sinuosus*), Suisun song sparrow (*Melospiza melodia maxillaris*), and tricolored blackbird (*Agelaius tricolor*). The giant garter snake is known to inhabit sloughs, canals, and low-gradient streams and freshwater marshes in the Delta. Vernal pools and other freshwater seasonal wetlands support several special-status crustaceans, including vernal pool tadpole shrimp (*Lepidurus packardi*) and vernal pool fairy shrimp (*Branchinecta lynchi*). Although it is severely declining because of a dramatic shrinkage of suitable habitat, the valley elderberry longhorn beetle has been found in the Delta region on McCormack-Williamson and New Hope tracts (CNDDB 2007).

San Joaquin River Basin to the Delta The current wildlife habitat value of this area is somewhat limited by the predominance of agricultural lands, which support a relatively low diversity of wildlife species. Remnant native vegetation patches are likely to support a high diversity of wildlife species. More than 100 special-status wildlife and plants occur in the San Joaquin River region. Most of the special-status wildlife species are associated with grasslands, freshwater emergent wetlands, lakes, and rivers that occur on the valley floor. Many of the species have been listed by Federal and State wildlife agencies because of habitat losses associated with agricultural development and water projects.

CVP/SWP Service Areas

The CVP and SWP service areas are dominated by agricultural land and urban development, which can support many wildlife species, most of which are highly adapted to these disturbed environments. The conflict between urban growth and conservation of native habitat has resulted in the listing of a number of wildlife species that were threatened with extinction. The region also supports a variety of exotic species, some of which are detrimental to survival of native species.

The California condor (*Gymnogyps californianus*), lightfooted clapper rail (*Rallus longirostris levipes*), California least tern (*Sternula antillarum brownie*), least Bell's vireo (*Vireo bellii pusillus*), Belding's Savannah sparrow (*Passerculus sandwichensis beldingi*), southwestern willow flycatcher (*Empidonax traillii extimus*), California gnatcatcher (*Polioptila californica*), Mohave ground squirrel (*Spermophilus mohavensis*), and Morro Bay kangaroo rat (*Dipodomys heermanni morroensis*) are examples of species that have been listed as threatened or endangered under the ESA and that could occur within the CVP and SWP service areas.

13.1.3 Other Wildlife Resources

Shasta Lake and Vicinity

Critical Deer Range Critical black-tailed deer winter range for the McCloud Flats and Cow Creek herds is located in the Shasta Lake and vicinity portion of

the primary study area in all five arms of the lake. Critical fawning range also is found along the south-facing slopes of Little Sugarloaf Creek (DFG 1998). Critical deer winter range can include movement corridors, staging areas where deer congregate, and habitats with high-quality winter forage or other elements that help deer to survive the winter. Winter ranges are at lower elevations and are fewer in number than summer ranges, and thus are more vulnerable to human impact. Deer from different summer ranges may use common winter ranges when breeding typically occurs, which contributes to genetic diversity (DFG 1998).

USFWS Habitat Evaluation Procedure Analysis Reclamation is working with USFWS to complete a Habitat Evaluation Procedure analysis to help quantify potential project impacts and meet Fish and Wildlife Coordination Act consultation requirements. To date, Habitat Evaluation Procedure studies and analyses have been completed for part of the Shasta Lake and vicinity portion of the primary study area. Additional planning and coordination are ongoing.

Incidental Observations Reclamation has maintained a database of special-status wildlife species incidentally observed during all biological surveys performed since 2002. The incidental species observations include the foothill yellow-legged frog, northwestern pond turtle (*Actinemys marmorota marmorata*), osprey (*Pandion haliaetus*), yellow-breasted chat (*Icteria virens*), and yellow warbler (*Dendroica petechia brewsteri*) (Figures 13-3a through 13-3f).

Upper and Lower Sacramento River, Delta, and CVP/SWP Service Areas For the upper and lower Sacramento River, Delta, and CVP/SWP service areas, no other wildlife resources were evaluated in addition to wildlife habitats, wildlife, and special-status wildlife as described previously in Sections 13.1.1 and 13.1.2.

13.2 Regulatory Framework

Biological resources in California are protected and/or regulated by a variety of Federal and State laws and policies. Key regulatory and conservation planning issues applicable to the project and alternatives under consideration are discussed below.

13.2.1 Federal

Federal Endangered Species Act

Pursuant to the ESA, USFWS and NMFS have authority over projects that may result in "take" of a Federally listed species. In general, ESA Section 7 prohibits persons (including private parties) from "taking" listed endangered or threatened fish and wildlife species on private property, and from "taking" listed endangered or threatened plant species in areas under Federal jurisdiction or in

violation of State law (16 U.S. Code (USC) 1532, 50 Code of Federal Regulations (CFR) 17.3). Under the ESA, the definition of "take" is to "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct" as part of an intentional or negligent act or omission. The term "harm" includes acts that result in death or injury to wildlife. Such acts may include significant habitat modification or degradation if it results in death or injury to wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. Section 7(a) of the ESA, as amended, requires Federal agencies to evaluate their actions with respect to any species that is proposed for listing or is listed as endangered or threatened. Section 7(a)(2) requires Federal agencies to ensure that activities they authorize, fund, or carry out are not likely to jeopardize the continued existence of a listed species or to destroy or adversely modify its critical habitat. If a Federal action may affect a listed species or its critical habitat, the responsible Federal agency must enter into formal consultation with USFWS or NMFS, depending on the species.

As defined in the ESA, critical habitat is a specific geographic area that is essential for the conservation of a threatened or endangered species and that may require special management and protection. It may include an area that is not currently occupied by the species but that will be needed for its recovery. Critical habitats are designated to ensure that actions authorized by Federal agencies will not destroy or adversely modify critical habitat, thereby protecting areas necessary for the conservation of the species.

Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act provides the basic authority for the involvement of USFWS in evaluating impacts on fish and wildlife from proposed water resource development projects. It requires that fish and wildlife resources receive consideration equal to that of other project features. It also requires Federal agencies that construct, license, or permit water resource development projects to first consult with USFWS (and NMFS in some instances) and State fish and wildlife agencies regarding the impacts of the proposed action on fish and wildlife resources and measures to mitigate these impacts.

Bald Eagle Protection Act

The bald eagle and golden eagle are Federally protected under the Bald Eagle Protection Act (16 USC 668–668c). It is illegal to take, possess, sell, purchase, barter, offer to sell or purchase or barter, transport, export, or import a live or dead bald or golden eagle or any eagle part, nest, or egg unless authorized by the Secretary of the Interior. The Bald Eagle Protection Act defines "take" as "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest or disturb" (16 USC 668–668d). USFWS has defined "disturb" under the act as follows (72 Federal Register 31132–31140 (June 5, 2007)):

> *Disturb means to agitate or bother a bald or golden eagle to a degree that causes, or is likely to cause, based on the best scientific information available, (1) injury to an eagle; (2) a decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior; or (3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior.*

Active nest sites are also protected from disturbance during the breeding season, generally January through August.

USFWS has proposed new permit regulations to authorize the take of bald and golden eagles under the Bald Eagle Protection Act, generally where the take to be authorized is associated with otherwise lawful activities (72 Federal Register 31141–31155 (June 5, 2007). With the delisting of the bald eagle in 2007, this act is the primary law protecting bald eagles and golden eagles. Violators are subject to fines and/or imprisonment for up to 1 year.

Migratory Bird Treaty Act

Migratory birds are protected under the Migratory Bird Treaty Act (MBTA) of 1918 (16 USC 703–711). The MBTA makes it unlawful to take, possess, buy, sell, purchase, or barter any migratory bird listed in 50 CFR Part 10, including feathers or other parts, nests, eggs, or products, except as allowed by implementing regulations (50 CFR 21). This prohibition includes direct and indirect acts, although harassment and habitat modifications are not included unless they result in direct loss of birds, nests, or eggs. The current list of species protected by the MBTA, which can be found in Title 50, Section 10.13 of the CFR, includes several hundred species, essentially all native birds. Loss of nonnative species, such as house sparrows, European starlings, and rock pigeons, is not covered by this statute.

U.S. Forest Service Sensitive Species

The National Forest Management Act requires USFS to "provide for a diversity of plant and animal communities" (16 USC 1604(g)(3)(B)) as part of its multiple-use mandate. USFS must maintain "viable populations of existing native and desired nonnative species in the planning area" (36 CFR 219.19). The Sensitive Species program is designed to meet this mandate and to demonstrate USFS's commitment to maintaining biodiversity on National Forest System lands. The program is a proactive approach to conserving species to prevent a trend toward listing under the ESA and to ensure the continued existence of viable, well-distributed populations. A "Sensitive Species" is any species of plant or animal that has been recognized by the Regional Forester to need special management to prevent the species from becoming threatened or endangered.

Shasta-Trinity National Forest Land and Resource Management Plan

The *Shasta-Trinity National Forest Land and Resource Management Plan* contains forest goals, standards, and guidelines designed to guide the management of the Shasta-Trinity National Forest. The following goals, standards, and guidelines related to wildlife resource issues associated with the study area were excerpted from the *Shasta-Trinity National Forest Land and Resource Management Plan* (USFS 1995).

U.S. Forest Service Survey and Manage Standards and Guidelines

In 1994, BLM and USFS adopted standards and guidelines developed as part of the *Northwest Forest Plan*. These standards and guidelines address management of habitat for late-successional and old-growth forest related species within the range of the northern spotted owl. The *Northwest Forest Plan* was designed to address human and environmental needs served by the Federal forests of the western part of the Pacific Northwest and Northern California. The development of the *Northwest Forest Plan* was triggered in the early 1990s by the listing of the northern spotted owl and marbled murrelet as threatened under the ESA.

To mitigate potential impacts on plant and wildlife species that have the potential to occur within the range of the northern spotted owl, surveys are required for species thought to be rare, or whose status is unknown because of a lack of information. These species became known as the Survey and Manage species. The *Northwest Forest Plan* has gone through several revisions since its implementation in 1994, including the elimination of the Survey and Manage Mitigation Measure Standards and Guidelines in 2004. However, these guidelines were reinstated in January 2006 as the result of a court order.

Biological Diversity

Goals (LRMP, p. 4-4) Integrate multiple resource management on a landscape level to provide and maintain diversity and quality of habitats that support viable populations of plants, fish, and wildlife.

Standards and Guidelines (LRMP, p. 4-14)

- **Natural Openings** – Management of natural openings will be determined at the project level consistent with desired future conditions.

- **Snags** – Over time, provide the necessary number of replacement snags to meet density requirements as prescribed for each land allocation and/or management prescription. Live, green culls and trees exhibiting decadence and/or active wildlife use are preferred.

- **Hardwood** – Apply the following standards in existing hardwood types:

    - Manage hardwood types for sustainability.

- Conversion to conifers will only take place to meet desired future ecosystem conditions.
- Where hardwoods occur naturally within existing conifer types on suitable timber lands, manage for a desired future condition for hardwoods as identified during ecosystem analysis consistent with management prescription standards and guidelines. Retain groups of hardwoods over single trees.

Threatened, Endangered, and Sensitive Species (Plants and Animals)

Goals (LRMP, p. 4-5)

- Monitor and protect habitat for Federally listed Threatened and Endangered and candidate species. Assist in recovery efforts for Threatened and Endangered species. Cooperate with the State to meet objectives for State-listed species.

- Manage habitat for sensitive plants and animals in a manner that will prevent any species from becoming a candidate for Threatened and Endangered status.

Goals (LRMP, p. 4-6)

- Meet habitat or population objectives established for management indicators.

- Cooperate with Federal, State, and local agencies to maintain or improve wildlife habitat.

- Maintain natural wildlife species diversity by continuing to provide special habitat elements within Forest ecosystems.

Standards and Guidelines (LRMP, pp. 4-29 through 4-30)

- Minimize accidental electrocution of raptors by ensuring that newly constructed overhead power lines meet safe design standards.

- Consider transplants, introductions, or reintroductions of wildlife species only after ecosystem analysis and coordination with other agencies and the public.

- Manage habitat for Neotropical migrant birds to maintain viable population levels.

- Develop interpretation/view sites for wildlife viewing, photography, and study. Provide pamphlets, slide shows, and other educational material that enhance the watchable wildlife and other interpretive programs.

- Maintain and/or enhance habitat for Federally listed threatened and endangered or USFS sensitive species consistent with individual species recovery plans.

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The *Management Guide for the Whiskeytown-Shasta-Trinity National Recreation Area*, including the Shasta Unit of the National Recreation Area, contains management strategies intended to achieve or maintain a desired condition. These strategies take into account opportunities, management recommendations for specific projects, and mitigation measures needed to achieve specific goals. The following strategies relative to wildlife resource issues associated with the project site were excerpted from the management guide (USFS 1996).

Vegetation (Management Guide, pp. IV-18 through IV-19)

- Prescribed burning, fuel break construction, and other forms of vegetation manipulation will be used to reduce fire hazards and improve forest health.

- Recreation sites will be inventoried and vegetative management plans will be developed to ensure healthy and safe vegetation complexes are maintained over time.

- Bald eagle nest territories will be inventoried and vegetation management plans will be developed to ensure that suitable nest and perch trees are maintained over time.

- Chaparral and woodland habitat management will occur to meet wildlife objectives.

- Interpretive materials will address the need to conserve rare plant communities in accordance with the National Recreation Area Interpretive Plan.

- Diversity of native species will be emphasized. Eradication program will be implemented for nonnative, introduced species in areas where healthy, botanically diverse plant communities are necessary to meet ecosystem management objectives.

Wildlife (Management Guide, pp. IV-19 through IV-20)

- Management activities will assure population viability for all native and nonnative desirable species. Management to insure viability will occur within occupied habitat for bald eagle, peregrine falcon, northern spotted owl, northern goshawk, willow flycatcher, northwestern pond turtle, Pacific fisher, Shasta salamander, and

candidate species in accordance with species and/or territory management plans, Forest Orders, and appropriate laws and policy.

- Surveys will continue within potential suitable habitats to determine occupancy status for Threatened, Endangered, sensitive, and candidate species.

- Cooperation will continue with the DFG and the USFWS regarding habitat management of wildlife species inhabiting the National Recreation Area. Consultation with USFWS will continue regarding habitat management for threatened and endangered species.

Section 404 of the Clean Water Act

USACE regulates discharges of dredged or fill materials into waters of the United States under Section 404 of the Clean Water Act. Waters of the United States include lakes, rivers, streams, and relatively permanent tributaries and adjacent wetlands. Wetlands are defined under Section 404 as areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support (and that do support under normal circumstances) a prevalence of vegetation typically adapted for life in saturated soil conditions. Activities that require a permit under Section 404 include, but are not limited to, placing fill or riprap, grading, mechanized land clearing, and dredging. Any activity that results in the deposit of dredged or fill material below the ordinary high-water mark of waters of the United States or within a jurisdictional wetland usually requires a Section 404 permit, even if the area is dry at the time the activity takes place.

Executive Order 11312: Invasive Species

Executive Order 13112 directs Federal agencies to use relevant programs and authorities to do all of the following:

- Prevent the introduction of invasive species

- Detect and respond rapidly to and control populations of such species in a cost-effective and environmentally sound manner

- Monitor invasive species populations accurately and reliably

- Provide for restoration of native species and habitat conditions in ecosystems that have been invaded

- Conduct research on invasive species and develop technologies to prevent introduction and provide for environmentally sound control of invasive species

- Promote public education on invasive species and the means to address them

- Refrain from authorizing, funding, or carrying out actions that it believes are likely to cause or promote the introduction or spread of invasive species in the United States or elsewhere unless, pursuant to guidelines that it has prescribed, the agency has determined and made public its determination that the benefits of such actions clearly outweigh the potential harm caused by invasive species; and that all feasible and prudent measures to minimize risk of harm will be taken in conjunction with the actions.

Executive Order 11312 established a national Invasive Species Council made up of Federal agencies and departments and a supporting Invasive Species Advisory Committee composed of State, local, and private entities. The Invasive Species Council and Advisory Committee oversee and facilitate implementation of the executive order, including preparation of a national invasive species management plan.

Executive Order 11990: Protection of Wetlands

Executive Order 11990 established the protection of wetlands and riparian systems as the official policy of the Federal government. It requires all Federal agencies to consider wetland protection as an important part of their policies and take action to minimize the destruction, loss, or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands.

Executive Order 13186: Migratory Birds

Executive Order 13186 directs executive departments and agencies to take certain actions to further implement the MBTA. It requires that each Federal agency taking actions that have, or are likely to have, a measurable negative effect on migratory bird populations develop and implement a memorandum of understanding with USFWS that shall promote the conservation of migratory bird populations.

Executive Order 13443: Facilitation of Hunting Heritage and Wildlife Conservation

Executive Order 13443 directs Federal agencies that have programs and activities that have a measurable effect on public land management, outdoor recreation, and wildlife management, including the U.S. Department of the Interior and the U.S. Department of Agriculture, to facilitate the expansion and enhancement of hunting opportunities and the management of game species and their habitat.

13.2.2 State

California Endangered Species Act

Under the CESA, DFG has the responsibility for maintaining a list of endangered and threatened species (California Fish and Game Code, Section 2070). DFG also maintains a list of "candidate species," which are species for which DFG has issued a formal notice that they are under review for addition to

the list of endangered or threatened species. In addition, DFG maintains lists of "species of special concern," which serve as species "watch lists." Pursuant to the requirements of CESA, an agency reviewing a proposed project within its jurisdiction must determine whether any State-listed endangered or threatened species may be present in the project study area and, if so, whether the proposed project would have a potentially significant impact on any of these species. In addition, DFG encourages informal consultation on any proposed project that may affect a species that is a candidate for state listing.

Project-related impacts on species listed as endangered or threatened under the CESA would be considered significant. State-listed species are fully protected under the mandates of the CESA. "Take" of protected species incidental to otherwise lawful management activities may be authorized under Section 2081 of the California Fish and Game Code. Under the CESA, "take" is defined as an activity that would directly or indirectly kill an individual of a species, but the definition does not include "harm" or "harass," as the Federal act does. As a result, the threshold for take under the CESA is higher than that under the ESA.

Authorization from DFG would be in the form of an incidental take permit or as a consistency determination (Section 2080.1(a) of the Fish and Game Code). Section 2080.1(a) of the Fish and Game Code authorizes DFG to accept a Federal biological opinion (BO) as the take authorization for a state-listed species when a species is listed under both the ESA and the CESA.

Sections 3503 and 3513 of the California Fish and Game Code—Protection of Birds of Prey

Under Section 3503 of the California Fish and Game Code, it is unlawful to take, possess, or needlessly destroy the nest or eggs of any bird. Section 3503.5 specifically states that it is unlawful to take, possess, or destroy any raptors (birds in the order of Falconiformes or Strigiformes (birds of prey)—i.e., eagles, hawks, owls, and falcons), including their nests or eggs. Section 3513 provides for adoption of the MBTA's provisions. It states that it is unlawful to take or possess any migratory nongame bird as designated in the MBTA or any part of such migratory nongame bird. These State codes offer no statutory or regulatory mechanism for obtaining an incidental take permit for the loss of nongame, migratory birds. Typical violations include destruction of active raptor nests resulting from removal of vegetation in which the nests are located. Violation of Sections 3503.5 and 3513 could also include disturbance of nesting pairs that results in failure of an active raptor nest.

Fully Protected Species under the Fish and Game Code

Protection of fully protected species is described in four sections of the Fish and Game Code (Sections 3511, 4700, 5050, and 5515) that list 37 fully protected species. These statutes prohibit take or possession at any time of fully protected species. DFG is unable to authorize incidental take of fully protected species when activities are proposed in areas inhabited by those species. DFG has

informed non-Federal agencies and private parties that they must avoid take of any fully protected species in carrying out projects.

Section 1602 of the California Fish and Game Code—Streambed Alteration

Diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by DFG, pursuant to Section 1602 of the California Fish and Game Code. The regulatory definition of a stream is a body of water that flows at least periodically or intermittently through a bed or channel having banks and supports wildlife, fish, or other aquatic life. This includes watercourses that have a surface or subsurface flow that supports or has supported riparian vegetation. DFG's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife. A DFG streambed alteration agreement must be obtained for a project that would result in an impact on a river, stream, or lake.

Section 401 Water Quality Certification/Porter-Cologne Water Quality Control Act

Under Section 401 of the Clean Water Act, an applicant for a Section 404 permit must obtain a certificate from the appropriate State agency stating that the intended dredging or filling activity is consistent with the State's water quality standards and criteria. In California, the authority to grant water quality certification is delegated by the State Water Resources Control Board to the nine Regional Water Quality Control Boards (RWQCB). Each of the RWQCBs must prepare and periodically update basin plans for water quality control in accordance with the Porter-Cologne Water Quality Control Act. Each basin plan sets forth water quality standards for surface water and groundwater, as well as actions to control nonpoint and point sources of pollution to achieve and maintain these standards. Basin plans offer an opportunity to protect wetlands through the establishment of water quality objectives. The RWQCB's jurisdiction includes Federally protected waters as well as areas that meet the definition of "waters of the state." A water of the State is defined as any surface water or groundwater, including saline waters, within the boundaries of California. The RWQCB has the discretion to take jurisdiction over areas not Federally protected under Section 401, provided that those areas meet the definition of waters of the State. Mitigation requiring no net loss of wetlands functions and values of waters of the State is typically required by the RWQCB.

California Department of Fish and Game Species Designations

DFG maintains an informal list of species called "species of special concern." These are broadly defined as plant and wildlife species that are of concern to DFG because of population declines and restricted distributions, and/or because they are associated with habitats that are declining in California. These species are inventoried in the CNDDB regardless of their legal status. Impacts on species of special concern may be considered significant.

13.2.3 Regional and Local

Shasta, Tehama, Glenn, Sutter, Sacramento, and Yolo counties and the cities of Redding, Colusa, and Sacramento have established codes and policies that address protection of natural resources, including vegetation, sensitive species, and trees, and are applicable to the project.

Shasta County's general plan emphasizes that the maintenance and enhancement of quality fish and wildlife habitat is critical to the recreation and tourism industry, and acknowledges that any adverse and prolonged decline of these resources could result in negative impacts on an otherwise vibrant industry. The general plan identifies efforts to protect and restore these habitats to sustain the long-term viability of the tourism and recreation industry (Shasta County 2004).

The City of Redding's general plan strives to strike a balance between development and conservation by implementing several measures such as creek-corridor protection, sensitive hillside development, habitat protection, and protection of prominent ridge lines that provide a backdrop to the city (City of Redding 2000).

Tehama County's general plan update provides an overarching guide to future development and establishes goals, policies, and implementation measures designed to address potential changes in county land use and development. The general plan identifies the importance of retaining agriculture as one of the primary uses of land in Tehama County (Tehama County 2009).

Glenn County's general plan provides a comprehensive plan for growth and development in Glenn County for the next 20 years (2007–2027). This plan recognizes that public lands purchased for wildlife preservation generate economic activity as scientists and members of the public come to view and study remnant ecosystems (Glenn County 1993).

The City of Colusa's general plan seeks to promote its natural resources through increased awareness and improved public access (City of Colusa 2007).

Sutter County's general plan contains policies that generally address preservation of natural vegetation, including wetlands. It requires that new development mitigate the loss of Federally protected wetlands to achieve "no net loss," but it does not include any other specific requirements (Sutter County 2010).

Sacramento County's general plan contains policies that promote protection of marsh and riparian areas, including specification of setbacks and "no net loss" of riparian woodland or marsh acreage (Sacramento County 1993). It also addresses the need to conserve vernal pools and ephemeral wetlands to ensure no net loss of vernal pool acreage. Several policies specifically promote protection of native oak trees, and, in some areas of the county, seek to ensure

that there is no net loss of canopy area. The general plan for the County of Sacramento is currently under revision.

Chapter 12.56, "Trees Generally," of the City of Sacramento Municipal Code addresses the protection of trees within the city boundaries, including general protection of all trees on city property and specific protection of heritage trees (City of Sacramento 2011).

Yolo County's general plan aims to provide an active and productive buffer of farmland and open space separating the Bay Area from Sacramento, and integrating green spaces into its communities (Yolo County 2009).

13.2.4 Federal, State, and Local Programs and Projects

California Bay-Delta Authority

The California Bay-Delta Authority was established as a State agency in 2003 to oversee implementation of CALFED for the 25 Federal and State agencies working cooperatively to improve the quality and reliability of California's water supplies while restoring the Bay-Delta ecosystem. The CALFED Ecosystem Restoration Program has provided a funding source for projects that include those involving acquisition of lands within the Sacramento River Conservation Area, initial baseline monitoring and preliminary restoration planning, and preparation of long-term habitat restoration management and monitoring plans.

Cantara Trustee Council

The Cantara Trustee Council administers a grant program that has provided funding for numerous environmental restoration projects in the primary study area, including programs in the Fall River watershed, Sulphur Creek, the upper Sacramento River, Middle Creek, lower Clear Creek, Battle Creek, Salt Creek, and Olney Creek. The Cantara Trustee Council is a potential local sponsor for future restoration actions in the primary study area. The Cantara Trustee Council includes representatives from DFG, USFWS, the Central Valley RWQCB, the California Sportfishing Protection Alliance, and the Shasta Cascade Wonderland Association.

Resource Conservation Districts

There are numerous resource conservation districts (RCD) within the study area. Once known as soil conservation districts, RCDs were established under California law with a primary purpose to implement local conservation measures. Although RCDs are locally governed agencies with locally appointed, independent boards of directors, they often have close ties to county agencies and the U.S. National Resources Conservation Service. RCDs are empowered to conserve resources within their districts by implementing projects on public and private lands and to educate landowners and the public about resource conservation. They are often involved in the formation and coordination of watershed working groups and other conservation alliances. In

the Shasta Lake and upper Sacramento River vicinity, districts include the Western Shasta County RCD and the Tehama County RCD. To the east are the Fall River and Pit River RCDs, and to the west and north are the Trinity County and Shasta Valley RCDs.

Riparian Habitat Joint Venture

The Riparian Habitat Joint Venture (RHJV) was initiated in 1994 and includes signatories from 18 Federal, State, and private agencies. The RHJV promotes conservation and the restoration of riparian habitat to support native bird population through three goals:

- Promote an understanding of the issues affecting riparian habitat through data collection and analysis.
- Double riparian habitat in California by funding and promoting on-the-ground conservation projects.
- Guide land managers and organizations to prioritize conservation actions.

RHJV conservation and action plans are documented in *The Riparian Bird Conservation Plan* (RHJV 2004). The conservation plan targets 14 "indicator" species of riparian-associated birds and provides recommendations for habitat protection, restoration, management, monitoring, and policy. The report notes habitat loss and degradation as one of the most important factors causing the decline of riparian birds in California. The RHJV has participated in monitoring efforts within the Sacramento National Wildlife Refuge Complex and other conservation areas. The RHJV's conservation plan identifies lower Clear Creek as a prime breeding area for yellow warblers and song sparrows, advocating a continuous riparian corridor along lower Clear Creek.

Sacramento River Advisory Council

In 1986 the California Legislature passed Senate Bill 1086, which called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance fisheries and riparian habitat in an area stretching from the confluence of the Sacramento River with the Feather River and continuing northward to Keswick Dam, about 4 miles north of Redding. The law established an advisory council that included representatives of Federal and State agencies, county supervisors, and representatives of landowners, water contractors, commercial and sport fisheries, and general wildlife and conservation interests. Responsibilities of the advisory council included development of the *Sacramento River Conservation Area Forum Handbook* to guide management of riparian habitat and agricultural uses along the river (Resources Agency 2003). This action also resulted in formation in May 2000 of the Sacramento River Conservation Area Forum, a nonprofit, public benefit corporation with a board of directors that includes private landowners and public interest representatives from a seven-county area, an appointee of the

California Resources Agency, and ex-officio members from six Federal and State resource agencies. The work of the organization is generally focused on planning actions and river management within the Sacramento River Conservation Area planning area.

Sacramento River Conservation Area Program

Senate Bill 1086 called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance both fisheries and riparian habitat. The Sacramento River Conservation Area Program has an overall goal of preserving remaining riparian habitat and reestablishing a continuous riparian ecosystem along the Sacramento River between Redding and Chico, and reestablishing riparian vegetation along the river from Chico to Verona. The program is to be accomplished through an incentive-based, voluntary river management plan. The *Upper Sacramento River Fisheries and Riparian Habitat Management Plan* (Resources Agency 1989), identifies specific actions to help restore the Sacramento River fishery and riparian habitat between the Feather River and Keswick Dam. The *Sacramento River Conservation Area Forum Handbook* (Resources Agency 2003) is a guide to implementing the program. The Keswick Dam to Red Bluff portion of the conservation area includes areas within the 100-year floodplain, existing riparian bottomlands, and areas of contiguous valley oak woodland, totaling approximately 22,000 acres. The 1989 fisheries restoration plan recommended several actions specific to the study area:

- Fish passage improvements at RBDD (recently completed)
- Modification of the Spring Creek Tunnel intake for temperature control (completed)
- Spawning gravel replacement program (ongoing)
- Development of side-channel spawning areas, such as those at Turtle Bay in Redding (ongoing)
- Structural modifications to the Anderson-Cottonwood Irrigation District Dam to eliminate short-term flow fluctuations (completed)
- Maintaining instream flows through coordinated operation of water facilities (ongoing)
- Improvements at the Coleman National Fish Hatchery (partially complete)
- Measures to reduce acute toxicity caused by acid mine drainage and heavy metals (ongoing)
- Various fisheries improvements on Clear Creek (partially complete)

- Flow increases, fish screens, and revised gravel removal practices on Battle Creek (beginning summer 2006, ongoing monitoring)

- Control of gravel mining, improvements of spawning areas, improvements of land management practices in the watershed, and protection and restoration of riparian vegetation along Cottonwood Creek (ongoing)

Sacramento River National Wildlife Refuge

The Sacramento River National Wildlife Refuge (SRNWR) is composed of many units between the cities of Red Bluff and Princeton. The SRNWR along the middle Sacramento River is part of the Sacramento National Wildlife Refuge Complex, consisting of five refuges and three wildlife management areas within the Sacramento Valley. Reaches and subreaches of the river are delineated based generally on transitions in fluvial geomorphic riverine conditions, although county boundaries were considered as well. The middle Sacramento River region between Red Bluff and Colusa includes three units within the Chico Landing Subreach that contain restoration project sites addressed in the *Sacramento River–Chico Landing Subreach Habitat Restoration Draft Environmental Impact Report* (CBDA 2005). In addition, three areas proposed for restoration in this area occur within the larger SRNWR units that were evaluated in the *Environmental Assessment for Proposed Restoration Activities on the Sacramento River National Wildlife Refuge* (USFWS 2001; CBDA 2005).

In June 2005, USFWS issued the *Sacramento River National Wildlife Refuge Final Comprehensive Conservation Plan and Environmental Assessment and Finding of No Significant Impact* (USFWS 2005b) to serve as an integrated management plan for land that it acquires and manages for inclusion in the SRNWR. The SRNWR final comprehensive conservation plan includes goals, objectives, and strategies to guide management of lands within the SRNWR. It also includes assessments of and establishes parameters for "compatible uses," which are uses that are considered compatible with the primary purposes for which the area was established. Riparian habitat restoration projects are being implemented under cooperative agreements between USFWS and other entities such as The Nature Conservancy (TNC) in accordance with the SRNWR final comprehensive conservation plan.

Sacramento River Wildlife Area

The Sacramento River Wildlife Area is managed by DFG and consists of approximately 3,770 acres of important riparian habitat located along a 70-mile reach of the lower Sacramento River. These lands are managed to protect and enhance habitat for wildlife species, and to provide the public with compatible, wildlife-related recreational uses. This management is guided by the *Sacramento River Comprehensive Management Plan* prepared in 2004.

Sacramento River Preservation Trust

The Sacramento River Preservation Trust is a private, nonprofit organization active in environmental education and advocacy to preserve the natural environmental values of the Sacramento River. The trust has participated in various conservation and land acquisition projects, including securing lands for the SRNWR. The group is pursuing designation of a portion of the Sacramento River between Redding and Red Bluff as a national conservation area.

Sacramento River Watershed Program

The Sacramento River Watershed Program is an effort to bring stakeholders together to share information and work together to address water quality and other water-related issues within the Sacramento River watershed. The group is funded congressionally through the U.S. Environmental Protection Agency. The program's primary goal is "to ensure that current and potential uses of Sacramento River watershed resources are sustained, restored, and where possible, enhanced while promoting the long-term social and economic vitality of the region." The Sacramento River Watershed Program manages grants for the Sacramento River Toxic Pollutants Control Program; performs extensive water quality monitoring, data collection, and data management for the watershed; and is instrumental in the study and monitoring of toxic pollutants. Although the program does not implement restoration projects, it is a potential partner for coordinating research and monitoring through consensus-based collaborative partnerships and promoting mutual education among the stakeholders of the Sacramento River watershed.

Sacramento Watersheds Action Group

The Sacramento Watersheds Action Group is a nonprofit corporation that secures funding for, designs, and implements projects that provide watershed restoration, streambank and slope stabilization, erosion control, watershed analysis, and road removal. The Sacramento Watersheds Action Group has successfully worked with local groups, agencies, and organizations to fund and complete restoration projects on the Sacramento River and tributaries downstream from Keswick Dam. Their projects include development of the *Sulphur Creek Watershed Analysis and Action Plan*, the Whiskeytown Reservoir Shoreline Erosion Control Project, the Sulphur Creek Crossing Restoration Project, and the Lower Sulphur Creek Realignment and Riparian Habitat Enhancement Project. The Sacramento Watersheds Action Group is a potential local sponsor for watershed restoration actions in the study area.

Shasta Land Trust

The Shasta Land Trust is a regional, nonprofit organization dedicated to conserving open space, wildlife habitat, and agricultural land. This organization works with public agencies and private landowners and is funded primarily through membership dues and donations. It employs various voluntary programs to protect and conserve valuable lands using conservation easements, land donations, and property acquisitions. The trust is a potential local partner for restoration activities in the Shasta Dam to Red Bluff area.

The Nature Conservancy

TNC is a private, nonprofit organization involved in environmental restoration and conservation throughout the United States and the world. TNC approaches environmental restoration primarily through strategic land acquisition from willing sellers and obtaining conservation easements. Some of the lands are retained by TNC for active restoration, research, or monitoring activities, while others are turned over to government agencies such as USFWS or DFG for long-term management. Lower in the Sacramento River basin, TNC has been instrumental in acquiring and restoring lands in the SRNWR and managing several properties along the Sacramento River. It also has pursued conservation easements on various properties at tributary confluences, including Cottonwood and Battle creeks.

The Trust for Public Land

The Trust for Public Land is a national, nonprofit organization involved in preserving lands with natural, historic, cultural, or recreational value, primarily through conservation real estate. This organization's Western Rivers Program has been involved in conservation efforts along the Sacramento River between Redding and Red Bluff (BLM's Sacramento River Bend Management Area), Battle Creek, Paynes Creek, Inks Creek, and Fenwood Ranch in Shasta County. The group promotes public ownership of conservation lands to ensure public access and enjoyment.

13.3 Environmental Consequences and Mitigation Measures

This section describes the environmental evaluation methods, assumptions, and specific criteria used to determine significance for each resource area, and discusses impacts and proposed mitigation measures. This impacts assessment evaluates the project's compliance with requirements outlined in the *Wildlife Resources Technical Report*. Mitigation measures are presented (as needed) to reduce impacts to a less than significant level.

13.3.1 Methods and Assumptions

The following sections describe the methods, processes, procedures, and assumptions used to formulate and conduct the environmental impact analysis.

This analysis of impacts on wildlife resources resulting from implementation of the project alternatives under consideration is based on review of existing documentation that addresses biological resources in or near the primary and extended study areas and on geographic information systems analysis.

Where specific habitat data were not available, suitable habitat data defined by California Wildlife Habitat Relationships (CWHR) were used to determine impacts.

The following assumptions about activity at Shasta Lake and vicinity have been made for the purposes of the impact analysis:

- Activity areas (construction areas for infrastructure and relocation areas) would be completely cleared.
- Cutting/clearing of vegetation would be conducted from late summer through late winter, to the extent feasible.
- Removal of cleared material could occur during the typical breeding season for birds in Shasta County.
- Removal of cleared vegetation would be done using conventional yarding systems and aerial (helicopter) systems.
- With the exception of Arbuckle Flat, no vegetation would be removed along the Pit Arm upstream from Painter Creek.
- No blasting would be required for the mining of materials within the current boundary of Shasta Lake.

For the upper Sacramento River and extended study area, the project has the potential to affect common wildlife and special-status wildlife species through the following impact mechanisms:

- Change in inundated width of the river from spring through fall
- Reduced frequency, duration, or magnitude of intermediate to large flows
- Altered geomorphic processes (e.g., meander, channel avulsion) along rivers
- Altered availability of groundwater
- Altered vegetative communities within the river corridor
- Temporary or permanent disturbance of habitat at Reading Island and gravel augmentation sites
- Mortality of individuals of special-status species at Reading Island and gravel augmentation sites

Potential effects on the upper Sacramento River and extended study area resulting from these impact mechanisms were assessed for common wildlife and special-status wildlife species associated with riparian and wetland habitats located between Shasta Dam and RBDD and within the extended study area that may be affected by altered hydrologic flows. It is assumed that construction-

related activities, their effects, and mitigation were considered in the "Shasta Lake and Vicinity" section. The assessment in this section was based in part on the potential effects on vegetation communities provided in Chapter 12, "Botanical Resources and Wetlands."

13.3.2 Criteria for Determining Significance of Effects

Significance criteria used to analyze the potential impacts of the project on wildlife resources include factual and scientific information and regulatory standards of county, State, and Federal agencies, including the State CEQA Guidelines. These criteria have been developed to establish thresholds to determine the significance of impacts pursuant to CEQA (Section 15064.7) and should not be confused with a "take" or adverse effect under the ESA. An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an environmental impact statement must be prepared. An EIS must identify reasonable means to "mitigate adverse environmental impacts" (40 E 1502.16(h)). An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on wildlife would be significant if project implementation would do any of the following:

- Result in mortality of State-listed or Federally listed wildlife species, or species that are candidates for listing or proposed for listing
- Have the potential to substantially reduce the habitat of any wildlife species, including those that are listed as endangered or threatened or are candidates or proposed for endangered or threatened status
- Have the potential to cause a wildlife population to drop below self-sustaining levels
- Have a substantial adverse effect, either directly or through habitat modifications, on any non-special-status wildlife species
- Substantially adversely affect, either directly or through habitat modifications, any wildlife species identified as a candidate, sensitive,

or special-status species in local or regional plans, policies, or regulations or by DFG or USFWS

- Interfere substantially with the movement of any native resident or migratory wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites

- Conflict with or violate the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, State, or Federal habitat conservation plan relating to the protection of wildlife species

- Conflict with any State or local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance

- Substantially reduce the habitat of a wildlife species, cause a wildlife species to drop below self-sustaining levels, threaten to eliminate an animal community, or substantially reduce the number or restrict the range of an endangered, rare, or threatened species

Significance statements are relative to both existing conditions (2005) and future conditions (2030) unless stated otherwise. Impact conclusions are made using the significance criteria described above and include consideration of the "context" of the action and the "intensity" (severity) of its effects in accordance with NEPA guidance (40 CFR 1508.27).

13.3.3 Topics Eliminated from Further Consideration

No topics related to wildlife resources that are included in the significance criteria listed above were eliminated from further consideration. All relevant topics are analyzed below.

13.3.4 Direct and Indirect Effects

This section identifies how wildlife could be affected by the project. The project could affect wildlife by doing any of the following:

- Causing construction-related effects at Shasta Dam and around Shasta Lake

- Altering flow regimes downstream from Shasta Lake and downstream from other reservoirs with altered operations

- Increasing water supply reliability, which in turn could contribute to human population growth or changes in agricultural land uses in the CVP and SWP service areas

By altering storage and reservoir operations, the project would change flow regimes in downstream waterways. In turn, these alterations to the flow regime could affect wildlife, particularly by affecting their riparian and wetland habitats along several waterways.

No-Action Alternative

Under the No-Action Alternative, Reclamation would not pursue an action to enlarge Shasta Dam. No new facilities would be constructed at Shasta Dam and no facilities around Shasta Lake would be relocated to accommodate higher lake levels; thus, there would be no construction-related impacts. In addition, releases from Shasta Dam or other CVP reservoirs would not change as a result of a Shasta Dam enlargement. Reasonably foreseeable projects identified elsewhere in this PDEIS, however, would occur and have effects on wildlife but those effects are unknown, largely speculative for many such projects, and therefore are not addressed in detail below.

Shasta Lake and Vicinity

Impact Wild-1 (No-Action): Take and Loss of Habitat for the Shasta Salamander No direct take of the Shasta salamander or loss of its habitat would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-2 (No-Action): Impacts on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat No impacts or loss of habitat for the foothill yellow-legged frog or tailed frog would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-3 (No-Action): Impacts on the Northwestern Pond Turtle and Its Habitat No direct take or decrease of habitat quality for the northwestern pond turtle would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-4 (No-Action): Impacts on the American Peregrine Falcon No impact on the American peregrine falcon would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-5 (No-Action): Take and Loss of Habitat for the Bald Eagle No take of loss of habitat for the bald eagle would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-6 (No-Action): Take and Loss of Nesting and Foraging Habitat for the Northern Spotted Owl No take or loss of nesting and foraging habitat for the northern spotted owl would occur because the project would not be

constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-7 (No-Action): Impacts on the Purple Martin and Its Nesting Habitat No impacts or loss of nesting habitat for the purple martin would occur because the project would not be constructed. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-8 (No-Action): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat No impacts or loss of foraging and nesting habitat for the willow flycatcher, Vaux's swift, yellow warbler, and yellow-breasted chat would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-9 (No-Action): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat No impact or loss of foraging and nesting habitat for the long-eared owl, northern goshawk, Cooper's hawk, great blue heron, and osprey would occur because the project would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-10 (No-Action): Take and Loss of Habitat for the Pacific Fisher No take or loss of habitat for the Pacific fisher would occur because the project would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-11 (No-Action): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, and Yuma Myotis), the American Marten, and Ringtail and Their Habitat No impact or loss of habitat for special-status bats (the pallid bat, spotted bat, western red bat, western mastiff bat, Townsend's big-eared bat, long-eared myotis, and Yuma myotis), the American marten, and ringtail would occur because the project would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-12 (No-Action): Impacts on Special-Status Terrestrial Mollusks (Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat No impact or loss of habitat for special-status terrestrial mollusks (Shasta sideband, Wintu sideband, Shasta chaparral, and Shasta hesperian) would occur because the project would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-13 (No-Action): Permanent Loss of Wildlife Habitat No permanent loss of habitat would occur because the project would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-14 (No-Action): Impacts on Other Birds of Prey (i.e., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species(i.e., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat No impact or loss of foraging and nesting habitat for other birds of prey and migratory bird species would occur because the project would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-15 (No-Action): Loss of Critical Deer Winter and Fawning Range No loss of deer winter and fawning range would occur because the project would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-16 (No-Action): Take and Loss of California Red-Legged Frog No loss of California red-legged frog habitat would occur because the project would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Wild-17 (No-Action): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Effects on riparian vegetation in the upper Sacramento River area from continuing the existing dam operation under the No-Action Alternative would not have a substantial adverse effect on special-status wildlife. This impact would be less than significant.

Implementing the No-Action Alternative would not result in changes to existing facilities or reservoir operations. The No-Action Alternative would continue to alter the structure and species composition of riparian vegetation resulting from continued operation of the existing Shasta Dam, as described in Chapter 12, "Botanical Resources and Wetlands." Operation of the dam has decreased early successional riparian communities and increased the extent of mid-successional riparian communities. Although early and mid-sucessional riparian vegetation provides different habitat values and some shifts in species use may occur, implementing the No-Action Alternative would not have a substantial adverse effect on special-status wildlife associated with riparian vegetation, nor would it be likely to cause a population to be eliminated. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-18 (No-Action): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes Future conditions for bank swallows are not expected to differ substantially from existing conditions because of the restoration projects being implemented on the Sacramento River. This impact would be less than significant.

Dam operations under the No-Action Alternative would continue to alter geomorphic processes. Loss of eroding banks during winter flood flows could

limit the formation of suitable nesting habitat for bank swallow. However, future conditions for bank swallows are not expected to differ substantially from existing conditions because of the restoration projects being implemented on the Sacramento River. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-19 (No-Action): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Changes in Flow Regime No adverse effects on vernal pool-associated wildlife species would occur. This impact would be less than significant.

The No-Action Alternative would not affect the hydrology of vernal pools or have an adverse effect on vernal pool–associated wildlife species. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-20 (No-Action): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Riparian habitat conditions would not differ from baseline conditions. This impact would be less than significant.

The No-Action Alternative would not conflict with existing plans promoting riparian habitat because conditions would not differ from the existing baseline. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-21 (No-Action): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program Under the No-Action Alternative, the gravel augmentation program would not be implemented. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Wild-22 (No-Action): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration of Reading Island Under the No-Action Alternative there would be no Reading Island restoration. Thus, there would be no impact. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta

Impact Wild-23 (No-Action): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Effects on riparian vegetation in the lower Sacramento River and Delta areas from continuing the existing dam operation under the No-Action Alternative would not have a substantial adverse effect on special-status wildlife. This impact would be less than significant.

This impact would be similar to Impact Wild-17 (No-Action) for the primary study area. The No-Action Alternative would continue to alter the structure and species composition of riparian habitat along the lower Sacramento River and

into the Delta resulting from continued operation of Shasta Dam. Dam operation, which has led to a decrease in early successional riparian communities and an increase in the extent of mid-successional riparian communities, would continue under the No-Action Alternative. Thus, the No-Action Alternative would affect habitats used by special-status wildlife species because early- and mid-successional riparian vegetation provide different habitat values. However, this change is expected to be small and is not likely to have a substantial adverse effect on special-status species, nor would it be likely to cause a population to be eliminated. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-24 (No-Action): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes Future conditions for bank swallows along the lower Sacramento River are not expected to differ substantially from existing conditions because of the restoration projects being implemented on the Sacramento River. This impact would be less than significant.

This impact would be similar to Impact Wild-18 (No-Action) for the primary study area. Dam operations under the No-Action Alternative would continue to alter geomorphic processes along the lower Sacramento River. Loss of eroding banks during winter flood flows could limit the formation of suitable nesting habitat for bank swallow. However, future conditions for bank swallows are not expected to differ substantially from existing conditions because of the restoration projects being implemented on the Sacramento River. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-25 (No-Action): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability No adverse effects on vernal pool–associated wildlife species along the lower Sacramento River and in the Delta would occur. This impact would be less than significant.

This impact would be similar to Impact Wild-19 (No-Action) for the primary study area. The No-Action Alternative would not affect the hydrology of vernal pools or have an adverse effect on vernal pool–associated wildlife species. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-26 (No-Action): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta No adverse effects on vernal pool–associated wildlife species along the lower Sacramento River and in the Delta would occur. This impact would be less than significant.

This impact would be similar to Impact Wild-20 (No-Action) for the primary study area. The No-Action Alternative would not conflict with existing plans promoting riparian habitat along the lower Sacramento River and in the Delta because conditions would not differ from the existing baseline. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas

Impact Wild-27 (No-Action): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes Changes to CVP and SWP water deliveries that would occur while the existing dam operation continues under the No-Action Alternative would not have a substantial adverse effect on special-status wildlife. This impact would be less than significant.

This impact would be similar to Impact Wild-17 (No-Action) for the primary study area and Impact Wild-21 (No-Action) for the lower Sacramento River and Delta. Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries to the CVP and SWP service areas would change because of several reasonably foreseeable projects that would occur with or without enlarging Shasta Dam. CVP and SWP deliveries could increase or decrease based on any number of factors between now and 2030. Given environmental regulations to protect sensitive habitats and species, these changes are not likely to have a substantial adverse effect on special-status species, nor would they be likely to cause a population to be eliminated. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability while contributing to increased survival of anadromous fish, actions that are consistent with the 2000 CALFED ROD. In addition to the common features above, CP1 primarily involves raising Shasta Dam 6.5 feet, an elevation change that would increase the reservoir's full pool by 8.5 feet and would enlarge the total storage space in the reservoir by 256,000 acre-feet. Under this plan, Shasta Dam operational guidelines would continue unchanged, with the additional storage retained for water supply reliability and increased anadromous fish survival.

Shasta Lake and Vicinity

Impact Wild-1 (CP1): Take and Loss of Habitat for the Shasta Salamander
Ground-disturbing activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, survey and manage species, MSCS-covered species, and BLM sensitive species. Operation of equipment in or removal of suitable habitat

during the wet season could result in direct impacts on this species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

Collectively, 39 sites are known to occur within the areas surveyed by NSR (impoundment and relocation areas). Individuals were observed in both limestone and nonlimestone habitats in each arm. Within the impoundment area, presence of the Shasta salamander is presumed in all CHWR habitat types where it has been located. Shasta salamanders present will not be able to move out of the inundation area and will drown during the inundation period. This impact would be significant.

Inundation resulting from a 6.5-foot dam raise would result in a loss of 7 acres of limestone habitat and 1,197 acres of nonlimestone habitat. Impacts on limestone and nonlimestone habitat by CWHR type providing suitable habitat in the impoundment area are summarized in Table 13-6.

Table 13-6. Impacts on Suitable Habitat for the Shasta Salamander in the Impoundment Area (6.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Limestone	0.00	0.82	0.00	5.17	0.00	1.50
Nonlimestone	222.14	42.84	348.85	203.70	122.02	257.57
Total	222.14	43.66	348.85	208.87	122.02	259.07

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping
Note:
*Acres are approximate.

Direct mortality of Shasta salamanders would occur in areas of suitable habitat where complete vegetation clearing is implemented and/or mechanized construction equipment is employed if these activities occur during the wet season when salamanders are on the surface. Construction activities in relocation areas would result in a loss of 35 acres of limestone habitat and 2,870 acres of nonlimestone habitat. This impact would be significant. Impacts on limestone and nonlimestone habitat by CWHR type providing suitable habitat in the relocation areas are summarized in Table 13-7.

Table 13-7. Impacts on Suitable Habitat for the Shasta Salamander in Relocation Areas

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Limestone	0.00	0.00	0.00	35.71	0.00	0.00
Nonlimestone	388.18	0.00	1083.45	1020.46	100.34	278.00
Total	388.18	0.00	1083.45	1056.17	100.34	278.00

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping
Note:
*Acres are approximate.

Implementation of the project would take place over 3 to 4 years. Mortality of individuals could occur over multiple years if ground-disturbing activities are conducted during the wet season. This impact would be significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed or in the species range (if appropriate). Shasta salamander surveys are ongoing and it is anticipated that protocol-level surveys will be conducted within the dam construction footprint and all relocation area footprints. Protocol-level surveys would provide specific information about the presence or absence of Shasta salamanders within individual construction footprints. Direct and indirect impacts based on those results will be reported in the FEIS. Additionally, other indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-2 (CP1): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and the tailed frog, a California species of special concern. Operation of equipment in or adjacent to riverine or riparian habitat would result in direct impacts on this species. In addition, inundation caused by the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. These impacts would be potentially significant.

Foothill yellow-legged frogs occur in many perennial streams within the impoundment area. They have been found in streams on all arms and the main body of the lake. Tailed frogs have not been found during surveys, but there are known occurrences in the McCloud and upper Sacramento arms. CWHR habitat types, montane riparian and riverine, are suitable habitat where these species might occur.

Individual foothill yellow-legged frog and tailed frogs will not be affected by the inundation caused by the raise of the dam. These animals will be able to swim upstream to suitable habitat.

Although frogs may move out of harms way, direct take of foothill yellow-legged frog and tailed frog could also occur as a result of project-associated construction activities in or near suitable aquatic habitat. Potential construction impacts include mortality of individuals because of equipment use and vehicle traffic within suitable aquatic and upland habitat. The potential for direct take would be temporary, occurring only during project construction. Project implementation could result in the degradation of suitable aquatic habitat

because of increased erosion, sedimentation, or accidental fuel leaks and spills. These impacts would be potentially significant.

Implementation of the project would take place over 3 to 4 years. Mortality of individuals could occur over multiple years if construction activities are conducted in perennial streams. This impact would be potentially significant.

Implementation of a 6.5-foot dam raise would result in inundation of 33 acres of habitat for the foothill yellow-legged frog and tailed frog. A total of 19 acres of suitable habitat would be lost because of vegetation removal associated with dam construction and construction in the relocation areas. Summaries of suitable habitat loss by arm are presented in Table 13-8.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed or in the species range (if appropriate). Indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Note:
*Acres are approximate

Impact Wild-3 (CP1): Impact on the Northwestern Pond Turtle and Its Habitat
Ground-disturbing activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take of the northwestern pond turtle, a California species of special concern, a USFS sensitive species, and an MSCS-covered species. These impacts would be potentially significant.

Individual northwestern pond turtles will not be impacted by the inundation caused by the raise of the dam. Lacustrine is suitable habitat for the northwestern pond turtle.

The northwestern pond turtle occurs throughout the perimeter of the impoundment area. In addition to aquatic habitats, this species uses upland habitats for nesting and overwintering. Nests are generally located on southfacing slopes of less than 60 degrees averaging 200 meters (660 feet) from an aquatic site (DFG 1994). Thus, loss of upland habitats adjacent to suitable aquatic habitat (within approximately 660 feet) could adversely affect this species.

Direct take of northern pond turtle eggs or juveniles could occur during the first inundation of habitat above 1,070 feet above msl. Turtles may lay eggs in suitable habitat that subsequently becomes inundated, resulting in the death of the eggs or overwintering juveniles. In addition, inundation caused by the raising of Shasta Dam would result in the conversion of suitable habitat to unsuitable lacustrine habitat. These impacts would be potentially significant.

Direct take of northwestern pond turtles could also occur as a result of project-associated construction activities in or near suitable aquatic and upland habitat. Potential construction impacts include mortality of individuals because of equipment use and vehicle traffic within suitable aquatic and upland habitat. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion, sedimentation, or accidental fuel leaks and spills. Additionally, it is assumed that all vegetation will be removed within the relocation areas.

Implementation of the project would occur over 3 to 4 years. Mortality of individuals could occur over multiple years if construction activities are conducted in suitable aquatic and upland habitat. This impact would be potentially significant.

Implementation of a 6.5-foot raise of the dam would result in a loss of 33 acres of suitable habitat for the northwestern pond turtle (montane riparian, fresh emergent, lacustrine, and riverine). Seven acres of riverine habitat would be converted to lacustrine habitat. Because there are equally valuable components lost or gained in either habitat, the quality of the habitat would not be compromised. However, maximum lake elevation is infrequent and would not benefit the species throughout the remainder of the year. Thus, the conversion of suitable habitats to lacustrine habitat remains an impact on northwestern pond turtle habitat.

A total of 19 acres of suitable aquatic habitat would be lost because of vegetation removal associated with dam construction and construction of the relocation areas. Summaries of suitable habitat lost by arm are presented in Table 13-9.

Table 13-9. Impacts on Suitable Habitat for the Northwestern Pond Turtle in the Impoundment Area and Relocation Areas (6.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Impoundment Area						
Lacustrine	0.00	0.00	0.00	0.00	0.00	0.00
Montane riparian	1.54	2.48	15.92	4.60	0.58	0.80
Riverine	0.00	0.35	2.30	3.81	0.59	0.00
Total	1.54	2.83	18.22	8.41	1.17	0.80
Relocation Areas						
Montane riparian	0.34	0.00	4.72	8.02	0.23	1.45
Riverine	0.00	0.00	0.39	3.75	0.00	0.00
Total	0.34	0.00	5.11	44.41	0.23	1.45

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping
Note:
*Acres are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed or in the species range (if appropriate). Impacts on upland habitats will be quantified based on proximity to aquatic habitat. Upland habitats will be quantified based on suitable slope, soil composition, and proximity to aquatic habitats. Indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-4 (CP1): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected and MSCS-covered species. This impact would be potentially significant.

Cliffs within the Shasta Lake and vicinity portion of the primary study area provide suitable nesting habitat for the peregrine falcon. Overstory and complete vegetation removal is expected to occur within the impoundment area in suitable cliff habitat. Thus, overstory vegetation removal occurring in or near suitable cliff habitat during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests. Additionally, because of the steep terrain, trees would be yarded by helicopter. Noise generated by chainsaws and helicopter yarding could cause the abandonment of nests, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant.

No known eyries would be inundated by a 6.5-foot raise in lake elevation; however, 8.5 vertical feet (full pool) of cliff habitat would be inundated. Peregrine falcons nest on sheer cliffs ranging in height from 75 to 2,000 feet. Eyries are generally located between 40 and 80 percent of total cliff height

(Pagel 1992). Based on the large area required for suitable nesting habitat for peregrine falcons, impacts on suitable cliff habitat for nesting would be less than significant. The conversion of uplands to lacustrine habitat would not adversely affect foraging habitat for the species because they frequently forage over water.

Implementation of the project would occur over 3 to 4 years. Impacts on nesting American peregrine falcons could occur over multiple years if construction activities were conducted in or adjacent to active nests. This impact would be potentially significant.

Because American peregrine falcons nest on vertical cliffs, construction or vegetation removal related to relocation areas is not anticipated to occur in suitable cliff habitat.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed or in the species range (if appropriate). Suitable cliff habitats will be quantified and impacts on cliff habitats will be assessed. Indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP1): Take and Loss of Habitat for the Bald Eagle Ground-disturbing activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed, fully protected, and USFS sensitive species, MSCS-covered species, and a BLM sensitive species. This impact would be significant.

Typically, 24 to 28 pairs nest in the vicinity of Shasta Lake. Vegetation removal within the impoundment area during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of bald eagle nests. Noise generated by vegetation removal, such as noise caused by helicopter yarding and chainsaw use, could also lead to nest abandonment, resulting in the incidental loss of fertile eggs or nestlings. The loss of nesting and foraging habitat would be a potentially significant impact.

Between eight and 14 nest trees may be impacted by any raise in elevation. Nest trees may be inundated by any of the three alternatives. If inundation of the impoundment area were to occur, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April or early June, nest trees would be flooded toward the end of the nesting season. If eagles were nesting in these trees, it would be likely that young would fledge before the nest tree died from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected. Because bald eagles generally use the same nest for multiple years, the loss of nest trees would be a significant impact.

Inundation could also affect erosion and bank stability, which could affect nest trees that are in close proximity to the impoundment area. This would be a potentially significant impact.

The increase in lake elevation may increase access to eagle nests by recreational boaters. The increase in noise and human disturbance may lead to nest abandonment and the incidental loss of fertile eggs or young. Additionally, habitat inundated within the impoundment area would result in a loss of roosting and potential nest trees. This impact would be significant.

One eagle nest is located in the relocation area at Gregory Beach. Removal of nest trees would be a potentially significant impact. Additionally, one nest occurs near the Bailey Cove trail, which could be impacted by noise generated by vegetation removal activities. Vegetation removal and additional construction activities in the relocation areas would result in the same impacts on nesting bald eagles as described for vegetation removal activities proposed in the impoundment areas. This impact would be significant.

Implementation of the project would occur over 3 to 4 years. Impacts on nesting bald eagles could occur over multiple years if construction activities are conducted in or adjacent to active nests. This impact would be significant.

Dam construction, vegetation removal and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in a loss of 2,492 acres in the impoundment area and 2,387 acres in the relocation areas of nesting and roosting habitat for the bald eagle. Potential nest and roost trees occur in blue oak woodland, blue oak–foothill pine, Douglas-fir, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine habitats with tree diameters larger than 24 inches. Impacts on suitable bald eagle habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-10.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. Bald eagle nesting activity changes from year to year. The number of bald eagle nests is subject to change based on eagle activity at the time of construction and the subsequent inundation. Reclamation is currently working with the USFS to determine the current eagle activity to revise the number of nest trees that may be impacted. Indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Note:

*Acreages are approximate and will be revised based on habitat containing suitable tree diameters.

Impact Wild-6 (CP1): Take and Loss of Nesting and Foraging Habitat for the Northern Spotted Owl Construction activities and vegetation removal associated with the dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the northern spotted owl, a Federally listed as threatened species and MSCS-covered species. In addition, inundation caused by the raising of Shasta Dam could result in inundation of nest trees and would result in the loss of habitat, including critical habitat for this species. This impact would be potentially significant.

Vegetation removal within the impoundment area during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the northern spotted owl. Noise generated by vegetation removal activities including helicopter yarding and chainsaw use could also lead to nest abandonment resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant. Additionally, portions of upper Squaw Creek and Pit arms have been designated as critical habitat for the northern spotted owl. The loss of nesting, foraging and critical habitat would be a potentially significant impact.

A 6.5-foot dam raise could result in inundation of nest trees and would result in the loss of nesting and foraging habitat for this species. Once inundation of the impoundment area occurs, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April or early June, nest trees would be flooded toward the end of the nesting season. If owls were nesting in these trees, it is likely that young would fledge before the nest tree dies from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected.

The increase in lake elevation could increase access to owl nests by recreational boaters. The increase in noise and human disturbance could lead to nest abandonment and the incidental loss of fertile eggs or young. This would be a potentially significant impact.

Additionally, construction activities and vegetation removal in relocation areas would also result in a loss of northern spotted owl nesting and foraging habitat. This would be a potentially significant impact.

Implementation of the project would occur over 3 to 4 years. Impacts on nesting northern spotted owls could occur over multiple years if construction activities were conducted in or adjacent to active nests. This impact would be potentially significant.

Dam construction, vegetation removal and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in a loss of 767 acres (20 acres of critical habitat) in the impoundment area and 2,349 acres in the relocation areas (19 acres of critical habitat) of nesting and foraging habitat for the northern spotted owl. CWHR types are a general representation of suitable nesting, roosting, and foraging habitat for northern spotted owl. Impacts on suitable spotted owl habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-11. The California Forest Practice Rules specify parameters for northern spotted owl nesting, roosting, and foraging habitats. Delineations of habitats defined by California Practice Rules are not available for this impact analysis.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-7 (CP1): Impact on the Purple Martin and Its Nesting Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant.

Based on data collected between 2007 and 2010, the number of purple martin nesting pairs ranged between 18 and 28. Shasta Lake is one of only two known interior breeding locations for purple martins in California. Purple martins nest only in snags (upslope and in the lake) in the vicinity of the Clikapudi Trail and east up the Pit Arm of the Shasta Lake vicinity of the primary study area. Overstory vegetation removal is proposed for the relocation of the Clikapudi Trail. With the exception of Arbuckle Flat, no vegetation would be removed from the Painter Creek inlet east on the Pit Arm.

Inundation of the impoundment area could result in the loss of nest trees in the lake and two known upland nest trees. Each nest tree contains several potential nest cavities at various heights above the water. Therefore, with an increase in inundation levels, potentially fewer nest cavities could be available from year to year. Loss of nest trees would be temporary, as trees that are inundated would die and become snags. New nesting snags would develop as dying trees are used by woodpeckers and cavities become available for purple martins. The temporal loss of nesting snags would be a significant impact.

Overstory vegetation removal is proposed for the relocation of the Clikapudi Trail. This could include removal of snags that are actively used for nesting or could provide nesting habitat for purple martin. Construction activities such as tree removal, site grading, and excavation and vegetation removal, including noise caused by helicopter yarding and chainsaw use during the nesting season, could result in the incidental loss of fertile eggs or nestlings or otherwise lead to nest abandonment. Loss of fertile eggs or nesting adults, or any activities resulting in nest abandonment, would be significant.

Implementation of the project would occur over 3 to 4 years. Impacts on nesting purple martins could occur over multiple years if construction activities were conducted in or adjacent to active nests. This impact would be significant.

Purple martins forage high in the air and above the tree canopy. Conversion of upland habitats to lacustrine habitat would not have an effect on foraging habitat. Therefore, there would be no impact on foraging habitat.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-8 (CP1): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat
Construction activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a State-listed endangered, USFS sensitive, and MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

Vegetation removal within the impoundment area during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of these species. Noise generated by vegetation removal activities including helicopter yarding and chainsaw use could also lead to nest abandonment, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant. The loss of nesting and foraging habitat would be a potentially significant impact.

A 6.5-foot dam raise would result in inundation of nesting and foraging habitat for these species. Understory vegetation in 15 percent of the impoundment area would be removed before inundation; the remainder would not survive the inundation. Therefore, inundation of the impoundment area would reduce the

nesting habitat for these species. If removal were completed outside of the breeding season, suitable nesting habitat would not be available and nesting would not be affected. However, 63 percent of vegetation would not be removed and would be inundated. Because peak inundation generally occurs in late April through early June, active nests established before and while lake levels were rising could be flooded. The loss of nests and nesting and foraging habitat from inundation would be a potentially significant impact.

Construction activities such as tree removal, site grading, and excavation and vegetation removal at the dam and in relocation areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to nest abandonment. Additionally, noise generated by project construction activities and vegetation removal, including helicopter yarding and chainsaw use, could lead to nest abandonment resulting in the incidental loss of fertile eggs or nestlings. Vegetation removal in relocation areas would also result in a loss of nesting and foraging habitat. This would be a potentially significant impact.

Implementation of the project would occur over 3 to 4 years. Impacts on these species could occur over multiple years if construction activities were conducted adjacent to active nests. This impact would be potentially significant.

Dam construction, vegetation removal and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in a loss of 792 acres in the impoundment area and 2,364 acres in the relocation areas of nesting and foraging habitat for the Vaux's swift (Douglas-fir, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine). It would result in a loss of 26 acres in the impoundment area and 15 acres in the relocation areas for the willow flycatcher, yellow warbler, and yellow-breasted chat (montane riparian).

Impacts on suitable willow flycatcher, Vaux's swifts, yellow warblers, and yellow-breasted chats habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-12.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-9 (CP1): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping

Note:

*Acres are approximate.

California species of special concern and an MSCS-covered species; northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the Cooper's hawk, an MSCS-covered species; the great blue heron, an MSCS-covered species; and the osprey, an MSCS-covered species. In addition, higher lake levels caused by raising Shasta Dam would result in the loss of foraging and nesting habitat for these species. This impact would be potentially significant.

Vegetation removal within the impoundment area during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of these species. Noise generated by vegetation removal activities, including helicopter yarding and chainsaw use, could also lead to nest abandonment, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant. The loss of nesting and foraging habitat would be a potentially significant impact.

A 6.5-foot dam raise could result in inundation of nest trees and would result in the loss of nesting and foraging habitat for this species. If inundation of the impoundment area were to occur, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April through early June, nest trees would be flooded toward the end of the nesting season. If these species were nesting in these trees, it is likely that young would fledge before the nest tree dies from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected. However, the loss of nesting and foraging habitat would be a potentially significant impact.

The increase in lake elevation could increase access to nests by recreational boaters. The increase in noise and human disturbance could lead to nest abandonment and the incidental loss of fertile eggs or young. This would be a potentially significant impact.

Construction activities such as tree removal, site grading, and excavation and vegetation removal at the dam and in relocation areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to nest abandonment. Additionally, noise generated by project construction activities and vegetation removal, including helicopter yarding and chainsaw use, could lead to nest abandonment, resulting in the incidental loss of fertile eggs or nestlings. Vegetation removal in relocation areas would also result in a loss of nesting and foraging habitat. This would be a potentially significant impact.

Implementation of the project would occur over 3 to 4 years. Impacts on these species could occur over multiple years if construction activities were conducted adjacent to active nests. This impact would be potentially significant.

Dam construction, vegetation removal and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in a loss of 580 acres in the impoundment area and 1,878 acres in the relocation areas of nesting and foraging habitat (Douglas-fir, montane hardwood–conifer, and ponderosa pine) for the long-eared owl and northern goshawk. There would be a loss of 1,050 acres in the impoundment area and 2,483 acres in the relocation areas of nesting and foraging habitat for the Cooper’s hawk and great blue heron (blue oak–foothill pine, closed-cone pine-cypress, Douglas-fir, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine).

Impacts on suitable habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-13.

Impacts on osprey are similar to those described for the bald eagle (Impact Wild-5 (CP1) and the other raptors addressed above).

Note:
*Acres are approximate

There are 54 osprey nests within the perimeter of Shasta Lake. Six nest trees would be affected by a 6.5-foot dam raise. Eleven osprey nests are located in

relocation areas. Removal of nest trees would be a potentially significant impact. Because osprey generally use the same nest for multiple years, the loss of 17 nest trees (31 percent) collectively between the impoundment area and relocation areas would be a potentially significant impact.

Osprey nests also occur on towers and structures around the dam, otherwise, there is no suitable habitat for raptors near the dam. Blasting may occur in the vicinity of the dam. This would have a similar impact on nesting ospreys as noise generated by helicopter yarding or large construction equipment, which could result in nest abandonment and the loss of fertile eggs or young. This would be a potentially significant impact.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. Osprey nesting activity changes from year to year. The number of osprey nests is subject to change based on osprey activity at the time of construction and the subsequent inundation. An analysis of indirect and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-10 (CP1): Take and Loss of Habitat for the Pacific Fisher
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Vegetation removal within the impoundment area while kits (i.e., young) are in natal den trees could result in the incidental loss of kits. Noise generated by vegetation removal activities including helicopter yarding and chainsaw use may also lead to abandonment of young. However, females frequently move kits if the natal den is disturbed or threatened. Because females will move kits, it is not likely that individuals would be affected. However, the loss of denning, resting, and foraging habitat would be a potentially significant impact.

A 6.5-foot dam raise could result in inundation of natal den trees and would result in the loss of denning, resting, and foraging habitat for this species. If inundation of the impoundment area were to occur, nest trees within the impoundment area would die. Females frequently move kits if threatened or disturbed. Because females will move kits, it is not likely that individuals would be affected. However, the loss of denning, resting, and foraging habitat would be a potentially significant impact.

Construction activities such as tree removal, site grading, and excavation and vegetation removal at the dam and in relocation areas while kits are in natal den trees could result in the incidental loss of kits. Impacts on habitat would be the same as described for the impoundment area. This would be a potentially significant impact.

Implementation of the project would occur over 3 to 4 years. Impacts on the Pacific fisher could occur over multiple years if construction activities were conducted adjacent to denning or resting habitat. This impact would be potentially significant.

Dam construction, vegetation removal and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in a loss of 605 acres in the impoundment area and 1,893 acres in the relocation areas of habitat (Douglas-fir, montane hardwood-conifer, montane riparian, and ponderosa pine) for the Pacific fisher. This impact would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-14.

Table 13-14. Impacts on Suitable Habitat for the Pacific Fisher in the Impoundment Area and Relocation Areas (6.5-Foot Dam Raise)

Note:
*Acres are approximate

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-11 (CP1): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, and Yuma Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared Myotis, a BLM sensitive species; the Yuma Myotis, a BLM sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Vegetation removal within the impoundment area while young bats are in maternity colonies or kits are in natal den trees could result in the incidental loss of young. Noise generated by vegetation removal activities including helicopter yarding and chainsaw use could also lead to young abandonment. Furthermore, depending on the season, the removal of large trees with cavities could result in the loss of pallid bat and Townsend's big-eared bat colonies. Potential direct impacts include the take of a maternity colony (females and young) and the take of individuals in a hibernaculum, which could eliminate an entire colony because of the loss of pregnant females. Mortality of young and the loss of reproductive and foraging habitat would be a potentially significant impact.

Inundation of a 6.5-foot dam raise would result in a loss of roosting and foraging habitat for special-status bats (pallid bat, spotted bat, western red bat, western mastiff bat, Townsend's big-eared bat, long-eared myotis, and Yuma myotis) that roost in hollow trees, snags, bridges, and caves. Loss of young could occur during the first inundation (above 1,070 feet msl) of bat maternity colony habitat because active maternity colonies could be flooded before young are volant (capable of flight). American marten and ringtails, which also use snags, hollow logs, and debris piles for reproduction and cover, could also be impacted. This impact would be potentially significant.

Two known caves, one occupied by Townsend's big-eared bats, are located on the Big Backbone Arm and would be wholly or partially inundated if the dam

were raised. Inundation of cave/cliff habitat could result in the loss of Townsend's big-eared bat, western mastiff bat, and long-eared myotis colonies. Potential direct impacts include the take of a maternity colony and the take of individuals in a hibernaculum, which could eliminate an entire colony because of the loss of pregnant females.

Spotted bats and long-eared myotis could also roost in crevices and caves in the Shasta Lake and vicinity portion of the primary study area. However, inundation of cave/cliff habitat is less likely to result in a significant impact on this population, because they do not roost colonially; thus, inundation of a cave would not result in the loss of an entire maternity colony.

Special-status bats may roost in bridges and could also be affected by bridge modification or removal. Direct impacts including mortality and the loss of roosting habitat would be significant.

Construction activities such as tree removal, site grading, and excavation and vegetation removal at the dam and in relocation areas while young bats are in maternity colonies or kits are in natal den trees could result in the incidental loss of young. Impacts on habitat would be the same as described for the impoundment area. This would be a potentially significant impact.

Implementation of the project would occur over 3 to 4 years. Impacts on these species could occur over multiple years if construction activities are conducted in or adjacent to reproductive habitat. This impact would be potentially significant.

Bats typically forage in open areas within the CWHR types listed as foraging habitat. Foraging habitat for the pallid bat, spotted bat, western mastiff bat, and Townsend's big-eared bat includes Douglas-fir, fresh emergent wetland, lacustrine, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine. These habitats are regionally abundant and therefore impacts on foraging habitat by inundation or vegetation removal in the relocation areas would be less than significant.

Dam construction, vegetation removal, and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in the loss of 13 acres in the impoundment area and 24 acres in the relocation areas of habitat for the pallid bat, spotted bat, western mastiff bat, Townsend's big-eared bat and Yuma myotis (barren, blue oak woodland, and blue oak-foothill pine). There would be a loss of 1,194 acres in the impoundment area and 2,821 acres in the relocation areas of habitat for the western red bat, long-eared myotis, and ringtail (barren, blue oak woodland, blue oak–foothill pine, closed-cone pine-cypress, Douglas-fir, mixed chaparral, montane hardwood, montane hardwood-conifer, montane riparian, and ponderosa pine); and a loss of 605 acres in the impoundment area and 1,893 acres in the relocation areas of habitat for the

American marten (Douglas-fir, montane hardwood-conifer, montane riparian, and ponderosa pine). This impact would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-15.

Note:
*Acreages are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-12 (CP1): Impacts on Special-Status Terrestrial Mollusks (Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat All of these species are designated USFS sensitive and survey and manage species and are proposed for Federal listing. The Shasta sideband is also an MSCS-covered species. Ground-disturbing activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of these species. This impact would be significant.

These species are found in nearly all CWHR habitats along the lake. The Shasta sideband and Wintu sideband are associated with limestone formations in the McCloud River and in the Pit and Squaw Creek arms, respectively. Shasta chaparral is widespread and Shasta hesperian is found in mesic or riparian inclusions in most CWHR habitats.

Vegetation removal in the impoundment areas and construction activities such as tree removal, site grading, and excavation and vegetation removal at the dam and in relocation areas in suitable habitat could result in direct take. In addition, these activities and the inundation caused by a 6.5-foot dam raise would result in the mortality of individuals and the permanent loss of suitable habitat.

Dam construction, vegetation removal and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in the loss of 1,195 acres in the impoundment area and 2,868 acres in the relocation areas of habitat for Shasta chaparral (annual grassland, barren, blue oak woodland, blue oak–foothill pine, closed-cone pine-cypress, Douglas-fir, mixed chaparral, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine), 260 acres in the impoundment area and 2,870 acres in the relocation areas for Shasta hesperian (Douglas-fir, montane hardwood conifer, and montane riparian), 5.17 acres of limestone habitat in the impoundment area and 35.71 acres in the relocation areas for the Shasta sideband, and 1.50 acres of limestone habitat in the impoundment area and no limestone habitat in the relocation areas for Wintu sideband. This impact would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-16.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect and temporary impacts will be provided in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-13 (CP1): Permanent Loss of General Wildlife Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in the permanent loss of habitat. This would be a potentially significant impact.

Dam construction, vegetation removal and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in a loss of 1,221 acres of general wildlife habitat in the impoundment area and 3,127 acres of general wildlife habitat in the relocation areas. Impacts on general wildlife habitat by CWHR type in the impoundment area and relocation areas are summarized in Tables 13-17 and 13-18.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Note:
**Acreage values are approximate.*

Impact Wild-14 (CP1): Impacts on Other Birds of Prey (i.e., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species (i.e., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam would result in the

loss of active nests and habitat for these species. This impact would be potentially significant.

Approximately 36 percent of the impoundment area would have either complete (15 percent) or overstory (21 percent) vegetation removal. If vegetation removal were to occur prior to or after the breeding season, there would be no impact on migratory birds or raptors. If inundation of the impoundment area were to occur, nest trees within the impoundment area would die. Because peak inundation generally occurs between late April and early June, nest trees would be flooded toward the end of the nesting season. If raptors were nesting in these trees, it is likely young would fledge before the nest tree died from the effects of inundation. However, approximately 84 percent of understory vegetation inundated could have ground or shrub nesting birds that would be impacted by inundation. Impacts on ground or understory nesters would be potentially significant.

Maximum inundation would occur in late April through early June during the breeding season and many nests could be established before and while lake levels are rising. In the portions of the impoundment where vegetation removal is not implemented, active bird nests would flood, resulting in mortality of young still dependent on the nest. This would be a potentially significant impact.

Additionally, removal of structures providing for raptor nests (e.g., power poles in the relocation areas could result in mortality of young. This would be a potentially significant impact.

Vegetation in relocation areas would be completely removed. If vegetation removal were to occur prior to or after the breeding season, there would be no impact on migratory birds or raptors.

Implementation of the project would occur over 3 to 4 years. Impacts on these species could occur over multiple years if construction activities were conducted in or adjacent to reproductive habitat. This impact would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP1): Loss of Critical Deer Winter and Fawning Range
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the

raising of Shasta Dam would result in the loss of critical deer range. This impact would be potentially significant.

Critical winter range is located on the west side of each arm of the lake, and critical fawning is located on the south-facing slope of Little Sugarloaf Creek. Critical range describes a deer corridor rather than specific habitats. Vegetation removal in the relocation areas and inundation of the impoundment area would result in the loss of critical winter and fawning range. This impact would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP1): Take and Loss of the California Red-Legged Frog
Reclamation is concurrently completing an assessment of California red-legged frog habitat, which will be submitted to USFWS for review. Using the results of this assessment, USFWS will determine whether surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and the California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is proposed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Wild-17 (CP1): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementation of CP1 would result in a modified flow regime that would reduce the frequency, duration, and magnitude of intermediate to large flows below Shasta Dam during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and the formation of off-channel habitats. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

The operation of Shasta Dam has substantially modified the natural flow regime within the primary study area. Construction and operation of the dam has limited the frequency and magnitude of intermediate to large flows in winter and spring, and has increased flow volumes during the active growing season

(primarily March through October). Project implementation would be expected to amplify these effects. Reducing the magnitude, frequency, and duration of intermediate to large flows could alter the dynamics and structure of wetland and riparian habitats that support special-status wildlife species along the Sacramento River, downstream from Shasta Dam, throughout the primary study area (see Chapter 12, "Botanical Resources," for more information). The effects of modified flow regimes would be attenuated downstream because of the cumulative tributary flow adding to the Sacramento River.

Special-status wildlife that could be affected by these changes includes special-status invertebrates, reptiles, amphibians, birds, and mammals, as discussed below.

- **Invertebrates** – Blue elderberry shrubs, the host plant for the valley elderberry longhorn beetle, are found throughout much of the Sacramento River's riparian corridor. Shrubs within the corridor are unlikely to be affected by modification of the existing flow regimes. Elderberry shrubs are not commonly found growing immediately next to the river's edge, but are often found on terraces or higher up the bank. Most of the effect on flow regime, including inundation during the growing season, would be concentrated in a narrow strip along the river channel that is already subjected to seasonal inundation. Because elderberry growing in these areas are already experience seasonal inundation periodically, the project is not likely to prevent establishment or substantially reduce the vigor of existing elderberry shrubs in the primary study area; therefore, this impact would be less than significant.

- **Reptiles and Amphibians** – The western pond turtle has been documented within the Sacramento River, and suitable habitat for the species is provided within the primary study area, including tributaries. Western pond turtles rely on habitat types (e.g., oxbow lakes) that have relatively slow rates of formation. Creation of new off-channel water bodies requires the periodic intermediate to large fall and winter flow events that drive the processes of meander migration and channel cutoff. Similarly, off-channel water bodies gradually "terrestrialize" (become terrestrial habitats) as they fill with sediment and organic detritus, and as they are colonized by vegetation. Consequently, activities that prevent the formation of off-channel water bodies (e.g., construction of levees and installation of bank armor) over the long term reduce the extent this important type of habitat for pond turtles. The increase in mean stage elevation resulting from project implementation could provide additional aquatic habitat for the species during some months of some years. However, less aquatic habitat could be available for northwestern pond turtle during winter, spring, and drought periods. Modifying the flow regime could also reduce the formation of off-channel water bodies over the long term. These

changes in habitat availability could reduce the size of the population along the Sacramento River over the long term. Therefore, alteration of habitat for the northwestern pond turtle would be a potentially significant impact.

- **Birds** – The riparian and wetland habitats along the Sacramento River floodway provide potential nesting and foraging habitat for western yellow-billed cuckoo, California yellow warbler, and yellow-breasted chat, all of which are special-status birds that nest in riparian vegetation. In addition, northern harrier and short-eared owl may nest in marshes in or adjacent to the stream channel. Other raptors—Cooper's hawk, Swainson's hawk, white-tailed kite, bald eagle, and osprey—may nest in trees in the riparian or oak woodlands in the study area. As described above, altering the flow regime could alter some existing riparian habitat. Over time, there would be less early successional (willow, cottonwood, and herbaceous dominated) and more mid-successional (mixed woodland) vegetation and a smaller amount of acreage recently disturbed by erosion or scouring after intermediate to large flows, as described in Chapter 12, "Botanical Resources." These long-term changes to the structure of riparian vegetation are expected to result in a reduction of habitat value sufficient to cause the loss of nesting territories or affect the reproductive success of some riparian foraging and nesting birds. The birds most affected by this alteration would be those that make the most extensive use of willow thickets and cottonwood and willow-dominated riparian forests. This impact on special-status bird species that nest in riparian vegetation would be potentially significant.

- **Mammals** – Special-status mammals potentially occurring in the project area include pallid bat, western red bat, and ringtail. Riparian habitat can provide important foraging and roosting habitat for bats, but these species are not typically dependent on riparian habitats. The amount of potential foraging habitat would not decrease, and available riparian habitats – even if modified by the new flow regime below Shasta Dam – would still be sufficient for roosting habitat such that impacts on special-status bats would be less than significant. Potential changes in riparian vegetation along the river channel in the study area would not substantially reduce habitat for ringtail. Therefore, impacts on special-status mammals would be less than significant.

Because of substantial long-term effects on the habitat of northwestern pond turtle and some riparian-nesting special-status bird species, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP1): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes CP1 would cause a

small reduction in the magnitude, duration, and frequency of intermediate to large flows, which also would alter the geomorphic processes along the Sacramento River, including the rate of bank erosion in the primary study area. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

There are five known colonies of bank swallow along the Sacramento River in the primary study area (CNDDB 2007). The bank swallow forms nesting colonies in steep-cut, eroding, river banks. Bank revetment has been preferentially applied to actively migrating bends which would otherwise be among the most suitable sites for bank swallow nests. The small reduction in intermediate to large flows by CP1 would cause a small reduction in the rate of erosion at the cut banks that remain unprotected by revetment. This alteration would not reduce the amount of bank swallow nesting habitat in the short or long term. Spring flows would remain comparable to existing and no-action conditions, and thus, the potential for spring flows to cause localized nest failure would remain comparable to existing and no-action conditions. Therefore, the impact to bank swallow would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-19 (CP1): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Changes in Flow Regime Construction-related disturbances at Shasta Dam are not anticipated to disturb or permanently remove vernal pool habitat for special-status wildlife species along the upper Sacramento River. Altered flow regimes resulting from project-related dam operation are also not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species. This impact would be less than significant.

Vernal pools are present in upland areas near the Sacramento River and its tributaries in the primary study area. These pools provide habitat for numerous special-status species, such as vernal pool tadpole shrimp, vernal pool fairy shrimp, and western spadefoot toad. Critical habitat for three special-status wildlife species – Conservancy fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp – Is located within the primary study area. Critical habitat for these species in the primary study area is confined to vernal pool communities (USFWS 2006).

Vernal pools are generally not present within the active floodplain of regulated rivers in the primary study area; thus, vernal pools are not anticipated to be affected by dam construction, use of staging areas, and/or movement of heavy equipment during construction. Changes in flow regime in the primary study area likely would not affect vernal pool special-status species. Therefore, this

impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP1): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

Several local and regional plans have been developed and adopted to promote conservation and enhancement of riparian habitat in the primary and extended study areas: the RHJV, Sacramento River Advisory Council Forum, Sacramento River Conservation Area Program, SRNWR comprehensive conservation plan and environmental assessment, and others. (See Section 13.2, "Regulatory Setting.")

Because the project may have a potentially significant impact on riparian vegetation within the primary and extended study areas, the quality of riparian habitat may be reduced or distribution may be limited. This potential consequence of the project could conflict with the goals developed in local and regional conservation plans for the Sacramento River. Conflict of the project with the local and regional plans would be a potentially significant impact. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP1): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program CP1 would not include the gravel augmentation program. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-22 (CP1): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration of Reading Island CP1 would not include Reading Island restoration. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta By altering storage and operations at several reservoirs, CP1 would change flow regimes in several downstream waterways. In turn, these alterations to the flow regime could particularly affect riparian and wetland habitats along these waterways. The potential effects on wildlife are similar to those discussed for the primary study area above. However, potential effects on flow and stages of the middle Sacramento River would be smaller than on the upper Sacramento River; changes in flows and

stages would diminish downstream from Red Bluff because of the effects of inflows from tributaries, and the effects of diversions and flood bypasses.

Impact Wild-23 (CP1): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementation of CP1 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. Although this change in surface and subsurface hydrology would be less than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats along the middle Sacramento River. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-17 (CP1). However, the effect of CP1 on flow in the Sacramento River would attenuate below RBDD because of the inflows from tributaries, and because of other diversions and flood bypasses. Nonetheless, along the middle Sacramento River, flow alterations could be sufficient to substantially affect habitat of western pond turtle and riparian-nesting birds as described for the upper Sacramento River. This impact would be potentially significant.

Flow alterations may not be sufficient to measurably affect special-status wildlife in the bypasses, along the Sacramento River below Colusa, or in the Delta. Flow alterations are more attenuated downstream by tributaries, diversions, and bypasses, and CalSim modeling indicated little change in the frequency and duration of bypass inundation. Also, downstream from Colusa, the river is confined to a narrow channel closely bordered by levees lined with riprap, and thus geomorphic processes (and thus riparian habitats) are relatively unresponsive to small changes in river flows. Furthermore, effects of flow alterations are also unlikely to extend to the Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the CVP and SWP). The guidelines for this management, which are described in the Long-Term Operations Criteria and Plan (OCAP), have been designed to maintain standards for Delta inflow. CVP and SWP operations must be consistent with the OCAP to allow coverage by USFWS's and NMFS's OCAP BOs. Thus, this project is not anticipated to cause an alteration in Sacramento River flow to the Delta sufficient to alter habitat for special-status wildlife species in the lower Sacramento River and Delta portion of the extended study area.

Because of the potential for substantial effects on western pond turtle and riparian-nesting birds in the middle Sacramento River (i.e., RBDD to Colusa), this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP1): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes The effect of CP1on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP1 on river flows would attenuate with distance downstream. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized bank and nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

There are more than 100 presumed extant colonies of bank swallow in Butte, Glenn, Colusa, Yuba, Yolo, Sutter, and Sacramento counties (CNDDB 2007). The effect on bank swallow along the lower Sacramento River would be similar to that described for the upper Sacramento River: a small reduction in the rate of erosion, but not a substantial change in the amount of bank swallow nesting habitat, or in spring flows that may cause localized nest failure. However, the effect of altered flow regimes on bank swallow nesting habitat along the lower Sacramento River would be smaller than along the upper Sacramento River, because flow alterations would be attenuated in the Sacramento River below RBDD because of the inflows from tributaries, and because of other diversions and flood bypasses. This impact on bank swallow would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP1): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Altered flow regimes as a result of dam operation associated with the project are not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species in the lower Sacramento River and Delta portion of the extended study area. This impact would be less than significant.

Vernal pools are present in upland areas near the Sacramento River and its tributaries in the extended study area. These pools provide habitat for numerous special-status species. Critical habitat for three special-status species – vernal pool fairy shrimp, vernal pool tadpole shrimp, and Conservancy fairy shrimp – Is located within the extended study area. Critical habitat for these species is confined to vernal pool communities (USFWS 2006).

Vernal pools are generally not present within the active floodplain of regulated rivers along the lower Sacramento River and in the Delta. Vernal pool special-

status species would also not likely be affected by changes in flow regime in the extended study area. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP1): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat Along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

As discussed in Impact Wild-20 (CP1) for the upper Sacramento River, several local and regional plans have been developed and adopted to promote conservation and enhancement of riparian habitat in the primary and extended study areas: the RHJV, Sacramento River Advisory Council Forum, Sacramento River Conservation Area Program, SRNWR comprehensive conservation plan and environmental assessment, and others. (See Section 13.2, “Regulatory Framework.”)

Because the project may have a potentially significant impact on riparian vegetation within the primary and extended study areas, the quality of riparian habitat may be reduced or distribution may be limited. This potential consequence of the project could conflict with the goals developed in local and regional conservation plans for the Sacramento River. Conflict of the project with the local and regional plans would be a potentially significant impact.

CVP/SWP Service Areas Increased water supplies or increased supply reliability could reduce a limitation on growth or on other activities that could affect wildlife in the primary and extended study areas, potentially resulting in significant effects. The effects of this growth would be analyzed in general plan Environmental Impact Reports and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these effects would be the responsibility of these local jurisdictions, and not of Reclamation. The expected increase in water yield relative to the entire CVP/SWP service areas would be small, however. Assuming that this new yield could be provided to any number of geographic areas within the CVP and SWP service areas, the project’s impact on growth that could affect vegetation would be minor. Similarly, projects potentially affecting most aquatic habitats and listed species would require permits from DFG, USACE, and USFWS; it is anticipated that effects on these resources would be avoided, minimized, and/or mitigated during those agency consultations. Because the extent, location, and timing of induced growth is currently highly uncertain, and in the future the effects of this growth would be

analyzed and mitigated during land use planning and environmental review for specific projects, growth-inducing effects on wildlife are not discussed further in this chapter. However, additional discussion of growth-inducing effects specific to the project alternatives is provided in Section 26.4, "Growth-Inducing Impacts," in Chapter 26, "Other Required Disclosures."

Impact Wild-27 (CP1): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP1 would change flow regimes in several downstream waterways. Modified flow regimes would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. However, based on the CalSim-II modeling results, the hydrologic effects on tributaries with CVP and SWP dams are expected to be less than effects on the Sacramento River. Most potential noticeable changes in flows and stages would diminish downstream from Red Bluff. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

Several riparian-associated or aquatic special-status wildlife species may be present in the CVP and SWP service areas, such as least Bell's vireo and arroyo toad. As discussed under Impact Wild-17 (CP1) for the upper Sacramento River and Impact Wild-21 (CP1) for the lower Sacramento River and Delta portion of the extended study area, construction and operation of Shasta Dam has limited the frequency and magnitude of intermediate to large flows in winter and spring, and has increased flow volumes during the active growing season (primarily March–October). Project implementation would be expected to amplify these effects. However, the effect of altered flow regimes by the project would attenuate in the Sacramento River below RBDD because of the inflows from tributaries, and because of other diversions and flood bypasses. Effects of flow alterations from Shasta Dam are also unlikely to extend to the CVP and SWP service areas because the reservoirs and diversions are managed as a single integrated system (consisting of the CVP and SWP). The guidelines for this management, which are described in the OCAP, have been designed to maintain standards for Delta inflow. CVP and SWP operations must be consistent with the OCAP to allow coverage by the OCAP biological opinion. Thus, this project is not anticipated to sufficiently alter flow to the CVP/SWP service areas to have a substantial effect on riparian habitat upon which special-status wildlife species depend. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Like CP1, this comprehensive plan focuses on enlarging Shasta Dam and Shasta Lake consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increased water supply reliability and increased survival of anadromous fish. In addition to the common features above, CP2 involves raising Shasta Dam 12.5 feet, an elevation change that would raise the full pool by 14.5 feet (6 feet higher than under CP1) and would enlarge the total storage space in the reservoir by 443,000 acre-feet.

With respect to wildlife impacts, dam construction activities for CP1 through CP5 would be so similar that they are considered to be identical for purposes of this analysis. Because CP2 would result in higher lake levels than CP1, CP2 would also require more relocation of utilities, public service facilities, and recreational facilities than CP1. However, the wildlife impact analysis for CP1 assumes maximum impacts related to mechanized vegetation clearing and construction within the relocation areas. Therefore, vegetation clearing and construction impacts within the relocation areas would be identical for CP1–CP5. Because CP2 would result in higher lake levels than CP1, CP2 would result in a larger (and deeper) area of inundation than CP1, in turn requiring more vegetation clearing within the inundation area than CP1.

Shasta Lake and Vicinity

Impact Wild-1 (CP2): Take and Loss of Habitat for the Shasta Salamander

Ground-disturbing activities associated with construction could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, survey and manage species, MSCS-covered species, and BLM sensitive species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the Shasta salamander. This impact would be significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of 10 acres of limestone habitat and 1,689 acres of nonlimestone habitat. Impacts on limestone and nonlimestone by CWHR type providing suitable habitat in the impoundment area are summarized in Table 13-19.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed or in the species range (if appropriate). Surveys of the Shasta salamander are ongoing and it is anticipated that protocol-level surveys will be conducted within the dam construction footprint and all relocation area footprints. Protocol-level surveys would provide specific information about the presence or absence of Shasta salamanders within individual construction footprints. Mitigation for acres affected would then be

refined based on these results. Direct and indirect impacts based on those results will be reported in the FEIS. Additionally, other indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-19. Impacts on Suitable Habitat for the Shasta Salamander in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Limestone	0.00	1.14	0.00	7.29	0.00	2.06
Nonlimestone	310.46	60.07	494.61	292.21	171.03	358.92
Total	310.46	61.21	494.61	299.50	171.03	360.98

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping
Note:
*Acreage values are approximate.

Impact Wild-2 (CP2): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and of the tailed frog, a California species of special concern. In addition, the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the foothill yellow-legged and tailed frogs. This impact would be potentially significant.

Implementation of a 12.5-foot raise of the dam would result in inundation of 45 acres of habitat for the foothill yellow-legged frog and tailed frog. A summary of suitable habitat loss by arm is presented in Table 13-20.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-20. Impacts on Suitable Habitat for the Foothill Yellow-Legged and Tailed Frog in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Montane riparian	2.72	3.23	20.57	6.12	1.00	1.19
Riverine	0.00	0.42	4.02	4.51	0.84	0.00
Total	2.72	3.65	24.59	10.63	1.84	1.19

Note:
*Acreage values are approximate.

Impact Wild-3 (CP2): Impact on the Northwestern Pond Turtle and Its Habitat
Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the northwestern pond turtle, an MSCS-covered species, a California species of special concern, and a USFS sensitive species. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion and sedimentation. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the northwestern pond turtle. This impact would be potentially significant.

Implementation of a 12.5-foot raise of the dam would result in conversion of 35 acres of montane riparian and 10 acres of riverine habitat to lacustrine habitat. Because there are equally valuable components lost or gained in either habitat, the quality of the habitat would not be compromised. However, maximum lake inundation would be infrequent (at most 1 month per year) and would not benefit the species throughout the remainder of the year. Thus, the conversion to lacustrine remains an impact on northwestern pond turtle habitat. A summary of suitable habitat loss by arm is presented in Table 13-21.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed or in the species range. Analysis impacts on upland habitats will be quantified. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-21. Impacts on Suitable Habitat for the Northwestern Pond Turtle in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm

Note:
*Acreage values are approximate.

Impact Wild-4 (CP2): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected species and MSCS-covered species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the American peregrine falcon.

Similar to CP1, overstory and complete vegetation removal is expected to occur within the impoundment area in suitable cliff habitat. Thus, overstory vegetation removal occurring in or near suitable cliff habitat during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests. Additionally, because of the steep terrain, trees would be yarded by helicopter. Noise generated by chainsaws and helicopter yarding could cause the abandonment of nests, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant.

No known eyries would be inundated with a 12.5-foot raise in lake elevation; however, 14.5 vertical feet (full pool) of cliff habitat would be inundated. Based on the large area required for suitable nesting habitat for peregrine falcons, impacts on suitable cliff habitat for nesting would be less than significant. The conversion of uplands to lacustrine habitat would not adversely affect foraging habitat for the species because they frequently forage over water. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP2): Take and Loss of Habitat for the Bald Eagle Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to

inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed species, fully protected species, and USFS sensitive species, an MSCSMSCS-covered species, and a BLM sensitive species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the bald eagle. This impact would be potentially significant.

Any raise in elevation would inundate between 8 and 14 nest trees. If inundation were to occur, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April or early June, nest trees would be flooded toward the end of the nesting season. If eagles were nesting in these trees, it would be likely that young would fledge before the nest tree died from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected. Because bald eagles generally use the same nest for multiple years, the loss of nest trees would be a significant impact.

Inundation could also affect erosion and bank stability, which could affect nest trees that are in close proximity to the impoundment area. This would be a potentially significant impact.

Inundation resulting from a 12.5-foot dam raise would result in a loss 1,132 acres of nesting and roosting habitat for the bald eagle. Potential nest and roost trees are located in blue oak woodland, blue oak–foothill pine, Douglas-fir, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine habitats with tree diameters larger than 24 inches. Impacts on suitable spotted owl habitat by CWHR type in the impoundment area are summarized in Table 13-22.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. Bald eagle nesting activity changes from year to year. The number of bald eagle nests is subject to change based on eagle activity at the time of construction and the subsequent inundation. Reclamation is currently working with the USFS to determine the current eagle activity to revise the number of nest trees that may be impacted. Indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-22. Impacts on Suitable Habitat for the Bald Eagle in the Impoundment Area (12.5-Foot Dam Raise)

Note:
*Acreages are approximate and will be revised based on habitat containing suitable tree diameters.

Impact Wild-6 (CP2): Take and Loss of Nesting and Foraging Habitat for the Northern Spotted Owl Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the northern spotted owl, a Federally listed as threatened species and MSCS-covered species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of habitat, including critical habitat for this species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the northern spotted owl. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of 1,080 acres (29 acres of critical habitat) of nesting and foraging habitat for the northern spotted owl. Impacts on suitable habitat for the spotted owl by CWHR type in the impoundment area are summarized in Table 13-23.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Note:

*Acres are approximate.

Impact Wild-7 (CP2): Impact on the Purple Martin and Its Nesting Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. Similar to CP1, nest trees occurring in the lake could be adversely affected by inundation and related vegetation removal. These impacts would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-8 (CP2): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a State-listed as endangered species, USFS sensitive species, and MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of 1,115 acres of nesting and foraging habitat for the Vaux's swift (Douglas-fir, montane hardwood, montane hardwood-conifer, montane riparian, and ponderosa pine) and 35 acres for the willow flycatcher, yellow warbler, and yellow-breasted chat (montane riparian).

Impacts on suitable habitats for the willow flycatcher, Vaux's swifts, yellow warbler, and yellow-breasted chat habitat by CWHR type in the impoundment area is summarized in Table 13-24.

Note:
**Acres are approximate.*

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-9 (CP2): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a California species of special concern and an MSCS-covered species; the northern goshawk, a California species of special concern, a USFS sensitive

species, and a BLM sensitive species; the Cooper's hawk, an MSCS-covered species; the great blue heron, an MSCS-covered species; and the osprey, an MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of foraging and nesting habitat for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of 1,080 acres of nesting and foraging habitat (Douglas-fir, montane hardwood–conifer, and ponderosa pine) for the long-eared owl and northern goshawk, and 1,473 acres of nesting and foraging habitat for the Cooper's hawk and great blue heron (blue oak–foothill pine, closed-cone pine-cypress, Douglas-fir, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine).

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-25.

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping

Note:
*Acres are approximate.

Impacts on the osprey would be similar to those described for CP1. There are 54 osprey nests within the perimeter of Shasta Lake. There are six nest trees that would be affected by a 12.5-foot dam raise. Eleven osprey nests are located in relocation areas. Removal of nest trees would be a potentially significant impact. Because osprey generally use the same nest for multiple years, the loss of 17 nest trees (31 percent) collectively between the impoundment area and relocation areas would be a potentially significant impact.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. Osprey nesting activity changes from year to year. The number of osprey nests is subject to change based on current eagle activity at the time of construction and the subsequent inundation. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-10 (CP2): Take and Loss of Habitat for the Pacific Fisher
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be identical to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of 855 acres of habitat (Douglas-fir, montane hardwood–conifer, montane riparian, and ponderosa pine) for the Pacific fisher.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-26.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Note:
**Acres are approximate.*

Impact Wild-11 (CP2): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, and Yuma Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared Myotis, a BLM sensitive species; the Yuma Myotis, a BLM sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in the loss of 18 acres of habitat for the pallid bat, spotted bat, western mastiff bat, Townsend's big-eared bat and Yuma myotis (barren, blue oak woodland, and blue oak–foothill pine); the loss of 1,677 acres of habitat for the western red bat long-eared myotis, and ringtail (barren, blue oak woodland, blue oak–foothill pine, closed-cone pine-cypress, Douglas-fir, mixed chaparral, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine); and the loss of 855 acres of habitat for the American marten (Douglas-fir,

montane hardwood–conifer, montane riparian, and ponderosa pine). This impact would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-27.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-12 (CP2): Impacts on Special-Status Terrestrial Mollusks (Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian) andTtheir Habitat All of these species are designated USFS sensitive and survey and manage species and are proposed for Federal listing. The Shasta sideband is also an MSCS-covered species. Ground-disturbing activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of this species. This would be a significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in the loss of 1,680 acres of habitat for the Shasta chaparral (annual grassland, barren, blue oak woodland, blue oak–foothill pine, closed-cone pine-cypress, Douglas-fir, mixed chaparral, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine), 367 acres in the impoundment area for Shasta hesperian (Douglas-fir, montane hardwood conifer, and montane riparian), 7 acres of limestone habitat for the Shasta sideband, and 2 acres of limestone habitat for the Wintu sideband. This impact would be potentially significant.

Note:
*Acres are approximate.

Impact Wild-13 (CP2): Permanent Loss of General Wildlife Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in a permanent loss of habitat. This would be a potentially significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of general wildlife habitat. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of 1,715 acres of general wildlife habitat in the impoundment area. Impacts on general wildlife habitat by CWHR type in the impoundment area are summarized in Table 13-29.

Table 13-29. Impacts on CWHR Habitats in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Annual grassland	0.36	0	1.53	0.53	0	0
Barren	0.77	0	0.36	0.00	0	0.00
Blue oak–foothill pine	7.05	0	0	0	2.46	5.27
Blue oak woodland	0	0	0	0	0	1.65
Closed-cone pine–cypress	24.40	0	8.95	14.89	32.72	262.31
Douglas-fir	0	0	0	0.06	0	0
Mixed chaparral	20.58	9.56	112.76	10.97	7.35	40.11
Montane hardwood	53.30	25.75	120.48	45.31	13.31	1.77
Montane hardwood–conifer	48.77	0.70	99.06	97.70	78.41	7.73

Note:
**Acres are approximate.*

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-14 (CP2): Impacts on Other Birds of Prey (i.e., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species(i.e., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of active nests and habitat for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in greater impacts on nesting migratory birds and raptors. This impact would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP2): Loss of Critical Deer Winter and Fawning Range
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of Shasta Dam would result in the loss of critical deer range. This would be a potentially significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in the loss of 1,679 acres of suitable deer habitat. This impact would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP2): Take and Loss of the California Red-Legged Frog
Reclamation is concurrently completing an assessment of California red-legged frog habitat, which will be submitted to USFWS for review. Based on this assessment, USFWS will determine whether surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is proposed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Wild-17 (CP2): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementation of CP2 would result in a modified flow regime that would reduce the frequency, duration, and magnitude of intermediate to large flows below Shasta Dam during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and the formation of off-channel habitats. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-17 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. The differences in flow regime among the alternatives are described in detail in Chapter 6, "Hydrology, Hydraulics, and Water Management." This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP2): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes CP2 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows, which also would alter the geomorphic processes along the Sacramento River, including the rate of bank erosion in the primary study area. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be similar to Impact Wild-18 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. Nonetheless, for the same reasons as CP1, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-19 (CP2): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Changes in Flow Regime Construction-related disturbances at Shasta Dam are not anticipated to disturb or permanently remove vernal pool habitat for special-status wildlife species along the upper Sacramento River. Altered flow regimes resulting from project-related dam operation are also not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species. This impact would be less than significant.

This impact would be similar to Impact Wild-19 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP2): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

This impact would be similar to Impact Wild-20 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP2): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program CP2 would not include the gravel augmentation program. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-22 (CP2): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration of Reading Island CP2 would not include Reading Island restoration. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Wild-23 (CP2): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementation of CP2 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. Although this change in surface and subsurface hydrology would be less than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats along the middle Sacramento River. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-23 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP2): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes The effect of CP2 on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP2 on river flows would attenuate with distance downstream. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may

cause localized bank and nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be similar to Impact Wild-24 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. Nonetheless, for the same reasons described for CP1, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP2): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Altered flow regimes as a result of dam operation associated with the project are not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species in the lower Sacramento River and Delta portion of the extended study area. This impact would be less than significant.

This impact would be similar to Impact Wild-25 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP2): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat Along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

This impact would be similar to Impact Wild-26 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas

Impact Wild-27 (CP2): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP2 would change flow regimes in several downstream waterways. Modified flow regimes would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. However, based on the CalSim-II modeling results,

the hydrologic effects on tributaries with CVP and SWP dams are expected to be less than effects on the Sacramento River. Most potential noticeable changes in flows and stages would diminish downstream from Red Bluff. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

This impact would be similar to Impact Wild-27 (CP1). The extent of the impact would be potentially greater under CP2 than under CP1 but less than under CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

CP3 is similar to CP1 and CP2. It focuses on the greatest practical enlargement of Shasta Dam and Shasta Lake consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increased water supply reliability and increased survival of anadromous fish. In addition to the common features above, CP3 involves raising Shasta Dam 18.5 feet, an elevation change that would increase the full pool by 20.5 feet and enlarge the total storage space in the reservoir by 634,000 acre-feet to 5.19 million acre-feet.

With respect to wildlife impacts, dam construction activities for CP1 through CP5 would be so similar that they are considered to be identical for purposes of this analysis. Because CP3 would result in higher lake levels than CP1, CP3 would also require more relocation of utilities, public service facilities, and recreational facilities than CP1. However, the wildlife impact analysis for CP1 assumes maximum impacts related to mechanized vegetation clearing and construction within the relocation areas. Therefore, vegetation clearing and construction impacts within the relocation areas would be identical for CP1 through CP5. Because CP3 would result in higher lake levels than CP1, CP3 would result in a larger (and deeper) area of inundation than CP1, in turn requiring more vegetation clearing within the inundation area than CP1.

Shasta Lake and Vicinity

Impact Wild-1 (CP3): Take and Loss of Habitat for the Shasta Salamander

Ground-disturbing activities associated with construction could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, survey and manage species, MSCS-covered species, and BLM sensitive species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an

18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the Shasta salamander. This impact would be significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of 15 acres of limestone habitat and 2,429 acres of nonlimestone habitat. Impacts on limestone and nonlimestone by CWHR type providing suitable habitat in the impoundment area are summarized in Table 13-30.

Table 13-30. Impacts on Suitable Habitat for the Shasta Salamander in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Limestone	0.00	1.63	0.00	10.51	0.00	2.85
Nonlimestone	437.60	90.04	723.57	424.44	242.77	510.99
Total	437.60	91.67	723.57	434.95	242.77	513.84

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping
Note:
*Acres are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed or in the species range (if appropriate). Surveys of the Shasta salamander are ongoing and it is anticipated that protocol-level surveys will be conducted within the dam construction footprint and all relocation area footprints. Protocol-level surveys would provide specific information about the presence or absence of Shasta salamanders within individual construction footprints. Mitigation for acres affected would then be refined based on these results. Direct and indirect impacts based on those results will be reported in the FEIS. Additionally, other indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-2 (CP3): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and of the tailed frog, a California species of special concern. In addition, the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the foothill yellow-legged and tailed frogs. This impact would be potentially significant.

Implementation of an 18.5-foot raise of the dam would result in inundation of 77 acres of habitat for the foothill yellow-legged frog and tailed frog. A summary of suitable habitat loss by arm is presented in Table 13-31.

Table 13-31. Impacts on Suitable Habitat for the Foothill Yellow-Legged and Tailed Frog in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Montane riparian	4.16	6.67	26.16	13.91	1.53	1.57
Riverine	0.00	0.88	5.24	15.43	1.41	0.00
Total	4.16	7.55	31.40	29.34	2.94	1.57

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping
Note:
*Acres are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-3 (CP3): Impact on the Northwestern Pond Turtle and Its Habitat
Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the northwestern pond turtle, an MSCS-covered species, a California species of special concern, and a USFS sensitive species. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion and sedimentation. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the northwestern pond turtle. This impact would be potentially significant.

Implementation of an 18.5-foot raise of the dam would result in the conversion of 54 acres of montane riparian and 23 acres of riverine habitat to lacustrine habitat. Because equally valuable components are lost or gained in either habitat, the quality of the habitat would not be compromised. However, maximum lake inundation would be infrequent (at most 1 month per year) and would not benefit the species throughout the remainder of the year. Thus, the conversion to lacustrine habitat would remain an impact on northwestern pond turtle habitat. A summary of suitable habitat loss by arm is presented in Table 13-32.

Table 13-32. Impacts on Suitable Habitat for the Northwestern Pond Turtle in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Montane riparian	4.16	6.67	26.16	13.91	1.53	1.57
Riverine	0.00	0.88	5.24	15.43	1.41	0.00
Total	4.16	7.55	31.40	29.34	2.94	1.57

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping
Note:
*Acres are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed or in the species range (if appropriate). Analysis impacts on upland habitats will be quantified. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-4 (CP3): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected species and MSCS-covered species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the American peregrine falcon.

Similar to CP1, overstory and complete vegetation removal is expected to occur within the impoundment area in suitable cliff habitat. Thus, overstory vegetation removal occurring in or near suitable cliff habitat during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests. Additionally, because of the steep terrain, trees would be yarded by helicopter. Noise generated by chainsaws and helicopter yarding could cause the abandonment of nests, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant.

No known eyries would be inundated with a 18.5-foot raise in lake elevation; however, 20.5 (full pool) vertical feet of cliff habitat would be inundated. Based on the large area required for suitable nesting habitat for peregrine falcons, impacts on suitable cliff habitat for nesting would be less than significant. The conversion of uplands to lacustrine habitat would not adversely affect foraging habitat for the species because they frequently forage over water. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP3): Take and Loss of Habitat for the Bald Eagle
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed species, fully protected species, and USFS sensitive species, an MSCS-covered species, and a BLM sensitive species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the bald eagle. This impact would be potentially significant.

Any raise in elevation would inundate between 8 and 14 nest trees. If inundation were to occur, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April or early June, nest trees would be flooded toward the end of the nesting season. If eagles were nesting in these trees, it would be likely that young would fledge before the nest tree died from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected. Because bald eagles generally use the same nest for multiple years, the loss of nest trees would be a significant impact.

Inundation could also affect erosion and bank stability, which could affect nest trees that are in close proximity to the impoundment area. This would be a potentially significant impact.

Inundation resulting from an 18.5-foot dam raise would result in a loss 1,637 acres of nesting and roosting habitat for the bald eagle. Potential nest and roost trees occur in blue oak woodland, blue oak–foothill pine, Douglas-fir, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine habitats with tree diameters greater than 24 inches. Impacts on suitable spotted owl habitat by CWHR type in the impoundment area are summarized in Table 13-33.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. Bald eagle nesting activity changes from year to year. The number of bald eagle nests is subject to change based on eagle activity at the time of construction and the subsequent inundation. Reclamation is currently working with the USFS to determine the current eagle activity to revise the number of nest trees that may be impacted. Indirect and temporary impacts will be analyzed in the FEIS. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-33. Impacts on Suitable Habitat for the Bald Eagle in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm
Blue oak woodland	0.00	0.00	0.00	0.00	0.00	1.94
Blue oak–foothill pine	10.36	0.00	0.00	0.00	4.29	6.81
Douglas-fir	0.00	0.00	0.00	0.36	0.00	0.00

Montane hardwood–conifer	70.68	0.99	150.42	140.93	111.63	10.55
Montane riparian	4.16	6.67	26.16	13.91	1.53	1.57
Ponderosa pine	215.11	30.72	188.19	161.74	49.56	57.50
Total	373.80	77.15	535.78	383.00	186.44	80.87

Source: Data compiled by North State Resources, Inc., in 2011 based on habitat assessments and mapping
Note:
**Acreages are approximate and will be revised based on habitat containing suitable tree diameters.*

Impact Wild-6 (CP3): Take and Loss of Nesting and Foraging Habitat for the Northern Spotted Owl Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the northern spotted owl, a Federally listed as threatened species and MSCS-covered species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of habitat, including critical habitat for this species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the northern spotted owl. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of 1,560 acres (42 acres of critical habitat) of nesting and foraging habitat for the northern spotted owl. Impacts on suitable spotted owl habitat by CWHR type in the impoundment area are summarized in Table 13-34.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-34. Impacts on Suitable Habitat for the Northern Spotted Owl in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm

Note:

*Acres are approximate.

Impact Wild-7 (CP3): Impact on the Purple Martin and Its Nesting Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. Similar to CP1, nest trees occurring in the lake could be adversely affected by inundation and related vegetation removal. These impacts would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-8 (CP3): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a State-listed as endangered species, USFS sensitive species, and MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of 1,614 acres of nesting and foraging habitat for the Vaux's swift (Douglas-fir, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine) and 54 acres for the willow flycatcher, yellow warbler, and yellow-breasted chat (montane riparian).

Impacts on suitable habitats for the willow flycatcher, Vaux's swift, yellow warbler, and yellow-breasted chat by CWHR type in the impoundment area are summarized in Table 13-35.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-35. Impacts on Suitable Habitat for the Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (acres*)					
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm

Impact Wild-9 (CP3): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a

California species of special concern and an MSCS-covered species; the northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the Cooper's hawk, an MSCS-covered species; the great blue heron, an MSCS-covered species; and the osprey, an MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of foraging and habitat for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss 1,560 acres of nesting and foraging habitat (Douglas-fir, montane hardwood-conifer, and ponderosa pine) for the long-eared owl and northern goshawk, and 2,120 acres of nesting and foraging habitat for the Cooper's hawk and great blue heron (blue oak-foothill pine, closed-cone pine-cypress, Douglas-fir, montane hardwood, montane hardwood-conifer, montane riparian, and ponderosa pine).

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-36.

Note:
*Acres are approximate.

Impacts on the osprey are similar to those described for CP1. There are 54 osprey nests within the perimeter of Shasta Lake. Seven nest trees would be affected by an 18.5-foot dam raise. Eleven osprey nests are located in relocation areas. Removal of nest trees would be a potentially significant impact. Because ospreys generally use the same nest for multiple years, the loss of 18 nest trees (33 percent) collectively between the impoundment area and the relocation areas would be a potentially significant impact.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. Osprey nesting activity changes from year to year. The number of osprey nests is subject to change based on current osprey activity at the time of construction and the subsequent inundation. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-10 (CP3): Take and Loss of Habitat for the Pacific Fisher
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of 1,242 acres of habitat (Douglas-fir, montane hardwood–conifer, montane riparian, and ponderosa pine) for the Pacific fisher.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-37.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-11 (CP3): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, and Yuma Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared Myotis, a BLM sensitive species; the Yuma Myotis, a BLM sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in the loss of 25 acres of habitat for the pallid bat, spotted bat, western mastiff bat, Townsend's big-eared bat, and Yuma myotis (barren, blue oak woodland, and blue oak–foothill pine); the loss of 2,412 acres of habitat for the western red bat, long-eared myotis and ringtail (barren, blue oak woodland, blue oak–foothill pine, closed-cone pine-cypress, Douglas-fir, mixed chaparral, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine); and the loss of 855 acres of habitat for the American marten (Douglas-fir, montane hardwood–conifer, montane riparian, and ponderosa pine). This impact would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-38.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-12 (CP3): Impacts on Special-Status Terrestrial Mollusks (Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat All of these species are designated USFS sensitive and survey and manage species and are proposed for Federal listing. The Shasta sideband is also an MSCS-covered species. Ground-disturbing activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta

Dam would result in the inundation of suitable habitat and direct take of this species. This would be a significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in the loss of 2,416 acres of habitat for the Shasta chaparral and Shasta hesperian (annual grassland, barren, blue oak woodland, blue oak-foothill pine, closed-cone pine-cypress, Douglas-fir, mixed chaparral, montane hardwood, montane hardwood-conifer, montane riparian, and ponderosa pine), 539 acres in the impoundment area for Shasta hesperian (Douglas-fir, montane hardwood conifer, and montane riparian), 11 acres of limestone habitat for the Shasta sideband and 3 acres of limestone habitat for the Wintu sideband. This impact would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-39.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-13 (CP3): Permanent Loss of General Wildlife Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in a permanent loss of habitat. This would be a potentially significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of general wildlife habitat. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of 2,472 acres of general wildlife habitat in the impoundment area. Impacts on general wildlife habitat by CWHR type in the impoundment area are summarized in Table 13-40.

Table 13-40. Impacts on CWHR Habitats in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (acres*)

Note:
*Acreage values are approximate.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-14 (CP3): Impacts on Other Birds of Prey (i.e., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species(i.e., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of active nests and habitat for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in greater impacts on nesting migratory birds and raptors. This impact would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP3): Loss of Critical Deer Winter and Fawning Range
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of Shasta Dam would result in the loss of critical deer range. This would be a potentially significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result the loss of 2,415 acres of suitable deer habitat. This impact would be potentially significant.

Additional analysis of impacts will be conducted in relation to suitable habitats available in the Shasta Lake watershed. An analysis of indirect impacts and temporary impacts will be completed in subsequent documents. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP3): Take and Loss of the California Red-Legged Frog
Reclamation is concurrently completing an assessment of California red-legged frog habitat, which will be submitted to USFWS for review. Based on this assessment, USFWS will determine whether surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is proposed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Wild-17 (CP3): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementation of CP3 would result in a modified flow regime that would reduce the frequency, duration, and magnitude of intermediate to large flows below Shasta Dam during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and the formation of off-channel habitats. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-17 (CP1). Altered flow regimes as a result of dam operation associated with the project could be greatest under CP3 because the alterations of flow regimes would be more substantial than under CP1 and CP2. The differences in flow regime among the alternatives are described in detail in Chapter 6, "Hydrology, Hydraulics, and Water Management." This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP3): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes CP3 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows, which also would alter the geomorphic processes along the Sacramento River, including the rate of bank erosion in the primary study area. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be similar to Impact Wild-18 (CP1). The extent of the impact would be potentially greater under CP1 or CP2. Nonetheless, for the same reasons as CP1, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-19 (CP3): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Changes in Flow Regime Construction-related disturbances at Shasta Dam are not anticipated to disturb or permanently remove vernal pool habitat for special-status wildlife species along the upper Sacramento River. Altered flow regimes resulting from project-related dam operation are also not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species. This impact would be less than significant.

This impact would be similar to Impact Wild-19 (CP1). The extent of the impact could be greatest under CP3 because the alterations of flow regimes would be more substantial than under CP1 and CP2; however, vernal pool habitats are not expected to be affected by the flows. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP3): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less

likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

This impact would be similar to Impact Wild-20 (CP1). These effects associated with the project could be greatest under CP3 because the alterations of flow regimes would be more substantial than under CP1 and CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP3): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program CP3 would not include the gravel augmentation program. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-22 (CP3): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration of Reading Island CP3 would not include Reading Island restoration. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Wild-23 (CP3): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementation of CP3 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. Although this change in surface and subsurface hydrology would be less than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-23 (CP1). These effects associated with the project could be greatest under CP3 because the alterations of flow regimes would be more substantial than under CP1 and CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP3): Impacts on Bank Swallow along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes The effect of

CP3on bank swallow habitat Along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP3 on river flows would attenuate with distance downstream. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized bank and nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be similar to Impact Wild-24 (CP1). The extent of the impact would be potentially greater under CP3 than under CP1 or CP2. Nonetheless, for the same reasons described for CP1, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP3): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Altered flow regimes as a result of dam operation associated with the project are not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species in the lower Sacramento River and Delta portion of the extended study area. This impact would be less than significant.

This impact would be similar to Impact Wild-25 (CP1). These effects associated with the project could be greatest under CP3 because the alterations of flow regimes would be more substantial than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP3): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

This impact would be similar to Impact Wild-26 (CP1). These effects associated with CP3 could be greatest under CP3 because the alterations of flow regimes would be more substantial than under CP1 and CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas

Impact Wild-27 (CP3): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP3 would change flow regimes in several downstream waterways. Modified flow regimes would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. However, based on the CalSim-II modeling results, the hydrologic effects in tributaries with CVP and SWP dams, outside of the primary study area, are expected to be less than effects on the Sacramento River. Most potential noticeable changes in flows and stages would diminish downstream from Red Bluff. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

This impact would be similar to Impact Wild-27 (CP1). These effects associated with the project could be greatest under CP3 because the alterations of flow regimes would be more substantial than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

The primary function of CP4 is to address survival of anadromous fish, while still improving water supply reliability. CP4 focuses on increasing the volume of cold water available to the temperature control device through reservoir reoperations and on raising Shasta Dam by 18.5 feet. As with CP3 and the common features above, this raise would increase the full pool by 20.5 feet and enlarge total reservoir storage space by 634,000 acre-feet.

In addition to the activities common to CP1–CP3, CP4 includes augmenting locations along the Upper Sacramento River segment of the study area with gravel to increase spawning habitat for anadromous fish. Gravel placement would occur at one or more sites per year over a 10-year period and would be accomplished by one of three methods; lateral berms, talus cone, direct placement in river; as appropriate depending on specific conditions, including geomorphology, of the augmentation site. To the extent available, existing river access points would be used to deliver gravel to the river; however, temporary new access roads would be needed in some cases, mostly adjacent to the river, and would be extended from existing dirt roads. Furthermore, under CP4, riparian, floodplain, and side channel habitat restoration would be constructed at Reading Island to restore habitat for anadromous salmonids in the Anderson

Creek Slough. This Reading Island project could involve some vegetation clearing.

With respect to wildlife impacts, dam construction activities for CP1–CP5 would be so similar that they are considered to be identical for purposes of this analysis. Because CP4 would result in higher lake levels than CP1, CP4 would also require more relocation of utilities, public service facilities, and recreational facilities than CP1. However, the wildlife impact analysis for CP1 assumes maximum impacts related to mechanized vegetation clearing and construction within the relocation areas. Therefore, vegetation clearing and construction impacts within the relocation areas would be identical for CP1–CP5. Because CP4 would result in higher lake levels than CP1, CP4 would result in a larger (and deeper) area of inundation than CP1, in turn requiring more vegetation clearing within the inundation area than CP1. CP4 would also involve some vegetation clearing in the Upper Sacramento River portion of the study area to provide access for gravel augmentation.

Shasta Lake and Vicinity

Impact Wild-1 (CP4): Take and Loss of Habitat for the Shasta Salamander
Ground-disturbing activities associated with construction could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, survey and manage species, MSCS-covered species, and BLM sensitive species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

This impact would be similar to Impact Wild-1 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-2 (CP4): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and of the tailed frog, a California species of special concern. In addition, the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. This impact would be potentially significant.

This impact would be similar to Impact Wild-2 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-3 (CP4): Impact on the Northwestern Pond Turtle and Its Habitat
Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the northwestern pond turtle, an MSCS-covered species, a California species of special concern, and a USFS sensitive species. In addition, project implementation could result in the degradation of suitable aquatic

habitat because of increased erosion and sedimentation. This impact would be potentially significant.

This impact would be similar to Impact Wild-3 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-4 (CP4): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected species and MSCS-covered species. This impact would be potentially significant.

This impact would be similar to Impact Wild-4 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP4): Take and Loss of Habitat for the Bald Eagle Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed species, fully protected species, and USFS sensitive species, an MSCS-covered species, and a BLM sensitive species. This impact would be significant.

This impact would be similar to Impact Wild-5 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-6 (CP4): Take and Loss of Nesting and Foraging Habitat for the Northern Spotted Owl Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the northern spotted owl, a Federally listed as threatened species and MSCS-covered species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of habitat, including critical habitat for this species. This impact would be potentially significant.

This impact would be similar to Impact Wild-6 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-7 (CP4): Impact on the Purple Martin and Its Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting

season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant.

This impact would be similar to Impact Wild-7 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-8 (CP4): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a State-listed as endangered species, USFS sensitive species, and MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-8 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-9 (CP4): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a California species of special concern and an MSCS-covered species; the northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the Cooper's hawk, an MSCS-covered species; the great blue heron, an MSCS-covered species; and the osprey, an MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of foraging and nesting habitat for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-9 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-10 (CP4): Take and Loss of Habitat for the Pacific Fisher Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss

of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

This impact would be similar to Impact Wild-10 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-11 (CP4): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, and Yuma Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared Myotis, a BLM sensitive species; the Yuma Myotis, a BLM sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

This impact would be similar to Impact Wild-11 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-12 (CP4): Impacts on Special-Status Terrestrial Mollusks (Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat All of these species are designated USFS sensitive and survey and manage species and are proposed for Federal listing. The Shasta sideband is also an MSCS-covered species. Ground-disturbing activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of this species. This would be a significant impact.

This impact would be similar to Impact Wild-12 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-13 (CP4): Permanent Loss of General Wildlife Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in a permanent loss of habitat. This would be a potentially significant impact.

This impact would be similar to Impact Wild-13 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-14 (CP4): Impacts on Other Birds of Prey (i.e., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species(i.e., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of active nests and habitat for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-14 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP4): Loss of Critical Deer Winter and Fawning Range
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of Shasta Dam would result in the loss of critical deer range. This would be a potentially significant impact.

This impact would be identical to Impact Wild-15 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP4): Take and Loss of the California Red-Legged Frog
Reclamation is concurrently completing an assessment of California red-legged frog habitat, which will be submitted to USFWS for review. Based on this assessment, USFWS will determine whether surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is proposed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Wild-17 (CP4): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementation of CP4 would result in a modified flow regime that would reduce the frequency, duration, and magnitude of intermediate to large flows below Shasta Dam during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and the formation of off-channel habitats. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Wild-17 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP4): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes CP4 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows, which also would alter the geomorphic processes along the Sacramento River, including the rate of bank erosion in the primary study area. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be the same as Impact Wild-18 (CP1) and would be less than significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-19 (CP4): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Dam Construction and from Changes in Flow Regime Construction-related disturbances at Shasta Dam are not anticipated to disturb or permanently remove vernal pool habitat for special-status wildlife species in the primary study area. Altered flow regimes resulting from project-related dam operation are also not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species. This impact would be less than significant.

This impact would be the same as Impact Wild-19 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP4): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

This impact would be the same as Impact Wild-20 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP4): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program CP4 would include the gravel augmentation program. Implementing the gravel augmentation program could result in temporary or short-term disturbance of riparian vegetation that has the potential to support special-status wildlife and there are no vernal pools or other seasonal wetland habitats at the augmentation sites. However, riparian-associated special-status wildlife species could be killed during riparian vegetation removal. Direct loss of individuals of riparian-associated special-status species during vegetation removal would be a potentially significant impact.

CP4 would include the gravel augmentation program. Implementing the gravel augmentation program could result in temporary disturbance of habitat or removal of riparian vegetation that has the potential to support special-status wildlife. Gravel augmentation would occur at one to a few sites per year over a 10-year period so the area of impact in a given year would be very small. A total of 15 potential augmentation sites have been identified between Keswick Dam and RBDD. Gravel placement itself is not expected to result in substantial adverse effects on any wildlife species, and there are no vernal pools or other seasonal wetland habitats at the augmentation sites. Short-term habitat loss also would not be sufficient to substantially affect any wildlife species. However, riparian-associated special-status wildlife species could be killed during riparian vegetation removal. Direct loss of riparian-associated special-status species during vegetation removal would be a potentially significant impact. Potential effects on special-status wildlife species are as follows:

- **Invertebrates** – Blue elderberry shrubs, the host plant for the valley elderberry longhorn beetle, are found throughout much of the Sacramento River's riparian corridor. Gravel augmentation activities have the potential to directly and indirectly affect blue elderberry shrubs, and valley elderberry longhorn beetles potentially present in the shrubs. Eleven individual elderberry shrubs and/or clumps are present within 100 feet of areas that would be disturbed during gravel

augmentation; these shrubs are located 20 feet or more from the access trail. No elderberry shrub removal is required; the nearest project activity is restricted to use of the access trail. Disturbance of elderberry shrubs would be a potentially significant impact.

- **Reptiles and Amphibians** – The northwestern pond turtle has been documented within the Sacramento River, and suitable habitat for the species is provided within the primary study area. Riparian vegetation that would be removed along the river corridor provides potential cover and foraging habitat for northwestern pond turtle. Augmentation activities would take place during the northwestern pond turtle breeding season so there is also potential to effect nests, eggs, or nesting females during vegetation clearing, grading, and gravel placement. Therefore, loss of habitat for the northwestern pond turtle would be a potentially significant impact.

- **Birds** – The riparian and wetland habitats along the Sacramento River floodway provide potential nesting and foraging habitat for western yellow-billed cuckoo, California yellow warbler, and yellow-breasted chat, all of which are special-status birds that nest in riparian vegetation. In addition, northern harrier and short-eared owl may nest in marshes in or adjacent to the stream channel. Other raptors – Cooper's hawk, Swainson's hawk, white-tailed kite, bald eagle, and osprey – may nest in trees in the riparian habitat in the study area. Gravel augmentation activities would be limited to a one-month window from late August to September each year. Therefore, gravel augmentation would generally be conducted outside of the nesting season of most of these species. However, there would still be some potential for active nests to be present in gravel augmentation and vegetation removal areas until mid September. For example, the nesting season for Swainson's hawk, white-tailed kite, and other raptors is from March 1 to September 15 and the nesting season of many other species extends through August 31. Therefore, vegetation removal or disturbance of active nests could result in direct mortality or loss or abandonment of active nests. This would be a potentially significant impact.

- **Mammals** – Special-status mammals potentially occurring in the project area include pallid bat, western red bat, and ringtail. Riparian habitat can provide important foraging and roosting habitat for bats, but these species are not typically dependent on riparian habitats. The amount of potential foraging habitat would not decrease appreciably, and available riparian habitats would still be sufficient for roosting habitat such that impacts on special-status bats would be less than significant. Removal of small amounts of riparian vegetation along the river channel in the study area would not substantially reduce habitat

for ringtail. Therefore, impacts on special-status mammals would be less than significant.

Because of the potential to affect valley elderberry longhorn beetle, northwestern pond turtle, and riparian-associated special-status birds, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-22 (CP4): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration of Reading Island Restoring connectivity between Anderson Creek Slough and the Sacramento River, rehabilitating the existing boat ramp, and constructing a handicap fishing access area could result in disturbance and short-term removal of riparian vegetation that support riparian-associated special-status wildlife species that could be killed during riparian vegetation removal. Direct loss of riparian-associated special-status species during vegetation removal would be a potentially significant impact.

CP4 would include restoration actions at Reading Island. Potential effects of these actions on special-status wildlife species are as follows:

- **Invertebrates** – Blue elderberry shrubs, the host plant for the valley elderberry longhorn beetle, are found throughout much of the Sacramento River's riparian corridor and may be present on the levee separating Anderson Slough and the Sacramento River. Elderberry shrubs may be present throughout Reading Island, including near the boat ramp and areas under consideration for constructing handicap fishing access. Construction activities on Reading Island have the potential to directly and indirectly affect blue elderberry shrubs, and valley elderberry longhorn beetles potentially present in the shrubs. Disturbance of elderberry shrubs would be a potentially significant impact.

- **Reptiles and Amphibians** – The northwestern pond turtle has been documented within the Sacramento River, and suitable habitat for the species is provided within the primary study area. Riparian vegetation that would be removed along the river corridor provides potential cover and foraging habitat for northwestern pond turtle. Boat ramp rehabilitation, construction of fishing access, and habitat restoration activities would take place during the northwestern pond turtle breeding season so there is also potential to effect nests, eggs, or nesting females during vegetation clearing, grading, and gravel placement. Therefore, loss of habitat for the northwestern pond turtle would be a potentially significant impact.

- **Birds** – The riparian habitat along the Sacramento River and Anderson Slough provide potential nesting and foraging habitat for western yellow-billed cuckoo, California yellow warbler, and yellow-breasted

chat, all of which are special-status birds that nest in riparian vegetation. In addition, northern harrier and short-eared owl may nest in marshes in or adjacent to the stream channel. Other raptors—Cooper's hawk, Swainson's hawk, white-tailed kite, bald eagle, and osprey—may nest in trees in the riparian habitat along these waterways and throughout Reading Island. Vegetation removal or disturbance of active nests could result in direct mortality or loss or abandonment of active nests. This would be a potentially significant impact.

- **Mammals** – Special-status mammals potentially occurring in the project area include pallid bat, western red bat, and ringtail. Riparian habitat can provide important foraging and roosting habitat for bats, but these species are not typically dependent on riparian habitats. The amount of potential foraging habitat would not decrease appreciably, and available riparian habitats would still be sufficient for roosting habitat such that impacts on special-status bats would be less than significant. Rehabilitating the existing boat ramp and constructing handicap fishing access would result in minimal vegetation removal. Restoring connectivity of the side channel between Anderson Slough and the river could result in greater amounts of vegetation removal, but this would still be a relatively small amount of riparian vegetation. Removal of small amounts of riparian vegetation along the river corridor, Anderson Slough, or Reading Island would not substantially reduce habitat for ringtail. Therefore, impacts on special-status mammals would be less than significant.

Because of the potential to affect valley elderberry longhorn beetle, northwestern pond turtle, and riparian-associated special-status birds, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Lower Sacramento River and Delta

Impact Wild-23 (CP4): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementation of CP4 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. Although this change in surface and subsurface hydrology would be less than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats along the middle Sacramento River. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for

some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Wild-23 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP4): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes The effect of CP4 on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP4 on river flows would attenuate with distance downstream. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized bank and nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be the same as Impact Wild-24 (CP1), and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP4): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Altered flow regimes as a result of dam operation associated with the project are not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species in the lower Sacramento River and Delta portion of the extended study area. This impact would be less than significant.

This impact would be the same as Impact Wild-25 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP4): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

This impact would be the same as Impact Wild-26 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas

Impact Wild-27 (CP4): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP4 would change flow regimes in several downstream waterways. Modified flow regimes would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. However, based on the CalSim-II modeling results, the hydrologic effects on tributaries with CVP and SWP dams are expected to be less than effects on the Sacramento River. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

This impact would be the same as Impact Wild-27 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 would address both the primary and secondary planning objectives. It involves enlarging Shasta Dam by 18.5 feet, which is consistent with the objectives of the 2000 CALFED ROD, and also includes the common features described above. In addition, CP5 involves (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing either additional or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. Formulation of specific environmental restoration features and increased recreation components is included in the Draft Feasibility Report.

CP5 would also include implementing the same gravel augmentation program and the same riparian, floodplain, and side channel habitat restoration at Reading Island as described for CP4.

Shasta Lake and Vicinity

Impact Wild-1 (CP5): Take and Loss of Habitat for the Shasta Salamander
Ground-disturbing activities associated with construction could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, survey and manage species, MSCS-covered species, and BLM sensitive species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

This impact would be similar to Impact Wild-1 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-2 (CP5): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and of the tailed frog, a California species of special concern. In addition, the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. This impact would be potentially significant.

This impact would be similar to Impact Wild-2 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-3 (CP5): Impact on the Northwestern Pond Turtle and Its Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the northwestern pond turtle, an MSCS-covered species, a California species of special concern, and a USFS sensitive species. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion and sedimentation. This impact would be potentially significant.

This impact would be similar to Impact Wild-3 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-4 (CP5): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected species and MSCS-covered species. This impact would be potentially significant.

This impact would be similar to Impact Wild-4 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-5 (CP5): Take and Loss of Habitat for the Bald Eagle
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed species, fully protected species, and USFS sensitive species, an MSCS-covered species, and a BLM sensitive species. This impact would be significant.

This impact would be similar to Impact Wild-5 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-6 (CP5): Take and Loss of Nesting and Foraging Habitat for the Northern Spotted Owl Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the northern spotted owl, a Federally listed as threatened species and MSCS-covered species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of habitat, including critical habitat for this species. This impact would be potentially significant.

This impact would be similar to Impact Wild-6 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-7 (CP5): Impact on the Purple Martin and Its Nesting Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant.

This impact would be similar to Impact Wild-7 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-8 (CP5): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a State-listed as endangered species, USFS sensitive species, and MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-8 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-9 (CP5): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a California species of special concern and an MSCS-covered species; the northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the Cooper's hawk, an MSCS-covered species; the great blue heron, an MSCS-covered species; and the osprey, an MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of foraging and nesting habitat for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-9 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-10 (CP5): Take and Loss of Habitat for the Pacific Fisher
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

This impact would be similar to Impact Wild-10 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-11 (CP5): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, and Yuma Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared Myotis, a BLM sensitive species; the Yuma Myotis, a BLM sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

This impact would be similar to Impact Wild-11 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-12 (CP5): Impacts on Special-Status Terrestrial Mollusks (Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat All of these species are designated USFS sensitive and survey and manage species and are proposed for Federal listing. The Shasta sideband is also an MSCS-covered species. Ground-disturbing activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of this species. This would be a significant impact.

This impact would be similar to Impact Wild-12 (CP3) and would be a significant impact. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-13 (CP5): Permanent Loss of General Wildlife Habitat
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in a permanent loss of habitat. This would be a potentially significant impact.

This impact would be similar to Impact Wild-13 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-14 (CP5): Impacts on Other Birds of Prey (i.e., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species(i.e., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of active nests and habitat for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-14 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-15 (CP5): Loss of Critical Deer Winter and Fawning Range
Construction activities and vegetation removal associated with the construction of raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of Shasta Dam would result in the loss of critical deer range. This would be a potentially significant impact.

This impact would be similar to Impact Wild-15 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Additional impacts may occur depending on specific restoration and recreation enhancement details. These impacts will be quantified when the details of the proposed actions are developed.

Impact Wild-16 (CP5): Take and Loss of the California Red-Legged Frog
Reclamation is concurrently completing an assessment of California red-legged frog habitat, which will be submitted to USFWS for review. Based on this assessment, USFWS will determine whether surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is proposed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Wild-17 (CP5): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementation of CP5 would result in a modified flow regime that would reduce the frequency, duration, and magnitude of intermediate to large flows below Shasta Dam during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and the formation of off-channel habitats. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in

substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Wild-17 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP5): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes CP5 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows, which also would alter the geomorphic processes along the Sacramento River, including the rate of bank erosion in the primary study area. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be the same as Impact Wild-18 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-19 (CP5): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Dam Construction and from Changes in Flow Regime Construction-related disturbances at Shasta Dam are not anticipated to disturb or permanently remove vernal pool habitat for special-status wildlife species in the primary study area. Altered flow regimes resulting from project-related dam operations are also not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species. This impact would be less than significant.

This impact would the same as Impact Wild-19 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP5): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

This impact would be the same as Impact Wild-20 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP5): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program CP5 includes the gravel augmentation program. Implementing the gravel augmentation program could

result in disturbance or removal of riparian vegetation that has the potential to support special-status wildlife. Gravel augmentation would occur at one to a few sites per year over a 10-year period so the area of impact in a given year would be very small. Thus, gravel placement is not expected to result in any substantial short- or long-term adverse effects on any wildlife species. However, riparian-associated special-status wildlife species could be killed during riparian vegetation disturbance or removal. Direct loss of individuals of riparian-associated special-status species during vegetation removal would be a potentially significant impact.

This impact would be the same as Impact Wild-21 (CP4) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-22 (CP5): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration of Reading Island Restoring connectivity between Anderson Creek Slough and the Sacramento River, rehabilitating the existing boat ramp, and constructing a handicap fishing access area could result in disturbance and short-term removal of riparian vegetation that support riparian-associated special-status wildlife species that could be killed during riparian vegetation removal. Direct loss of riparian-associated special-status species during vegetation removal would be a potentially significant impact.

This impact would be the same as Impact Wild-22 (CP4) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Lower Sacramento River and Delta

Impact Wild-23 (CP5): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementation of CP5 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years, and would increase the volume of flows from spring through fall of most years. Although this change in surface and subsurface hydrology would be less than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats along the middle Sacramento River. Reduced formation of off-channel habitat would be a substantial long-term effect on the habitat of western pond turtle. Also, although the total amount of riparian vegetation would not be substantially altered, the portion of riparian vegetation in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. In particular, these changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Wild-23 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP5): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes The effect of CP5 on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP5 on river flows would attenuate with distance downstream. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized bank and nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be the same as Impact Wild-24 (CP3), and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP5): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Altered flow regimes as a result of dam operation associated with the project are not anticipated to temporarily disturb or permanently remove vernal pool habitat for special-status wildlife species in the lower Sacramento River and Delta portion of the extended study area. This impact would be less than significant.

This impact would be the same as Impact Wild-25 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP5): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be less likely to be attained. This potential conflict between the project and local and regional plans to promote riparian habitat would be a potentially significant impact.

This impact would be the same as Impact Wild-26 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas

Impact Wild-27 (CP5): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP5 would change flow regimes in several downstream waterways. Modified flow regimes would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. However, based on the CalSim-II modeling results,

the hydrologic effects on tributaries with CVP and SWP dams are expected to be less than effects on the Sacramento River. Most potential noticeable changes in flows and stages would diminish downstream from Red Bluff. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

This impact would be the same as Impact Wild-27 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

13.3.5 Mitigation Measures

Table 13-41 presents a summary of mitigation measures for wildlife resources.

Table 13-41. Summary of Mitigation Measures for Wildlife Resources

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Wild-1: Take and Loss of Habitat for the Shasta Salamander	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure Wild-1: Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander.

Key:
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant
S = significant
SU = significant and unavoidable
TBD = to be determined

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Wild-18 (CP1), Wild-19 (CP1), Wild-21, Wild-22, Wild-24 (CP1), Wild-25 (CP1), and Wild-27 (CP1). Mitigation is provided below for the remaining impacts of CP1 on wildlife species.

Mitigation Measure Wild-1 (CP1): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander To avoid or minimize impacts on the Shasta salamander, the following measures will be implemented:

Inundation Area It is unfeasible to quantify the number of individual Shasta salamanders that would be lost in the impoundment area. Direct loss of individuals and of limestone habitat from inundation cannot be mitigated. Mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of Shasta salamander habitat.

Potential mitigation lands containing comparable Shasta salamander habitat have been identified adjacent to the project. Shasta salamander has been found in both limestone and nonlimestone habitat in this site. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS.

Vegetation Removal and Construction Activities

- Protocol-level surveys will be conducted in all relocation areas to determine presence or absence of the Shasta salamander. If absent, no further mitigation is required.

- When feasible, use of heavy equipment and excavation in limestone substrates will be avoided.

- To minimize impacts on individuals, preconstruction surveys, in consultation with DFG and USFS, will be conducted by a qualified biologist prior to construction activities during the wet season. Individuals will be relocated to suitable limestone habitat in the vicinity of detection.

- In occupied relocation areas, mitigation measures developed for loss of suitable limestone and nonlimestone habitat in the impoundment area will be applied.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot

be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-2 (CP1): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog To avoid or minimize impacts on the foothill yellow-legged frog and tailed frog, the following measures will be implemented:

Inundation Area Individual foothill yellow-legged frog and tailed frogs will not be affected by the inundation caused by the raise of the dam. Animals will be able to swim upstream to suitable habitat.

It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of foothill yellow-legged frog and tailed frog habitat lost to inundation. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined.

Potential mitigation lands containing comparable foothill yellow-legged frog and tailed frog habitat have been identified adjacent to the project. The foothill yellow-legged frog is found in this area. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS.

Vegetation Removal and Construction Activities

- To the extent feasible, projects planned in relocation areas will be designed to avoid construction in perennial streams and their associated riparian zones.

- When instream construction activities must occur, a preconstruction survey of the foothill yellow-legged frog and tailed frog adults, larvae, and eggs will be conducted by a qualified biologist before ground-disturbing activities begin in perennial stream and riparian habitat. This survey will be conducted within the construction boundary no more than 1 week before instream or adjacent riparian construction activities begin. If foothill yellow-legged frog or tailed frog adults, larvae, or eggs are detected, the biologist in coordination with DFG and USFS will relocate them to a suitable stream habitat outside the construction boundary. If frogs are absent, no further surveys will be required.

- If adults are found to actively use the stream where construction activities are intended to take place, a qualified biologist will relocate all individuals to suitable habitat outside the construction zone daily before instream activities resume.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring

and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-3 (CP1): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle To avoid or minimize impacts on the northwestern pond turtle, the following measures will be implemented:

Inundation Area Individual northwestern pond turtles will not be impacted by the inundation caused by the raise of the dam. Lacustrine is suitable habitat for the northwestern pond turtle. The loss of northwestern pond turtle nests in the inundation zone if inundated while eggs are in the nest is unavoidable.

It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of northwestern pond turtle habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined.

Potential mitigation lands containing comparable northwestern pond turtle habitat have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS.

Vegetation Removal and Construction Activities

- To the extent feasible, projects planned in relocation areas will be designed to avoid all suitable aquatic habitat and its associated riparian zone.

- When construction activities are to occur within suitable northwestern pond turtle habitat as defined in Impact Wild-3 (CP1), a qualified biologist will conduct a minimum of one preconstruction survey for northwestern pond turtles and their nests. The survey will be conducted no more than 1 week prior to construction. If a pond turtle nest is found, the biologist will flag the site and determine whether construction activities can avoid impacting the nest. If the nest cannot be avoided, DFG and the USFS will be contacted for further direction and construction activities in that location will be halted.

- In the event that a pond turtle is observed within the construction limits, the contractor will temporarily halt construction activities until a qualified biologist has moved the turtle to a safe location within suitable habitat outside of the construction limits.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot

be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-4 (CP1): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers To avoid or minimize impacts on nesting American peregrine falcons, the following measures will be implemented:

Inundation Area Individual American peregrine falcons will not be impacted by the inundation caused by the raise of the dam.

Vegetation Removal and Construction Activities

- To the extent feasible, projects planned in relocation areas will be designed to avoid suitable cliff habitat.

- If vegetation removal or construction occurs outside of the breeding season (February 1 through July 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- For proposed construction activities between February 1 and July 31 within 0.5 mile of a known American peregrine falcon eyrie or suitable habitat identified in Impact Wild-4 (CP1), a qualified biologist will conduct a protocol-level survey. The survey will be conducted no more than 2 weeks before construction begins. If an active nest is found, a qualified biologist, in consultation with DFG, will determine the construction-free buffer zone to be established around the nest until the young have fledged. In consultation with DFG, a plan will be developed to monitor whether construction activity is disturbing the nesting process and to determine when the young have fledged.

Implementation of this mitigation measure will reduce impacts on American peregrine falcon to a less than significant level.

Mitigation Measure Wild-5 (CP1): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers To avoid or minimize impacts on nesting bald eagles, the following measures will be implemented:

Inundation Area

- For each year of project activity, all active bald eagle nests will be located using the National Bald Eagle Management Guidelines (USFWS 2007b).

- During initial inundation of the impoundment area, active eagle nests occurring within the inundation area will be protected by the placement of floating buoys and signage prohibiting access to the

established buffer developed in consultation with DFG, USFS, and USFWS (see measures below).

- It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of bald eagle habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Potential mitigation lands containing comparable bald eagle habitat have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS.

Vegetation Removal and Construction Activities

- For each year of vegetation removal or construction activity, all active bald eagle nests will be located and mapped using the National Bald Eagle Management Guidelines (USFWS 2007b).

- If vegetation removal or construction occurs outside of the breeding season (January 1 through August 1), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If vegetation removal is to occur between January 1 and August 1, a 660-foot to 0.5-mile buffer will be established around active nests in consultation with DFG and USFS. No vegetation removal or construction activity will occur within the established buffer during the limited operating period.

The avoidance and relocation measures for vegetation removal and construction activities and the nest protection measures within the inundation area would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-6 (CP1): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Northern Spotted Owl and Establish Buffers To avoid or minimize impacts on nesting northern spotted owls, the following measures will be implemented:

Inundation Area

- All suitable habitat within 1.3 miles of the impoundment and relocation areas will be delineated by type using California Forest Practice Rules to determine suitable nesting and roosting habitat for the northern spotted owl.

- For each year of vegetation removal or construction activity, protocol-level surveys using current approved USFWS protocol will be conducted in all delineated suitable northern spotted owl habitat.

- If nests are found, during initial inundation of the impoundment area, active northern spotted owl nests located within the inundation area will be protected by the placement of floating buoys and signage prohibiting access to the established buffer developed in consultation with DFG and USFS (see measures below).

- It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of northern spotted owl habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Potential mitigation lands containing comparable northern spotted owl habitat have been identified adjacent to the project. Additional discussion of how these lands may be applied as mitigation will be presented in the FEIS.

Vegetation Removal and Construction Activities

- For each year of vegetation removal or construction activity, protocol-level surveys using current approved USFWS protocol will be conducted in all delineated suitable northern spotted owl habitat.

- If vegetation removal or construction occurs outside of the breeding season (February 1 through August 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If vegetation removal is to occur between February 1 and August 31, a 660-foot to 0.5-mile buffer will be established around active nests in consultation with DFG, USFS and USFWS. No vegetation removal or construction activity will occur within the established buffer during the limited operating period.

The avoidance and relocation measures for vegetation removal and construction activities and the nest protection measures within the inundation area would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-7 (CP1): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers To avoid or minimize impacts on nesting purple martins, the following measures will be implemented:

Inundation Area Individual purple martins actively nesting within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated.

Vegetation Removal and Construction Activities

- To the extent feasible, all snags in the Pit Arm will be retained. Vegetation will not be removed from the Pit Arm from Painter Creek north, with exception of Arbuckle Campground, which will recruit snags from trees that will die from inundation.

- If vegetation removal or construction occurs outside of the breeding season (April 1 through August 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to take place on the Pit Arm from April 1 through August 31, a qualified biologist will conduct a protocol-level survey to locate active nests. The survey will be conducted no more than 2 weeks before construction begins. If an active nest is found, a qualified biologist, in consultation with DFG, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with DFG, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

- A monitoring and adaptive management plan will be developed to explore and develop options to provide additional nesting habitat for the purple martin (e.g., artificial nesting structures, girdling trees to develop snags).

Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures would not protect purple martins actively nesting within the impoundment area when the lake reaches maximum inundation and might not fully mitigate the loss of snags used for nesting. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP1): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers To avoid or minimize impacts on nesting willow flycatchers, Vaux's swifts, yellow warblers, and yellow-breasted chats, the following measures will be implemented:

Inundation Area Individuals actively nesting within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated.

It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of willow flycatcher, Vaux's swift, yellow warbler, and yellow-breasted chat habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined.

Potential mitigation lands containing comparable willow flycatcher, Vaux's swift, yellow warbler, and yellow-breasted chat habitat have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS.

Vegetation Removal and Construction Activities

- To the extent feasible, projects planned in relocation areas will be designed to avoid riparian habitat.

- To the extent feasible, construction activities will be avoided within riparian habitat and snags suitable for Vaux's swift nesting.

- If vegetation removal or construction occurs outside of the breeding season (April 1 through August 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to occur within 250 feet of suitable habitat for willow flycatchers, Vaux's swifts, yellow warblers, and yellow-breasted chats between April 1 and August 31, a qualified biologist will conduct a preconstruction survey no more than 2 weeks before construction activities begin. If an active nest is found, a qualified biologist, in consultation with DFG, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with DFG, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

- If willow flycatchers are detected during the preconstruction survey, protocol-level surveys using a current approved USFWS protocol will be conducted to locate and monitor active nests.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities; however, these measures would not protect individuals actively nesting within the impoundment area when the lake reaches maximum inundation. Also, the

effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-9 (CP1): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, and Great Blue Heron and Establish Buffers To avoid or minimize impacts on nesting special-status raptors, the following measures will be implemented:

Inundation Area It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of habitat of these species. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS.

Vegetation Removal and Construction Activities

- To the extent feasible, construction activities will be avoided within riparian habitat.

- If vegetation removal or construction takes place outside of the breeding season (February 1 through August 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to take place within 0.25 mile of suitable habitat for the long-eared owl, northern goshawk, Cooper's hawk, and great blue heron between February 1 and August 31, a qualified biologist will conduct a preconstruction survey no more than 2 weeks before construction activities begin. Protocol-level surveys will be conducted in suitable goshawk habitat.

- If vegetation removal is to occur between February 1 and August 31, a construction-free buffer will be established around active nests in consultation with DFG and USFS. No vegetation removal or construction activity will occur within the established buffer during the limited operating period.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot

be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-10 (CP1): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Surveys for the Pacific Fisher and Establish Buffers To avoid or minimize impacts on Pacific fisher natal dens, the following measures will be implemented:

Inundation Area Pacific fisher natal dens within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated. However, female fishers often move young to alternate natal dens if threatened or disturbed.

It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of Pacific fisher habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined.

Potential mitigation lands containing comparable habitat and where Pacific fishers are known to occur have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS.

Vegetation Removal and Construction Activities

- If vegetation removal or construction occurs outside of the breeding season (February 1 through May 1), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to occur in suitable habitat for the Pacific fisher between February 1 and May 1, a qualified biologist will conduct a preconstruction survey for potential natal or maternity den trees no more than 2 weeks before construction activities begin. If an active den is found, a qualified biologist, in consultation with USFS, BLM (if on BLM land), and USFWS, will determine a construction-free buffer zone to be established around the den until the mother and young have dispersed. In consultation with USFWS, a plan will be developed to monitor whether construction activity is disturbing the reproductive success and to determine when the young have dispersed.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-11 (CP1): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for Special-Status Bats, American Marten, and Ringtails and Establish Buffers To avoid or minimize impacts on bats and ringtails, the following measures will be implemented:

Inundation Area Maternity colonies or natal dens within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated. However, female western red bats, American martens, and ringtails would be expected to move young to alternate locations if threatened or disturbed.

It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of habitat of these species. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined.

Potential mitigation lands containing comparable habitat where these species are known to be found have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation and at what ratios will be presented in the FEIS.

Vegetation Removal and Construction Activities

- A preconstruction survey conducted by a qualified bat biologist for roosting bats will be conducted prior to the inundation or removal of any bridges, buildings, known caves or trees 12 inches or larger in diameter at breast height. If no active roosts are found, then no further action will be warranted. If a maternity roost is present, in consultation with DFG, a qualified bat biologist will determine the extent of construction-free zones around active nurseries. If either a maternity roost or a hibernacula is present, either of the following measures will be implemented.

To the extent feasible, the project will be redesigned to avoid the loss of the maternity or hibernacula roost.

- If the project cannot be redesigned, removal of the occupied tree or structure should begin before maternity colonies form (i.e., prior to March 1) or after young are volant (flying) (i.e., after July 31). The established disturbance-free buffer will be observed during the maternity roost season (March 1 through July 31).

- If a nonbreeding bat hibernacula is found in a structure or tree scheduled for removal, the individuals will be safely evicted, under the direction of a qualified bat biologist (as determined by a memorandum of understanding with DFG), by opening the roosting area to allow air flow through the cavity. Removal of the tree or structure will follow

not before the following day (i.e., there should be at least 1 night between initial disturbance for air flow and the demolition). This action will allow bats to leave during dark hours, thus increasing their chance of finding new roosts with a minimum of potential predation during daylight. Trees with roosts that need to be removed should first be disturbed at dusk, just prior to removal that same evening, to allow bats to escape at night.

- For the American marten and ringtail, if vegetation removal or construction occurs outside of the breeding season (February 1 through May 1), no further mitigation is necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to occur in suitable habitat for the American marten and ringtail between February 1 and May 1, a qualified biologist will conduct a preconstruction survey for potential natal or maternity den trees no more than 2 weeks before construction activities begin. If an active den is found, a qualified biologist, in consultation with DFG and USFS, will determine a construction-free buffer zone to be established around the den until the mother and young have dispersed. In consultation with DFG and USFS, a plan will be developed to monitor whether construction activity is disturbing the reproductive success and to determine when the young have dispersed.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the loss of some individuals from inundation cannot be mitigated. Also, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-12 (CP1): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks To avoid or minimize impacts on special-status terrestrial mollusks, the following measures will be implemented:

Inundated Area It is infeasible to quantify the loss of individuals in the impoundment area. The loss of individuals and loss of limestone habitat (for Shasta and Wintu sideband snails) cannot be mitigated. Suitable limestone habitat will be quantified. It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of the habitat of these species. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined.

Potential mitigation lands containing comparable special-status habitat have been identified adjacent to the project. Shasta sideband, Shasta chaparral, and Shasta hesperian snails have been found at this site. Additional discussion of how these lands could be applied as mitigation and at what ratios will be presented in the FEIS.

Vegetation Removal and Construction Activities

- When feasible, use of heavy equipment and excavation in limestone substrates and riparian or mesic habitats will be avoided.

- Guidelines provided in *Management Recommendations for Survey and Manage Terrestrial Mollusks* (Burke et al. 1999) will be applied.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the loss of some individuals from inundation cannot be mitigated. Also, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-13 (CP1): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of wildlife habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Potential mitigation lands containing comparable habitat and where these species are known to occur have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation will be presented in the FEIS. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-14 (CP1): Conduct Preconstruction Surveys for Other Nesting Raptors and Migratory Birds and Establish Buffers To avoid or minimize impacts on nesting raptors and migratory birds, the following measures will be implemented:

Inundation Area Individuals actively nesting within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated. However, tree-nesting species might fledge prior to loss of the nest, because it is anticipated that the structure will remain through the duration of the breeding season.

It is anticipated that mitigation lands will be acquired and placed in conservation easements to mitigate for the loss of the habitat of these species.

Additionally, opportunities for restoration and enhancement of habitat will be explored and defined.

Potential mitigation lands containing comparable habitat have been identified adjacent to the project. Additional discussion of how these lands could be applied as mitigation and at what ratios will be presented in the FEIS.

Vegetation Removal and Construction Activities

- To the extent feasible, construction activities will be avoided within riparian habitat.

- If vegetation removal or construction occurs outside of the breeding season (February 1 through August 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- For raptors, if proposed vegetation removal and construction activities are to occur within 0.25 mile of suitable habitat for nesting raptors between February 1 and August 31, a qualified biologist will conduct a preconstruction survey no more than 2 weeks before construction activities begin. If an active nest is found, a qualified biologist, in consultation with DFG, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with DFG, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the loss of some individuals from inundation cannot be mitigated. Also, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. This impact, therefore, is considered significant and unavoidable.

Mitigation Measure Wild-15 (CP1): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range Implement Mitigation Measure Wild-13 for loss of critical deer wintering and fawning range. Similar to Mitigation Measure Wild-13 (CP1), this impact is considered significant and unavoidable.

Mitigation Measure Wild-16 (CP1) Mitigation has yet to be determined for potential impacts to the California red-legged frog. At this time, no feasible mitigation has been determined. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area Reclamation will implement Mitigation Measure Bot-7 (CP1), "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities," described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-17 (CP1) to a less than significant level.

Mitigation Measure Wild-20 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Reclamation will implement Mitigation Measure Bot-7 (CP1), "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities," described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-20 (CP1) to a less than significant level.

Mitigation Measure Wild-23 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes Reclamation will implement Mitigation Measure Bot-7 (CP1), "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities," described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-23 (CP1) to a less than significant level.

Mitigation Measure Wild-26 (CP1): Implement Mitigation Measure Bot-7 (CP1): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta Reclamation will implement Mitigation Measure Bot-7 (CP1), "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities," described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-26 (CP1) to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Wild-18 (CP2), Wild-19 (CP2), Wild-21 (CP2), Wild-22 (CP2), Wild-24 (CP2), Wild-25 (CP2), and Wild-27 (CP2). Mitigation is provided below for the remaining impacts of CP2 on wildlife species.

Mitigation Measure Wild-1 (CP2): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Implementation of this mitigation measure will reduce impacts on the Shasta salamander; however, because impacts cannot be fully mitigated, Impact Wild-1 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-2 (CP2): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog This mitigation measure is identical to Mitigation Measure Wild-2 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-2 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-3 (CP2): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-3 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-3 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-4 (CP2): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-4 (CP1). Implementation of this mitigation measure will reduce Impact Wild-4 (CP2) to a less than significant level.

Mitigation Measure Wild-5 (CP2): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-5 (CP1). Implementation of this mitigation measure will reduce impacts on individual bald eagles nesting during the implementation of the project; however, all nest trees in the inundation zone will be lost; therefore, Impact Wild-5 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-6 (CP2): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Northern Spotted Owl and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-6 (CP1). Implementation of this mitigation measure will reduce impacts on individual northern spotted owls nesting during the implementation of the

project; however, nest trees located within the inundation zone will be lost; therefore, Impact Wild-6 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-7 (CP2): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-7 (CP1). Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures might not fully mitigate the loss of snags used for nesting; therefore, Impact Wild-7 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP2): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-8 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-8 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-9 (CP2): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, and Great Blue Heron and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-9 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-9 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-10 (CP2): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Pacific Fisher and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-10 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-10 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-11 (CP2): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for Special-Status Bats, American Marten, and Ringtails and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-11 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-11 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-12 (CP2): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks This mitigation measure is identical to Mitigation Measure Wild-12 (CP1). Implementation of this mitigation measure will reduce impacts on special-status

terrestrial mollusks; however, because impacts cannot be fully mitigated, Impact Wild-12 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-13 (CP2): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-13 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-14 (CP2): Conduct Preconstruction Survey for Other Nesting Raptors and Migratory Birds and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-14 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-14 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-15 (CP2): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range This mitigation measure is identical to Mitigation Measure Wild-15 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-15 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-16 (CP2) Mitigation has yet to be determined for potential impacts to the California red-legged frog. At this time, no feasible mitigation has been determined. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area This mitigation measure is identical to Mitigation Measure Bot-7 (CP2). Implementation of this mitigation measure would reduce Impact Wild-17 (CP2) to a less than significant level.

Mitigation Measure Wild-20 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area This mitigation measure is identical to Mitigation Measure Bot-7 (CP2). Implementation of this mitigation measure would reduce Impact Wild-20 (CP2) to a less than significant level.

Mitigation Measure Wild-23 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes This mitigation measure is identical to Mitigation Measure Bot-7 (CP2)Implementation of this mitigation measure would reduce Impact Wild-23 (CP2) to a less than significant level.

Mitigation Measure Wild-26 (CP2): Implement Mitigation Measure Bot-7 (CP2): Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta This mitigation measure is identical to Mitigation Measure Bot-7 (CP2)Implementation of this mitigation measure would reduce Impact Wild-26 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impacts Wild-18 (CP3), Wild-19 (CP3), Wild-21 (CP3), Wild-22 (CP3), Wild-24 (CP3), Wild-25 (CP3), and Wild-27 (CP3). Mitigation is provided below for the remaining impacts of CP3 on wildlife species.

Mitigation Measure Wild-1 (CP3): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Implementation of this mitigation measure will reduce impacts on the Shasta salamander; however, because impacts cannot be fully mitigated, Impact Wild-1 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-2 (CP3): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog This mitigation measure is identical to Mitigation Measure Wild-2 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-2 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-3 (CP3): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-3 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-3 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-4 (CP3): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-4 (CP1). Implementation of

this mitigation measure will reduce Impact Wild-4 (CP3) to a less than significant level.

Mitigation Measure Wild-5 (CP3): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-5 (CP1). Implementation of this mitigation measure will reduce impacts on individual bald eagles nesting during the implementation of the project; however, all nest trees in the inundation zone will be lost; therefore, Impact Wild-5 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-6 (CP3): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Northern Spotted Owl and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-6 (CP1). Implementation of this mitigation measure will reduce impacts on individual northern spotted owls nesting during the implementation of the project; however, nest trees located within the inundation zone will be lost; therefore, Impact Wild-6 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-7 (CP3): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-7 (CP1). Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures might not fully mitigate the loss of snags used for nesting; therefore, Impact Wild-7 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP3): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-8 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-8 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-9 (CP3): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, and Great Blue Heron and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-9 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-9 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-10 (CP3): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Pacific Fisher and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-10 (CP1). Implementation of this mitigation measure will reduce impacts

to these species; however, because impacts cannot be fully mitigated, Impact Wild-10 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-11 (CP3): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for Special-Status Bats, American Marten, and Ringtails and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-11 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-11 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-12 (CP3): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks This mitigation measure is identical to Mitigation Measure Wild-12 (CP1). Implementation of this mitigation measure will reduce impacts on special-status terrestrial mollusks; however, because impacts cannot be fully mitigated, Impact Wild-12 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-13 (CP3): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-13 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-14 (CP3): Conduct Preconstruction Survey for Other Nesting Raptors and Migratory Birds and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-14 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-14 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-15 (CP3): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range This mitigation measure is identical to Mitigation Measure Wild-15 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-15 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-16 (CP3) Mitigation has yet to be determined for potential impacts to the California red-legged frog. At this time, no feasible mitigation has been determined. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP3): Implement Mitigation Measure Bot-7 (CP3) to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area This mitigation measure is identical to Mitigation Measure Bot-7 (CP3)Implementation of this mitigation measure would reduce Impact Wild-17 (CP3) to a less than significant level.

Mitigation Measure Wild-20 (CP3): Implement Mitigation Measure Bot-7 (CP3) to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Wild-20 (CP3) to a less than significant level.

Mitigation Measure Wild-23 (CP3): Implement Mitigation Measure Bot-7 (CP3) to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Wild-23 (CP3) to a less than significant level.

Mitigation Measure Wild-26 (CP3): Implement Mitigation Measure Bot-7 (CP3) to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Wild-26 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts Wild-18 (CP4), Wild-19 (CP4), Wild-22 (CP4), Wild-24 (CP4), Wild-25 (CP4), and Wild-27 (CP4). Mitigation is provided below for the remaining impacts of CP4 on wildlife species.

Mitigation Measure Wild-1 (CP4): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Implementation of this mitigation measure will reduce impacts on the Shasta salamander; however, because impacts cannot be fully mitigated, Impact Wild-1 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-2 (CP4): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog This mitigation measure is identical to Mitigation Measure Wild-2 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-2 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-3 (CP4): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-3 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-3 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-4 (CP4): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-4 (CP1). Implementation of this mitigation measure will reduce Impact Wild-4 (CP4) to a less than significant level.

Mitigation Measure Wild-5 (CP4): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-5 (CP1). Implementation of this mitigation measure will reduce impacts on individual bald eagles nesting during the implementation of the project; however, all nest trees in the inundation zone will be lost; therefore, Impact Wild-5 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-6 (CP4): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Northern Spotted Owl and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-6 (CP1). Implementation of this mitigation measure will reduce impacts on individual northern spotted owls nesting during the implementation of the project; however, nest trees located within the inundation zone will be lost; therefore, Impact Wild-6 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-7 (CP4): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-7 (CP1). Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures might not fully mitigate the loss of snags used for nesting; therefore, Impact Wild-7 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP4): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-8 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-8 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-9 (CP4): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, and Great Blue Heron and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-9 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-9 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-10 (CP4): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Pacific Fisher and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-10 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-10 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-11 (CP4): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for Special-Status Bats, American Marten, and Ringtails and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-11 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-11 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-12 (CP4): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks This mitigation measure is identical to Mitigation Measure Wild-12 (CP1). Implementation of this mitigation measure will reduce impacts on special-status terrestrial mollusks; however, because impacts cannot be fully mitigated, Impact Wild-12 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-13 (CP4): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-13 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-14 (CP4): Conduct Preconstruction Survey for Other Nesting Raptors and Migratory Birds and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-14 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-14 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-15 (CP4): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range This mitigation measure is identical to Mitigation Measure Wild-15 (CP1).

Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-15 (CP4) is considered significant and unavoidable.

Mitigation Measure Wild-16 (CP4) Mitigation has yet to be determined for potential impacts to the California red-legged frog. At this time, no feasible mitigation has been determined. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP4): Implement Mitigation Measure Bot-7 (CP1) to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Wild-17 (CP4) to a less than significant level.

Mitigation Measure Wild-20 (CP4): Implement Mitigation Measure Bot-7 (CP1) to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Wild-20 (CP4) to a less than significant level.

Mitigation Measure Wild-21 (CP4): Conduct Preconstruction Surveys for Elderberry Shrubs, Northwestern Pond Turtle, and Nesting Riparian Raptors and Other Nesting Birds. Avoid Removal or Degradation of Elderberry Shrubs and Avoid Vegetation Removal Near Active Nest Sites To avoid impacts on valley elderberry longhorn beetle, northwestern pond turtle, and nesting raptors, and other nesting birds, the following measures will be implemented:

Valley Elderberry Longhorn Beetle:

- A worker awareness training program for construction personnel will be conducted by a qualified biologist/restoration ecologist before augmentation activities begin. The program will inform all construction personnel about the life history and status of the beetle, the need to avoid damaging the elderberry plants, and the possible penalties for not complying with these requirements. Written documentation of the training will be submitted to USFWS within 30 days of the completion of training.

- Elderberry shrubs shall be protected through establishment of a fenced avoidance area. Fencing will be placed at least 20 feet from the dripline of the shrubs where they occur along the access trail. Signs will be posted along the avoidance area. The signs will state: “This area is the habitat of the valley elderberry longhorn beetle, a threatened species, and must not be disturbed. This species is protected by the Endangered Species Act of 1973, as amended. Violators are subject to

prosecution, fines, and imprisonment." Signs will be readable from a distance of 20 feet and will be maintained during construction activities.

- No insecticides, herbicides, fertilizers, or other chemicals that might harm the beetle or its host plant will be used within 100 feet of elderberry shrubs. Roadways and disturbed areas within 100 feet of elderberry shrubs will be watered at least twice a day and as needed to minimize dust emissions.

Northwestern Pond Turtle:

- When construction activities are to occur within suitable northwestern pond turtle habitat as defined in Impact Wild-3 (CP1), a qualified biologist will conduct a minimum of one preconstruction survey for northwestern pond turtles and their nests. The survey will be conducted no more than 1 week prior to construction. If a pond turtle nest is found, the biologist will flag the site and determine whether construction activities can avoid impacting the nest. If the nest cannot be avoided, DFG will be contacted for further direction and construction activities in that location will be halted.

- In the event that a pond turtle is observed within the construction limits, the contractor will temporarily halt construction activities until a qualified biologist has moved the turtle to a safe location within suitable habitat outside of the construction limits.

Birds:

- For each year of vegetation removal for gravel augmentation activity, all active bald eagle nests will be located and mapped using the National Bald Eagle Management Guidelines (USFWS 2007).

- In consultation with DFG and USFS, a 660-foot to 0.5-mile buffer will be established around active nests. Vegetation will be retained and no construction activities will occur within this buffer.

- If proposed vegetation removal would occur between April 1 and August 31, a qualified biologist will conduct a preconstruction survey for nesting special-status birds no more than 2 weeks before construction activities begin. If an active nest is found, a qualified biologist, in consultation with DFG, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with DFG, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

The avoidance measures for elderberry and the nest protection measures within the gravel augmentation sites would effectively mitigate impacts on riparian-associated special-status wildlife species to a less than significant level.

Mitigation Measure Wild-23 (CP4): Implement Mitigation Measure Bot-7 (CP1) to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Wild-23 (CP4) to a less than significant level.

Mitigation Measure Wild-26 (CP4): Implement Mitigation Measure Bot-7 (CP1) to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Wild-26 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Wild-18 (CP5), Wild-19 (CP5), Wild-24 (CP5), Wild-25 (CP5), and Wild-27 (CP5). Mitigation is provided below for the remaining impacts of CP5 on wildlife species.

Mitigation Measure Wild-1 (CP5): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Implementation of this mitigation measure will reduce impacts on the Shasta salamander; however, because impacts cannot be fully mitigated, Impact Wild-1 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-2 (CP5): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog This mitigation measure is identical to Mitigation Measure Wild-2 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-2 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-3 (CP5): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-3 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-3 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-4 (CP5): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-4 (CP1). Implementation of

this mitigation measure will reduce Impact Wild-4 (CP5) to a less than significant level.

Mitigation Measure Wild-5 (CP5): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-5 (CP1). Implementation of this mitigation measure will reduce impacts on individual bald eagles nesting during the implementation of the project; however, all nest trees in the inundation zone will be lost; therefore, Impact Wild-5 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-6 (CP5): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Northern Spotted Owl and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-6 (CP1). Implementation of this mitigation measure will reduce impacts on individual northern spotted owls nesting during the implementation of the project; however, nest trees located within the inundation zone will be lost; therefore, Impact Wild-6 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-7 (CP5): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-7 (CP1). Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures might not fully mitigate the loss of snags used for nesting; therefore, Impact Wild-7 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP5): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-8 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-8 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-9 (CP5): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, and Great Blue Heron and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-9 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-9 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-10 (CP5): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Pacific Fisher and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-10 (CP1). Implementation of this mitigation measure will reduce impacts

to these species; however, because impacts cannot be fully mitigated, Impact Wild-10 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-11 (CP5): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for Special-Status Bats, American Marten, and Ringtails and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-11 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-11 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-12 (CP5): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks This mitigation measure is identical to Mitigation Measure Wild-12 (CP1). Implementation of this mitigation measure will reduce impacts on special-status terrestrial mollusks; however, because impacts cannot be fully mitigated, Impact Wild-12 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-13 (CP5): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-13 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-14 (CP5): Conduct Preconstruction Survey for Other Nesting Raptors and Migratory Birds and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-14 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-14 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-15 (CP5): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range This mitigation measure is identical to Mitigation Measure Wild-15 (CP1). Implementation of this mitigation measure will reduce impacts to these species; however, because impacts cannot be fully mitigated, Impact Wild-15 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-16 (CP5) Mitigation has yet to be determined for potential impacts to the California red-legged frog. At this time, no feasible mitigation has been determined. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP5): Implement Mitigation Measure Bot-7 (CP3) to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area This mitigation measure is

identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Wild-17 (CP5) to a less than significant level.

Mitigation Measure Wild-20 (CP5): Implement Mitigation Measure Bot-7 (CP3) to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Wild-20 (CP5) to a less than significant level.

Mitigation Measure Wild-21 (CP5): Implement Mitigation Measure Wild-21 (CP4) to Reduce Impacts on Riparian-Associated Special-Status Wildlife Species During Implementation of the Gravel Augmentation Program This mitigation measure is identical to Mitigation Measure Wild-21 (CP4). Implementation of this mitigation measure would reduce Impact Wild-21 (CP5) to a less than significant level.

Mitigation Measure Wild-22 (CP5): Conduct Preconstruction Surveys for Elderberry Shrubs, Northwestern Pond Turtle, and Nesting Riparian Raptors and Other Nesting Birds. Avoid Removal or Degradation of Elderberry Shrubs and Avoid Vegetation Removal near Active Nest Sites To avoid impacts on valley elderberry longhorn beetle, northwestern pond turtle, nesting raptors, and other nesting birds, the following measures will be implemented as part of the Reading Island project:

Valley Elderberry Longhorn Beetle:

- Prior to implementing any construction activities associated with Reading Island restoration plans, including constructing recreational facilities, a survey shall be conducted to identify and map all elderberry shrubs.

- New roads, trails, and recreational facilities shall be constructed a minimum of 100 feet from elderberry shrubs.

- Removal and disturbance of elderberry shrubs shall be avoided, to the extent feasible, during construction activities to restore connectivity between the Sacramento River and Anderson Slough and during rehabilitation of the boat ramp.

- A worker awareness training program for construction personnel will be conducted by a qualified biologist / restoration ecologist before gravel augmentation activities begin. The program will inform all construction personnel about the life history and status of the beetle, the need to avoid damaging the elderberry plants, and the possible penalties for not complying with these requirements. Written documentation of the training will be submitted to USFWS within 30 days of the completion of training.

- Elderberry shrubs shall be protected through establishment of a fenced avoidance area. Fencing will be placed at least 20 feet from the dripline of the shrubs. Signs will be posted along the avoidance area. The signs will state: "This area is the habitat of the valley elderberry longhorn beetle, a threatened species, and must not be disturbed. This species is protected by the Endangered Species Act of 1973, as amended. Violators are subject to prosecution, fines, and imprisonment." Signs will be readable from a distance of 20 feet and will be maintained during construction activities.

- No insecticides, herbicides, fertilizers, or other chemicals that might harm the beetle or its host plant will be used within 100 feet of elderberry shrubs. Roadways and disturbed areas within 100 feet of elderberry shrubs will be watered at least twice a day and as needed to minimize dust emissions.

- If removal of elderberry shrubs during construction of the river connection is unavoidable, Reclamation shall consult with USFWS. No project construction shall proceed in areas potentially containing valley elderberry longhorn beetle until a BO has been issued by USFWS, and Reclamation has abided by all pertinent conditions in the BO relating to the proposed construction. Relocation of existing elderberry shrubs and planting of new elderberry seedlings shall be implemented on a no-net-loss basis. Compensatory mitigation for elderberry shrubs that would be removed from their current locations would be developed in consultation with USFWS during the Section 7 consultation process. Compensatory mitigation may include planting replacement elderberry seedlings or cuttings and associated native plants within BLM managed public lands on Reading Island or purchasing credits at an approved mitigation bank, or a combination thereof. Relocated and replacement shrubs and associated native plantings shall be placed in conservation areas providing a minimum of 1,800 square feet per transplanted shrub.

Northwestern Pond Turtle:

This mitigation measure is identical to Mitigation Measure Wild-21 (CP4) for northwestern pond turtles.

Birds:

- For each year of vegetation removal for Reading Island restoration and recreation construction, all active bald eagle nests will be located and mapped using the National Bald Eagle Management Guidelines (USFWS 2007b).

- In consultation with DFG and USFS, a 660-foot to 0.5-mile buffer will be established around active nests. Vegetation will be retained and no construction activities will occur within this buffer.

- If proposed vegetation removal would occur between April 1 and August 31, a qualified biologist will conduct a preconstruction survey for nesting special-status birds no more than 2 weeks before construction activities begin. If an active nest is found, a qualified biologist, in consultation with DFG, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with DFG, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

The avoidance measures for elderberry and the nest protection measures within the Reading Island construction sites would effectively mitigate impacts on riparian-associated special-status wildlife species to a less than significant level.

Mitigation Measure Wild-23 (CP5): Implement Mitigation Measure Bot-7 (CP3) to Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Wild-23 (CP5) to a less than significant level.

Mitigation Measure Wild-26 (CP5): Implement Mitigation Measure Bot-7 (CP3) to Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Wild-26 (CP5) to a less than significant level.

13.3.6 Cumulative Effects

A large number of past actions have occurred in the study area. These past actions have substantially degraded wildlife resources within the primary and extended study areas. This degradation is indicated by the number of species that have been listed as threatened or endangered under the CESA and ESA, or considered species of special concern by DFG.

Past actions have caused these effects by converting habitat to developed or agricultural land uses, altering biotic interactions or physical processes, and damaging or causing mortality from human activities (e.g., vegetation removal during road, levee, or utility maintenance).

Flood control and water supply projects have also altered physical processes within the study area's remaining natural vegetation. Levees have isolated large areas of floodplain from rivers and streams throughout the study area, reducing the frequency of inundation and sediment scour and deposition and altering the extent and quality of riparian habitats. By reducing the magnitude and frequency of winter and spring peak flows and increasing the volume of summer and fall flows, water storage projects have altered the riparian habitats

that were not isolated from rivers by levees. In particular, the operation of Shasta Dam (beginning in 1945) and the other major reservoirs of the CVP and SWP has strongly affected aquatic and riparian communities along the Sacramento River, other Central Valley rivers, and in the Delta (Fremier 2003; TNC et al. 2008).

The effects of climate change on operations at Shasta Lake could potentially affect wildlife both at the lake and downstream. As described in the Climate Change Projection Appendix, climate change could result in higher reservoir releases in the future because of an increase in winter and early-spring inflow into the lake from high-intensity storm events. The change in reservoir releases could be necessary to manage for flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in flooding frequency, downstream habitat for wildlife, and water temperatures which could affect habitat along the Sacramento River and in the Delta. Climate change is also expected to result in changes to conditions for agricultural land and forest land, which are both habitat types. See Chapter 10, "Agriculture and Important Farmland," for a detailed discussion of effects on these habitat types.

Shasta Lake and Vicinity

The construction of Shasta Dam and the subsequent flooding of the area now known as Shasta Lake affected botanical and wildlife resources endemic to the region. For example, based on population locations, Shasta snow-wreath populations may have connected at the confluence of the Pit River, Squaw Creek, McCloud River, and Sacramento River prior to inundation. The creation of Shasta Lake fragmented this species habitat and populations. As a result, these populations are more vulnerable to extirpation.

As described in Section 13.3, without mitigation, CP1 through CP5 could cause potentially significant effects on wildlife habitats and special-status wildlife species in the primary and extended study areas. These effects could be caused by project construction activities; increased elevations of the water surface of Shasta Lake; and alteration of the flow regime of the Sacramento River and associated geomorphic processes, and thus of riparian vegetation. Although causing similar effects, CP1 through CP5 differ in the magnitude of their effects. At Shasta Lake and its vicinity, these potential adverse effects would be similar for all alternatives, but differ with the height of the dam raise: the effects of CP2 would be greater than CP1, but less than CP3 through CP5 (which would be identical). Along the upper Sacramento River and in the extended study area, potential adverse effects would be the result of altered flow regimes and would differ with both the height of the dam raise and operation of the dam: the effects of CP2 would be greater than CP1 and CP4 (which would be identical), but less than CP3 and CP5 (which also would have identical effects).

At Shasta Lake and vicinity, CP1 through CP5 would cause the take and loss of habitat for numerous species including Shasta salamander, foothill yellow-

legged frog, tailed frog, Northwestern pond turtle, American peregrine falcon, bald eagle, northern spotted owl, purple martin, Vaux's swift, yellow warbler, yellow-breasted chat, long-eared owl, northern goshawk, Cooper's hawk, osprey, Pacific fisher, and other special-status species. The wildlife mitigation measures described in Section 13.3.5 would reduce impacts on wildlife resources, although the adverse effects of CP1 through CP5 caused by construction activities and inundation would not be eliminated. Because the overall effect of past actions on these species has been cumulatively significant, and the likely additional effects of reasonably foreseeable future actions on wildlife habitat at Shasta Lake and in its vicinity, the adverse effects under CP1 through CP5 would cause a cumulatively considerable incremental contribution to the significant cumulative impact on wildlife.

Upper Sacramento River and Extended Study Area

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability As described in Chapter 2, "Alternatives" without mitigation, CP1 could cause potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species in the primary and extended study areas. These effects could be caused by alteration of the flow regime of the Sacramento River and associated geomorphic processes in the primary study area or the extended study area, or both. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP1 would be cumulatively considerable. With implementation of Mitigation Measure Bot-7, "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP1 would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP1 could contribute to potentially significant affects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP1, CP1 would not make a considerable contribution to a potentially significant cumulative effect.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability The cumulative effects of CP2 would be similar to those of CP1, but greater in magnitude. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP2 would be cumulatively considerable. With implementation of Mitigation Measure Bot-7, "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered

Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP2 would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP2 could contribute to potentially significant affects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP2, CP2 would not make a considerable contribution to a potentially significant cumulative effect.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply The cumulative effects of CP3 would be similar to those of CP1, but greater in magnitude. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP3 would be cumulatively considerable. With implementation of Mitigation Measure Bot-7, "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP3 would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP3 could contribute to potentially significant affects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP3, CP3 would not make a considerable contribution to a potentially significant cumulative effect.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability The cumulative effects of CP4 would be similar to those of CP1, but greater in magnitude. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP4 would be cumulatively considerable. With implementation of Mitigation Measure Bot-7, "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP4 would no

longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP4 could contribute to potentially significant affects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP4, CP4 would not make a considerable contribution to a potentially significant cumulative effect.

CP5 – 18.5-Foot Dam Raise, Combination Plan The cumulative effects of CP5 would be similar to those of CP1, but greater in magnitude. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP5 would be cumulatively considerable. With implementation of Mitigation Measure Bot-7, "Develop and Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP5 would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP5 could contribute to potentially significant affects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP5, CP5 would not make a considerable contribution to a potentially significant cumulative effect.

Chapter 14
Cultural Resources

This chapter describes the affected environment and environmental consequences related to cultural resources for the dam and reservoir modifications proposed under the SLWRI. More detailed discussion of cultural resources is presented in *Cultural Resources Alternatives Assessment for the Shasta Lake Water Resources Investigation, Shasta and Tehama Counties, California* (Byrd et al. 2008) and *Native American Tribal Coordination, Shasta Lake Water Resources Investigation, California* (Nilsson et al. 2008), which were prepared for the project. These Technical Reports will not be publicly distributed because they contain confidential information on the locations of cultural resources.

14.1 Affected Environment

For the purposes of the cultural resources assessment, studies were limited to the Shasta Lake and vicinity (77,088 acres) and the upper Sacramento River (16,113 acres), for a total of 93,201 acres (see Byrd et al. (2008) for a complete discussion of the study area extent by alternative). Project impacts to cultural resources are not expected to extend beyond this primary study area. Shasta Lake and vicinity includes the existing reservoir, the maximum inundation area, and a 0.25-mile buffer. The 0.25-mile buffer encompasses the area around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.).The upper Sacramento River is defined by the 100-year floodplain from Keswick Dam, north of Redding, southward to the Red Bluff Diversion dam.

To evaluate the potential effects that the proposed undertaking may have on cultural resources within the 93,201-acre study area, archival and records searches were conducted. Information concerning potential Native American concerns within the study area was gathered from historic and ethnographic literature and from initial discussions with tribes and Native American individuals. The results of these efforts are summarized below, following a brief discussion of the regional context.

14.1.1 Regional Setting

This section provides a regional framework of the study area including sections on the prehistoric, ethnohistorical, and historical context of the study area. Because of the regional nature of cultural resources, the Shasta Lake vicinity and upper Sacramento River area are discussed together.

Prehistoric Context

The following presentation provides a temporally organized discussion of the archaeological record. There is a long history of archaeological investigations in the upper Sacramento Valley region, although the early investigations were sporadic rather than sustained research programs. Notably, a great deal of fieldwork has been carried out around Shasta Lake, largely on USFS lands. Radiocarbon dating and temporally diagnostic artifacts have been used to create a framework for understanding the age of cultural resources in the area as well as changes through time. This framework provides baseline information on how cultural resources can contribute to history and regional research issues.

The Terminal Pleistocene time segment (ca. 13,500-11,600 before present, calibrated using radiocarbon dating (cal BP)) is minimally represented and poorly understood in this region. What little evidence exists suggests that people passing through the area were wide-ranging, mobile hunters and gatherers who periodically exploited large game (Haynes 2002). Archaeological data from this time period, primarily represented by isolated fluted and/or bifacially thinned spear points and Pleistocene fauna remains, is limited to two cave sites in the study area.

The earliest evidence for occupation of the region largely falls between ca. 8000-5000 BP. Most assemblages dating to this interval are affiliated with the Borax Lake Pattern (Fredrickson 1974) and include wide-stemmed projectile points, handstones, milling slabs, ovoid flake tools, along with a variety of other utilitarian items. The diversified nature of these artifact assemblages indicates people occupying the area were likely foragers who moved their residential bases frequently to exploit seasonal changes in resource distribution (Hildebrandt and Hayes 1983, 1993; Kowta et al. 2000; Sundahl and Henn 1993).

Several new projectile point forms appeared in the archaeological record around 5000 BP, including Squaw Creek Contracting-stemmed, Pollard Diamond-shaped, and McKee series. These points have been assigned to the Squaw Creek Pattern (5700-3200 BP) by Sundahl (1992b). Despite the appearance of these new forms, similarities in the rest of the assemblage composition with the preceding Borax Lake Pattern suggest people occupying the area during this time period were also relatively mobile foragers (Basgall and Hildebrandt 1989, Kowta et al. 2000).

A major change in the regional settlement-subsistence pattern appears to have occurred between ca. 4,000 to 1,600 years ago. This period has been identified as the Whiskeytown Pattern (Sundahl 1992b), and is represented by a wide range of corner- and side-notched projectile points assigned to the Clikapudi series, as well as hand stones, milling slabs, notched pebble net weights, and mortars and pestles (see also the Deadman and Kingsley complexes in Tehama County; Greenway 1982, Johnson 1984). Analysis of data from archaeological sites dating to this time period, has led Basgall and Hildebrandt (1989) to propose a shift from the preceding generalized forager strategy to a "fission-fusion" model of subsistence-settlement where larger groups of people occupied residential camps during the fall and winter months, but then split into smaller foraging groups who moved between productive resource patches during the remainder of the year. The fall-winter residential sites are thought to have been concentrated along the northern Sacramento Valley foothills, where salmon and acorns could be readily obtained (Baker 1990, Bevill and Nilsson 1993, Sundahl 1999).

Two distinct patterns have been identified as corresponding with the most recent time period (from 1,600 years ago to contact) in the region. The first, referred to as the Augustine Pattern/Shasta Complex, is thought to reflect a more sedentary subsistence-settlement adaptation than what was practiced in the preceding time periods. Initially, from 1,250 to 750 years ago, square-stemmed Gunther Barbed projectile points (with lower frequencies of expanding-stem variants), winged drills, bipointed fish gorges, bone gaming pieces, incised bone pendants, and varied shell beads are characteristic. These materials have been associated with the arrival of the Wintu in Northern California, and are thought to reflect a sedentary adaptation made possible by a subsistence system dependent on the large-scale storage of salmon and acorns (Broughton 1988; George 1981; Sundahl 1982, 1992a; Wohlgemuth 1992).

During this same time frame, a contrasting record is found in upland areas surrounding the northern Sacramento Valley. It is represented by much smaller sites and rather simple assemblages consisting of small side- and corner-notched projectile points, a limited number of Gunther series forms, hopper mortars and pestles, hand stones, milling slabs, and notched pebble weights. On the east side of the valley, these findings are assigned to the Tehama Pattern (Clewett and Sundahl 1982, Sundahl 1992a), and are thought to reflect a more mobile pattern of settlement by populations speaking Hokan languages (e.g., Yana) pushed to the hinterlands by the late-arriving Wintu, who ultimately restricted access to the Sacramento River.

Ethnohistorical Context

Ethnohistorical investigations indicate that at the end of the prehistoric era and into the historic era, much of the study area was primarily occupied by the Wintu (LaPena 1978), but some of their territorial boundaries have been contested for many years. The most commonly accepted map of Wintu territory was produced by Du Bois (1935), and shows that the Wintu controlled the

Sacramento, McCloud, and Squaw Creek drainages, and all but the easternmost segment of the Pit River Arm. This arm crosses into a boundary area between Northern Yana (Johnson 1978, Sapir and Spier 1943) and Achomawi (Pit River) tribes (Olmsted and Stewart 1978). Wintu people also lived along the Sacramento River from Shasta Dam down to the confluence of the river with Cottonwood and Battle creeks. Nomlaki territory took over south of Cottonwood Creek/Battle Creek and extended down past what is now the Red Bluff Diversion Dam (Goldschmidt 1951, 1978).

There has been a great deal of ethnohistoric and ethnographic discussion of the Wintu owing largely to the records amassed by late nineteenth- and early twentieth-century observers. Therefore, the Wintu can be considered one of the best known Native American groups in California. Most of the villages were located on the McCloud and Pit rivers and the general area south of the Pit River to just south of Redding. One hundred and six (43 percent) of the named Wintu ethnographic villages fall within the current study area.

Historical Context

The area that would become Shasta and Tehama counties was not explored by Europeans during the Spanish period of California history. Initial exploration occurred in 1821 when a Mexican expedition explored the Sacramento River nearly as far north as the future site of Redding, encountering Native populations as they traversed the region. Subsequently, European trappers in Northern California spread European diseases that had disastrous effects on the Native Americans. Notably, a devastating epidemic spread through the Sacramento Valley during the 1830s that may have killed as much as 75 percent of the native population.

In 1848, mining (especially for copper) began along the Trinity River and other Sacramento River tributaries, bringing as many as 50,000 people to the area. American immigrants increasingly occupied territory, and new logging and mining operations destroyed hunting grounds and salmon fisheries that were part of the traditional home of Native Americans such the Wintu. Criminal violence and the policy of relocation to reservations nearly eliminated the Native American population in the upper Sacramento River Valley by 1870. Those who remained lived in the mountains, like the Wintu, who maintained a salmon fishery along the McCloud River.

The mining boom lead to the construction of smelters, mills, and towns (such as Keswick) that flourished in the late 1800s and early 1900s. Falling copper prices, growing environmental concerns over pollution from smelters, and the U.S. Government’s efforts at protection and conservation of public lands ended major operations by the 1920s.

Logging started in 1852 and included sugar pine, white pine, red fir, and cedar. Sawmills quickly sprang up, along with associated roads. Transporting logs and milled lumber became easier after the completion of the railroad through Red

Bluff and Redding, and the Blue Ridge Flume, completed in 1874. These transportation advances allowed lumber milling to be concentrated in the valley, and Red Bluff and other mill towns to thrive.

Agriculture dominated the valley land along the Sacramento River. Cattle farming was key initially, and remained an important product in the area through the mid-twentieth century, especially with the development of the dairy industry. Early settlers practiced dry farming, growing wheat and fruit, including peaches, pears, and plums. Farmers later diversified and transitioned from wheat to fruits, nuts, vineyards, and vegetable crops in the late 1800s through the 1920s. Ultimately, intensive irrigated agriculture dominated the area.

Throughout the historic era, transportation was an important focus of infrastructure development. Over time, foot travel and transportation by horse or stage coach on a number of historic trails gave way to river, railroad, and ultimately, automobile travel. Hopeful settlers and miners poured into the study area along the California-Oregon Trail between 1840 and 1860, passing thorough the upper Sacramento River and Pit River valleys. A segment of the Siskiyou Trail was used by the northern railroad in 1877 and Interstate 5 follows this route today. Many early roads in the study area operated in conjunction with ferries across the Sacramento River. Several important bridges are located in the study area, along with the remains of many others, including the Centennial Bridge in Red Bluff and the Dog Creek Bridge in Shasta County.

Towns such as Red Bluff, Redding, Keswick, and Kennett boomed, along with the region's developing transportation network. The construction of Shasta and Keswick dams promoted a new period of prosperity that carried through the expansion of the lumber industry and the rise of the recreation industry in the mid-twentieth century.

Efforts to preserve the Nation's forests began in the late 1800s. The Shasta Forest Reserve was created in 1905. The area also included many homesteads and Indian allotments granted to local Wintus in the 1880s. In preparation for inundation by Shasta Lake, the United States purchased land including these allotments, homesteads, and many other properties in the late 1930s. Around the same time, fish were recognized as an important natural resource in California, and the first of several salmon fish hatcheries were constructed in 1872 at the salmon spawning grounds near the confluence of the McCloud and Pit rivers.

Recreation, especially in the mountains, also played an important role in the region's history. In the early twentieth century, private fishing clubs, such as the Bollibokka Club, flourished. In the 1930s, USFS began to encourage the recreational use of the forests by the broader public, constructing campgrounds and picnic areas. Recreation in the national forests expanded with the formation

of Shasta Lake. New campgrounds were added, along with boat launches and access roads.

Hydroelectric power and water storage were also important facets of the region's history. Starting in 1922, Pacific Gas and Electric Company built dams and power plants in the Pit River area. In 1935, the Federal Government decided to proceed with building the Central Valley Project to store and deliver Sacramento River water as far south as Fresno County. Work was completed in the 1940s at Shasta Dam and Keswick Dam and Powerhouse, located downriver from Shasta Dam. Power generated at Shasta Dam and transmitted to the Central Valley Project pumps provided electricity to supply the lift pumps raising water into the main canal system. The system used the natural channels of the Delta to move water from Redding to Tracy, the head of the Delta-Mendota Canal.

14.1.2 Archaeological Resources and Historical Structures

This section discusses known archaeological resources and historic structures within the primary study area.

Shasta Lake and Vicinity

A total of 134 cultural resources studies has been previously conducted that intersect or are fully contained within the Shasta Lake area. Of these, 80 percent were surveys, the remainder being overview/research designs, excavations, or other compliance reports. More than half of the surveys are considered to have had systematic coverage; the rest were either reconnaissance efforts or the methods were unknown. Overall, only 8 percent of the study area has been surveyed; 5 percent in a systematic manner and 3 percent using reconnaissance methods.

The records search identified 261 cultural resources within the study area, including 190 prehistoric sites, 45 historic-era resources, and 26 resources with both prehistoric and historic-era components.

The 215 recorded prehistoric-era resources and components are widely distributed throughout the study area and include the following:

- Forty-two major residential sites
- Thirty-seven residential sites
- Fifty-five artifact scatters
- Seventy-seven scatters of flaked stone tools and manufacturing debris
- Two caves
- Two sites of unknown character

The 71 recorded historic-era resources and components include the following:

- Thirteen structures, including seven bridges, one dam, one railroad bridge and grade, one aerial-tramway, one rock wall/alignment complex, one building foundation, and one concentration of wooden A-frames
- Seven linear features consisting of one railroad, five road segments and one line of wooden poles
- Seven mining locales that include two quarries and five sites with various mining-related features and residential elements.
- Fifteen artifact scatters
- Two ranching complexes
- Fourteen residential sites
- Two town complexes – both are mining-related and one includes a cemetery
- Two orchards represented by wooden poles and fruit trees
- One cemetery represented by two grave stones
- Seven historic-era Native American cemeteries, all but one of which is also associated with a major prehistoric residential component. Each of these cemeteries was subject to government removal of burials and reburial in a government cemetery outside the Shasta Lake inundation area
- One historic-era Native American residential site that also has a prehistoric residential component

Another 19 historic-era cemeteries (containing both Native American and Euro-American burials) within the footprint of Shasta Lake have not been formally recorded. They were subject to burial removal and subsequent reburial outside the reservoir area. It is possible that a number of these cemeteries may retain additional human remains, and are potentially subject to periodic exposure when the reservoir level fluctuates.

The Dog Creek Bridge is currently listed on the National Register of Historic Places (NRHP). The NRHP is the Nation's official list of cultural resources worthy of preservation. Authorized under the National Historic Preservation Act of 1966, the NRHP is part of a national program to coordinate and support public and private efforts to identify, evaluate, and protect our historic and

archeological resources. Properties listed in the NRHP include districts, sites, buildings, structures, and objects that are significant in American history, architecture, archeology, engineering, and culture. All properties and districts listed in or determined eligible for listing in the NRHP must be considered in the planning of Federal undertakings. Shasta Dam and property has been determined eligible for the NRHP as part of the Central Valley Project through a consensus determination with the State Historic Preservation Officer (SHPO). Another 24 resources have been determined ineligible by consensus determination with SHPO. These include 15 historic-era resources, seven prehistoric sites, and two resources with both prehistoric and historic-era components.

Upper Sacramento River (Keswick Dam to Red Bluff)

Based on the records search results, 97 cultural resources studies intersect or are fully contained within this area. Of these, 86 percent are surveys, along with overviews, excavation reports, and historical architectural evaluation reports. Most of the surveys had systematic coverage methods (75 percent). In all, 23 percent of the area has been surveyed, mostly by systematic methods (15 percent), and the rest by reconnaissance methods.

A total of 79 recorded cultural resources fall within this area. These include 45 prehistoric sites, 20 historic-era resources, and 14 resources with both historic-era and prehistoric components.

The 59 prehistoric resources and components within the study area include the following:

- Thirteen major residential sites
- Twenty-two residential sites
- Seven rock shelters
- Five artifact scatters.
- Five flaked stone tool and manufacturing debris scatters
- Four rock art (petroglyph) sites
- Three sites of unknown character

The recorded prehistoric sites are concentrated in the southern portion of the study area, from Battle Creek near Table Mountain southward (71 percent), along with a small concentration of sites at the northern end of the upper Sacramento River area near Redding (18.6 percent). Eleven prehistoric sites have been subjected to some form of archaeological excavation.

The 34 recorded historic-era resources and components within the study area include the following:

- Ten structures
- Seven linear features consisting of five roads, one wagon train, and a powerline
- Five flume remnants (two of which were associated with orchards)
- Three mining locales, including a mining complex and two adits
- Five artifact scatters
- One ranching complex
- The historic-era structures include five bridges, a ferry crossing, a rock wall, a dam, one concrete dance pavilion, and a power substation building complex
- Three historic-era Native American residential sites

One archaeological site (referred to as the Benton Track Site or *Magmas*) is currently listed on the NRHP. In addition, the Diestelhorst Bridge in Redding and the Anderson-Cottonwood Irrigation District Diversion Dam have been determined eligible for the NRHP. Two sites are listed as ineligible for the NRHP by the California Office of Historic Preservation.

Native American Traditional Cultural Properties and Sacred Sites

A traditional cultural property is generally defined based on its association with cultural practices or beliefs of a living community rooted in a community's history, and are important in maintaining community cultural identity (Parker and King 1998). Executive Order No. 13007 defines a sacred site as "any specific, discrete, narrowly delineated location on Federal land that is identified by an Indian tribe, or Indian individual determined to be an appropriately authoritative representative of an Indian religion, as sacred by virtue of its established religious significance to, or ceremonial use by, an Indian religion; provided that the tribe or appropriately authoritative representative of an Indian religion has informed the agency of the existence of such a site."

The records search at the Information Center revealed that no traditional cultural properties have been formally recorded. The Native American Heritage Commission (NAHC) reviewed its sacred lands file and identified sacred land filings within the study area. Their locations are confidential.

There is a strong likelihood that additional traditional cultural properties are present within the study area based on ethnohistoric data and initial discussions with Native Americans. The study area was the focus of intensive Native American occupation during historic times, with a variety of religious, economic, historic, and other values identified by Native American groups. Ten

groups, including those listed by the Native American Heritage Commission, represent Native American interests in the study area. They include the following: Grindstone Indian Rancheria, Paskenta Band of Nomlaki Indians, Pit River Environmental Council, Pit River Tribe of California, Redding Rancheria, Shasta Nation, United Tribe of Northern California, Inc., Winnemem Wintu Tribe, Wintu Educational and Cultural Council, and the Wintu Tribe of Northern California. Notably, the Winnemem Wintu and the Pit River tribes live within the Shasta Lake area, where they continue to actively practice many aspects of their traditional culture. Both groups have related that a complex cultural landscape of village sites, ceremonial areas, sacred sites, burial sites, and resource areas intersects the study area.

Tribal consultation has clearly indicated that all local Native American groups are deeply concerned regarding the environmental and cultural effects of the project. Native Americans who supplied information for the SLWRI were, by and large, unwilling to provide comprehensive information on traditional cultural properties within the study area at this point in the investigation. They did, however, provide some general information on the number of potential traditional cultural properties (TCP) in the general region and these statements are well supported by ethnohistoric studies.

Members of the Pit River Madesi Band stated that 22 ethnographic villages and associated burial grounds are located within the existing reservoir and proposed reservoir areas. One tribal member also noted that several TCPs exist within the Pit 6 and Pit 7 Dam areas.

The Winnemem Wintu have identified important localities within the study area, many of which are locations where ceremonies are regularly conducted. Along the McCloud River, these include Children’s Rock, Coyote Rock, Dekkas Rock, doctoring pools near Nawtawaket Creek, Eagle Rock and Samwel Cave, Hirz Bay, *Kaibai* village, North Gray Rocks, Puberty Rock, Saddle Rock, and *Watawacket* village and spiritual area. Along the Sacramento River, important localities include the Antlers area, Delta area, Doney Creek, Gregory Creek, LaMoine area, Packers Bay, Pollard’s area, middle Salt Creek, and Sims area. The Winnemem Wintu have strong traditional and contemporary connections with the land, and their ongoing use of many archaeological and religious sites is fundamental to the well-being of their culture, particularly the education of their youth.

The Winnemem Wintu have also documented the location of some 155 ancestral villages within the Shasta Lake area. At least 81 village locations are known along the lower McCloud River and lower Pit River. An additional 73 villages are known to have existed on the eastern side of the Sacramento River. These village locations once contained between one and 30 houses each, some had associated cemeteries, and each had a power place. Some of these villages are already under the waters of Shasta Lake, while others are just above the

current Shasta Lake water level. The Winnemem Wintu have estimated that 120 of the known villages are still accessible (above the current high-water line).

14.2 Regulatory Framework

Under Federal and State law, effects to significant cultural resources—which include archaeological remains, historic-period structures, and traditional cultural properties—must be considered as part of the environmental analysis of a proposed project. Federal guidelines define TCPs as those that have "association with cultural practices or beliefs of a living community that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community" (Parker and King 1998). Examples of traditional cultural properties include: a location associated with the traditional beliefs of a Native American group about its origins, its cultural history, or the nature of the world; a location where Native American religious practitioners have historically gone, and are known or thought to go today, to perform ceremonial activities in accordance with traditional cultural rules of practice.

Criteria for defining significant cultural resources are stipulated in 36 Code of Federal Regulations (CFR) Part 60.4 (Determinations of Eligibility for Inclusion in the National Register of Historic Places); the National Historic Preservation Act (NHPA) of 1966, as amended (NHPA; 16 U.S. Code (USC) 470 et seq.); and the California Environmental Quality Act (CEQA, revised 2005). Both NHPA and CEQA are applicable to Federal projects in California. In addition, 36 CFR 800 outlines the compliance process for Section 106 of the NHPA. Eligible properties are those which "(a)...are associated with events that have made a significant contribution to the broad patterns of our history; or (b) that are associated with the lives of persons significant in our past; or (c) that embody the distinctive characteristics of a type, period, or method of construction, or that represent a significant and distinguishable entity whose components may lack individual distinction; or (d) that have yielded, or may be likely to yield, information important in prehistory or history" (36 CFR 60.4).

14.2.1 Federal

Under Section 106 of the NHPA, Federal agencies must consider effects to eligible resources ("historic properties") from the proposed undertaking, in consultation with SHPO and other parties. This includes identification (usually through archival research, field inventories, public interpretation, and/or test evaluations) of cultural resources eligible for the NRHP, assessment of adverse effects to eligible properties, and resolution of adverse effects. The revised regulations emphasize consultation with appropriate Native American communities (in the case of prehistoric, ethnographic, or traditional cultural properties), and the preparation of Memoranda of Agreement (MOA) among involved agencies and parties.

Native American burials are also protected by Federal law. The Native American Graves Protection and Repatriation Act (Public Law 101-601; 25 USC 3001-3013) protects Native American burial sites and controls the removal of human remains, funerary objects, sacred objects, and items of cultural patrimony on Federal and tribal lands.

The American Indian Religious Freedom Act (42 USC Section 1996) states that it is the policy of the United States to "protect and preserve for American Indians their inherent right of freedom to exercise the traditional religions of the American Indian, Eskimo, Aleut, and Native Hawaiians, including but not limited to access to sites, use and possession of sacred objects, and the freedom to worship through ceremonials and traditional rites." The provisions of American Indian Religious Freedom Act guarantee access to traditional sites on Federal lands and noninterference with religious practices. Consultation under American Indian Religious Freedom Act with American Indian groups can simultaneously satisfy the requirements of NEPA as well.

Indian Sacred Sites as also addressed in Executive Order 13007 (24 May 1996) and establishes that Federal agencies are responsible for allowing American Indian religious practitioners access to and ceremonial usage of sacred American Indian sites on Federal land. The agency will keep the locations of such sites confidential and will avoid adversely affecting the integrity of these sites.

14.2.2 State

Under CEQA, the lead non-Federal agency (state, county, city, or other) must consider potential effects to important or unique cultural resources. While the language and consultation process is somewhat different between the NHPA and CEQA, the definitions of eligible properties and of adverse impacts are essentially the same. Evaluations under CEQA consider a resource's potential eligibility to the California Register of Historical Resources.

California law also protects Native American burials, skeletal remains, and associated grave goods regardless of their antiquity, and provides for the sensitive treatment and disposition of those remains (California Health and Safety Code Section 7050.5, California Public Resources Code Sections 5097.94 et seq.).

14.2.3 Regulatory Compliance

Currently, there is no undertaking authorized by Congress involving the raising of Shasta Dam. Reclamation has initiated the Section 106 process to notify the SHPO and Native American groups of the study and to begin the consultation process to obtain information regarding Native American cultural resources in the study area. If a project involving raising of the dam is authorized by Congress, the Section 106 process would continue with additional efforts to refine an area of potential effect (APE) and further identify historic properties. Initially, a complete inventory of cultural resources would be conducted within

the APE of the selected alternative. The APE would include, at a minimum, the new inundation area, construction areas (including dam construction and ecosystem enhancements), staging areas, and facility and utility relocations. Additional investigations would likely include the following:

- Archaeological survey of previously unsurveyed areas to inventory surface sites, including areas sensitive for buried resources
- Historic archival investigations to place historic-era sites in a local context
- Ethnographic and ethnohistoric investigations to obtain greater detail regarding areas of importance to Native American tribes and groups
- Evaluations to determine whether cultural resources identified within the APE are eligible for inclusion in the NRHP, assess potential adverse effects to historic properties, and consult in an effort to resolve any identified adverse effects

Cultural resources are evaluated for inclusion in the NRHP based on criteria found at 36 CFR Part 60. Typically, the cultural resources consultant provides eligibility recommendations, and Reclamation makes determinations of eligibility in consultation with SHPO, the public (if they are consulting parties) and tribes (for sites of religious or cultural significance). In this process, previous determinations of eligibility may need to be reevaluated because of the passage of time or other factors, and it is important to acknowledge the special expertise of Indian tribes when assessing the eligibility of properties to which they attach ceremonial and cultural significance. It would be possible to evaluate some cultural resources with survey-level data. However, test excavations would be required to accurately evaluate many archaeological resources to determine if they are, in fact, historic properties.

Reclamation is required to consider the effects of any potential project on historic properties within the APE. The criteria for assessing adverse effects are found in 36 CFR Part 800.5(a)(1), which states that “an adverse effect is found when an undertaking may alter, directly or indirectly, any characteristic of a historic property that qualify the property for inclusion in the National Register…” Examples of adverse effects include physical destruction, alteration, a change in the property’s setting, or the introduction of visual, atmospheric, or audible elements that diminish the integrity of the property’s significant historic features (36 CFR Part 800.5(a)(2)).

As part of the Section 106 process, Reclamation is responsible for making a finding regarding whether the undertaking would have an adverse effect on historic properties. This assessment of adverse effects is made in consultation with SHPO and Indian tribes that attach religious and cultural significance to

identified historic properties. Reclamation would then seek concurrence from SHPO on the determination of effect.

Consultation then continues among Reclamation, SHPO, and other consulting parties on possible options for avoiding, minimizing, or mitigating the adverse effects. This includes notifying the Council when adverse effects are found and inviting the Council to participate. Archaeological data recovery excavation is the most frequent way to resolve or mitigate adverse effects on historic properties determined eligible under Criterion D. Properties determined eligible under Criteria A through C typically require more varied actions to resolve adverse effects. If SHPO, Reclamation, and the Council (if participating) agree to measures to resolve adverse effects to historic properties, these are formalized in an MOA. Other consulting parties may be invited to sign the MOA. The Section 106 process is completed once the terms of the MOA have been met. In rare cases, if consultation fails to result in agreement on resolving adverse effects, consultation may be terminated pursuant to the process detailed in 36 CFR Part 800.7

14.3 Environmental Consequences and Mitigation Measures

This chapter is organized by the project alternatives described in Chapter 2, "Alternatives," and discusses environmental consequences associated with implementation of the project alternatives. It also describes potential mitigation measures associated with impacts to cultural resources that are significant or potentially significant.

The environmental setting for this chapter includes only the primary study area, Shasta Lake and vicinity, and the upper Sacramento River between Keswick and the Red Bluff Diversion Dam, as explained in Section 14.1. No potential impacts are expected in the extended study area; therefore, cultural resources investigations were conducted only in the primary study area. The extended study area is not discussed further in this section.

14.3.1 Impact Assessment Methods and Assumptions

The standard Section 106 process of the NHPA follows a series of steps that are described in the 36 CFR Part 800 regulations that implement the NHPA. These steps are as follows:

- Initiate Section 106 Process, 36 CFR Part 800.3
- Identify Historic Properties, 36 CFR Part 800.4
- Assess Adverse Effects, 36 CFR Part 800.5
- Resolve Adverse Effects, 36 CFR Part 800.

In the event that historic properties within the APE for an undertaking would be subject to adverse effects, the Section 106 process is most often completed with

the signing of an agreement document specifying measures that will be taken to avoid, minimize, or mitigate those effects.

The SLWRI is a feasibility-level study, and there is no authorization for raising Shasta Dam at this time. Reclamation will not have a specific undertaking until such time as Congress makes a decision regarding whether to authorize a project that would involve raising the dam and appropriates funding for this purpose. Therefore, this feasibility study has gathered existing data and information that can be used in environmental documents to estimate the impact of the proposed action on historic properties or sites of cultural significance. The Section 106 regulations allow Federal agencies to conduct "nondestructive project planning activities before completing compliance with Section 106" (36 CFR Part 800.1[c]), and the regulations encourage Federal agencies to consider a broad range of alternatives during the planning process for the undertaking. Given the schedule for the feasibility study and the Environmental Impact Statement, and the sizes of the alternatives, cultural resource surveys for the purpose of Section 106 compliance will not be completed until such time as an alternative is selected and funding is authorized by Congress. In the interim, the assessment of effects to cultural resources presented in this document is based on existing knowledge of site locations and an analysis of the sensitivity of the study area to contain additional sites.

As part of compliance with 36 CFR Part 800 regulations, Reclamation conducted a records search for the APE to assess which portions of the APE have been previously inventoried, and to identify all previously recorded cultural resources. Methods used for the cultural resources analysis included archival records searches (that identified previously records sites, site records and Native American ethnographic studies), agency consultation, Native American consultations, and comparisons of the study alternatives. Information on archaeological and historical structures was obtained for sites within the primary study area that may be affected by alternative plans. Sensitivity analyses were also conducted for prehistoric and historic-era resources to address data gaps using methods tailored to each data set. Native American issues and resource locations within the primary study area were discussed during meetings with Native American groups and individuals.

Archaeological and Historic-Era Structural Resources

Overall, the frequency and distribution of formally recorded cultural resources within the study area gives only a limited and incomplete picture of the actual number of resources. This is mainly due to limited systematic surveys: 5 percent of the Shasta study area and 15 percent of the upper Sacramento River. As such, many cultural resources have not been identified or formally recorded.

A comparative sensitivity analysis was therefore conducted that took into account both documented and undocumented cultural resources (including archaeological sites and historic-era structures) for each of the alternatives proposed for raising Shasta Dam. The sensitivity analysis was restricted to the

Shasta Lake and vicinity, and did not include the upper Sacramento River since no impact differences between alternatives have been identified within this area.

Separate sensitivity analyses using methods tailored to each data set were conducted for prehistoric and historic-era sites to estimate the total number of cultural resources present within each alternative (see Byrd et al. (2008) for methodological details and specific data). The prehistoric sensitivity analysis used a weights-of-evidence quantitative analysis to predict the overall density and distribution of sites. In contrast, the historic-era sensitivity study gathered archival data (mainly maps) within the study area to make predictions regarding the number and type of potential unrecorded historic-era resources (both structures and sites) by alternative. Results of the prehistoric and historic-era sensitivity analyses were integrated to provide quantitative estimates of the total number of cultural resources after full inventory.

A second records search was completed to identify recorded cultural resources in specific areas of the upper Sacramento River where construction activities would take place in certain alternatives associated with ecosystem restoration, including spawning gravel augmentation and floodplain and riparian habitat restoration. For these construction areas, existing access roads were excluded, but a records search buffer of 0.125-mile was added to all other project elements. It should be noted that the proposed construction areas are concept-level, and may be relocated or deleted as a result of design development, consultation, or other factors.

Traditional Cultural Properties and Sacred Sites

Public and stakeholder coordination meetings were conducted on behalf of Reclamation with Native American tribal groups whose traditional territories overlap the study area. This included meetings and/or workshops with groups and individuals representing major tribes and/or extended family groups in the Shasta/Redding area regarding potential effects to cultural resources from a plan to enlarge Shasta Dam and Reservoir. The primary intent of these meetings was to strengthen communication with tribal groups and individuals; solicit, clarify, and document major concerns and issues; and establish a preferred method/ approach to maintaining effective communication during the remainder of the SLWRI and in future endeavors.

Federally recognized Native American tribes were invited to begin the consultation process at an information meeting, followed by additional contact by telephone to learn of their concerns regarding the SLWRI, and to gain an initial sense of where sensitive resource localities are situated within the primary study area. Non-Federally recognized Native American groups and individuals with an interest in the study area were also contacted. There were also in-person visits to tribal members to collect information.

Seven tribal groups were invited to an information meeting held on April 4, 2007, in Redding, California. The purpose of the meeting was to provide

general information about the SLWRI, initiate Section 106 consultation with groups desiring to participate in the project, and introduce Elena Nilsson, a consultant for Reclamation, as the Native American Tribal Coordination study lead. Invitations were sent to the following: Grindstone Rancheria, Paskenta Rancheria, Pit River Tribe, Redding Rancheria, Shasta Nation, Winnemem Wintu, and Wintu Tribe and Toyon-Wintu Center. The meeting was attended by representatives from the Winnemem Wintu and the Madesi Band of the Pit River Tribe.

From August 2007 to March 2008, nine meetings were held with Native American groups whose traditional territories overlap with the SLWRI study area. The purpose of the meetings was to solicit, clarify, and document major concerns and issues regarding the project, and to establish a preferred method/approach to maintaining effective communication during the remainder of the SLWRI study and in future endeavors. Five groups participated in these meetings, including the Grindstone Indian Rancheria (one meeting), Paskenta Band of Nomlaki Indians (one meeting), Pit River Tribe (three meetings), Shasta Nation (one meeting), and Winnemem Wintu (three meetings).

Currently, no traditional cultural properties are formally recorded at the Information Center. The Native American Heritage Commission, however, has stated that sacred sites are present in the study area. No additional investigations have been undertaken to identify and formally document traditional cultural properties in large part because Native American groups are unwilling to provide sufficiently detailed information at this stage in the study. Based on initial statements provided by Native Americans and previous ethnographic and ethnohistoric studies, it is predicted that a considerable number of traditional cultural properties are present in the study area.

14.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State and CEQA Guidelines, Section 15126.4(a).

Federal Criteria

Under Federal regulation (36 CFR Section 800(a)(1)):

> *"An adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Consideration shall be given to all qualifying characteristics of a historic property, including those that may have been identified subsequent to the original evaluation of the property's eligibility for the National Register. Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative."*

Examples of adverse effects (36 CFR Section 800(a)(2)) include the following:

- Physical destruction, damage, or alteration, including moving the property from its historic location
- Isolation from, or alteration of, the setting
- Introduction of intrusive elements
- Neglect leading to deterioration or destruction
- Transfer, sale, or lease from Federal ownership

State Criteria

California regulations require that effects to cultural resources must be considered only for resources meeting the criteria for eligibility to the California Register of Historical Resources, outlined in Section 5024.1 of the California Public Resources Code. Demolition, replacement, substantial alteration, or relocation of an eligible resource are all actions that could change those elements of the resource which make it eligible. The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Under the State CEQA Guidelines, impacts on cultural resources may be considered significant if a project alternative would result in any of the following:

- Cause a substantial adverse change in the significance of a historical resource, as defined in Guidelines Section 15064.5
- Cause a substantial adverse change in the significance of an archaeological resource pursuant to Guidelines Section 15064.5

- Disturb human remains, including those interred outside formal cemeteries

According to the above criteria, the project would be considered to have a significant impact on cultural resources if it would result in any of the following:

- Substantial adverse change in the significance of an historical resource
- Substantial adverse change in the significance of a unique archaeological resource
- Disturbance or destruction of unique paleontological resource or site or unique geologic feature
- Disturbance of any human remains, including those interred outside of formal cemeteries
- Elimination of important examples of the major periods of California history or prehistory

Statements of impact significance are relative to both existing conditions (Year 2005) and future conditions (Year 2030), unless stated otherwise. Only those elements of a resource which contribute to its eligibility need to be considered; effects to noncontributing elements are less than significant.

14.3.3 Direct and Indirect Effects

This section describes the environmental consequences of the SLWRI alternatives, and proposed mitigation measures for any impacts determined to be significant or potentially significant.

No-Action Alternative

Dam construction, infrastructure and facilities relocation, additional reservoir area inundation, and construction activities adjacent to the upper Sacramento River would not occur under the No-Action Alternative. Therefore, no additional traditional cultural properties or areas of concern above the current reservoir level would be impacted, and conditions would be the same as existing.

Shasta Lake and Vicinity

Impact Culture-1 (No-Action): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Archaeological sites (as well as historic cemetery locations) within the existing Shasta Lake fluctuation zone will continue to be impacted by fluctuations in the height of the reservoir during ongoing operations with the No-Action Alternative. As stated above, dam construction, infrastructure and facilities relocation, and additional reservoir area inundation would not occur under the No-Action Alternative;

therefore, no impacts on cultural resources related to construction or inundation are expected. Mitigation is not required for the No-Action Alternative.

Impact Culture-2 (No-Action): Inundation of Traditional Cultural Properties and Sacred Sites Traditional cultural properties and sacred sites within the existing Shasta Lake fluctuation zone will continue to be impacted by fluctuations in the height of the reservoir during ongoing operations with the No-Action Alternative. As stated above, additional reservoir area inundation would not occur under the No-Action Alternative; therefore, no impacts on cultural resources related to inundation are expected. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Culture-3 (No-Action): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction Archaeological sites (as well as historic cemetery locations) in or near the upper Sacramento River will continue to be impacted by water operations with the No-Action Alternative. As stated above, construction activities adjacent to the upper Sacramento River would not occur under the No-Action Alternative; therefore, no impacts on cultural resources related to construction are expected. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Cultural resources potentially impacted by this alternative include those within: (1) the proposed additional 1,229-acre inundation area; (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area; and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.). It should be noted that sites typically extend into the inundation and reservoir area for more than one alternative.

Shasta Lake and Vicinity

Impact Culture-1 (CP1): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant. Sensitivity studies estimate that, with complete surveys, impacts associated with CP1 inundation and areas would include approximately 212±54 prehistoric resources (Table 14-1). The historic-era archival study documented 355 localities that may potentially contain historic-era remains within this inundation area.

Sensitivity studies estimate that, with complete surveys, the CP1 fluctuation zone would include approximately 675±172 prehistoric resources. The historic-era archival study documented 529 localities that may potentially contain historic-era remains.

Table 14-1. Cultural Resources Impacts for CP1

Inundation Area	
Prehistoric sites	212±54
Historic-era archival localities	355
Fluctuation Zone	
Prehistoric sites	675±172
Historic-era archival localities	529
0.25-Mile Buffer	
All cultural resources	Fewer than CP2

Note:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec 106.

Sensitivity studies estimate that with complete surveys, the ¼-mile buffer area for CP1 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may potentially contain historic-era remains. Although the full extent and locations of project impacts within the buffer zone related to construction are not yet available for CP1, impacts would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible for listing under NHPA, and how many of the eligible resources will sustain adverse impacts from this alternative, this impact would be significant. Mitigation for this impact is proposed in Section 14.3.1.

Impact Culture-2 (CP1): Inundation of Traditional Cultural Properties and Sacred Sites This impact would be significant and unavoidable. Due to the confidential nature of sacred land filings, it is unknown whether these locations are situated within the study area. Several tribal groups have identified traditional cultural properties and sacred sites that would be adversely impacted by CP1.

The NAHC identified sacred land filings within the study area. These locations are confidential, thus making it unclear whether or not they are situated within the CP1 area.

Two particularly important Winnemem Wintu locations that would be impacted by CP1 include Puberty Rock and the doctoring pools near Nawtawaket Creek. CP1 could submerge Puberty Rock, restricting the Winnemem Wintu from holding the puberty ceremony at this important location. Although Puberty Rock would still be accessible for portions of the year, when lake levels are lower, CP1 would increase the frequency of inundation. The relocation of the rock to higher ground is not possible, as, in the Winnemem worldview, its location is preordained and connected with the nearby “two sisters” mountain (Bollibokka Mountain). Puberty Rock also marks the location of an extensive village with housepits and burials. CP1 would inundate additional burials at this

location, which would require removal and relocation. The Winnemem Wintu have estimated that 120 ancestral villages still accessible above the current high waterline of Shasta Lake would be adversely impacted by CP1.

The Pit River Madesi Band members state that 22 ethnographic villages, associated burial grounds, and several TCPs are located within the existing reservoir and proposed inundation or fluctuation areas.

The local Native American community has identified several locations in the study area that they consider to be sacred; notable among these are Puberty Rock and the doctoring pools near Nawtawaket Creek. Inundation or other adverse impacts to these places likely cannot be mitigated because the importance of the identified properties and sacred sites is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible.

Although it is impossible at this stage to say how many of these resources will be adversely impacted due to inundation as a result of implementing CP1, this impact would be significant and unavoidable. Mitigation for this impact is not available.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Culture-3 (CP1): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction
Construction activities adjacent to the upper Sacramento River associated with downstream ecosystem enhancements would not occur under CP1; therefore, no impacts on cultural resources related to construction are expected. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Cultural resources potentially impacted by this alternative include those within (1) the proposed additional 1,734-acre inundation area, (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area, and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.).

Shasta Lake and Vicinity
Impact Culture-1 (CP2): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant. Sensitivity studies estimate that, with complete surveys, inundation associated with CP2 would include approximately 224±57 prehistoric resources (Table 14-2). The historic-era archival study documented 371 localities that may potentially contain historic-era remains within this inundation area.

Table 14-2. Cultural Resources Impacts for CP2

Inundation Area	
Prehistoric sites	224±57
Historic-era archival localities	371
Fluctuation Zone	
Prehistoric sites	675±172
Historic-era archival localities	529
0.25-Mile Buffer	
All cultural resources	Fewer than CP3

Note:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec. 106.

Sensitivity studies estimate that, with complete surveys, the fluctuation zone for CP2 would include approximately 675±172 prehistoric resources. The historic-era archival study documented 529 localities that may potentially contain historic-era remains.

Sensitivity studies estimate that, with complete surveys, the 0.25-mile buffer zone for CP2 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may potentially contain historic-era remains. Although the full extent and locations of project impacts related to construction activities within the buffer zone are not yet available for this alternative, they would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts from CP2, this impact would be significant. Inundation or other adverse impacts to affected resources likely cannot be mitigated because the importance of the identified properties and sacred sites is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible. Mitigation for this impact is proposed in Section 14.3.1.

Impact Culture-2 (CP2): Inundation of Traditional Cultural Properties and Sacred Sites Alternative CP2 is similar to Alternative CP1 with respect to its potential to cause or be affected by inundation. The NAHC identified sacred land filings within the study area. These locations are confidential, thus making it unclear whether or not they are situated within the CP2 area. For the same reasons that apply to CP1, this impact would be significant and unavoidable. Mitigation for this impact is not available.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Culture-3 (CP2): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction
Construction activities adjacent to the upper Sacramento River associated with downstream ecosystem enhancements would not occur under CP2; therefore, no

impacts on cultural resources related to construction are expected. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Cultural resources potentially impacted by this alternative include those within (1) the proposed additional 2,497-acre inundation area, (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area, and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.).

Shasta Lake and Vicinity

Impact Culture-1 (CP3): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant. Sensitivity studies estimate that, with complete surveys, inundation associated with CP3 would include approximately 243±63 prehistoric resources (Table 14-3). The historic-era archival study documented 391 localities that may potentially contain historic-era remains within this inundation area.

Table 14-3. Cultural Resources Impacts for CP3

Inundation Area	
Prehistoric sites	243±63
Historic-era archival localities	391
Fluctuation Zone	
Prehistoric sites	675±172
Historic-era archival localities	529
0.25-Mile Buffer	
All cultural resources	Fewer than CP5, same as CP4

Note:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec. 106.

Sensitivity studies estimate that, with complete surveys, the fluctuation zone for CP3 would include approximately 675±172 prehistoric resources. The historic-era archival study documented 529 localities that may potentially contain historic-era remains.

Sensitivity studies estimate that, with complete surveys, the 0.25-mile buffer zone for CP3 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may contain historic-era remains. Although the full extent and locations of project impacts related to construction activities within the buffer zone are not yet available for this alternative, they would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts from CP3, this impact would be significant. Inundation or other adverse impacts to affected resources likely cannot be mitigated because the importance of the identified properties and sacred sites is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible. Mitigation for this impact is proposed in Section 14.3.1.

Impact Culture-2 (CP3): Inundation of Traditional Cultural Properties and Sacred Sites Alternative CP3 is similar to Alternative CP1 with respect to its potential to cause or be affected by inundation. The NAHC identified sacred land filings within the study area. These locations are confidential, thus making it unclear whether or not they are situated within the CP3 area. For the same reasons that apply to CP1, this impact would be significant and unavoidable. Mitigation for this impact is not available.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Culture-3 (CP3): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction Construction activities adjacent to the upper Sacramento River associated with downstream ecosystem enhancements would not occur under CP3; therefore, no impacts on cultural resources related to construction are expected. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

Cultural resources potentially impacted by this alternative include those within (1) the proposed additional 2,497-acre inundation area, (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area, and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.). CP4 also includes downstream ecosystem enhancements with spawning gravel augmentation and floodplain and riparian habitat restoration, both of which would entail construction activities adjacent to the upper Sacramento River.

Shasta Lake and Vicinity

Impact Culture-1 (CP4): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant. Sensitivity studies estimate that with complete surveys, inundation associated with CP4 would include approximately 243±63 prehistoric resources (Table 14-4). The historic-era archival study documented 391 localities that may potentially contain historic-era remains within this inundation area.

Table 14-4. Cultural Resources Impacts for CP4

Inundation Area	
Prehistoric sites	243±63
Historic-era archival localities	391
Fluctuation Zone	
Prehistoric sites	601±154
Historic-era archival localities	524
0.25-Mile Buffer	
All cultural resources	Fewer than CP5, same as CP3

Note:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec. 106.

Sensitivity studies estimate that, with complete surveys, the fluctuation zone for CP4 would include approximately 601±154 prehistoric resources. The historic-era archival study documented 524 localities that may potentially contain historic-era remains.

Sensitivity studies estimate that, with complete surveys, the 0.25-mile buffer zone for CP4 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may potentially contain historic-era remains. Although the full extent and locations of project impacts related to construction activities within the buffer zone are not yet available for this alternative, they would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts from CP4, this impact would be significant. Inundation or other adverse impacts to affected resources likely cannot be mitigated because the importance of the identified properties and sacred sites is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible. Mitigation for this impact is proposed in Section 14.3.1.

Impact Culture-2 (CP4): Inundation of Traditional Cultural Properties and Sacred Sites Alternative CP4 is similar to Alternative CP1 with respect to its potential to cause or be affected by inundation. The NAHC identified sacred land filings within the study area. These locations are confidential, thus making it unclear whether or not they are situated within the CP4 area. For the same reasons that apply to CP1, this impact would be significant and unavoidable. Mitigation for this impact is not available.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Culture-3 (CP4): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction This impact would be significant. Previous cultural resource studies indicated the presence of cultural resources in or near proposed downstream construction

areas related to spawning gravel augmentation and floodplain and riparian habitat restoration.

A total of 17 cultural resources have been recorded within the records search areas, consisting of eight prehistoric sites, six historic-era resources, and three resources with prehistoric and historic-era components. As mapped, thirteen of these cultural resources exist only in the 1/8-mile buffer areas, and only four of these cultural resources extend into proposed construction areas. It should be noted that the proposed construction areas are concept-level and may be relocated or deleted as a result of design development, consultation, or other factors.

Although it is impossible at this stage to say how many eligible resources will sustain adverse impacts from CP4, this impact would be significant. Mitigation for this impact is proposed in Section 14.3.1.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Cultural resources potentially impacted by this alternative include those within (1) the proposed additional 2,497-acre inundation area, (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area, and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.). CP5 also includes downstream ecosystem enhancements with spawning gravel augmentation and floodplain and riparian habitat restoration, both of which would entail construction activities adjacent to the upper Sacramento River.

Shasta Lake and Vicinity

Impact Culture-1 (CP5): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant. Sensitivity studies estimate that, with complete surveys, inundation associated with CP5 would include approximately 243±63 prehistoric resources (Table 14-5). The historic-era archival study documented 391 localities that may potentially contain historic-era remains within this inundation area.

Sensitivity studies estimate that, with complete surveys, the fluctuation zone for CP5 would include approximately 675±172 prehistoric resources. The historic-era archival study documented 529 localities that may potentially contain historic-era remains.

Table 14-5. Cultural Resources Impacts for CP5

Inundation Area	
Prehistoric sites	243±63
Historic-era archival localities	391
Fluctuation Zone	
Prehistoric sites	675±175
Historic-era archival localities	529
0.25-Mile Buffer	
All cultural resources	Largest quantity

Note:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec. 106.

Sensitivity studies estimate that, with complete surveys, the 0.25-mile buffer zone for CP5 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may potentially contain historic-era remains. Although the full extent and locations of project impacts related to construction activities within the buffer zone are not yet available for this alternative, they would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts from CP5, this impact would be significant. Inundation or other adverse impacts to affected resources likely cannot be mitigated because the importance of the identified properties and sacred sites is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible. Mitigation for this impact is proposed in Section 14.3.1.

Impact Culture-2 (CP5): Inundation of Traditional Cultural Properties of Native American Concern Alternative CP5 is similar to Alternative CP1 with respect to its potential to cause or be affected by inundation. The NAHC identified sacred land filings within the study area. These locations are confidential, thus making it unclear whether or not they are situated within the CP5 area. For the same reasons that apply to CP1, this impact would be significant and unavoidable. Mitigation for this impact is not available.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Culture-3 (CP5): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction This impact would be significant. Previous cultural resource studies indicated the presence of cultural resources in or near in proposed downstream construction areas related to spawning gravel augmentation and floodplain and riparian habitat restoration.

A total of 17 cultural resources have been recorded within the records search areas, consisting of eight prehistoric sites, six historic-era resources, and three

resources with prehistoric and historic-era components. As mapped, thirteen of these cultural resources exist only in the 1/8-mile buffer areas, and only four of these cultural resources extend into proposed construction areas. It should be noted that the proposed construction areas are concept-level and may be relocated or deleted as a result of design development, consultation, or other factors.

Although it is impossible at this stage to say how many eligible resources will sustain adverse impacts from CP5, this impact would be significant. Mitigation for this impact is proposed in Section 14.3.1.

14.3.4 Mitigation Measures

This section discusses mitigation measures for each significant impact described in the environmental consequences section, as presented in Table 14-6.

Table 14-6. Summary of Mitigation Measures for Cultural Resources

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Culture-1: Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure Culture-1: Comply with Section 106 of the NHPA.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Culture-2: Inundation of Traditional Cultural Properties and Sacred Sites	LOS before Mitigation	NI	SU	SU	SU	SU	SU
	Mitigation Measure	None required.	None available.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact Culture-3: Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction	LOS before Mitigation	NI	NI	NI	NI	S	S
	Mitigation Measure	None required.	No mitigation needed; thus, none proposed.			Mitigation Measure Culture-3: Implement Mitigation Measure Culture-1: Comply with Section 106 of the NHPA.	
	LOS after Mitigation	NI	NI	NI	NI	LTS	LTS

Key:
LOS = level of significance
LTS = less than significant
NHPA = National Historic Preservation Act
NI = No Impact
S = significant
SU = significant and unavoidable

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP1): Comply with Section 106 of the NHPA Process Reclamation is committed to and will comply with the Federal NHPA Section 106 consultation process to avoid, minimize, or mitigate any significant, adverse impacts to cultural resources and historic properties due to CP1, to the extent possible. The following measures, consisting of inventory, evaluation, and treatment processes, would be conducted by Reclamation as part of the environmental reviews to ensure compliance with Section 106 of the NHPA. Coordination will continue with the relevant Native American tribes and other interested parties in the area. The mitigation measures that would reduce the impacts of the site-specific studies to less than significant levels are:

- **Conduct Class III cultural resources surveys of portions of the project APE that have not been surveyed** – Before any ground disturbance takes place in the project area (including areas of ancillary activities, such as staging areas and access routes), Class III cultural resource surveys covering the APE would be conducted to locate and record cultural resources. Where appropriate, subsurface discovery efforts also would be undertaken to identify buried archaeological sites.

- **Plan activities to avoid known cultural resources** – Before carrying out ground-disturbing activities, areas that have been delineated as containing cultural resources would be demarcated, and all ground-disturbing or related activities would be planned to avoid these areas.

- **Evaluate significance of resources that cannot be avoided** – If cultural resources cannot be avoided through careful planning of the activities associated with an alternative, additional research or test excavation (as appropriate) would be undertaken to determine whether the resources meet NRHP and/or CEQA significance criteria.

- **Develop treatment process to mitigate effects of project upon significant resources** – Impacts on significant resources that cannot be avoided would be mitigated in a manner that is deemed appropriate for the particular resources. Mitigation for significant resources may include, but would not be limited to, data recovery, public interpretation, performance of a Historic American Building Survey or Historic American Engineering Record, or preservation by other means.

These impacts would be less than significant after mitigation. It is possible, however, that adverse impacts to traditional cultural properties likely cannot be mitigated. Therefore, these impacts are potentially significant and unavoidable.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP2): Comply with Section 106 of the NHPA Reclamation is committed to and will comply with the Federal NHPA Section 106 consultation process to avoid, minimize, or mitigate any significant, adverse impacts to cultural resources and historic properties due to CP2, to the extent possible. The following measures, consisting of inventory, evaluation, and treatment processes, would be conducted by Reclamation as part of the environmental reviews to ensure compliance with Section 106 of the NHPA. Coordination will continue with the relevant Native American tribes and other interested parties in the area. The mitigation measures that would reduce the impacts of the site-specific studies to less than significant levels are:

- **Conduct Class III cultural resources surveys of portions of the project APE that have not been surveyed** – Before any ground disturbance takes place in the project area (including areas of ancillary activities, such as staging areas and access routes), Class III cultural resource surveys covering the APE would be conducted to locate and record cultural resources. Where appropriate, subsurface discovery efforts also would be undertaken to identify buried archaeological sites.

- **Plan activities to avoid known cultural resources** – Before carrying out ground-disturbing activities, areas that have been delineated as containing cultural resources would be demarcated, and all ground-disturbing or related activities would be planned to avoid these areas.

- **Evaluate significance of resources that cannot be avoided** – If cultural resources cannot be avoided through careful planning of the activities associated with an alternative, additional research or test excavation (as appropriate) would be undertaken to determine whether the resources meet NRHP and/or CEQA significance criteria.

- **Develop treatment process to mitigate effects of project upon significant resources** – Impacts on significant resources that cannot be avoided would be mitigated in a manner that is deemed appropriate for the particular resources. Mitigation for significant resources may include, but would not be limited to, data recovery, public interpretation, performance of a Historic American Building Survey or Historic American Engineering Record, or preservation by other means.

These impacts would be less than significant after mitigation. It is possible, however, that adverse impacts to traditional cultural properties likely cannot be mitigated. Therefore, these impacts are potentially significant and unavoidable.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP3): Comply with Section 106 of the NHPA Reclamation is committed to and will comply with the Federal NHPA Section 106 consultation process to avoid, minimize, or mitigate any significant, adverse impacts to cultural resources and historic properties due to CP3 to the extent possible. The following measures, consisting of inventory, evaluation, and treatment processes, would be conducted by Reclamation as part of the environmental reviews to ensure compliance with Section 106 of the NHPA. Coordination will continue with the relevant Native American tribes and other interested parties in the area. The mitigation measures that would reduce the impacts of the site-specific studies to less than significant levels are:

- **Conduct Class III cultural resources surveys of portions of the project APE that have not been surveyed** – Before any ground disturbance takes place in the project area (including areas of ancillary activities, such as staging areas and access routes), Class III cultural resource surveys covering the APE would be conducted to locate and record cultural resources. Where appropriate, subsurface discovery efforts also would be undertaken to identify buried archaeological sites.

- **Plan activities to avoid known cultural resources** – Before carrying out ground-disturbing activities, areas that have been delineated as containing cultural resources would be demarcated, and all ground-disturbing or related activities would be planned to avoid these areas.

- **Evaluate significance of resources that cannot be avoided** – If cultural resources cannot be avoided through careful planning of the activities associated with an alternative, additional research or test excavation (as appropriate) would be undertaken to determine whether the resources meet NRHP and/or CEQA significance criteria.

- **Develop treatment process to mitigate effects of project upon significant resources** – Impacts on significant resources that cannot be avoided would be mitigated in a manner that is deemed appropriate for the particular resources. Mitigation for significant resources may include, but would not be limited to, data recovery, public interpretation, performance of a Historic American Building Survey or Historic American Engineering Record, or preservation by other means.

These impacts would be less than significant after mitigation. It is possible, however, that adverse impacts to traditional cultural properties likely cannot be mitigated. Therefore, these impacts are potentially significant and unavoidable.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP4): Comply with Section 106 of the NHPA Reclamation is committed to and will comply with the Federal NHPA Section 106 consultation process to avoid, minimize, or mitigate any significant, adverse impacts to cultural resources and historic properties due to CP4 to the extent possible. The following measures, consisting of inventory, evaluation, and treatment processes, would be conducted by Reclamation as part of the environmental reviews to ensure compliance with Section 106 of the NHPA. Coordination will continue with the relevant Native American tribes and other interested parties in the area. The mitigation measures that would reduce the impacts of the site-specific studies to less than significant levels are:

- **Conduct Class III cultural resources surveys of portions of the project APE that have not been surveyed** – Before any ground disturbance takes place in the project area (including areas of ancillary activities, such as staging areas and access routes), Class III cultural resource surveys covering the APE would be conducted to locate and record cultural resources. Where appropriate, subsurface discovery efforts also would be undertaken to identify buried archaeological sites.

- **Plan activities to avoid known cultural resources** – Before carrying out ground-disturbing activities, areas that have been delineated as containing cultural resources would be demarcated, and all ground-disturbing or related activities would be planned to avoid these areas.

- **Evaluate significance of resources that cannot be avoided** – If cultural resources cannot be avoided through careful planning of the activities associated with an alternative, additional research or test excavation (as appropriate) would be undertaken to determine whether the resources meet NRHP and/or CEQA significance criteria.

- **Develop treatment process to mitigate effects of project upon significant resources** – Impacts on significant resources that cannot be avoided would be mitigated in a manner that is deemed appropriate for the particular resources. Mitigation for significant resources may include, but would not be limited to, data recovery, public interpretation, performance of a Historic American Building Survey or Historic American Engineering Record, or preservation by other means.

These impacts would be less than significant after mitigation. It is possible, however, that adverse impacts to traditional cultural properties likely cannot be mitigated. Therefore, these impacts are potentially significant and unavoidable.

Mitigation Measure Culture-3 (CP4): Implement Mitigation Measure Culture-1 (CP4): Comply with Section 106 of the NHPA This mitigation measure is the same as Mitigation Measure Culture-1 (CP4). Implementation of mitigation measure Culture-1 would reduce Impact Culture-3 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP5): Comply with Section 106 of the NHPA Reclamation is committed to and will comply with the Federal NHPA Section 106 consultation process to avoid, minimize, or mitigate any significant, adverse impacts to cultural resources and historic properties due to CP5 to the extent possible. The following measures, consisting of inventory, evaluation, and treatment processes, would be conducted by Reclamation as part of the environmental reviews to ensure compliance with Section 106 of the NHPA. Coordination will continue with the relevant Native American tribes and other interested parties in the area. The mitigation measures that would reduce the impacts of the site-specific studies to less than significant levels are:

- **Conduct Class III cultural resources surveys of portions of the project APE that have not been surveyed** – Before any ground disturbance takes place in the project area (including areas of ancillary activities, such as staging areas and access routes), Class III cultural resource surveys covering the APE would be conducted to locate and record cultural resources. Where appropriate, subsurface discovery efforts also would be undertaken to identify buried archaeological sites.

- **Plan activities to avoid known cultural resources** – Before carrying out ground-disturbing activities, areas that have been delineated as containing cultural resources would be demarcated, and all ground-disturbing or related activities would be planned to avoid these areas.

- **Evaluate significance of resources that cannot be avoided** – If cultural resources cannot be avoided through careful planning of the activities associated with an alternative, additional research or test excavation (as appropriate) would be undertaken to determine whether the resources meet NRHP and/or CEQA significance criteria.

- **Develop treatment process to mitigate effects of project upon significant resources** – Impacts on significant resources that cannot be avoided would be mitigated in a manner that is deemed appropriate for

the particular resources. Mitigation for significant resources may include, but would not be limited to, data recovery, public interpretation, performance of a Historic American Building Survey or Historic American Engineering Record, or preservation by other means.

These impacts would be less than significant after mitigation. It is possible, however, that adverse impacts to traditional cultural properties likely cannot be mitigated. Therefore, these impacts are potentially significant and unavoidable.

Mitigation Measure Culture-3 (CP5): Implement Mitigation Measure Culture 1 (CP5): Comply with Section 106 of the NHPA This mitigation measure is the same as Mitigation Measure Culture-1 (CP5). Implementation of mitigation measure Culture-1 would reduce Impact Culture-3 (CP5) to a less than significant level.

14.3.5 Cumulative Effects

It is not possible to predict all future impacts to cultural resources within the study area. However, given the large number of archaeological sites and Native American sacred areas (villages, cemeteries, and ceremonial places) that have already been inundated by the reservoir, it is likely that raising Shasta Dam by any height would have a significant cumulative effect to resources in the study area.

Chapter 15
Indian Trust Assets

15.1 Affected Environment

This section describes the affected environment related to Indian Trust Assets (ITA) for the proposed dam and reservoir modifications at Shasta Lake.

The affected environment for ITAs is the primary study area, within which all construction activities will take place, and which includes Shasta Lake's expanded inundation area, relocations within approximately 0.25 miles of the shoreline, and the upper Sacramento River from Shasta Dam to the Red Bluff Diversion Dam.

The extended study area would only be affected by changes in CVP and SWP operations, and includes the Sacramento River to the Delta and the CVP and SWP water service areas. For additional details on the primary and extended study areas, please refer to Section 1.3 and Figures 1-1 and 1-2 of the PDEIS. The action alternatives are not anticipated to have impacts on ITAs as a result of changes in CVP and SWP operations; therefore, the extended study area was not evaluated for ITAs.

Indian Trust Lands in the region around the primary study area are shown in Figure 15-1.

Several Federally recognized tribes are located in the region surrounding the primary study area (Table 15-1).

This page left blank intentionally.

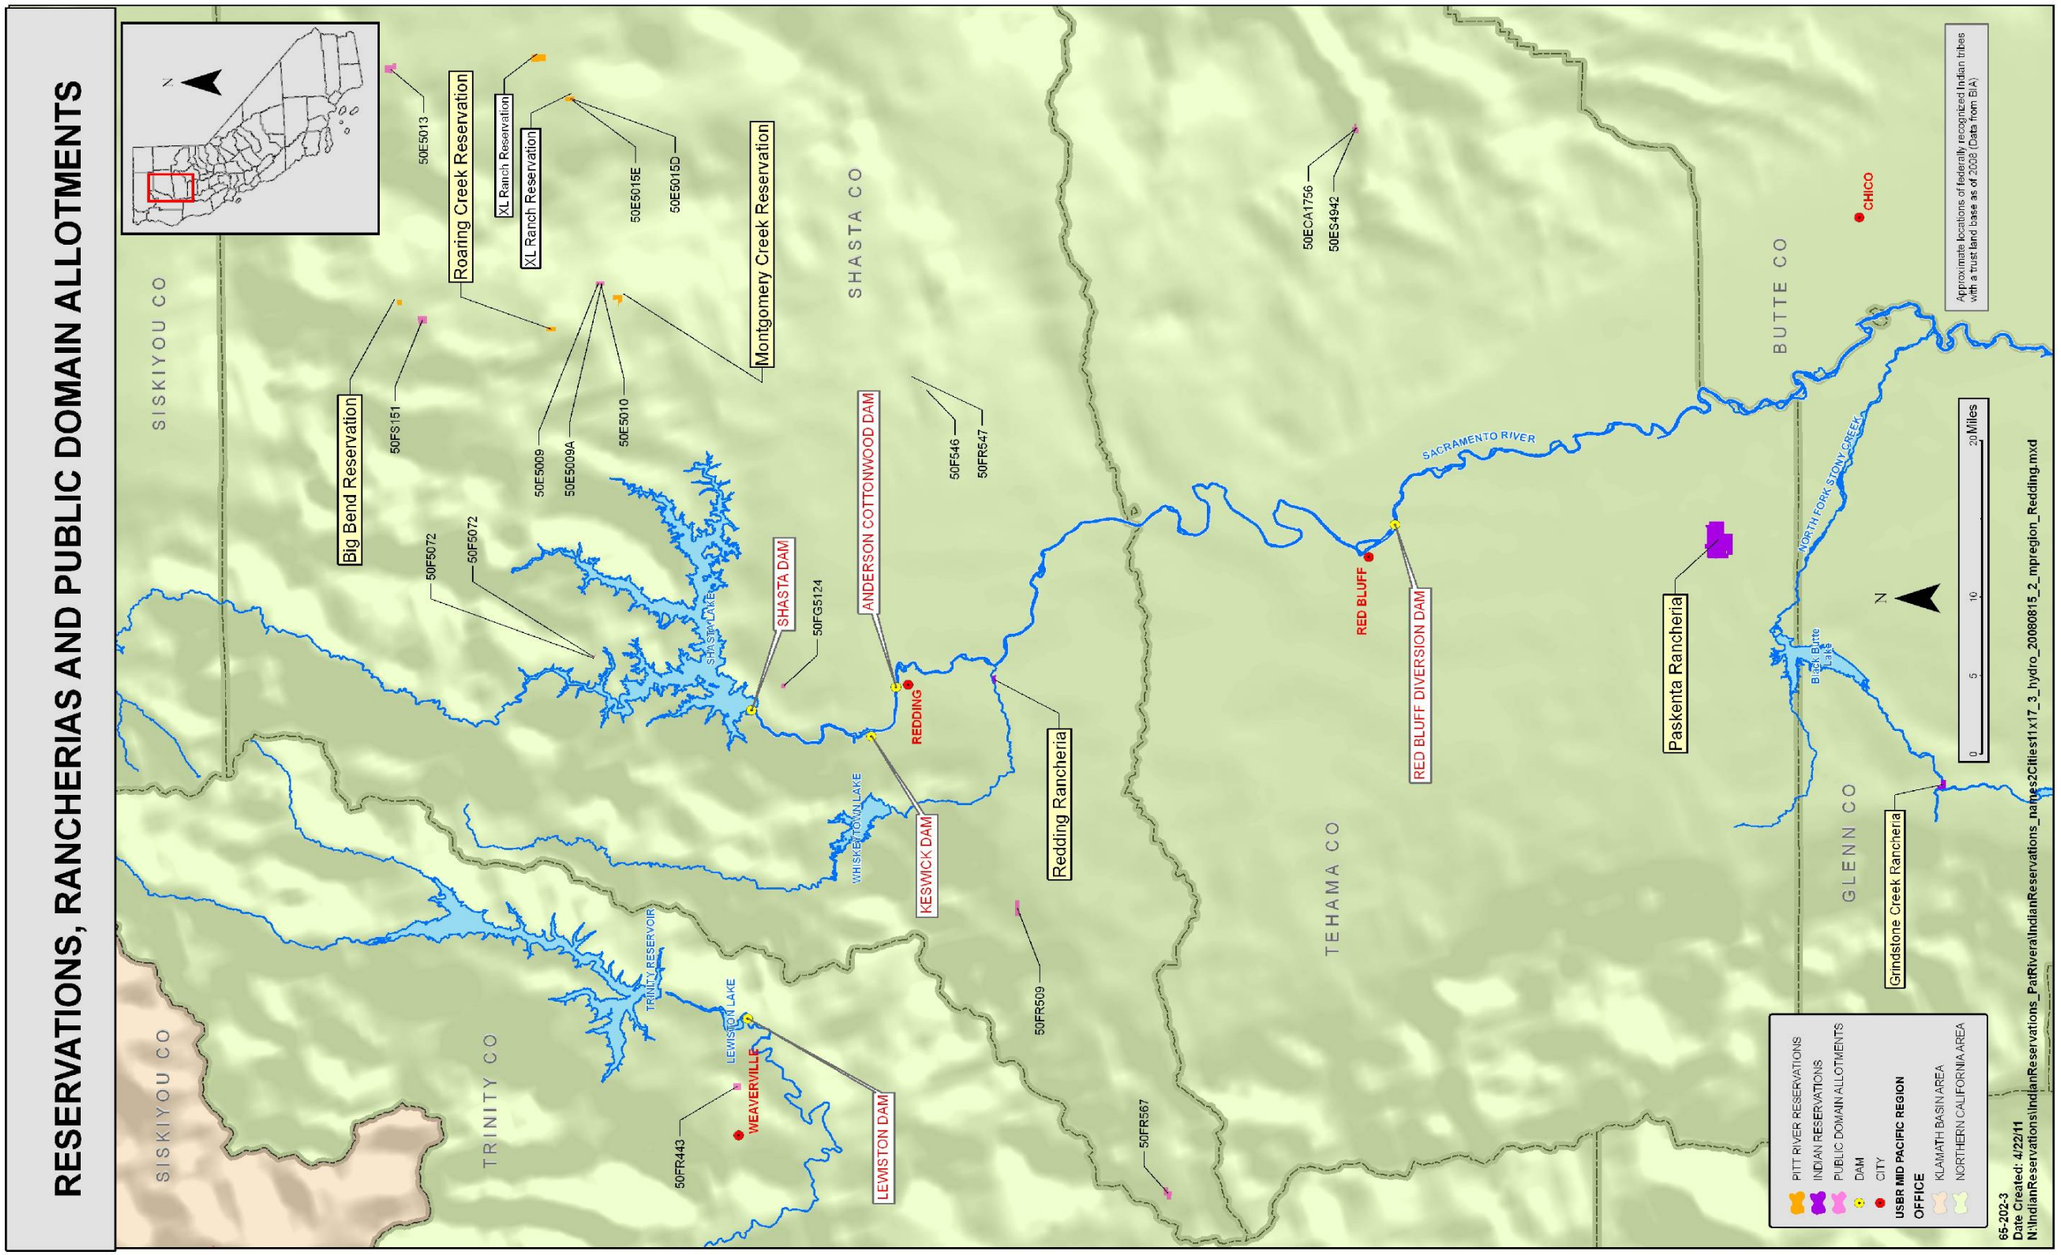

Figure 15-1. Reservations, Rancherias and Public Domain Allotments in Primary Study Area

This page left blank intentionally.

Table 15-1. Federally Recognized Tribes in Region Surrounding Primary Study Area

Tribe	Affiliation
Grindstone Indian Rancheria of Wintun- Wailaki Indians	Wintun, Wailaki
Paskenta Band of Nomlaki Indians	Nomlaki
Pit River Tribe Environmental Office	Pit River, Wintun
Pit River Tribe	Pit River Achumawi Wintun
Redding Rancheria	Wintu, Pit River, Yana

15.2 Regulatory Framework

ITAs are legal interests in property held in trust by the U.S. for Federally recognized Indian tribes or individual Indians. An Indian trust has three components: (1) the trustee, (2) the beneficiary, and (3) the trust asset. ITAs can include land, minerals, Federally reserved hunting and fishing rights, Federally reserved water rights, and in-stream flows associated with trust land. Beneficiaries of the Indian trust relationship are Federally recognized Indian tribes with trust land; the United States is the trustee. By definition, ITAs cannot be sold, leased, or otherwise encumbered without approval of the United States. The characterization and application of the United States trust relationship have been defined by case law that interprets Congressional acts, executive orders, and historic treaty provisions.

The Federal Government, through treaty, statute, or regulation, may take on specific, enforceable fiduciary obligations that give rise to a trust responsibility to Federally recognized tribes and individual Indians possessing trust assets. Courts have recognized an enforceable Federal fiduciary duty with respect to Federal supervision of Indian money or natural resources, held in trust by the Federal Government, where specific treaties, statutes, or regulations create such a fiduciary duty.

Consistent with President William J. Clinton's 1994 memorandum, *Government-to-Government Relations with Native American Tribal Governments* (Federal Register, Vol. 59, No. 85, May 4, 1994, pages 22951–22952), Reclamation assesses the effect of its programs on tribal trust resources and Federally recognized tribal governments. Reclamation is tasked to actively engage Federally recognized tribal governments and consult with such tribes on government-to-government level when its actions affect ITAs. The U.S. Department of the Interior Departmental Manual, Part 512.2 (1995), ascribes the responsibility for ensuring protection of ITAs to the heads of bureaus and offices. The Department of the Interior is required to "protect and preserve Indian trust assets from loss, damage, unlawful alienation, waste, and depletion"

(Secretarial Order No. 3215, *Principles for the Discharge of the Secretary's Trust Responsibility*, Reclamation 2000). It is the general policy of the Department of the Interior to perform its activities and programs in such a way as to protect ITAs and avoid adverse effects whenever possible. Reclamation complies with procedures contained in Departmental Manual, Part 512.2, guidelines, which protect ITAs. Reclamation carries out its activities in a manner that protects trust assets and avoids adverse impacts, when possible. When Reclamation cannot avoid adverse impacts, it will provide appropriate mitigation or compensation. Reclamation is responsible for assessing whether action alternatives CP1 through CP5 have the potential to affect ITAs. Reclamation will comply with procedures contained in Departmental Manual, Part 512.2, guidelines, which protect ITAs.

15.3 Environmental Consequences and Mitigation Measures

This section discusses environmental consequences and potential mitigation associated with ITAs that could result from implementing the alternatives described in this PDEIS.

15.3.1 Methods and Assumptions

A detailed description of both the primary and extended study areas was provided to the Bureau of Indian Affairs' Regional ITA Coordinator. The Regional ITA Coordinator examined both the project area descriptions and records held by the Bureau of Indian Affairs and Reclamation, and determined that the proposed action does not have potential to affect ITAs. There are no ITAs in the primary study area.

15.3.2 Direct and Indirect Effects

The following section describes the potential environmental consequences of the project.

No-Action Alternative

Under the No-Action Alternative, there are no impacts to ITAs because no new facilities would be constructed and existing operations would continue as historically.

CP1 Through CP5

There are no tribes possessing legal property interests held in trust by the United States in the study area for any of the proposed comprehensive plans (CP1 through CP5). The nearest ITA is a Public Domain Allotment approximately 5 miles north-northwest of the project location.

Cumulative Impacts

There are no impacts to ITAs as a result of the proposed action; therefore, the proposed action would not contribute to cumulative impacts to ITAs.

Chapter 16
Socioeconomics, Population, and Housing

16.1 Affected Environment

This section describes socioeconomics, population, and housing characteristics in the primary and extended study areas. For a more in-depth description, see the *Socioeconomics, Population, and Housing Technical Report*.

16.1.1 Socioeconomics

Socioeconomics covers age, race/ethnicity, income/poverty, employment and labor force, business and industry, and government and finance. The data presented in this section reflect conditions that existed before the U.S. recession that began in late 2007 and became apparent beginning in 2008. Changes to the California and U.S. economies attributable to the recession resulted in increases in unemployment rates statewide; therefore, actual unemployment rates in the study area are now generally higher than presented in this section. This section uses the pre-recession figures to reflect economic conditions that were current in 2005, when the notice of intent for the SLWRI was released. Using these earlier figures does not affect the conclusions in the environmental impact analysis presented in this Environmental Impact Statement (except that with a higher unemployment rate, employment generated by project construction could result in a greater benefit to the local economy). For more details, see the *Socioeconomics, Population, and Housing Technical Report*.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Race/Ethnicity In 2005, the white population represented more than 83 percent of the populations of Shasta and Tehama counties, but substantial increases were observed in many minority groups (U.S. Census Bureau 2006a, 2006b). Tehama County's minority populations also increased between 2000 and 2005. Trends observed in the two counties generally coincide with statewide trends, where Hispanic, Asian–Pacific Islander, and American Indian populations all grew by more than approximately 12 percent over the 5-year period.

Income/Poverty Jurisdictions within the primary study area have underperformed when compared to the statewide averages for income levels and poverty rates. Median household incomes in Shasta and Tehama counties were sizably lower than the statewide average in 2000 and 2005, although Shasta County experienced a substantial increase in incomes in the 5-year period. With median household incomes of $34,520 and $42,227 in 2004 and 2005,

respectively, Shasta County and Tehama County had incomes averaging between $11,000 and $19,000 less than the statewide average for 2005. Overall poverty rates and child poverty rates have also been higher in the primary study area than in California as a whole.

Employment and Labor Force Since 1990, employment rates in both Shasta and Tehama counties have consistently been below the statewide average. Because of the cyclical nature of the area's natural resource–related industries and other factors, Shasta and Tehama counties were characterized by substantially higher unemployment rates during the 1990s (Shasta County 2004). In 2005, Tehama County registered a 7.3 percent unemployment rate, while unemployment in Shasta County totaled 6.9 percent of the population. As a result of its larger population, Shasta County maintained a labor force of just under 83,000 people in 2005, or more than three times that of Tehama County.

Business and Industry Economic activities in the primary study area coincide in many ways with the industrial composition of California as a whole. Trade, transportation, and utilities, followed by governmental services made up the top two industrial sectors both locally and statewide in 2002. In Shasta and Tehama counties, government employees and employees in the trade, transportation, and utilities sectors account for more than 20 percent of the total workforce. Similarly, educational and health services, including teachers and health workers, also ranks in the top five industries in both counties and California generally.

Some differences also exist between the industrial makeup of the two counties and that of California as a whole. For example, manufacturing plays an important role in Tehama County (14.9 percent) and California (11.3 percent) as a whole, but a comparatively small role in Shasta County. Professional and business services registers as the third largest industry at the statewide level (14.6 percent), but represents a smaller portion of employment in Shasta County (9.1 percent) and Tehama County (5.4 percent). Additionally, farm employment makes up a sizeable portion of the total workforce in Tehama County (7.4 percent), but accounts for a comparatively small portion of the workforce in Shasta County (1.6 percent) and California as a whole (2.5 percent).

Projections of future growth depict slightly different economic trends in Shasta and Tehama counties than at the statewide level. California's professional and business industry is expected to grow by almost 30 percent by 2014 (compared to 2004 levels) and the educational and health services industry is expected to grow by more than 25 percent in that time. These industries also represent the top two growth industries in Shasta County, but growth rates are expected to be slightly less in the county (24 percent and 22 percent, respectively).

Established businesses, along with new businesses that locate in the area, will play an important role in the expansion of the local economy projected by the State. Table 1-11 in the *Socioeconomics, Population, and Housing Technical*

Report displays a number of the major employers in the primary study area. This list of employers includes a range of businesses with a payroll of more than 500 people. Three of the nine businesses provide health care to local residents. Other employers include a wholesale distribution center, a wholesale nursery, and a manufacturer of industrial materials.

Government and Finance Shasta and Tehama counties are the critical local governments in the primary study area. Each county has a primary urban center (Redding in Shasta County and Red Bluff in Tehama County), with a limited number of small cities and towns and large amounts of rural land surrounding it. Because the two counties are largely rural, their total revenues and expenditures are relatively low when compared to other jurisdictions in California.

Revenues generated by Shasta County are used for a range of governmental activities. As described in the *Socioeconomics, Population, and Housing Technical Report*, expenditures increased from $302.8 million in the 2007–2008 fiscal year to $319.7 million in the 2008-2009 fiscal year. Expenditures decreased substantially in the 2009-2010 fiscal year to $309.6 million as a result of decreased spending on transportation-related projects. Welfare, social services, and other public assistance has consistently been the largest expenditure for Shasta County (more than $94.1 million in 2010), but remained relatively constant between 2007 and 2010. Police, fire, and other public safety activities represented the second largest expenditure category with more than $79.7 million in the 2009-2010 fiscal year.

Observed trends in Tehama County's revenues and expenditures have been generally similar to those experienced in Shasta County. Because of its smaller size, Tehama County's total revenues are substantially less than those of Shasta County ($112.3 million in the 2009-2010 fiscal year, compared to $309.6 million in Shasta County), but Tehama County experienced an overall decrease in revenue growth between 2007 and 2010.

Expenditures in Tehama County are also consistent with trends observed in Shasta County.

Lower Sacramento River and Delta

Race/Ethnicity Overall, the majority of people in the nine-county lower Sacramento River and Delta portion of the extended study area are white (53.0 percent), but the proportion of population identified as white varies substantially between counties. The white population of Butte County (79.1 percent) in 2005 was the highest proportion of any county in the area, while San Joaquin County had the lowest proportion of white residents (42.9 percent) (DOF 2007a). These proportions are still generally higher than that observed at the statewide level in 2005 (44.4 percent).

Income/Poverty Income and poverty characteristics for the lower Sacramento River and Delta area are similar to those for California as a whole. The median

household income of the majority of counties within the nine-county area is similar to or higher than the statewide median household income ($53,629).

Poverty levels for both individuals and children in the lower Sacramento River and Delta counties were similar to the statewide level. San Joaquin (14.2 percent), Butte (16.4 percent), and Yolo (17.8 percent) counties had higher overall poverty rates than California as a whole (13.3 percent) in 2006. The percentage of people below the poverty level is expected to follow national and statewide economic trends.

Employment and Labor Force Employment and labor trends in the nine counties of the lower Sacramento River and Delta are generally consistent with statewide trends. The area maintains a labor force of more than 1.9 million people, representing approximately 11 percent of California's labor force (17.7 million).

In the nine-county area in 2005, approximately 5.3 percent of the labor force was classified as unemployed. This unemployment rate compared to a statewide total of 5.4 percent for the same period. Although the total unemployment rate was similar to California's unemployment rate, unemployment within the lower Sacramento River and Delta counties varied substantially. Generally, the counties with the highest unemployment rates in 2005 had greater dependence on the agricultural industry and a reduced industrial diversity. Four of the five counties with unemployment rates above the statewide average maintained more than 60 percent of their land mass in agricultural production (DOF 2007b, 2007c, 2007d, 2007e, 2007f).

Business and Industry Business and industry in the lower Sacramento River and Delta counties is composed primarily of five industries: government; trade, transportation, and utilities; educational and health services; professional and business services; and leisure and hospitality. These five industries consistently rank in the top five industries of the nine counties of the lower Sacramento River and Delta portion of the extended study area.

Government and Finance A total of 55 cities and towns and a range of special districts are located within the nine counties of the lower Sacramento River and Delta. This collection of governmental entities provides valuable public services to the lower Sacramento River and Delta area—education, fire protection, employment development, emergency services, and crime prevention and control. These agencies and special districts rely primarily on tax revenue disbursed by State government, local sales and property taxes and fees, and the disbursement of Federal funds. This greater reliance on existing tax structures and rates, and a productive economic base, makes relatively reliable and affordable CVP and SWP water and power even more valuable, because its availability and affordability helps foster local business activity and thus indirectly helps sustain the fiscal health of local service providers. Similarly, flood protection provided by Shasta Dam helps protect and sustain

the appraised value of property within the dam's floodplain, again helping to protect the fiscal health of local service providers.

Total revenues and expenditures vary substantially between the nine counties of the lower Sacramento River and Delta because of the relative sizes of the counties and the services they provide. Revenues include payments received through taxes, licenses and permits, grants from other governments, charges for services, and others. Expenditures include payments made by a jurisdiction to buy goods, pay its employees, and provide services to its residents. Revenues and expenditures range from the approximately $65 million budgeted in Glenn County for 2006-2007 to Contra Costa County's approximately $1.2 billion budget.

CVP/SWP Service Areas

Race/Ethnicity The population within the CVP and SWP service areas continues to diversify. The proportion of the statewide population made up of minority groups has been steadily increasing. Almost all of the minority groups in the CVP and SWP service areas (except Black or African-American) experienced double-digit population growth between 2000 and 2005 (U.S. Census Bureau 2002, 2006b). Hispanics are the largest minority population in California and many members of this ethnic group work on farms that receive some or all of their water from the CVP and SWP.

Income/Poverty Poverty levels for both individuals and children in California decreased slightly between 2000 and 2005. The percentage of people below the poverty level is expected to follow national and statewide economic trends.

Employment and Labor Force Employment and labor force trends observed in the CVP and SWP service areas are generally synonymous with the trends observed at the statewide level because of the expanse of the CVP and SWP service areas. California's total labor force increased consistently from year to year between 2002 and 2005. In each year, California added between 100,000 and 200,000 individuals to the labor force. (As stated previously, the data presented in this section reflect conditions that existed before the U.S. recession that began in late 2007. This section uses the pre-recession figures to reflect economic conditions that were current in 2005, when the notice of intent for the SLWRI was released.)

Increases in California's total labor force have been relatively consistent; the statewide unemployment rate has fluctuated slightly since 2000. California's unemployment rate was lowest in 2000 (5.0 percent) and increased steadily over the subsequent 3 years (to 6.8 percent in 2003). The unemployment rate was 5.4 percent in 2005, equal to the state's 2001 unemployment rate.

Business and Industry Business and industry trends for the CVP and SWP service areas are assumed to be equal to those at the statewide level because of the expanse of these service areas. The trade, transportation, and utilities

industry represents the largest industry, measured by total employees, in California. Government is California's second largest industry, and the professional and business services, educational and health services, and leisure and hospitality industries all play important roles in the state's economy.

Government and Finance The state of California represents the most appropriate level of detail for the CVP and SWP service areas because of the expanse of the service areas and the interdependent nature of government and finance provision. California currently ranks as the seventh largest economy in the world and provides goods and services to more than 37 million people, making it the largest state in the nation. As a result, State government manages a large annual volume of revenues and expenditures. The State of California's proposed 2011–2012 budget includes a total of approximately $123 billion in revenues and transfers and a total of more than $127 billion in total expenditures (State of California 2011). Many of the State's expenditures represent grants and other funding made available to local jurisdictions throughout California. These funds may be used for a variety of services, such as health and human services, environmental protection, and resource management.

16.1.2 Population

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

The area surrounding Shasta Dam comprises generally smaller cities and towns with two larger, primary urban areas in each of the two counties (Shasta County and Tehama County). Almost 39 percent of the population in Shasta County and more than 65 percent in Tehama County lived in unincorporated areas in 2006. By comparison, only 17.7 percent of the population in the entire state of California lived in unincorporated areas in 2005. In total, the populations of Shasta and Tehama counties make up less than 1 percent of the total population in California.

The cities of Redding and Red Bluff are the two largest urban areas in the primary study area. Redding, with a total of 89,162 residents in 2006, is the most populous city in the region. Red Bluff is the second largest city in the region and the largest city in Tehama County, with a total of 13,529 residents in 2006. Remaining cities within the primary study area – Anderson, Shasta Lake, and Tehama – all contained fewer than 11,000 residents in 2006.

Although Shasta and Tehama counties are still comparatively small, both counties have been growing substantially during the past 15-20 years. Since 1990, the population of Shasta County has increased by more than 22 percent. During that time, the populations of Redding and Anderson have increased by approximately 33 percent and 26 percent, respectively. A similar situation has been observed in Tehama County, where total population has grown by almost

23 percent since 1990. Most of this new growth has occurred in the unincorporated areas of Tehama County, rather than in existing cities.

Shasta and Tehama counties are expected to continue this growth trend, with substantial growth in Tehama County. The State of California projects that Shasta County's population will increase by 86 percent by 2050 to a total of approximately 332,000 residents (DOF 2007g). This increase is approximately 26 percent higher than expected at the statewide level (60.0 percent).

Lower Sacramento River and Delta

As described in the *Socioeconomics, Population, and Housing Technical Report*, roughly 4 million people live in the nine-county area that makes up the lower Sacramento River and Delta area (Butte, Colusa, Contra Costa, Glenn, Sacramento, San Joaquin, Sutter, and Yolo counties). This population represents approximately 11 percent of California's total population. Sacramento County and Contra Costa County are the two largest counties in the area, with approximately 1.4 million and 1.0 million residents, respectively, in 2006 (DOF 2007a). Of the nine counties in the area, only Sacramento County (56.8 percent) is expected to have grown at a slower rate than California as a whole (60.0 percent increase) through 2050. All other counties in the area are expected to increase their populations by at least 72 percent over that time.

CVP/SWP Service Areas

In 2006, California contained a total of 37,195,240 residents. Approximately 80 percent of the state's population resides in the incorporated areas of its 58 counties (DOF 2007a). Similar to the state as a whole, most of the population of the CVP and SWP service areas is concentrated within urban areas. Outside of these fast-growing population centers, most of the lands within the CVP and SWP service areas are rural, with irrigated agriculture being the predominant land use and driver of the local and regional economies.

California's population has increased by almost 25 percent since 1990 and is projected to increase by approximately 60 percent to more than 59 million people by 2050. This substantial population increase will result in a sizeable increase in water and energy demand across the state. The proportion of the statewide population made up of minority groups has been steadily increasing.

16.1.3 Housing

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

As shown in the *Socioeconomics, Population, and Housing Technical Report*, as would be expected, provision of housing in the primary study area generally coincides with the population trends discussed above. Shasta County (75,240 units in 2006) maintains almost three times the amount of housing units in Tehama County (25,881 units). Of the nearby cities, Redding provides the largest supply of housing in the region, with more than 37,000 housing units.

Redding's units represent roughly half the total housing units in Shasta County. Red Bluff provides the second largest housing stock in the area, with almost 6,000 units.

Overall, single-family dwelling units are the predominant housing type in the primary study area. Vacancy rates were generally higher than the statewide average (5.9 percent), with the exception of Redding (5.0 percent) and Anderson (5.8 percent). Tehama County registered the highest vacancy rate in the primary study area, with 10.8 percent of all housing units vacant. The average household size in jurisdictions of the primary study area ranged from as low as 2.39 persons per household (Tehama) to as high as 2.66 persons per household (Anderson and Shasta Lake). All of these totals were lower than the average persons per household at the statewide level (2.94 persons).

Lower Sacramento River and Delta

As shown in the *Socioeconomics, Population, and Housing Technical Report*, housing characteristics in the nine-county area that makes up the lower Sacramento River and Delta are generally similar to those at the statewide level. In 2006, the area contained approximately 1.5 million housing units. Similar to population, this total represents approximately 11 percent of California's housing stock (approximately 13 million houses). Overall, single-family housing makes up a larger proportion of the total housing stock in the nine-county area (72.5 percent) than recorded at the statewide level (57.3 percent) in 2006 (DOF 2007a).

The vacancy rate in the nine-county area in 2006 was lower (4.0 percent) than the rate observed at the statewide level (5.9 percent). Vacancy in the majority of counties (six of nine) within the lower Sacramento River and Delta area was substantially lower than California as a whole (DOF 2007a).

Average household size in the lower Sacramento River and Delta area is generally lower than that observed at the statewide level. In total, an average of 2.74 persons lived in the households of the nine-county area in 2006. This compared to an average of 2.94 persons for California as a whole (DOF 2007a).

CVP/SWP Service Areas

A description of housing in the CVP and SWP service areas is not included because it would not be affected by the project.

16.2 Regulatory Framework

The assessment of socioeconomic resources is guided primarily by Federal laws and policies. State and local laws and policies typically promote economic development and diversity, environmental justice, public health and safety, housing, and other concerns of the residents within their jurisdictions. As noted

below, NEPA documents must include an assessment of potential conflicts with State and local plans and policies.

16.2.1 Federal

The major Federal laws and regulations guiding the assessment of socioeconomic resources are summarized below.

National Environmental Policy Act

Section 102 of NEPA requires Federal agencies to "insure the integrated use of the natural and social sciences" in planning and decision making (42 U.S. Code Section 4332).

Section 1502.16(c) of NEPA requires Federal agencies to identify potential conflicts between a proposed action and related plans and policies of Federal, state, and local agencies and Indian tribes. This requirement helps Federal agencies identify potential conflicts that may cause adverse effects on the social and economic environment of a study area because many agency and tribal plans and policies are designed to protect the people residing within their jurisdictions and/or the local economy they depend upon for their economic livelihoods.

Council on Environmental Quality

The Council on Environmental Quality's "Regulations for Implementing the Procedural Provisions of NEPA" (40 Code of Federal Regulations (CFR) 1500 to 1508) provide guidance related to social and economic impact assessment by noting that the "human environment" assessed under NEPA is to be "interpreted comprehensively" to include "the natural and physical environment and the relationship of people with that environment" (40 CFR 1508.14). Furthermore, these regulations require agencies to assess "aesthetic, historic, cultural, economic, social, or health" effects, whether direct, indirect, or cumulative (40 CFR 1508.8). Some Federal agencies, including the U.S. Bureau of Land Management and U.S. Forest Service, have developed socioeconomics-related handbooks and instructional memoranda to help the preparers of Environmental Impact Statements comply with NEPA with respect to socioeconomics resources.

Executive Order 12898—Environmental Justice

In 1994, President Bill Clinton issued Executive Order 12898 regarding environmental justice. This order requires Federal agencies to "identify and address" disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low-income populations in the United States. The Council on Environmental Quality issued guidance in 1997 to help Federal agencies incorporate environmental justice concerns into their NEPA procedures. Environmental justice issues are specifically addressed in Chapter 24, "Environmental Justice," of this PDEIS.

16.2.2 State

Most state and local governments have plans and policies intended to protect and expand the local and regional economies affecting the communities and residents within their jurisdictions. Some of these plans and policies are also intended to promote public health and safety while minimizing conflicts between new development projects of all types; their associated traffic, air, and noise impacts; and the social environment within which local residents live and work. State plans and policies also frequently address other social and economic impact topics, including fiscal conditions and related public services that affect local residents' quality of life.

In California, the California Environmental Protection Agency adopted its own environmental justice policy in 2004. Pursuant to Sections 71110 to 71113 of the California Public Resources Code, the California Environmental Protection Agency has developed this policy (or strategy) to provide guidance to its resource boards, departments, and offices. It is intended to help achieve the State's goal of "achieving fair treatment of people of all races, cultures and incomes with respect to the development, adoption, implementation and enforcement of environmental laws and policies."

16.2.3 Regional and Local

Each of California's counties, including Shasta and Tehama counties, has its own plans, ordinances, and other policies designed to protect and improve a wide range of socioeconomic conditions. Specifically addressed in these plans, ordinances, and policies are housing, employment opportunities for minorities and low-income populations and others, economic diversification, and business activity in general.

Shasta County

Shasta County General Plan Two primary elements of the *Shasta County General Plan* (Shasta County 2004) address socioeconomic resources: Housing and Economic Development. The Housing Element of the *Shasta County General Plan* establishes several goals and policies related to ensuring adequate housing provision, especially affordable housing, in the county. Shasta County's housing policies and programs are grouped into six primary categories, each supporting an identified goal. These categories and the goal associated with each are listed below.

- **Housing Supply**
  - **Goal –** To establish and implement policies and programs that will:
    - Contribute to the provision of an adequate supply and diversity of safe, healthy, and affordable housing for all income levels to meet the needs of residents in the unincorporated areas of Shasta County.

  - Satisfy the requirements of the Regional Housing Needs Allocation Plan for Shasta County for the 2004-2009 Housing Element period, specifically to realize the construction of new units as follows: Very Low Income – 300 units; Low Income – 255 units; Moderate Income – 1,035 units; and Above Moderate Income – 810 units.

- **Conserve and Improve Existing Affordable Housing**
  - **Goal –** To conserve, improve, and expand the inventory of existing affordable housing stock in the incorporated areas of the County, specifically to realize the conservation and/or rehabilitation of the following units: Rehabilitation (150): 60 units – Very Low Income; 55 units – Low Income; 25 units – Moderate Income; and 10 units – Above Moderate Income; Conservation (150): 90 units – Very Low Income; 53 units – Low Income; and 7 units – Moderate Income.
- **Housing Development Constraints**
  - **Goal –** To continue to remove all County constraints, as is practical and legal, which have the potential to hinder or impede the development of affordable housing projects.
- **Special Needs**
  - **Goal –** To continue to work collectively with local agencies to enhance and expand the outreach programs designed to provide accessible and affordable housing, including supportive services, for those persons with special needs including the elderly, large families, single mothers, children, developmentally and physically disabled persons, the mentally ill, farmworkers, and the homeless.
- **Energy Conservation**
  - **Goal –** To explore, implement, and promote energy conservation practices in all eligible existing and new housing projects.
- **Fair Housing**
  - **Goal –** To continue to utilize all feasible means to promote, expand, and ensure equal access to available, safe, decent, affordable housing opportunities in the unincorporated area without bias or prejudice for any reason for all economic segments of the County.

The Economic Development Element of the *Shasta County General Plan* (Shasta County 2004) establishes the following two overall objectives for economic development:

- **ED-1 –** Economic development plans, programs, and policies shall contribute to a stable and healthy economy in Shasta County, which includes provision of a land development pattern, planning process, and

regulatory atmosphere conducive to maintaining employment opportunities for County residents and fostering new economic development.

- **ED-2** – Seek economic diversity that increases the variety, type and scale of business, industrial, and manufacturing activities.

To support these objectives, Shasta County has established three primary policies for implementation. These policies emphasize the reuse and revitalization of existing development and full use of existing infrastructure for new business opportunities. To attract business to Shasta County, a number of incentive programs are employed, including community development block grants, economic assistance through a county redevelopment agency, and business development and retention assistance through an economic development corporation. Additionally, a 50-square-mile State-defined enterprise zone (one of only 39 in California) has been designated in portions of Redding, Shasta Lake, Anderson, and unincorporated Shasta County. Enterprise zones are generally designated in locations characterized by high poverty rates. Businesses locating within these areas may receive State-supported incentives such as sales and use tax credits, hiring assistance tax credits, and special business expense deductions (Shasta County 2004).

Tehama County

In the *Tehama County General Plan*, updated in 2009 (Tehama County 2009), Tehama County set out three "fundamental concepts" that relate to population growth and demographic shifts: (1) accommodating growth, but not limiting growth or accepting uncontrolled growth; (2) locating major growth along the Interstate 5 transportation corridor; and (3) organizing growth according to a range of community types. These concepts emphasize where Tehama County expects to locate new growth and how they plan to accommodate it. Specifically, the Interstate 5 corridor plays a significant role for the placement of new development, and Tehama County attempts to provide a range of housing types for the diversity of needs created within the community. This emphasis on housing diversity may become more crucial as aging residents' housing preferences change.

The following housing-related goals in the general plan are relevant to the project:

- **Goal HE-3: Adequate Sites** – Ensure the provision of adequate sites and facilities to support future housing needs.

- **Goal HE-5: Housing Conservation** – Work to improve, maintain and conserve the County's existing housing stock.

- **Goal HE-6: Addressing Constraints** – Address and wherever possible remove, governmental constraints to the maintenance, improvement, or development of housing to meet the needs of County residents.

- **Goal HE-7: Fair Housing/Equal Opportunity** – Promote equal housing opportunities for all persons without discrimination regardless of age, race, sex, marital status, ethnic background, household composition, sources of income, or other arbitrary factors.

Relevant economic development–related goals contained in the draft general plan are as follows:

- **Goal ED-3** – Expand the economic base while maintaining a healthy and diverse local economy that meets the present and future employment, shopping, recreational, public safety, and service needs of Tehama County residents.

- **Goal ED-4** – Work toward providing adequate infrastructure to support commercial, industrial, and recreational development within Tehama County including clean-up of contaminated industrial sites.

- **Goal ED-7:** Protect and enhance environmentally sensitive lands and natural resources while, at the same time, promoting business expansion, retention, and recruitment.

Shasta and Tehama counties function as the primary agencies responsible for implementing policies and programs aimed at addressing employment and labor force issues within the project's primary study area.

16.3 Environmental Consequences and Mitigation Measures

Based on the review of the affected environment provided in Section 16.1 of this chapter, this section describes the potential environmental consequences resulting from each of the proposed alternatives. Direct, indirect, and cumulative effects of the alternatives are discussed below. When potential environmental consequences are identified, specific mitigation measures to offset the potential effects of the alternatives are presented. Potential effects and mitigation measures address topics related to population and housing, employment and labor force, business and industry, and government and finance.

16.3.1 Methods and Assumptions

Population, Housing, and Demographics

The evaluation and discussion of the potential impacts of the project alternatives on population, demographic, and housing characteristics was based on a review

of published material pertaining to the primary and extended study areas. California Department of Finance population and demographics databases and projections, U.S. Census Bureau population and demographics data, the general plans of jurisdictions within the study areas, and other similar source documents were reviewed.

Population effects were evaluated based on changes in the total number of temporary and/or permanent residents resulting from construction and operations activities that would be completed as a part of project implementation. Housing effects were assessed based on estimated short- and long-term housing needs resulting from population changes expected as a result of the project's construction and operational activities. Effects of the project on local and regional demographic characteristics were assessed quantitatively, when available data allowed. When quantitative analysis of effects was not possible at this broader geographic level, qualitative effects were identified based on the projected makeup (e.g., ethnicity, economic class) of any population changes expected to result from project implementation.

Employment and Labor Force

The determination of potential impacts on employment and the labor force was based on a review of relevant information related to current conditions. Existing documents such as the California Employment Development Department's employment and labor force databases, the Economic Development and Housing elements of the *Shasta County General Plan* (2004), and the *Tehama County General Plan* (2009) were reviewed, along with estimates of employment (temporary and permanent jobs created) for each proposed alternative.

To quantify the potential job creation resulting from each proposed alternative, IMPLAN (IMpact analysis for PLANning) modeling was completed by economists at Reclamation. Developed from the analytical work conducted by Wassily Leontief in the late 1930s, IMPLAN modeling uses a branch of economics known as Input/Output analysis. Input/Output models are essentially accounting tables that trace the linkages of interindustry purchases and sales within a given region, and within a given year. The Input/Output model yields "multipliers" that are used to calculate the total direct, indirect, and induced effects on jobs, income, and output generated per dollar of spending on various types of goods and services in the local economic study area. IMPLAN was originally developed by the U.S. Forest Service and is now maintained and marketed by the Minnesota IMPLAN Group, Inc.

Several assumptions were necessary to complete IMPLAN modeling of the project. The following assumptions were used:

- IMPLAN modeling was completed for CP1 (which involves raising Shasta Dam by 6.5 feet); CP2 (which involves raising the dam by 12.5

feet); and CP3, CP4, and CP5 (all of which involve raising the dam by 18.5 feet).

- Construction periods of approximately 36 months, 48 months, and 60 months, respectively, were assumed under CP1, CP2, and CP3, CP4, and CP5.

- The "local economic study area" was defined as the four-county region of Shasta, Siskiyou, Tehama, and Trinity counties.

- A total labor force of 350 construction workers would be needed for CP4, and a similar level for the other four alternatives in proportion to the required construction activities.

- All 350 construction workers would be drawn directly from the local economic area. (High unemployment in the primary study area and the availability of necessary worker skill sets supports this assumption.)

In addition to IMPLAN modeling, the) was used to determine the effects of the five dam raise alternatives on CVP agricultural users. The Central Valley Production Model (CVPM) is a regional economic model of irrigated agricultural production that simulates the decisions of agricultural producers (farmers) in the Central Valley of California. The model included 22 crop production regions in the Central Valley and 20 categories of crops. Based on the changes in water availability expected with each alternative, the CVPM predicts cropping patterns, land use, and water use in the Central Valley. These predictions are then used to calculate expected changes in net income resulting from each alternative during dry, wet, and average water years. Although the model's income-related projections were generally used to determine effects on business and industrial activity, the overall change in business net income (or profits) is a good indicator for potential changes in employment opportunities in affected sectors.

Business and Industry

The discussion of potential impacts on business and industry is based on a review of relevant information on current conditions, specifically existing documents such as California Employment Development Department documents, the Economic Development Element of the *Shasta County General Plan* (2004) and the *Tehama County General Plan* (2009), and estimates of business and industry effects for each action alternative.

To quantify the potential effect on job creation and personal incomes resulting from each alternative, IMPLAN modeling was completed by Reclamation economists. A description of IMPLAN modeling, generally, and the specific assumptions used related to the project are provided in the previous section.

Government and Finance

The determination and discussion of potential impacts on government and finance was based on a review of relevant information on current conditions, specifically documents such as the Economic Development Element of the *Shasta County General Plan* (2004) and the *Tehama County General Plan* (2009), and estimates of local government and finance effects for each dam-raise alternative.

Because no quantitative analysis of the effect of the action alternatives on local government and finance has yet been completed, this analysis depends heavily on a qualitative discussion of potential impacts. Areas of potential impacts were identified by comparing existing conditions and probable future conditions. In many cases, the estimates completed as part of the IMPLAN and CVPM modeling served as the basis for impact estimates. These two models determine expected trends in employment, personal incomes, business incomes, agricultural production, and other data types to quantifiably estimate the impacts of the proposed alternatives. Because these local characteristics directly influence activities at the local level, they represent critical considerations in the analysis and conclusions presented in this section.

16.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on socioeconomics, population, and housing would be significant if project implementation would do any of the following:

- Induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure)

- Displace substantial numbers of people or housing, necessitating the construction of replacement housing elsewhere

- Produce a substantial burden on the existing housing stock within the local community because of an increased housing demand created by nonlocal project employees

- Require sizeable numbers of new workers in a particular industrial sector from outside the local area during construction or operation for effective implementation

- Substantially increase the risk of housing or other property damage caused by flooding

- Cause a substantial decrease in the number of opportunities for temporary or long-term direct employment within the primary study area or the extended study area (within Shasta County, Tehama County, or nearby cities and towns, specifically Redding, Anderson, Shasta Lake, and Red Bluff)

- Compete with established industries for workers within the labor force or associated resources to the extent that there would be a shortage of workers available to related businesses

- Cause a substantial decrease in the number of opportunities for temporary or long-term increases in personal and/or disposable incomes within the primary or extended study area (within Shasta County, Tehama County, or nearby cities and towns, specifically Redding, Anderson, Shasta Lake, and Red Bluff)

- Considerably decrease the sales and/or incomes of businesses in the primary or extended study areas

Significance statements are relative to both existing conditions (2005) and future conditions (2030) unless stated otherwise.

16.3.3 Topics Eliminated from Further Discussion

In contrast to the primary study area and the lower Sacramento River and Delta portion of the extended study area, additional flood control capacity provided by CP1–CP5 is not expected to substantially affect the CVP and SWP service areas beyond the lower Sacramento River and Delta. Dam operations (i.e., storage and release scenarios) in the CVP and SWP service areas are expected to continue according to management plans similar to those currently in place. Therefore, no flood-related impact on population and housing would occur in the CVP and SWP service areas. This topic is not discussed further under CP1–CP5.

16.3.4 Direct and Indirect Effects

Similar to the approach used in Section 16.1, “Affected Environment,” the following discussion of environmental consequences in the primary study area

does not separate Shasta Lake and vicinity from the upper Sacramento River (Shasta Dam to Red Bluff) because of the regional interdependence of socioeconomic characteristics. Instead, environmental consequences are discussed for the entire primary study area and the two counties that encompass it, Shasta and Tehama counties.

No-Action Alternative

Under the No-Action Alternative, no additional Federal action would be taken to address water reliability issues or increase anadromous fish survival. Therefore, Shasta Dam and Shasta Lake would continue to operate as they currently do, with some future modifications (currently not known) expected into the future. With the No-Action Alternative, water reliability is expected to become an increasing issue as demand for water increases to meet the needs of California's growing population. Over time, water conservation and reuse efforts would increase and water provision is expected to shift from such areas as agricultural production to urban uses. Environmental restoration, flood control, and hydropower generation are expected to continue similar to existing conditions. Like water demand, electricity demand in California is expected to increase substantially in the future. This increased demand is expected to create localized shortages in energy availability over time.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) Under the No-Action Alternative, population, demographic, and housing conditions are expected to continue following current growth trends described in Section 16.1, "Affected Environment"; the projected employment and labor force characteristics summarized in Section 16.1 would also continue. The relatively large number of new construction-related jobs that would be created by all five action alternatives would not be created. Therefore, this alternative would have no impact on population and housing or on employment and the labor force.

In addition, the business and industrial activities of the primary study area would continue as summarized in Section 16.1. The relatively large and temporary increase in business activity that would occur during construction would not occur. Therefore, the No-Action Alternative would have no impact on business and industrial activity.

Furthermore, the local government and finance conditions and trends projected in Section 16.1 would continue because new facilities would not be constructed and existing facilities would not be altered, expanded, or demolished. The positive fiscal effects associated with the increase in sales and income tax revenue from construction-related spending would not occur. Therefore, the No-Action Alternative would have no impact on government and finance.

Lower Sacramento River and Delta Under the No-Action Alternative, the projected population, demographic, and housing conditions and development

conditions described in Section 16.1, "Affected Environment," would remain unchanged. There would be no impact on population, demographics, or housing.

In addition, the local government and finance conditions described in Section 16.1 would continue because no new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. The positive fiscal effects associated with the increase in sales and income tax revenue resulting from construction-related spending would not occur. Therefore, the No-Action Alternative would have no impact on government and finance.

The impacts of the No-Action Alternative on employment and the labor force and on business and industrial activity in the lower Sacramento River and Delta area are described below.

Impact Socio-1 (No-Action): Potential for Reduced Employment Opportunities for Lower Sacramento River and Delta Area Residents The No-Action Alternative has the potential to result in periodic water and power supply disruptions from increasing demand on the existing supply caused by population growth. These disruptions could result in adverse economic effects on the lower Sacramento River and Delta portion of the extended study area. This impact would be potentially significant.

Under the No-Action Alternative, the risk of CVP and SWP water supply disruptions and Western Area Power Administration and DWR power supply disruptions in the lower Sacramento River and Delta area would be higher than the risk of such disruptions in the long term under each of the five action alternatives. Although the likelihood of such disruptions is difficult to predict, the CalSim-II modeling performed to simulate future water and power supply conditions under 2030 No-Action Alternative conditions, and 2030 conditions under each of the action alternatives, indicates that all five action alternatives would enhance CVP and SWP water and power supply conditions relative to 2030 No-Action Alternative conditions. (Please note that CalSim modeling of power supply conditions for the 2030 No-Action Alternative is not currently available.)

An increase in the risk of water and power supply disruptions could in turn increase the likelihood that temporary and adverse socioeconomic effects would take place during related reductions in economic activity, including reductions in employment opportunities. Adverse economic effects during times of drought, blackouts, or other types of water or power supply disruptions could also include delays in hiring employees or layoffs if businesses experience water and/or power rate increases as a result of water and power purveyors seeking other, more expensive replacement sources. This impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Socio-2 (No-Action): Potential for Temporary Disruptions in Business and Industrial Activity in the Lower Sacramento River and Delta Area If water

or power supply disruptions were to occur, they could cause temporary reductions in business and industrial activity, especially where water- and power-intensive industries and businesses are found. This impact would be potentially significant.

As discussed under Impact Socio-1 (No-Action) above, an increase in the risk of water or power supply disruptions could occur in the lower Sacramento River and Delta portion of the extended study area under the No-Action Alternative. If such disruptions were to occur, they could cause temporary reductions in business and industrial activity, especially in areas where water- and power-intensive industries and businesses are found. Because the No-Action Alternative could have adverse effects on businesses and industrial activity in the case of drought, blackouts, or other types of water or power supply disruptions, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas Under the No-Action Alternative, the projected population, demographic, and housing conditions and development conditions described in Section 16.1, "Affected Environment," would remain unchanged. No impact would occur. Therefore, potential effects of the No-Action Alternative on population, demographics, or housing in this geographic region are not discussed further.

In addition, the local government and finance conditions in the CVP and SWP service areas described in Section 16.1 would continue. The positive fiscal effects associated with the increase in sales and income tax revenue resulting from construction-related spending would not occur. Therefore, no impact would occur under the No-Action Alternative. Potential effects of this alternative on government and finance in this geographic region are not discussed further.

The impacts of the No-Action Alternative on employment and the labor force and on business and industrial activity in the CVP and SWP service areas are described below.

Impact Socio-3 (No-Action): Potential for Reduced Employment Opportunities for Residents Within the CVP and SWP Service Areas The No-Action Alternative has the potential to result in periodic water and power supply disruptions from increasing demand on the existing supply caused by population growth. These disruptions could result in variability in economic activity, which could reduce or delay employment opportunities in the CVP and SWP service areas. This impact would be potentially significant.

Under the No-Action Alternative, the risk of CVP and SWP water supply disruptions and Western Area Power Administration and DWR power supply disruptions would be higher than the risk of such disruptions in the long term under each of the five proposed action alternatives. The likelihood of such

disruptions is difficult to predict; however, the CalSim-II modeling performed to simulate future water and power supply conditions under 2030 No-Action Alternative conditions, and 2030 conditions under each of the action alternatives, indicates that all five action alternatives would enhance CVP and SWP water and power supply conditions relative to 2030 No-Action Alternative conditions. (Please note that CalSim modeling of power supply conditions for the 2030 No-Action Alternative is not currently available.)

An increase in the risk of water and power supply disruptions, including drought, blackouts, or other types of water or power disruptions, could in turn increase the likelihood of temporary and adverse socioeconomic effects. Adverse economic effects during times of these disruptions could reduce economic activity and also result in delays in hiring employees or layoffs if businesses were to experience water and/or power rate increases as a result of water and power purveyors seeking other, more expensive replacement sources. This impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Socio-4 (No-Action): Potential for Temporary Disruptions in Business and Industrial Activity in the CVP and SWP Service Areas If water or power supply disruptions were to occur, they could cause temporary reductions in business and industrial activity, especially where water- and power-intensive industries and businesses are found. This impact would be potentially significant.

As discussed under Impact Socio-3 (No-Action) above, an increase in the risk of water or power supply disruptions could occur in the CVP and SWP service areas under the No-Action Alternative. If such disruptions were to occur, they could cause temporary reductions in business and industrial activity, especially in areas where water- and power-intensive industries and businesses are found. Because the No-Action Alternative could have adverse effects on businesses and industrial activity in the case of drought, blackouts, or other types of water or power supply disruptions, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 would increase the full pool capacity of Shasta Lake to 4,810 thousand acre-feet (TAF) and increase the surface area of the pool to 30,710 acres. It is expected that implementing CP1 would result in the replacement or modification of eight bridges and relocation of approximately 45 existing structures. The total construction cost associated with CP1 would be approximately $827 million and the annual operational cost would be $42.6 million. This alternative would generate approximately $27.0 million in annual water supply reliability benefits and $15.1 million average annual equivalent anadromous fish restoration benefits. CP1 would increase hydropower

generation by approximately 42 gigawatt-hours (GWh) per year, equivalent to approximately $2.4 million in hydropower benefits.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP1): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 450 new direct jobs would be created as a result of construction activities associated with CP1. All 450 construction workers are expected to come from the local labor force; therefore, a temporary population increase is not expected. This impact would be less than significant.

Approximately 450 new construction workers would be needed over the 36-month construction period to support the construction activities related to the 6.5-foot raise of Shasta Dam. Given the availability, experience, and expertise of the existing labor force within the primary study area, it is expected that the necessary workers would be available in the surrounding two-county area (Shasta and Tehama counties). Therefore, no construction workers are expected to be sourced from outside the primary study area, and no employees (or very few) would need to relocate to the project area during the construction period. Even if a relatively small number of workers were to come from outside the local area, sufficient housing capacity (e.g., rental housing, motel, and apartment vacancies) exists in the area. Thus, effects on population and housing in the primary and extended study areas are not expected; if they were to occur, they would be very minor. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP1): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities Construction activities associated with CP1 are assumed to generate approximately 450 new construction jobs, 580 indirect jobs in various construction-related support industries, and 790 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These new jobs are expected to provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

Concrete workers, workers with large-scale construction experience, general laborers, and others would be drawn from the existing local construction industry. These jobs represent a relatively small increase (less than 0.6 percent) in the total labor force in the two counties of the primary study area, but would represent a substantial increase in employment for many of the cities surrounding the project site, where employment has consistently been below the statewide average (EDD 2011).

Although the increase in employment represents a small percentage increase for the two-county area, the employment opportunities created by CP1 represent a substantial contribution in counties that have consistently registered high unemployment rates (EDD 2011). Both Shasta and Tehama counties were characterized by unemployment rates around 7 percent between 2002 and 2005. Similarly, since 2000, the cities of Anderson, Shasta Lake, and Red Bluff have all experienced unemployment rates 2 percentage points or more above the statewide average (EDD 2011).

As stated above, IMPLAN modeling calculates "direct" employment generated by individual alternatives as well as "indirect and induced" positions that are created by construction-related and operational activities. Indirect employment may be to support hiring in businesses that provide materials to the construction effort; in service-related industries that provide food, beverages, and other goods to construction workers; or in more technical industries, such as consulting firms and other businesses. Induced employment is jobs that are created in the region due to increased household spending and not limited to construction-related activities.

In addition to the 450 direct construction-related jobs to be created from CP1, an additional 580 indirect jobs are expected to be created from construction support industries, and 790 induced jobs from increased household spending near the project area. The generation of 1,820 new positions (direct, indirect, and induced) approximately represents a 1.5 percent increase in the total 2004 labor force of the four counties of the local economic study area used in the IMPLAN modeling (Shasta, Tehama, Trinity, and Siskiyou), which totaled approximately 123,000 employees. A 1.5 percent increase in employment represents a substantial increase in total employment, especially for an area experiencing the recent unemployment rates observed in the primary study area.

Because CP1 would create direct, indirect, and induced jobs in an area with high unemployment rates, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP1): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 450 new construction jobs resulting from CP1, the potential exists for workers from other industries to move to jobs related to construction at Shasta Dam. Given the size of the construction industry in the primary study area, and the high unemployment rate in the area, this impact would be less than significant.

As the 450 new positions created under CP1 are filled, the potential exists for the positions to be filled by individuals currently working in related industries within the local community. This transfer of workers from related industries to the Shasta project could create a labor shortage in the related industry, if particularly skilled workers are required. In 2004, Shasta County registered

4,500 employees in the construction industry, while construction industry workers in Tehama County equaled only 650 individuals, for a total of 5,150 construction workers in the area (EDD 2011). Given total employment levels and current unemployment trends in the primary study area, the 450 new construction-related jobs are not expected to substantially affect the local labor force. If a high number of workers were to be sourced from Tehama County, a limited effect could be observed because of the small number of workers in the construction industry in that county. Overall, however, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP1): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Based on calculations completed as a part of Reclamation's IMPLAN socioeconomic model process, it is estimated that more than $126.1 million in personal income would be directly paid to employees in the primary study area each year of construction under CP1. This amount of personal income is a more than 1.6 percent increase in annual income in the local economic study area. In addition, more than $57.4 million is expected to be generated in various construction-related and other industries in the primary study area each year of construction under CP1. This impact would be beneficial.

In 2004, total personal income in the four counties of the local economic study area was in excess of $7.6 billion. With more than $4.8 billion in personal income that year, Shasta County contributed more than half of this total. Based on the results of modeling performed using Reclamation's IMPLAN model, an estimated $126.1 million would be directly paid each year to the approximately 450 construction workers required to complete the job during the proposed 36-month construction period for CP1. Based on the IMPLAN estimate, the increase in annual personal incomes expected from CP1 represents an increase of approximately 1.6 percent. The positions expected from implementation are anticipated to be union positions and would be paid according to union wage and benefit standards.

Based on the generation of 1,370 indirect and induced jobs resulting from implementation of CP1, it is estimated that $57.4 million in personal income would be available for residents of the local economic study area each year during the proposed 36-month construction period. This personal income would be generated in industries that would support the construction efforts at Shasta Dam.

Taken together, it is expected that direct, indirect, and induced personal income resulting from CP1 would exceed $183.6 million per year of construction activities within the local economic study area (used in IMPLAN modeling). The $183.6 million in personal income generated represents approximately 2.4 percent of all annual personal income in the local economic study area in 2004.

Increases in personal income projected for the local economic study area are expected to be most prominent in Siskiyou, Tehama, and Trinity counties, where total personal income recorded in 2004 was 25 percent of that registered in Shasta County. In general terms, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP1): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP1 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 36-month construction period. This impact would be beneficial.

A large amount of construction material (e.g., concrete, rock) would be needed to raise Shasta Dam by 6.5 feet, as prescribed in CP1. Of this material, it is expected that most would be sourced from businesses within the primary study area. As a result of the large quantity of purchases expected, local businesses would experience temporary increases in sales and profits over the 36-month construction period. Increased sales and profits could be reinvested into existing businesses, invested in new ventures or diversification, translated into increased salaries and wages for employees, or used in other ways. The exact scale of the increase in business sales and profits has not yet been calculated, but it is expected that this amount would be substantial. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP1): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP1 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) during the construction period. This additional income, in combination with the construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP1 would likely also result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases has not yet been calculated; however, this impact would be beneficial.

Based on the results of modeling performed using Reclamation's IMPLAN model, implementation of CP1 is expected to generate more than $550.7 million in total personal income, with approximately $378.4 million in direct income and $172.3 million in indirect and induced income during the proposed 36-month construction period. In addition to this increase in personal incomes, most of the construction materials would be purchased within the primary study area, generating a substantial amount of revenue and profits for local businesses.

In combination, increased personal incomes and construction-related spending are expected to substantially increase the total sales tax revenues of local jurisdictions within the primary study area. Larger amounts of local sales tax revenue could then be used to establish new programs and initiatives or bolster existing ones through additional funding. New and improved programs and initiatives would provide benefits to local residents.

As a result of the increased employment and personal incomes anticipated from implementation of CP1, it is expected that a temporary increase in State sales and income tax would likely occur. During the construction period, more than $550.7 million in personal income is expected to be generated by direct, indirect, and induced employment produced by the project. The increase in personal income would increase spending at local businesses within the primary study area, and this additional spending would result in sizeable State sales tax revenues. This increased revenue source would likely return to the primary study area via statewide programs and policies.

For the reasons described above, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP1): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP1, the overall risk of flooding below Shasta Dam and its related consequences to the primary study area are expected to be reduced. Although heavy-rain events would continue to occur in the region and locally, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, there would be less damage to existing structures and a smaller loss of potential future development; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

In Reclamation's *Initial Alternatives Information Report* (Reclamation 2004), flood control was identified as a secondary objective of the project. Increased flood control is to be emphasized when the two primary objectives of the project, increased fish survival and increased water supply reliability, can be met. Periodic flood events in the Sacramento Valley frequently cause substantial damage to properties adjacent to the valley's many waterways. Currently, Shasta Dam provides substantial protection from such flooding damage for downstream residents.

CP1 would increase the storage capacity of Shasta Lake by 256,000 acre-feet. This added capacity would provide greater flexibility in Reclamation's ability to use the reservoir for flood control purposes, thereby increasing the threshold at which seasonal heavy-rain events produce flood conditions downstream from the dam. The benefits of this increase in capacity and related flood control options would be most evident along the upper Sacramento River within the

primary study area. Structures and inhabitants in this floodplain experience the most direct effects from storage releases during flood events. CP1 would reduce the frequency, magnitude, and duration of future flood events that have affected structures and their residents in this part of the primary study area in the past.

The loss of jobs and adverse effects on economic well-being and livelihoods is an often-overlooked consequence of catastrophic flood events. Avoiding a larger number of these events, and possibly decreasing the magnitude and duration of flooding under certain high-flow events, is expected to reduce the overall economic hardships faced by residents of the primary study area.

Structures and businesses located on the river and inhabitants of the floodplain experience the most direct effects from flood releases downstream. However, flood events could also affect those who do not live on the river or in the floodplain but work downstream from the dam at businesses subject to flood damage. The reduced risk of flood events associated with CP1 is expected to also reduce the business and personal income losses resulting from substantial damage to structures and businesses located adjacent to downstream waterways in the primary study area.

Implementation of CP1 would reduce damage to structures, loss of business and personal income, loss of jobs, and other adverse effects on economic well-being in the primary study area. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP1): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, it is expected that implementation of CP1 would create at least two new maintenance-related positions for the Shasta Dam facilities. These two positions are expected to be permanent and would continue once the 36-month construction period is complete. This impact would be beneficial.

Reclamation estimates that with the 6.5-foot increase of Shasta Dam proposed in CP1, at least two new permanent maintenance positions would be required to ensure efficient operation of dam facilities. These two positions are expected to be union positions, and would consequently provide union-level wages and benefits. Both positions would be filled after completion of the construction activities associated with CP1 and would continue for the foreseeable future. This impact, though small, would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP1): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta
Construction activities associated with CP1 have the potential to result in a temporary increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of

construction materials sourced outside of the primary study area, indirect increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be beneficial.

As a result of construction activities that would be completed during implementation of CP1, temporary increases in indirect employment would be expected in the lower Sacramento River and Delta portion of the extended study area. It is expected that a small amount of the construction materials necessary for CP1 are expected to be obtained from outside the primary study area. During the construction period, businesses that provide construction materials would be expected to increase employment to meet project demand. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP1): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area That Support the Construction Industry It is expected that a small amount of the construction materials used for CP1 are expected to be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the lower Sacramento River and Delta area during the construction period. This impact would be beneficial.

A significant amount of construction materials would be needed to raise Shasta Dam by 6.5 feet, as prescribed in CP1. Of these materials, it is expected that a small amount would be purchased from construction-related businesses in the extended study area, including the lower Sacramento River and Delta area. These purchases may include raw or refined materials, infrastructure-related products, and/or equipment required for the construction process. As a result of the purchases expected, businesses in the lower Sacramento River and Delta portion of the extended study area are expected to experience a temporary increase in sales and profits during the construction period. Similar to businesses within the primary study area, increased sales and profits could be reinvested into the existing businesses, invested in new ventures or diversification, translated into increased salaries and wages for employees, or used in other ways. The exact scale of the increase in business sales and profits within the lower Sacramento River and Delta area has not yet been calculated, but it is assumed that this amount would be substantial. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP1): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases In addition to local tax revenues, CP1 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

As a result of the increased employment and personal incomes anticipated as a part of implementation of CP1, it is expected that a short-term increase in State sales and income tax revenues would also occur. In the construction period, more than $550.7 million in personal income would be generated by direct, indirect, and induced employment produced by the project. This large amount of income would direct substantial income tax revenues to the State via State income tax requirements. These additional revenues would contribute substantially to the State budget and would be distributed to jurisdictions within the lower Sacramento River and Delta portion of the extended study area via statewide programs and policies. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP1): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP1, the overall risk of flooding and its related consequences below Shasta Dam is expected to be reduced. Although heavy-rain events would continue to occur in the region, CP1 is intended to provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would be expected; this, in turn, would reduce salary and wage losses for residents in and near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

Residents of the lower Sacramento River and Delta portion of the extended study area would benefit from the additional flexibility and flood control operations during flood events that would occur as a result of CP1. With the additional capacity provided by this alternative, the effects of large rain events would be reduced as a result of the improved management of systemwide flood control operations. Hydroelectric facilities within the lower Sacramento River and Delta area would likely experience flood events of somewhat less duration and magnitude, thus reducing the potential effects on vulnerable houses and property within the floodplain.

The loss of jobs and adverse effects on economic well-being and livelihoods is an often-overlooked consequence of catastrophic flood events. Avoiding a larger number of these events, and possibly decreasing the magnitude and duration of floods under certain high-flow events, is expected to reduce the overall economic hardships faced by residents of the lower Sacramento River and Delta areas. The effects of heavy-rain events would be better managed and the risk of flood-related effects could be reduced as far downstream as Sacramento.

In addition, fewer flooding events would result in less damage to businesses located adjacent to waterways during some flood events. This reduction in damage would reduce the amount of time employees would be without pay

because of flood conditions and damage. This reduction in flood damage would reduce residents' salary and wage losses from these catastrophic events.

Implementation of CP1 would reduce damage to structures, loss of business and personal income, loss of jobs, and other adverse effects on economic well-being in the lower Sacramento River and Delta areas. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP1): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas That Support the Construction Industry A small amount of the construction materials used during construction under CP1 are expected to be purchased within the extended study area, including the CVP and SWP service areas. These purchases are predicted to increase sales and profits of businesses within the CVP and SWP service areas during the construction period of CP1. This impact would be beneficial.

A small amount of the construction materials used during construction under CP1 are expected to be purchased from construction-related businesses in the extended study area, including the CVP and SWP service areas. These purchases may include raw or refined materials, infrastructure-related products, and/or equipment required for the construction process. As a result of the large quantity of purchases expected, businesses in the CVP and SWP service areas are expected to experience a short-term increase in sales and profits over the construction period. The exact scale of the increase in business sales and profits within the CVP and SWP service areas has not yet been calculated, but it is assumed that this amount would be substantial. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP1): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas During Construction Implementation of CP1 may require temporarily reducing the reservoir level either throughout the construction period or at critical times. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

Construction activities implemented as part of CP1 would require adding large quantities of concrete to Shasta Dam. To complete this sizeable task, it may be necessary to reduce the reservoir's water table to accommodate construction. A reduced water table may be needed either for the duration of construction or at critical points in the construction process. Regardless of the approach needed, a reduced water table would limit the amount of water and/or hydropower that would be available from the dam for use in the CVP and SWP service areas. As

a result, there could be periods in which water or hydropower availability within the CVP and SWP system may be more limited, especially during dry periods.

To address potential temporary shortages in water or hydropower caused by reduced availability at Shasta Dam, replacement water or hydropower supplies would need to be sourced elsewhere to maintain current service needs. Depending on the conditions of the water or energy markets at the time of need, these replacement resources could be more expensive than water or hydropower obtained from Shasta Dam. The additional expense of obtaining water or hydropower resources could produce a minor negative effect on water and power customers if replacing these resources would be substantially more expensive. This impact would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5.

Impact Socio-15 (CP1): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases CP1 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

As a result of the increased employment and personal incomes anticipated as a part of implementation of CP1, it is expected that a short-term increase in State sales and income tax revenues would occur. During the construction period for CP1, more than $550.7 million in personal income would be generated by direct, indirect, and induced employment produced by the project. This large amount of income would direct substantial income tax revenues to the State via State income tax requirements. These additional revenues would contribute substantially to the State budget and would be distributed to jurisdictions within the CVP and SWP service areas via statewide programs and policies. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP1): Long-Term Increase in Agricultural Income and Jobs in the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on CVPM modeling, improved water availability and reliability expected to result from implementation of CP1 would substantially increase agricultural net income in the CVP and SWP service areas and increase the number of agricultural positions in these areas. This increase in production and jobs would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

Of the CVP and SWP's water users, agricultural users benefit the most from increased water availability and reliability because of more consistent irrigation opportunities throughout the year. Based on the outputs of CVPM modeling, CP1 would improve long-term water availability and reliability within the CVP

and SWP service areas via adding water storage capacity. Long-term improvements to the availability and reliability of water are expected to allow farmers within the CVP and SWP service areas to substantially increase agricultural production, especially in dry years. It was estimated that CP1 would increase the net agricultural income within the 22 CVPM regions by more than $3.3 million in an average year and up to $11.1 million during dry years. In wet years, net income is projected to decrease slightly ($400,000).

To support the increased agricultural production expected during the implementation of CP1, more agricultural workers would be needed. The CVPM does not estimate the number of additional agricultural positions that would be created as a result of improved irrigation, but the resulting increase in water reliability and availability has the potential to strengthen and extend the existing growing season in the CVP and SWP service areas. This would enable existing employees to work for a longer period in the fields, while also increasing the total workers needed during the growing season. These additional agricultural workers are expected to be distributed across the CVP and SWP service areas. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP1): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability
Implementation of CP1 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP1), this additional storage capacity would improve the long-term availability and reliability of water in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences, in the future. This impact would be beneficial.

In addition to improving agricultural production, implementation of CP1 would increase water availability and reliability for industrial and urban users within the CVP and SWP service areas. For these users, the additional 265,000 acre-feet of storage capacity proposed by CP1 is expected to substantially reduce the long-term risk of water and power shortages from periodic flow constraints. As a result, water and power users would likely experience fewer water and power shortages caused by reduced reservoir levels, such as those experienced in dry years. This reduction in water and power shortages, along with avoidance of the related loss of economic production, represents a substantial benefit for users in the CVP and SWP service areas. This benefit would be most pronounced for water- and power-intensive industries that are heavily dependent on consistent water and power availability. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP2 would increase the full pool capacity of Shasta Lake to 4,995 TAF and increase the surface area of the pool of the reservoir to 31,350 acres. It is expected that implementing CP2 would result in the replacement or modification of eight bridges and relocation of approximately 100 existing structures. The total construction cost associated with CP2 would be approximately $913 million and the annual operational cost would be $46.4 million. This alternative would generate approximately $25.0 million in annual water supply reliability benefits and $9.6 million average annual equivalent anadromous fish restoration benefits. CP2 would increase hydropower generation by approximately 68 GWh per year, equivalent to approximately $3.9 million in hydropower benefits.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP2): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 370 new direct jobs would be created as a result of construction activities associated with CP2. All 370 construction workers are expected to come from the local labor force; therefore, a short-term population increase is not expected. This impact would be less than significant.

This impact is similar to Impact Socio-1 (CP1). A 48-month construction period was considered here for CP2. As described above under Impact Socio-1 (CP1), a short-term population increase is not expected with implementation of CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP2): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities Construction activities associated with CP2 are assumed to generate approximately 370 new direct construction jobs, 480 indirect jobs in various construction-related support industries, and 650 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These new jobs are expected to provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

This impact is similar to Impact Socio-2 (CP1). Under CP2, approximately 370 new short-term, direct construction jobs would be created, in addition to 480 indirect jobs expected to be created in various construction-related support industries, and 650 induced jobs created because of increased household spending near the project area. Total direct, indirect, and induced employment under CP2 would be less than CP1; however, these positions would last

approximately 48 months under CP2, compared to 36 months under CP1. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP2): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 370 new construction jobs resulting from CP2, the potential exists for workers from other industries to move to jobs related to construction at Shasta Dam. Given the size of the construction industry in the primary study area, and the high unemployment rate in the area, this impact would be less than significant.

This impact would be similar to Impact Socio-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP2): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Based on calculations completed as a part of Reclamation's IMPLAN socioeconomic model process, it is estimated that more than $104.4 million in personal income would be directly paid to employees in the primary study area each year of the 48 month construction period under CP2. This amount of personal income is a more than 1.4 percent increase in annual income in the local economic study area. In addition, approximately $47.6 million in indirect and induced income is expected to be generated in various construction-related and other industries in the primary study area each year of construction under CP2. This impact would be beneficial.

This impact is similar to Impact Socio-4 (CP1). CP2 is estimated to generate $104.4 million in direct personal income each year of construction from the 370 direct construction-related jobs that would be created. This amount of personal income is roughly a 1.4 percent increase in annual income in the local economic study area. In addition, indirect and induced personal income totaling $47.6 million per year of construction is expected to be generated in various construction-related and other industries in the primary study area that would support construction under CP2.

Taken together, it is expected that direct, indirect, and induced personal income resulting from CP2 would be approximately $152.0 million per year of construction within the local economic study. Direct, indirect, and induced annual personal income under CP2 would be less than CP1; however, this income would be generated over 48 months under CP2 (for a total of $608.0 million), compared to 36 months under CP1 (for a total of $550.7 million). This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP2): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP2 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 48-month construction period. This impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-5 (CP1). Because of the longer project duration and larger dam raise proposed under CP2, short-term increases in sales and profits for businesses in the primary study area would be larger than those under CP1. The size of these increases has not yet been quantified, but it is expected that the additional time and materials required to implement CP2 would generate more sales and profits than CP1 for construction-related and service-oriented businesses. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP2): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP2 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) over the 48-month construction period. This additional income, in combination with the construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP2 would likely also result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases has not yet been calculated; however, this impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-6 (CP1). Because of the larger total personal income (direct, indirect, and induced) over the construction period expected to result from implementation of CP2, it is assumed that the short-term increase in local sales tax revenues generated by CP2 would be greater than that from CP1. Construction-related activities under CP2 are also expected to result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. These additional revenues would likely be cycled back to local government coffers through statewide programs and policies. The increases in State sales and income taxes are expected to be larger under CP2 than under CP1. All of these increases are expected to be more beneficial for the relevant local jurisdictions. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP2): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP2, the overall risk of flooding below Shasta Dam and its related consequences to the primary study area are expected to be reduced.

Although heavy-rain events would continue to occur in the region and locally, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, there would be less damage to existing structures and a smaller loss of potential future development; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-7 (CP1). CP2 would increase the total storage capacity of Shasta Lake by 443,000 acre-feet. CP2 would therefore provide approximately 187,000 acre-feet more storage capacity in the reservoir than CP1. This additional capacity provided with the 12.5-foot dam raise would increase the flood control capabilities compared to both existing conditions and CP1 by further reducing the risk of flooding downstream from Shasta Dam. The overall risk of flooding and its associated adverse effects on property, housing, and businesses downstream from Shasta Dam and residents throughout the primary study area would therefore be further reduced.

The increased storage capacity proposed as a part of CP2 would also reduce the risk of job loss from flooding and its related effects to a greater extent than the capacity increase proposed under CP1. The increased storage capacity would further reduce the risk of flood-level conditions downstream from the dam. Related effects from flooding on the economic livelihood of residents of the primary study area would similarly be reduced.

Fewer flooding events would occur and less damage would be inflicted on property adjacent to downstream waterways during some flood events. This reduction in flood damage would also reduce residents' salary and wage losses resulting from these catastrophic events.

For the reasons described above, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP2): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, it is expected that implementation of CP2 would create at least two new maintenance-related positions for the Shasta Dam facilities. These two positions are expected to be permanent and would continue once the 48-month construction period is complete. This impact would be beneficial.

This impact would be the same as Impact Socio-8 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP2): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta
Construction activities associated with CP2 have the potential to result in a short-term increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction material sourced outside of the primary study area, indirect increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-9 (CP1). A larger potential temporary increase in indirect employment in construction-related businesses of the lower Sacramento River and Delta area would be expected under CP2 than under CP1. Estimated total construction costs for CP2 are approximately 10.4 percent higher than costs for CP1. Therefore, it is expected more income would be allocated to indirect positions in construction-related businesses under CP2. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP2): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area That Support the Construction Industry It is expected that a small amount of the construction materials used for CP2 are expected to be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the lower Sacramento River and Delta area over the 48-month construction period of CP1. This impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-10 (CP1). Because of the longer project duration and larger dam raise proposed under CP2, short-term increases in sales and profits for construction-related businesses in the lower Sacramento River and Delta area are expected to be larger than those under CP1. The size of these increases has not yet been quantified, but because additional time and materials would be required, implementing CP2 would likely generate more sales and profits for construction-related and service-oriented businesses. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP2): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases In addition to local tax revenues, CP2 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-11 (CP1) because the construction period would be longer and more construction materials would be needed. The increased employment and personal incomes anticipated as a part of implementation of CP2 are expected to cause an increase in short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues would likely be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP2): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP2, the overall risk of flooding and its related consequences below Shasta Dam is expected to be reduced. Although heavy-rain events would continue to occur in the region, CP2 is intended to provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would be expected; this, in turn, would reduce salary and wage losses for residents in or near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-12 (CP1). CP2 would provide approximately 187,000 acre-feet more storage capacity in the reservoir than CP1. This additional capacity would increase the flood control capabilities beyond the existing capabilities at Shasta Dam and the capabilities proposed under CP1, and would further reduce the risk of flooding downstream from the dam. The overall risk of flooding and its associated adverse effects on property, housing, businesses, and residents of the lower Sacramento River and Delta area would be reduced with implementation of CP2. Flood risk reduction effects identified earlier for CP1 would apply to CP2, but the positive effects would be greater because of the direct relationship between the proposed dam heights, corresponding capacity of the reservoir, and associated increase in flood control operations and management flexibility.

Increased storage capacity proposed as a part of CP2 would also reduce the risk of job loss from flooding and its related effects in the lower Sacramento River and Delta area, when compared to CP1. A reduction in the risk of flood-level conditions downstream from the dam would thus strengthen the economic livelihood of downstream residents in the lower Sacramento River and Delta area.

Fewer flooding events would occur and less damage would be inflicted on businesses located adjacent to downstream waterways during some flood

events. This reduction in flood damage would reduce residents' salary and wage losses resulting from these catastrophic events.

For the reasons described above, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP2): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas That Support the Construction Industry A small amount of the construction materials used during construction under CP2 are expected to be purchased within the extended study area, including the CVP and SWP service areas. These purchases are predicted to increase sales and profits of businesses within the CVP and SWP service areas over the 48-month construction period of CP2. This impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-13 (CP1). Because of the longer project duration and larger dam raise proposed under CP2, short-term increases in sales and profits for construction-related businesses in the extended study area, including the CVP and SWP service areas, are expected to be larger than those for CP1. The size of these increases has not yet been quantified, but it is expected that the additional time and materials required to implement CP2 would generate more sales and profits for construction-related and service-oriented businesses. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP2): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas During Construction Implementation of CP2 may require temporarily reducing the reservoir level either throughout the 48-month project duration or at critical times. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

This impact is similar to Impact Socio-14 (CP1), except that the project construction period would be longer and reductions in reservoir levels could last longer under CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5.

Impact Socio-15 (CP2): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases In addition to local tax revenue, CP2 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the CVP and SWP service

areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-15 (CP1). Short-term increases in State sales and income taxes are expected to be larger under CP2 than under CP1. All of these increases are expected to be more beneficial for the relevant local jurisdictions. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP2): Long-Term Increase in Agricultural Income and Jobs in the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on CVPM modeling, improved water availability and reliability expected to result from implementation of CP2 would substantially increase agricultural net income in the CVP and SWP service areas and increase the number of agricultural positions in these areas. This increase in production and jobs would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

This impact is similar to Impact Socio-16 (CP1). Because of the increase in the availability and reliability of water associated with implementation of CP2, the long-term increase in indirect employment within the agricultural sector is expected to be larger than under CP1. Based on the outputs of CVPM modeling, CP2 is estimated to generate an additional $11.5 million in net income during dry years and $7.1 million in average years, when compared to existing conditions. In wet years, net income is projected to decrease slightly ($200,000). This overall increase in net income is expected to stimulate more employment opportunities in the agricultural sector to support the higher crop production that would likely be the result of additional irrigation deliveries under CP2 (compared to CP1). This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP2): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability Implementation of CP2 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP2), this additional storage capacity would improve the long-term availability and reliability of water in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences, in the future. This impact would be beneficial.

This impact would be the similar to Impact Socio-17 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

CP3 would increase the full pool capacity of Shasta Lake to 5,186 TAF and increase the surface area of the pool to 32,100 acres. It is expected that implementing CP3 would result in the replacement or modification of eight bridges and relocation of approximately 130 existing structures. The total construction cost associated with CP3 would be approximately $1,064 million and the annual operational cost would be $53.7 million. This alternative would generate approximately $26.7 million in annual water supply reliability benefits and $25.0 million average annual equivalent anadromous fish restoration benefits. CP3 would increase hydropower generation by approximately 96 GWh per year, equivalent to approximately $5.4 million in hydropower benefits.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP3): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 350 new direct jobs would be created as a result of construction activities associated with CP3. All 350 construction workers are expected to come from the local labor force; therefore, a short-term population increase is not expected. This impact would be less than significant.

This impact is similar to Impacts Socio-1 (CP1) and Socio-1 (CP2). CP3 would add 191,000 acre-feet of storage capacity beyond the capacity anticipated in CP2, for a total increase of 634,000 acre-feet. As with the other two dam raise alternatives, approximately 350 new construction workers would be needed to complete the 18.5-foot raise proposed in CP3. Approximately 60 months of work (compared to the 48 months proposed under CP2) would be required to complete the construction activities proposed under CP3. Workers for this effort would also come from the local labor pool. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP3): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities
Construction activities associated with CP3 are assumed to generate approximately 350 new direct construction jobs, 450 indirect jobs in various construction-related support industries, and 610 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These new jobs are expected to provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

This impact is similar to Impact Socio-2 (CP1) and Socio-2 (CP2). Under CP3, approximately 350 new short-term, direct construction jobs would be created, in addition to 450 indirect jobs expected to be created in various construction-related support industries, and 610 induced jobs created because of increased

household spending near the project area. Total direct, indirect, and induced employment under CP3 would be less than CP1 and CP2; however, these positions would last approximately 60 months under CP3, compared to 36 months under CP1 and 48 months under CP2. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP3): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 350 new construction jobs resulting from CP3, the potential exists for workers from other industries to move to jobs related to construction at Shasta Dam. Given the size of the construction industry in the primary study area, and the high unemployment rate in the area, this impact would be less than significant.

This impact would be similar to Impacts Socio-3 (CP1) and Socio-3 (CP2) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP3): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Based on calculations completed as a part of Reclamation's IMPLAN socioeconomic model process, it is estimated that more than $97.3 million in personal income would be directly paid to employees in the primary study area each year of the 60 month construction period under CP3. This amount of personal income is a more than 1.3 percent increase in income in the local economic study area. In addition, more than $44.3 million in indirect and induced income is expected to be generated in various construction-related and other industries in the primary study area each year of construction under CP3. This impact would be beneficial.

This impact is similar to Impacts Socio-4 (CP1) and Socio-4 (CP2). CP3 is estimated to generate $97.3 million in direct personal income each year of construction from the 350 direct construction-related jobs that would be created. This amount of personal income is roughly a 1.3 percent increase in annual income in the local economic study area. In addition, indirect and induced personal income totaling $44.3 million per year of construction is expected to be generated in various construction-related and other industries in the primary study area that would support construction under CP3.

Taken together, it is expected that direct, indirect, and induced personal income resulting from CP3 would be approximately $141.7 million per year of construction within the local economic study. Direct, indirect, and induced annual personal income under CP3 would be less than CP1 and CP2; however, this income would be generated over 60 months under CP2 (for a total of $708.4 million), compared to 36 months under CP1 (for a total of $550.7 million) and to 48 months under CP2 (for a total of $608.0 million). This impact

would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP3): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP3 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 60-month construction period. This impact would be beneficial.

This impact is similar to but more beneficial than Impacts Socio-5 (CP1) and Socio-5 (CP2). CP3 would require the largest dam height increase and therefore the greatest construction expenditures over the total construction period. As a result, CP3 is expected to generate more business sales and profits than CP1 and CP2 in construction-related and service-oriented businesses in the primary study area. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP3): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP3 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) over the 60-month construction period. This additional income, in combination with the construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP3 would likely also result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases has not yet been calculated: however, this impact would be beneficial.

This impact is similar to but more beneficial than Impacts Socio-6 (CP1) and Socio-6 (CP2). CP3 is estimated to generate more direct personal income than CP1 and CP2. This larger amount of personal income generated is expected to result in more local sales tax revenues in the primary study area than under the other two alternatives. Construction-related activities under CP3 are also expected to result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. These additional revenues would likely be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP3): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP3, the overall risk of flooding and its related consequences below Shasta Dam are expected to be reduced. Although heavy-rain events would continue to occur in the region and locally, the project is

intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, there would be less damage to existing structures and a smaller loss of potential future development; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact is similar to but more beneficial than Impacts Socio-7 (CP1) and Socio-7 (CP2). CP3 would create 634,000 acre-feet more storage capacity than current capacity, more than 40 percent more than would be provided by CP2. CP3 would therefore provide substantially more flood protection than either CP1 or CP2. As a result, CP3 would result in a greater reduction than CP1 and CP2 in the risk of damage to property and structures from flooding along the upper Sacramento River.

The increased storage capacity proposed as a part of CP3 would result in a larger decrease in the risk of job loss from flooding and its related effects than would occur under CP1 or CP2. CP3 would increase storage space in Shasta Lake and provide approximately 191,000 more acre-feet of storage than either of the two previous alternatives. The increased storage capacity would create a greater reduction in the risk of flood-level conditions downstream from the dam. Related effects from flooding on the economic livelihood of residents of the primary study area would similarly be reduced. In addition, the reduction in flood damage would reduce residents' salary and wage losses resulting from these catastrophic events.

For the reasons described above, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP3): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, it is expected that implementation of CP3 would create at least two new maintenance-related positions for the Shasta Dam facilities. These two positions are expected to be permanent and would continue once the 60-month construction period is complete. This impact would be beneficial.

This impact would be the same as Impacts Socio-8 (CP1) and Socio-8 (CP2) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP3): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta Construction activities associated with CP3 have the potential to result in a short-term increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction materials sourced outside of the primary study area, indirect

increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-9 (CP2). A larger potential temporary increase in indirect employment in construction-related businesses of the lower Sacramento River and Delta area would be expected under CP3. Estimated total construction costs for CP3 are approximately 16.5 percent higher than costs for CP2. Therefore, it is expected more income would be allocated to indirect positions in construction-related businesses would be expected under CP3. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP3): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area That Support the Construction Industry It is expected that a small amount of the construction materials used for CP3 are expected to be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the lower Sacramento River and Delta area over the 60-month construction period of CP3. This impact would be beneficial.

This impact is similar to but more beneficial than Impacts Socio-10 (CP1) and Socio-1 (CP2). Because of the longer project duration and greater construction expenditures associated with the larger dam raise proposed under CP3, short-term increases in sales and profits for construction-related businesses in the lower Sacramento River and Delta area are expected to be larger than those CP2. The size of these increases has not yet been quantified, but it is expected that because additional time and materials would be required, implementing CP3 would generate more sales and profits for construction-related and service-oriented businesses. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP3): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Relate Personal Income and Purchases In addition to local tax revenues, CP3 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact is similar to but more beneficial than Impacts Socio-11 (CP1) and Socio-11 (CP2) because the construction period would be longer and more construction materials would be needed. The increased employment and personal incomes anticipated as a part of implementation of CP3 are expected to cause an increase in short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues would

likely be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP3): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP3, the overall risk of flooding and its related consequences below Shasta Dam is expected to be reduced. Although heavy-rain events would continue to occur in the region, CP3 is intended to provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would be expected; this, in turn, would reduce salary and wage losses for residents in and near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-12 (CP2). CP3 would provide approximately 191,000 acre-feet more storage capacity in the reservoir than CP2. This additional capacity would increase the flood control capabilities beyond the existing capabilities at Shasta Dam and the capabilities proposed under CP2, and would further reduce the risk of flooding downstream from the dam. The overall risk of flooding and its associated adverse effects on property, housing, businesses, and residents of the lower Sacramento River and Delta area would be reduced with implementation of CP3. Flood risk reduction effects identified earlier for CP2 would apply to CP3, but the positive effects would be greater because of the direct relationship between the proposed dam heights, corresponding capacity of the reservoir, and associated increase in flood control operations and management flexibility.

Increased storage capacity proposed as a part of CP3 would also reduce the risk of job loss from flooding and its related effects in the lower Sacramento River and Delta, when compared to CP2. A reduction in the risk of flood-level conditions downstream from the dam would thus strengthen the economic livelihood of downstream residents in the lower Sacramento River and Delta portion of the extended study area. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP3): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas That Support the Construction Industry A small amount of the construction materials used during construction under CP3 are expected to be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the CVP and SWP service areas over the 60-month construction period of CP3. This impact would be beneficial.

This impact is similar to but more beneficial than Impacts Socio-13 (CP1) and Socio-13 (CP2) because the construction period would be longer and more construction materials would be needed. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP3): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas During Construction Implementation of CP3 may require temporarily reducing the reservoir level either throughout the 60-month construction period or at critical times. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

This impact is similar to Impacts Socio-14 (CP1) and Socio-14 (CP2), except that the project construction period would be longer. This impact would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5.

Impact Socio-15 (CP3): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases In addition to local tax revenue, CP3 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact is similar to but more beneficial than Impact Socio-15 (CP2). Short-term increases in State sales and income taxes are expected to be larger under CP3 than under CP2. All of these increases are expected to be more beneficial for the relevant local jurisdictions. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP3): Long-Term Increase in Agricultural Income and Jobs in the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on CVPM modeling, improved water availability and reliability expected to result from implementation of CP3 would substantially increase agricultural net income in the CVP and SWP service areas and increase the number of agricultural positions in these areas. This increase in production and jobs would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

This impact is similar to Impacts Socio-16 (CP1) and Socio-16 (CP2). Because of the increase in the availability and reliability of water associated with implementation of CP3, the long-term increase in indirect employment within

the agricultural sector is expected to be larger than under CP1 and CP2 (6.5-foot and 12.5-foot dam raise, respectively). Based on the outputs of CVPM modeling, CP3 is estimated to generate an additional $15.3 million in net income during dry years and $6.8 million in average years, when compared to existing conditions. In wet years, CP3 is expected to produce a $700,000 increase in net income. This increase is in contrast to the loss in net income projected for CP1 and CP2. The projected increase in net income under CP3 is expected to stimulate a greater number of employment opportunities in the agricultural sector than under CP1 and CP2, because this alternative would likely generate higher crop production. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP3): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability Implementation of CP3 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP3), this additional storage capacity would improve long-term water availability and reliability in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences, in the future. This impact would be beneficial.

This impact would be the similar to the other CPs and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 would increase the full pool capacity of Shasta Lake to 5,186 TAF and increase the surface area of the pool to 32,100 acres. It is expected that implementing CP4 would result in the replacement or modification of eight bridges and relocation of approximately 130 existing structures. The total construction cost associated with CP4 would be approximately $1,070 million and the annual operational cost would be $54.0 million. This alternative would generate approximately $27.0 million in annual water supply reliability benefits and $49.2 million average annual equivalent anadromous fish restoration benefits. CP4 would generate approximately 138 GWh per year, equivalent to approximately $7.6 million in hydropower benefits.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP4): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 350 new direct jobs would be created as a result of construction activities associated with CP4. All 350 construction workers are expected to come from the local labor force;

therefore, a short-term population increase is not expected. This impact would be less than significant.

This impact would be the same as Impact Socio-1 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP4): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities Construction activities associated with CP4 are assumed to generate approximately 350 new construction jobs, 450 indirect jobs in various construction-related support industries, and 610 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These new jobs are expected to provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

This impact would be the same as Impact Socio-2 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP4): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 350 new construction jobs resulting from CP4, the potential exists for workers from other industries to move to jobs related to construction at Shasta Dam. Given the size of the construction industry in the primary study area, and the high unemployment rate in the area, this impact would be less than significant.

This impact would be the same as Impact Socio-3 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP4): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Construction activities for CP4 would last 60 months, compared to 36 and 48 months for CP1 and CP2, respectively (but gravel augmentation would continue for 120 months). Based on calculations completed as a part of Reclamation's IMPLAN socioeconomic model process, it is estimated that more than $97.9 million in personal income would be directly paid to employees in the primary study area each year of construction. This amount of personal income is a more than 1.3 percent increase in income in the local economic study area. In addition, more than $44.5 million in indirect and induced income is expected to be generated in various construction-related and other industries in the primary study area each year of construction under CP4. This impact would be beneficial.

This impact would be very similar to Impact Socio-4 (CP3), varying only with relatively minor construction activities associated with downstream restoration,

and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP4): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP4 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 60-month construction period. This impact would be beneficial.

This impact would be very similar to Impact Socio-5 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP4): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP4 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) over the 60-month construction period. This additional income, in combination with the construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP4 would likely also result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases has not yet been calculated; however, this impact would be beneficial.

This impact would be very similar to Impact Socio-6 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP4): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP4, the overall risk of flooding and its related consequences below Shasta Dam are expected to be reduced. Although heavy-rain events would continue to occur in the region and locally, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, there would be less damage to existing structures and a smaller loss of potential future development; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be the same as Impact Socio-7 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP4): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, it is expected that implementation of CP4 would create at least two new

maintenance-related positions for the Shasta Dam facilities. These two positions are expected to be permanent and would continue once the 60-month construction period is complete. This impact would be beneficial.

This impact would be the same as Impact Socio-8 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP4): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta
Construction activities associated with CP4 have the potential to result in a short-term increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction material sourced outside of the primary study area, indirect increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be beneficial.

This impact would be very similar to Impact Socio-9 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP4): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area That Support the Construction Industry It is expected that a small amount of the construction materials used for CP4 are expected to be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the lower Sacramento River and Delta area over the 60-month construction period of CP4. This impact would be beneficial.

This impact would be very similar to Impact Socio-10 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP4): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases In addition to local tax revenues, CP4 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact would be very similar to Impact Socio-11 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP4): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP4, the overall risk of flooding and its related consequences below Shasta Dam is expected to be reduced. Although heavy-rain events would continue to occur in the region, CP4 is intended to provide

greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would be expected; this, in turn, would reduce salary and wage losses for residents in and near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be the same as Impact Socio-12 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP4): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Aras That Support the Construction Industry A small amount of the construction materials used during construction under CP4 are expected to be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the CVP and SWP service areas over the 60-month construction period of CP4. This impact would be beneficial.

This impact would be very similar to Impact Socio-13 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP4): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas During Construction Implementation of CP4 may require temporarily reducing the reservoir level either throughout the 60-month project duration or at critical times. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

This impact is similar to Impact Socio-14 (CP3), except that the project construction period would be longer. This impact would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5.

Impact Socio-15 (CP4): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases In addition to local tax revenue, CP4 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact would be very similar to Impact Socio-15 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP4): Long-Term Increase in Agricultural Income and Jobs within the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on CVPM modeling, improved water availability and reliability expected to result from implementation of CP4 would substantially increase agricultural net income in the CVP and SWP service areas. This increase in production would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

This impact would be the same as Impact Socio-16 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP4): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability Implementation of CP4 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP4), this additional storage capacity would improve long-term water availability and reliability in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences, in the future. This impact would be beneficial.

This impact would be the similar to the other CPs and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 would increase the full pool capacity of Shasta Lake to 5,186 TAF and increase the surface area of the pool to 32,100 acres. It is expected that implementing CP5 would result in the replacement or modification of eight bridges and relocation of approximately 130 existing structures. The total construction cost associated with CP5 would be approximately $1,073 million and the annual operational cost would be $54.1 million. This alternative would generate approximately $26.7 million in annual water supply reliability benefits and $25.0 million average annual equivalent anadromous fish restoration benefits. CP5 would generate approximately 96 GWh per year, equivalent to approximately $5.4 million in hydropower benefits.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP5): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 350 new direct jobs would be created as a result of construction activities associated with CP5.

All 350 construction workers are expected to come from the local labor force; therefore, a short-term population increase is not expected. This impact would be less than significant.

This impact would be the same as Impact Socio-1 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP5): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities Construction activities associated with CP5 are assumed to generate approximately 350 new direct construction jobs, 450 indirect jobs in various construction-related support industries, and 620 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These new jobs are expected to provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

This impact would be very similar to Impact Socio-2 (CP3), varying only with relatively minor construction activities associated with shoreline and tributary restoration, and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP5): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 350 new construction jobs resulting from CP5, the potential exists for workers from other industries to move to jobs related to construction at Shasta Dam. Given the size of the construction industry in the primary study area, and the high unemployment rate in the area, this impact would be less than significant.

This impact would be the same as Impact Socio-3 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP5): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Construction activities for CP5 would last 60 months, compared to 36 and 48 months for CP1 and CP2, respectively. (Gravel augmentation activities would last 120 months, however.) Based on calculations completed as a part of Reclamation's IMPLAN socioeconomic model process, it is estimated that more than $98.2 million in personal income would be directly paid to employees in the primary study area each year of construction. This amount of personal income is a more than 1.3 percent increase in income in the local economic study area. In addition, more than $44.7 million in indirect and induced income is expected to be generated in various construction-related and other industries in the primary study area each year of construction under CP5. This impact would be beneficial.

This impact would be very similar to Impact Socio-4 (CP3), varying only with relatively minor construction activities associated with downstream, shoreline, and tributary restoration, and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP5): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP5 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 60-month construction period. This impact would be beneficial.

This impact would be very similar to Impact Socio-5 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP5): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP5 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) over the 60-month construction period. This additional income, in combination with the construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP5 would likely also result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases has not yet been calculated; however, this impact would be beneficial.

This impact would be very similar to Impact Socio-6 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP5): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP5, the overall risk of flooding and its related consequences below Shasta Dam are expected to be reduced. Although heavy-rain events would continue to occur in the region and locally, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, there would be less damage to existing structures and a smaller loss of potential future development; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be the same as Impact Socio-7 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP5): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, it is expected that implementation of CP5 would create at least two new maintenance-related positions for the Shasta Dam facilities. These two positions are expected to be permanent and would continue once the 60-month construction period is complete. This impact would be beneficial.

This impact would be the same as Impact Socio-8 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP5): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta Construction activities associated with CP5 have the potential to result in a short-term increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction materials sourced outside of the primary study area, indirect increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be beneficial.

This impact would be very similar to Impact Socio-9 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP5): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area That Support the Construction Industry It is expected that a small amount of the construction materials used for CP5 are expected to be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the lower Sacramento River and Delta area over the 60-month construction period of CP5. This impact would be beneficial.

This impact would be very similar to Impact Socio-10 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP5): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases In addition to local tax revenues, CP5 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact would be very similar to Impact Socio-11 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP5): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area *As* a result of the

added reservoir capacity under CP5, the overall risk of flooding and its related consequences below Shasta Dam is expected to be reduced. Although heavy-rain events would continue to occur in the region, CP5 is intended to provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would be expected; this, in turn, would reduce salary and wage losses for residents in and near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be the same as Impact Socio-12 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP5): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas That Support the Construction Industry A small amount of the construction materials used during construction under CP5 are expected to be purchased within the extended study area, including the CVP and SWP service areas. These purchases are predicted to increase sales and profits of businesses within the CVP and SWP service areas over the 60-month construction period of CP5. This impact would be beneficial.

This impact would be very similar to Impact Socio-13 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP5): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas During Construction Implementation of CP5 may require temporarily reducing the reservoir level either throughout the 60-month project duration or at critical times. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

This impact would be the same as Impact Socio-14 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5.

Impact Socio-15 (CP5): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases In addition to local tax revenue, CP5 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local

government coffers through statewide programs and policies. This impact would be beneficial.

This impact would be very similar to Impact Socio-15 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP5): Long-Term Increase in Agricultural Income and Jobs in the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on CVPM modeling, improved water availability and reliability expected to result from implementation of CP5 would substantially increase agricultural net income in the CVP and SWP service areas. This increase in production would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

This impact would be the same as Impact Socio-16 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP5): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability Implementation of CP5 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP5), this additional storage capacity would improve long-term water availability and reliability in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences, in the future. This impact would be beneficial.

This impact would be the similar to the other CPs and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

16.3.5 Mitigation Measures

Table 16-1 presents a summary of mitigation measures for socioeconomics, population, and housing.

Table 16-1. Summary of Mitigation Measures for Socioeconomics, Population, and Housing

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5

Key:
B = beneficial
LOS = level of significance
LTS = less than significant
NA = not applicable
PS = potentially significant

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Socio-1 (CP1) through Socio-13 (CP1) and Impacts Socio-15 (CP1) through Socio-17 (CP1). Mitigation is provided below for the other impact of CP1.

Mitigation Measure Socio-14 (CP1): Secure Replacement Water or Hydropower During Project Construction To address potential temporary shortages in water or hydropower caused by reduced availability at Shasta Dam during construction, replacement water or hydropower supplies would need to be sourced elsewhere to maintain current service needs. Depending on the conditions of the water or energy markets at the time of need, these replacement resources could be more expensive than water or hydropower obtained from Shasta Dam. The additional expense of obtaining water or hydropower resources could potentially produce a minor negative effect on water and power customers if replacement of these resources is substantially more expensive.

To eliminate the potential impact of project construction on water and/or hydropower purchases, Reclamation will identify the need for replacement water or hydropower early in project implementation and will secure such resources at the lowest cost possible. Reclamation will provide these replacement resources to business and industry in the CVP and SWP service areas at costs comparable to water or hydropower obtained from Shasta Dam.

Implementation of this mitigation measure would reduce Impact Socio-14 (CP1) to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Socio-1 (CP2) through Socio-13 (CP2) and Impacts Socio-15 (CP2) through Socio-17 (CP2). Mitigation is provided below for the other impact of CP2.

Mitigation Measure Socio-14 (CP2): Secure Replacement Water or Hydropower During Project Construction This mitigation measure is identical to Mitigation Measure Socio-14 (CP1). Implementation of this mitigation measure would reduce Impact Socio-14 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impacts Socio-1 (CP3) through Socio-13 (CP3) and Impacts Socio-15 (CP3) through Socio-17 (CP3). Mitigation is provided below for the other impact of CP3.

Mitigation Measure Socio-14 (CP3): Secure Replacement Water or Hydropower During Project Construction This mitigation measure is identical to Mitigation Measure Socio-14 (CP1). Implementation of this mitigation measure would reduce Impact Socio-14 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts Socio-1 (CP4) through Socio-13 (CP4) and Impacts Socio-15 (CP4) through Socio-17 (CP4). Mitigation is provided below for the other impact of CP4.

Mitigation Measure Socio-14 (CP4): Secure Replacement Water or Hydropower During Project Construction This mitigation measure is identical to Mitigation Measure Socio-14 (CP1). Implementation of this mitigation measure would reduce Impact Socio-14 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts Socio-1 (CP5) through Socio-13 (CP5) and Impacts Socio-15 (CP5) through Socio-17 (CP5). Mitigation is provided below for the other impact of CP5.

Mitigation Measure Socio-14 (CP5): Secure Replacement Water or Hydropower During Project Construction This mitigation measure is identical to Mitigation Measure Socio-14 (CP1). Implementation of this mitigation measure would reduce Impact Socio-14 (CP5) to a less than significant level.

16.3.6 Cumulative Effects

Water reliability and electrical demand are expected to become increasingly important issues as demand for water and electricity increases to meet the needs of California's growing population. Over time, water conservation and reuse efforts will increase and water provision is expected to shift from such areas as agricultural production to urban uses. Environmental restoration, flood control, and hydropower generation are expected to continue in a manner similar to existing conditions.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Primary Study Area In the primary study area, effects related to increases in population and housing during construction under CP1 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to increases in population and housing demand would not be significant. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or

require sizeable numbers of new workers from outside the local area. Implementing CP1 would result in beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

Extended Study Area Without mitigation, CP1 could cause a potentially significant adverse effect on business and industrial activity in the CVP and SWP service areas. This adverse effect would be a potential temporary reduction in Shasta project water or hydropower supplied to CVP and SWP service areas during construction. With implementation of Mitigation Measure Socio-14 (CP1), adverse effects from CP1 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not contribute to a cumulatively considerable incremental contribution to cumulative effects related to the temporary reduction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP1 would also result in beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Primary Study Area In the primary study area, effects related to increases in population and housing during construction under CP2 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to increases in population and housing demand would not be significant. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or require sizeable numbers of new workers from outside the local area. Implementing CP2 would cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, the beneficial effects of CP2 in the primary study area would be greater than those of CP1. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

Extended Study Area The adverse effects of CP2 would be the same as those of CP1. With implementation of Mitigation Measure Socio-14 (CP2), adverse effects from CP2 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not contribute to a cumulatively considerable incremental contribution to cumulative effects related to the temporary reduction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP2 would result in less than significant effects on population and housing and also cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, the beneficial effects of CP2 in the extended study area would be greater than those of CP1. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

Primary Study Area In the primary study area, effects related to increases in population and housing during construction under CP3 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to increases in population and housing demand would not be significant. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or require sizeable numbers of new workers from outside the local area. CP3 would cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, the beneficial effects of CP3 in the primary study area would be greater than those of CP1 and CP2. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

Extended Study Area The adverse effects of CP3 would be the same as those of CP1. With implementation of Mitigation Measure Socio-14 (CP3), adverse effects from CP3 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not contribute to a cumulatively considerable incremental contribution to cumulative effects related to the temporary reduction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP3 would result in less than significant effects on population and housing and also cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, the beneficial effects of CP3 in the extended study area would be greater than those of CP1 and CP2. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Primary Study Area In the primary study area, effects related to increases in population and housing during construction in CP4 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to increases in population and housing demand would not be significant. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or

require sizeable numbers of new workers from outside the local area. CP4 would cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, in the primary study area, the beneficial effects of CP4 would be the same as those of CP3. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

Extended Study Area The adverse effects of CP4 would be the same as those of CP1. With implementation of Mitigation Measure Socio-14 (CP4), adverse effects from CP4 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not contribute to a cumulatively considerable incremental contribution to cumulative effects related to the temporary reduction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP4 would result in less than significant effects on population and housing and also cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. In the extended study area, the beneficial effects of CP4 for population and housing, employment, and the labor force would be the same as those of CP3. For business and industrial activity, CP4 would be more beneficial than CP3. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Primary Study Area In the primary study area, effects related to increases in population and housing during construction under CP5 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to increases in population and housing demand would not be significant. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or require sizeable numbers of new workers from outside the local area. CP5 would cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, in the primary study area, the beneficial effects of CP5 would be the same as those of CP3. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

Extended Study Area The adverse effects of CP5 would be the same as those of CP1. With implementation of Mitigation Measure Socio-14 (CP5), adverse effects from CP5 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not contribute to a cumulatively considerable incremental contribution to cumulative effects related to the temporary reduction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP5 would result in less than significant effects on population and housing and also cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, in the extended study area, the beneficial effects of CP3 would be the same as those of CP3. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative effects on socioeconomic resources.

Chapter 17
Land Use and Planning

17.1 Affected Environment

This chapter describes the affected environment related to land uses and planning for the dam and reservoir modifications proposed under the SLWRI.

Because of the potential influence of the proposed modification of Shasta Dam and water deliveries over a large geographic area, the SLWRI includes both a primary study area and an extended study area. The primary study area has been further divided into Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). The extended study area has been further divided into the lower Sacramento River and Delta and the CVP/SWP service areas.

The setting for land uses and planning in the Shasta Lake and vicinity portion of the primary study area consists of the portion of Shasta County north of Shasta Dam. This area encompasses Shasta Lake, lands surrounding the lake, and parts of the Pit River, Squaw Creek, McCloud River, and Sacramento River watersheds. Land use and planning in this area are influenced by land ownership, the presence of rural lakeside communities, and topography.

The setting for land uses and planning in the upper Sacramento River portion of the primary study area consists of the portion of Shasta County south of Shasta Dam and Tehama County. The incorporated cities of Shasta Lake, Redding, Anderson, and Red Bluff, all located along the Interstate 5 (I-5) corridor, establish urban settings in the otherwise rural upper Sacramento Valley. The upper Sacramento Valley is characterized by rolling hills with mountains to the north, east, and west. Land use and planning in this area are influenced by land ownership, historic land use patterns, topography, and population densities.

The land use and planning setting for the extended study area consists of 24 counties downstream from the Red Bluff Diversion Dam and encompasses all areas served by the CVP and the SWP. Land use and planning in the extended study area are influenced by the same factors identified for the upper Sacramento River study area. The type and focus of land use and planning may vary, however, in the large urban areas located in the extended study area.

17.1.1 Land Use

Shasta Lake and Vicinity

Land uses in the Shasta Lake and vicinity portion of the primary study area consist primarily of open space and other land uses that support recreational

activities in the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). The USFS manages the Shasta Unit of the NRA. Federally owned lands in the NRA total 235,740 acres, including Shasta Lake; lands held in private ownership total 10,347 acres. A small area around Shasta Dam is administered by Reclamation. In addition, the California Department of Transportation manages the I-5 corridor, and the Union Pacific Railroad (UPRR) manages the rail corridor that crosses the primary study area (Figure 17-1).

The following land use designations are applied to lands managed by the Shasta Unit of the NRA. Riparian Reserves, the largest land use designation in the NRA, are located in areas along rivers, streams, lakes, and wetlands, including the area inundated by Shasta Lake. Riparian Reserves were established to provide natural corridors throughout the NRA. Approximately 25 percent of the land in the NRA is designated Matrix and Adaptive Management; these areas generally emphasize recreation and visual quality. Late Successional Reserves (LSR) and Administratively Withdrawn Areas each account for 20 percent of the land use designations in the NRA. LSRs are characterized by large blocks of land reserved for northern spotted owl and other species that are dependent on late successional old-growth forest. Lands with this designation are scattered throughout the NRA; these lands have a natural appearance, with much of the land area covered with late successional forest vegetation.

The Shasta Unit of the NRA is not managed for timber harvest. Vegetation removal is permitted for fuel breaks, hazard tree removal, protection of life and property, prevention of significant losses caused by insects or disease, and wildlife habitat management.

Recreational and commercial land uses occupy 2 percent of the land managed by the Shasta-Trinity National Forest (STNF) within the Shasta Unit of the NRA. Recreational use in the NRA exceeds 2 million visitor days annually. Water-oriented activities, such as boating, fishing, waterskiing, and house-boating, are the main attractions. Marinas that currently operate on Shasta Lake include Antlers, Sugarloaf, Shasta, Lakeview, Holiday Harbor, Packers Bay, Bridge Bay, Silverthorn, Jones Valley, and Digger Bay. Other recreational land uses include hiking, camping, picnicking, and off-highway vehicle activities. A planning permit has been issued by the STNF to decommission Digger Bay and construct a new marina at Turntable Bay, but the permit was not exercised and has since been revoked.

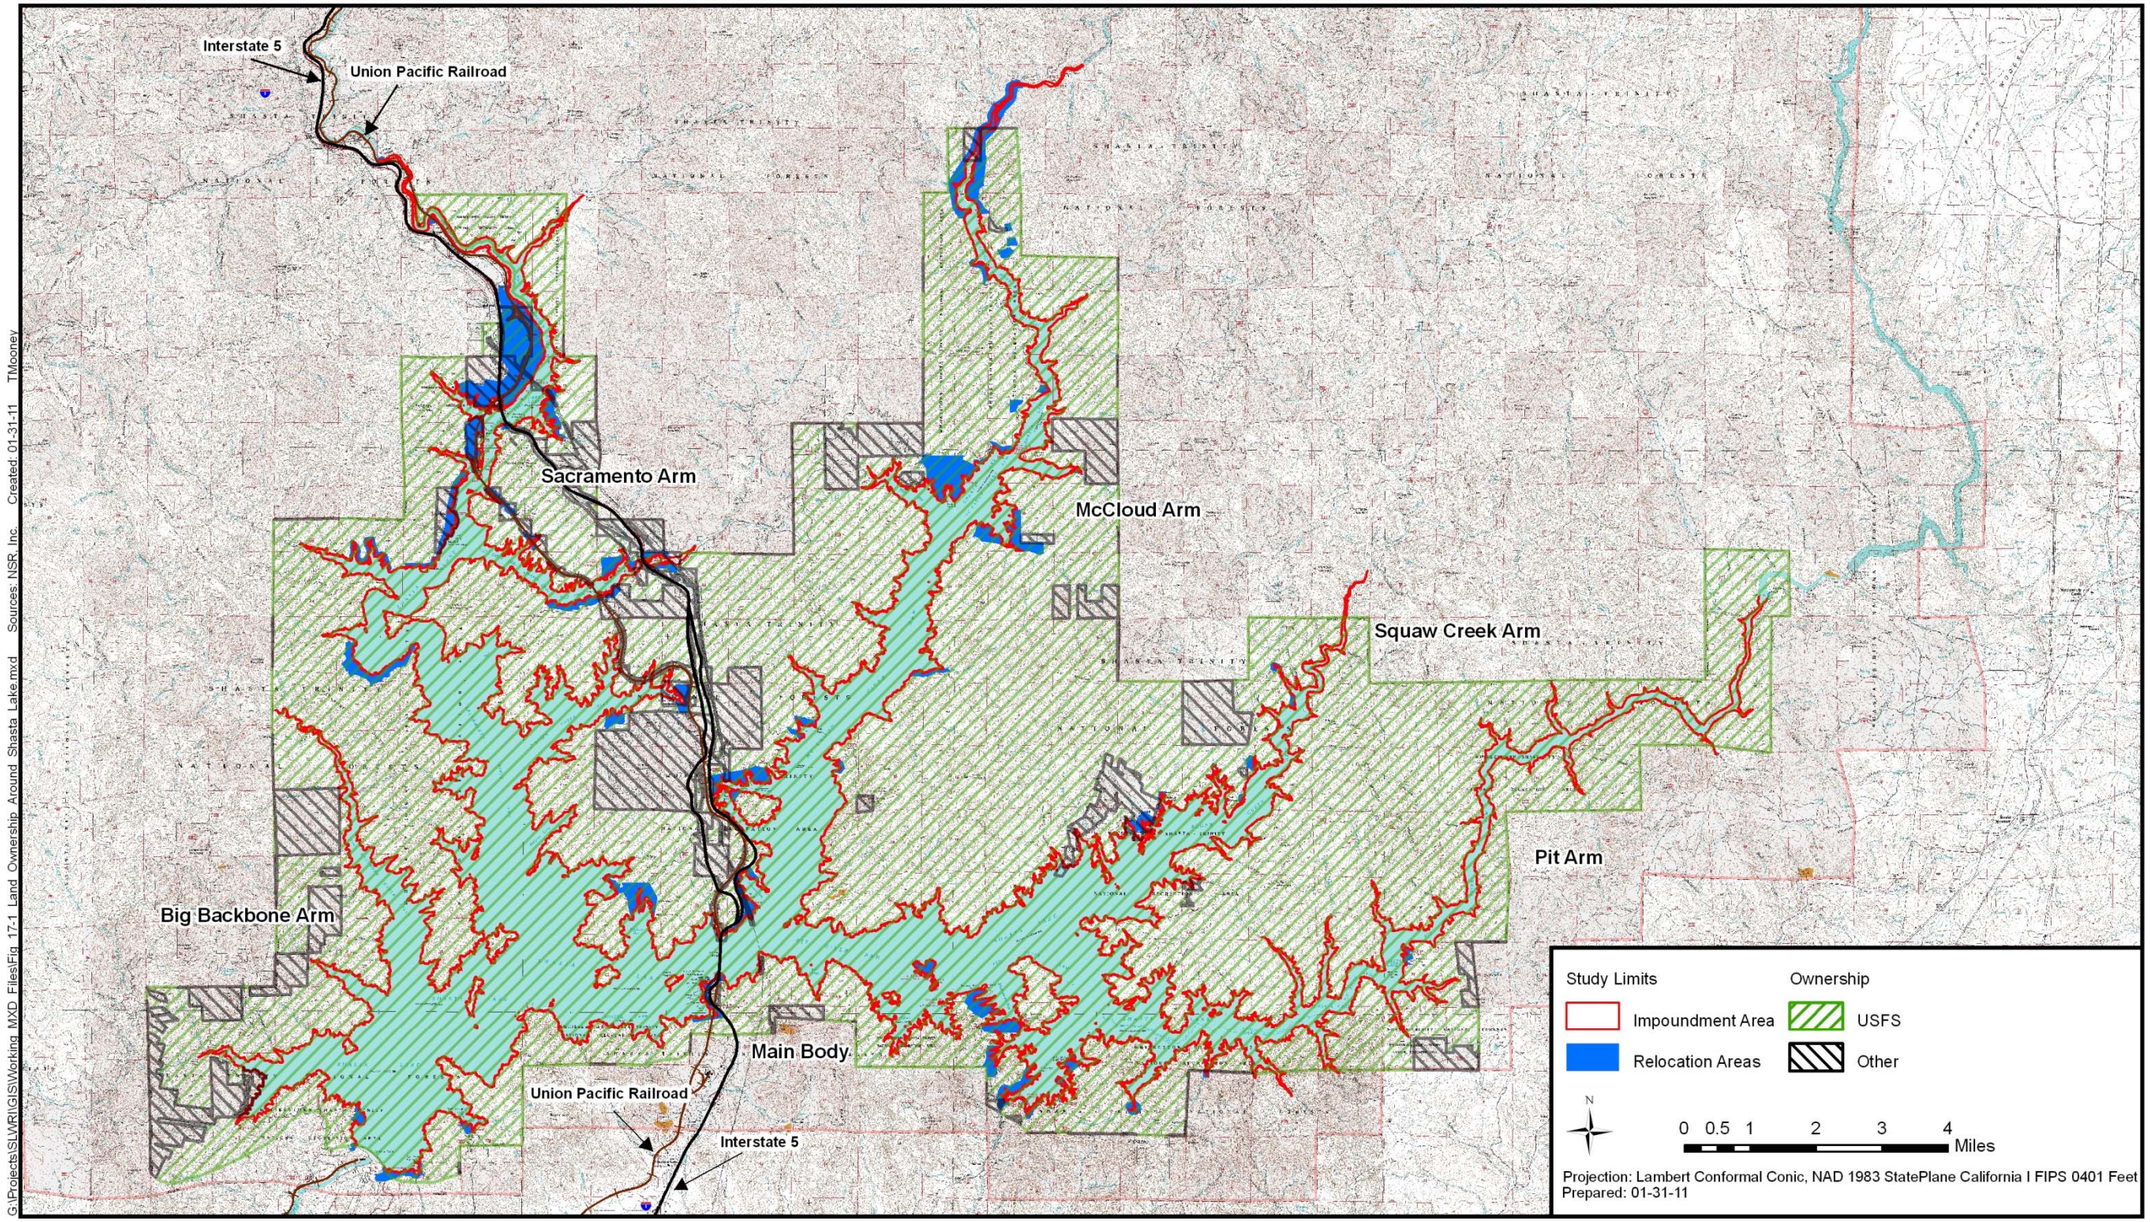

Figure 17-1. Land Ownership Around Shasta Lake

This page left blank intentionally.

Commercial land uses in the NRA include resorts, marinas, campgrounds, restaurants, motels, grocery stores, and service stations. Resorts typically operate in conjunction with marinas and include Sugarloaf Resort, Lakeview Resort, Bridge Bay Resort, Jones Valley Resort, Shasta Marina Resort, Silverthorn Resort, and Antlers Resort and Marina. Some resorts on Shasta Lake must move their docks substantial distances from their land-based facilities during periods of low water levels.

The USFS operates recreation residential tracts at Salt Creek, Silverthorn, Campbell Creek, and Didallas Creek; these tracts combined contain 160 privately owned cabins on National Forest System lands. USFS policy is to manage these tracts and residences for individual recreational use and to keep the areas as close as possible to their natural state. Only minimal improvements are permitted, and structures must blend into the natural environment.

Mining and grazing do not take place in the NRA. There are no grazing permits authorized for the Shasta Unit of the NRA, primarily because of a lack of suitable range. Federal lands in the NRA, except those with valid existing rights, were withdrawn from mineral entry by the legislation that created the NRA. Reclamation and USFS conducted validity determinations on most of the claims existing at that time and contested the majority of them based on the absence of a valid discovery. There are five claims in the NRA that predate the withdrawal. The lands covered by these claims remain open to mineral leasing, but there are no approved operating plans for these claims. Hard rock minerals in the NRA are available for prospecting, exploration, and development under solid mineral leasing regulations (36 Code of Federal Regulations (CFR) Subpart 3583). Authorization for this land use requires permits and leases subject to USFS terms and conditions to protect the values of the NRA.

Land uses on privately owned lands in the NRA generally consist of commercial, recreational, and residential land uses associated with the NRA. Approximately 20 percent of the privately held lands in the NRA are developed. Commercial development consists primarily of service industries supporting residents and recreational visitors.

Residential land uses are typically characterized as low density and rural. Established small communities along Shasta Lake include Lamoine, Lakehead, Lakeshore, and Sugarloaf, which are located on the Sacramento Arm of Shasta Lake. Farther south is the residential community of O’Brien, which is located between the Sacramento and McCloud arms near I-5.

The McCloud River, a portion of which is located in the Shasta Lake and vicinity portion of the primary study area, is eligible for listing as Wild and Scenic under the Federal Wild and Scenic Rivers Act (WSRA). In addition, although it is not state-listed as Wild and Scenic, the McCloud River receives certain protections under the California Public Resources Code (PRC), Section 5093.542, established through enactment of the California Wild and Scenic

Rivers Act, as amended (Sections 5093.50 – 5093.70). The effects of the proposed enlargement of Shasta Lake on the McCloud River are discussed in Chapter 25 of this EIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Land uses in the upper Sacramento River area consist of urban, residential, municipal and industrial, and agricultural uses. Urban development is located in the valley and is concentrated along the transportation corridors provided by I-5, State Route 273, and the UPRR. Incorporated cities located in the valley along I-5 in the upper Sacramento River study area are the cities of Shasta Lake, Redding, Anderson, and Red Bluff. Cottonwood, an unincorporated community located along the I-5 corridor, also has residential and commercial development.

Small rural communities characterize development patterns 5 to 8 miles east and west of the I-5 corridor. Many of these communities have their origins in the early settlement of Shasta County and Tehama County, as evidenced by the agriculture, grazing, and timber operations typical of the upland areas. These communities usually consist of small community centers surrounded by vast tracts of fields and forest that are dotted with home sites (Shasta County 2004).

The northern, western, and eastern portions of Shasta County are relatively uninhabited because the lands in these areas are managed by USFS for timber, wildlife, and wilderness uses. Lands managed by USFS in the western and southeastern portions of Tehama County are also relatively uninhabited.

The National Park Service manages lands in the upper Sacramento River study area, including the Whiskeytown Unit of the NRA, west of Keswick, and Lassen Volcanic National Park, in the northeastern corner of Tehama County. The U.S. Bureau of Land Management (BLM) manages the 12,194-acre Sacramento River Bend Management Area on the east side of the Sacramento River northeast of Red Bluff.

Lower Sacramento River and Delta

Land uses in the extended study area vary greatly because of differences in population, economy, and environment. Land uses in the Sacramento River valley are principally agricultural and open space, with urban development focused around the state capital in the Sacramento metropolitan area. The primary private land use in the region is agriculture. As of 1997, the Sacramento Valley area contained more than 11,000 farms on about 4.3 million acres. Urban development has occurred along major highway corridors, primarily in Sacramento, Placer, El Dorado, Yolo, Solano, and Sutter counties, and has caused some agricultural land to be taken out of production. For those lands that remain agricultural, soil conditions allow a wide variation in crop mix.

The American River is in the lower Sacramento River and Delta portion of the extended study area. Two sections of the American River, the North Fork American River from its source in the Sierra Nevada to the Iowa Hill Bridge

near Colfax, and the lower American River from Nimbus Dam to the river's confluence with the Sacramento River in the city of Sacramento, are listed as Wild and Scenic under the Federal WSRA and State PRC.

The listed segment of the North Fork American River is designated as a wild river under the Federal WSRA and State PRC. The listed segment is above any regulated reaches and is not under the control of the Central Valley Project or the State Water Project. The downstream end of the listed segment is more than 70 river miles and 50 air miles upstream from the confluence with the Sacramento River and is thus too far away to be affected by any hydraulic changes in the Sacramento River.

The lower American River is regulated by Folsom Dam, which is approximately 7 miles upstream from Nimbus Dam. Both Shasta Dam and Folsom Dam release water in accordance with their operational requirements, including releases to maintain water quality for fisheries, municipal use, and agricultural use, and for exports to the San Joaquin Valley. Both dams have operational requirements for the sections of the Sacramento and lower American rivers above their confluence, and they also have shared operational requirements for the Sacramento River and Delta below the confluence. Therefore, operational changes at one dam could require operational changes at the other. For example, reduced releases from Shasta Dam could require increased releases from Folsom Dam to meet flow requirements in the lower Sacramento River and Delta.

The lower American River is designated as a recreational river under the Federal WSRA and State PRC. Fishing and boating, including rafting and canoeing, are the primary recreational activities on the river. In addition, much of the lower American River's south shore is part of the American River Parkway. Joggers, bicyclists, walkers, and families use the riverside trails and beaches of this extensive park system.

CVP/SWP Service Areas

The CVP, operated by Reclamation, is the largest water storage and delivery system in California, covering 29 of the state's 58 counties. Most of the CVP service area is in the Central Valley, and about 90 percent of the south-of-Delta contractual delivery is for agricultural uses (Reclamation 2007).

Most of the population of the CVP service area is concentrated within urban areas. The CVP service area includes various municipal and industrial water contractors and water districts that serve portions of the Sacramento and Stockton metropolitan areas and the San Francisco Bay Area. Outside these population centers, most of the CVP service area is rural, with irrigated agriculture the predominant land use and economic driver (Reclamation 2007).

SWP water is delivered to contracting agencies in Northern California, the San Francisco Bay Area, the Central Coast, San Joaquin Valley, and Southern California.

Land uses in the CVP/SWP service areas vary and include agricultural, municipal and industrial, commercial, open space, grazing, and timber production.

17.1.2 Planning

Shasta Lake and Vicinity

Federal Land Use Planning Federal lands are not subject to county or city general plans. Land use planning direction for the NRA is guided by Federal legislation (including 36 CFR part 292 subpart B), regional forest directives, and forest-specific management directives found in the STNF Land and Resource Management Plan (LRMP).

The STNF LRMP is based on three broad management strategies: preservation, biodiversity, and sustainable development for people. Resources are categorized by type (e.g., air resources, fisheries, lands) and assigned management goals, standards, and guidelines. The following goals describe the desired future condition of the STNF:

- Lands
  - Plan for long-range land ownership adjustments that support resource objectives.
  - Provide for continued use and new development of hydroelectric facilities.

The six broad categories of land use that apply to the STNF are Congressionally Reserved Areas, LSRs, Administratively Withdrawn Areas, Riparian Reserves, Matrix, and Adaptive Management Areas (USFS 1995). The LRMP requires each type of land use to be managed in accordance with specific standards and guidelines pertaining to each resource type. Lands designated as Riparian Reserve, for example, have specific management standards and guidelines for air quality, biological diversity, fire and fuels, etc. The following describes each type of land use in the STNF:

- **Late Successional Reserves** – LSRs have been established to protect and enhance conditions of late-successional and old-growth forest ecosystems and to ensure the support of related species, including the northern spotted owl. The applicable management prescription is:
  - Provide special management for LSRs and threatened and endangered species. The management prescription includes special,

selected sensitive wildlife species that are primarily dependent on late seral stage conditions.

- **Administratively Withdrawn Areas** – These areas are identified in the LRMP and include recreation and visual areas, backcountry, and other areas where management emphasis precludes scheduled timber harvesting. The applicable management prescriptions are:

  - **Unroaded Non-Motorized Recreation** – Provide for semi-primitive non-motorized recreation opportunities in unroaded areas outside existing wilderness areas while maintaining predominantly natural-appearing areas with only subtle modifications.

  - **Limited Roaded Motorized Recreation** – Provide for semi-primitive motorized recreation opportunities while maintaining predominantly natural-appearing areas with some modifications.

  - **Roaded, High Density Recreation** – Provide areas that are characterized by a substantially modified natural environment.

  - **Special Area Management** – Provide for protection and management of special interest areas and research natural areas.

  - **Heritage Resource Management** – The primary theme of this prescription is to protect designated cultural resource values, interpret significant archaeological and historical values for the public, and encourage scientific research of these selected properties.

- **Riparian Reserves** – Provide an area along streams, wetlands, ponds, lakes, and unstable and potentially unstable areas where riparian-dependent resources receive primary emphasis. The applicable management prescription is:

  - Maintain or enhance riparian areas, wildlife and fisheries habitat, and water quality by emphasizing streamside and wetland management.

- **Matrix** – Includes Federal lands outside the categories of the designated areas listed above. Matrix lands are where most timber harvest would occur and where standards and guidelines are in place to ensure appropriate conservation of ecosystems as well as provide habitat for rare and lesser known species. The applicable management prescriptions are:

  - **Roaded Recreation** – Provide for an area where there are moderate evidences of the sights and sounds of humans.

  - **Wildlife Habitat Management** – The primary purpose of this prescription is to maintain and enhance big game, small game, upland game bird, and nongame habitat to provide adequate hunting and viewing opportunities.

- **Adaptive Management Areas** – Manage lands on an ecosystem basis in terms of both technical and social challenges, and in a manner consistent with applicable laws. There are no management prescriptions associated with Adaptive Management Areas.

The LRMP provides another more specific layer of land use planning guidance for the NRA in the Management Guide: Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity NRA (USFS 1996). This document provides the following land use guidance:

- Those private lands that would enhance outdoor recreation opportunities and/or the conservation of scenic, scientific, historic, and other values contributing to the public enjoyment of the NRA should be acquired as opportunities arise.

- Land exchanges will be pursued in accordance with the Forest Land Adjustment Guide. Lands directly adjacent to the shoreline will have the highest priority.

- Lands with significant known pollution sources arising from a history of mining discharge will not be acquired.

- Coordination will take place with Shasta County to allow those private land developments and resource production proposals that will maintain or enhance NRA values, and to disallow or phase out private land uses that detract from those values.

- Coordination will take place with county, State, and other Federal agencies on development, management, and regulatory oversight of recreation opportunities and facilities to ensure consistency with NRA objectives.

- Planning will take place with owners and managers of travel and utility corridors through the NRA (railroad, highway, and major power lines) to minimize the visual impacts of these corridors on the aesthetic value of the NRA.

The STNF coordinates with Shasta County to ensure that private development in the NRA maintains or enhances NRA values through local zoning regulations.

County Land Use Planning Land-use planning on non-Federal land is the province of local governments in California. All cities and counties in California are required by the State to adopt a general plan establishing goals and policies for long-term development, protection from environmental hazards, and conservation of identified natural resources (California Government Code 65300). General plans lay out the pattern of future residential, commercial, industrial, agricultural, open-space, and recreational land uses on non-Federal land within a community. To facilitate implementation of planned growth patterns, general plans identify goals and/or policies to establish land use patterns.

Local governments implement general plans by adopting zoning, subdivision, grading, and other ordinances. Zoning ordinances identify specific types of land uses that may be allowed on a given site and establish specific development standards. Zoning regulations vary from jurisdiction to jurisdiction. However, typical standards promulgated in zoning ordinances include the siting of structures relative to parcel boundaries, architectural design (including height limitations), and the percentage of building coverage allowed relative to the overall square footage of a parcel.

The *Shasta County General Plan* (Shasta County 2004) provides planning guidance for privately owned land in Shasta County. Land use directives are provided in the form of goals, policies, objectives, standards, and guidelines. The following land uses described in the general plan are present in the Shasta Lake and vicinity portion of the primary study area:

- **Rural Residential** – Encompasses areas that receive minimal urban services, usually in or near a rural community center and areas with no urban services that are located in areas of the county characterized by one or more of the following conditions:
    - Severe limitations on septic tank use
    - Uncertain long-term availability of water
    - Proximity to lands categorized as timber, grazing, or crop lands
    - Remoteness from urban, town, and rural community centers
    - Extreme wildland fire hazard
    - Inaccessibility via county-maintained roads
- **Existing Residential** – This designation may be applied to residential areas that existed before 1984 and that do not fit the land use designation or density applied to surrounding properties.

- **Mixed Use** – This category recognizes that in a rural setting the strict segregation of different land use types, which is typically found in urban environments, is neither necessary nor practical. At this scale, conflicts that may result from the intermixing of land uses may be addressed by County zoning and development standards related to screening setbacks and architectural design.

- **Commercial Recreational** – This designation provides opportunities for the development of privately owned lands characterized by the natural environment for the purpose of providing commercial recreation activities that use and provide for the enjoyment of the natural environment. Examples of commercial recreation include campgrounds, fishing and hunting clubs, dude ranches, boating facilities, and recreational vehicle parks. Other uses such as a restaurant or small grocery store may be permitted when accessory to, supportive of, and compatible with the recreation activity.

- **Natural Resources Protection**

  - **Community Parks** – Provides for large-scale community recreation facilities

  - **Habitat** – Provides for protection of significant wildlife habitat resources

Shasta County land use actions and decisions on non-Federal land in the NRA are subject to STNF review and approval pursuant to 36 CFR part 292 subpart B.

Upper Sacramento River (Shasta Dam to Red Bluff)

Land use planning in the upper Sacramento River area consists of general plans adopted by Shasta and Tehama counties and the cities of Shasta Lake, Redding, Anderson, and Red Bluff. BLM lands in this area are managed in accordance with the Redding Resource Management Plan (RMP), discussed in the Regulatory Framework section below.

Local Land Use Planning

Shasta County The *Shasta County General Plan* (2004) designates the following land uses along the Sacramento River from Shasta Dam south to the Tehama County line:

- Rural residential
- Greenway
- Habitat resource
- Natural habitat

- **Agricultural** – cropland
- **Agricultural** – small-scale crops, grazing
- Mineral resources

Tehama County Tehama County is currently updating its general plan. The *Draft Plan and Background Report* were circulated to the public in May 2007. The associated Environmental Impact Report has not been completed. The current *Tehama County General Plan* (1983) designates the following land uses along the Sacramento River from the Shasta County line in the north to Red Bluff:

- Habitat resource, resource lands, and public/wilderness
- Cropland and grazing
- General commercial
- Scenic easement and open space
- Commercial recreation
- Urban and city
- Rural small lot, rural large lot, and suburban

City of Shasta Lake The *City of Shasta Lake General Plan* was adopted in 1999. The general Plan designates the following land uses along Shasta Dam Boulevard, the primary roadway leading up to Shasta Dam:

- Community park
- 100-year floodplain
- Public facilities
- Commercial
- Mixed use
- Rural residential (1 unit/2 acres, 1 unit/5 acres)
- Suburban residential (3 units/acre)
- Urban residential (10 units/acre)
- **Urban residential** – High (20 units/acre)

City of Redding The City of Redding adopted an updated general plan in 2000 (City of Redding 2000). The general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Greenway
- Park, Park-Golf

- Public Facility; Public Facility-School
- Recreational
- General Office
- General Commercial
- Neighborhood Commercial
- Residential (2–3.5, 3.5–6, 6–10 units/acre)
- Critical Mineral Resource Overlay
- Mixed Use Neighborhood Overlay

City of Anderson The City of Anderson released its updated general plan in May 2007 (City of Anderson 2007). The general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Commercial
- Industrial
- Public/Quasi-Public
- Medium-Density Residential
- Rural Residential/Rural Estate

City of Red Bluff The City of Red Bluff most recently amended its General Plan Land Use Element in 1993. The general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Primary Floodplain
- Exclusive Agriculture
- General Commercial
- Central Business Districts
- Single-Family Residential
- General and Neighborhood Apartment Districts
- General Industrial
- Public Agency District
- Park

Lower Sacramento River and Delta
