The lower Sacramento River and Delta are within the planning jurisdiction of Butte, Colusa, Contra Costa, Glenn, Sacramento, Solano, Sutter, Yolo, and Yuba counties. The largest cities in this region are Antioch, Chico, Davis, Fairfield, Martinez, Marysville, Pittsburgh, Sacramento, Vacaville, Vallejo, West Sacramento, and Woodland. Each of these entities currently has adopted general plans and zoning ordinances. Land use planning documents are adopted by Federal agencies for Federally managed lands in the lower Sacramento River and Delta areas.

CVP/SWP Service Areas

The CVP extends from the Cascade Range near Redding in the north to the Tehachapi Mountains near Bakersfield in the south. The CVP serves farms, homes, and industry in California's Central Valley as well as major urban centers in the San Francisco Bay Area. SWP contractors are in the southern San Joaquin Valley, Central Coastal area, and Southern California. CVP and SWP service areas include portions of the primary and extended study area. CVP water irrigates more than 3 million acres of farmland and provides drinking water to nearly 2 million consumers. SWP deliveries are 70 percent urban and 30 percent agriculture, serving 20 million Californians and more than 600,000 irrigated acres, respectively. Each of the counties and incorporated cities in the CVP and SWP service areas has adopted general plans and zoning ordinances. Federally managed lands in the service areas are managed in accordance with land use and planning documents similar to the STNF LRMP and the BLM's RMP, and military installations located in the service areas have their own planning processes.

17.2 Regulatory Framework

17.2.1 Federal

Federal land use policies apply only to actions on, or affecting the uses of, Federal lands. Federal lands in the primary study area consist of the following:

- National Forest lands managed by the STNF around Shasta Lake
- Lands along the Sacramento River just south of Shasta Dam managed by Reclamation
- Lands managed by BLM along the Sacramento River south of Shasta Dam as far downstream as Red Bluff

Entry upon or use of these Federally administered lands would require approval from the appropriate Federal entity(ies).

Federal Land Policy and Management Act

The Federal Land Policy and Management Act was enacted to change the Federal public lands policy from disposal to retention. The act directs Federal agencies to apply land use principles that emphasize conservation; these include the principles of multiple use and sustained yield land management policies. The Federal Land Policy and Management Act consolidated and articulated BLM's management responsibilities and applies primarily to this Federal land management agency. Title V of the Federal Land Policy and Management Act also granted the Secretary of the Interior and the Secretary of Agriculture the authority to issue rights-of-way for various uses, including reservoirs.

Code of Federal Regulations

USFS personnel administer their responsibilities for regulating use and protecting National Forest lands under Title 36 of the CFR and sections of titles 16, 18, and 21. Public services directives from the code are integrated into the STNF LRMP and include the following topics: fire and fuels management, facilities management, law enforcement, and land management.

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF LRMP is a forestwide land use plan developed to guide resource management on the STNF. Six broad categories are used to define management strategies. The management strategies (known as land allocations) are implemented through management prescriptions that provide specific standards and guidelines for forest resource management (USFS 1995).

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The Management Guide for the NRA contains management strategies intended to achieve or maintain desired conditions for the NRA. The document supplements the STNF LRMP by providing specific information about current conditions in the NRA, desired future conditions for the NRA, and management recommendations for the NRA. The STNF is responsible for administering the Shasta and Trinity units of the NRA.

BLM's Redding Resource Management Plan

BLM's Redding RMP (BLM 1994) provides guidance for the management of cultural resources, fire, grazing, minerals, vegetation, water quality, wildlife and fish habitats, and other resources and issues in Shasta County. The RMP governs land use on BLM lands, including lands in the Sacramento River Management Area. Planning issues addressed in the RMP include land tenure adjustments, such as land acquisition, exchange, and sale; recreation management; access; and forest management, including harvesting, herbicide use, and special-status species.

The RMP was amended by the 1994 Record of Decision for the *Northwest Forest Plan* (Final Supplemental Environmental Impact Statement for Amendments to Forest Service and Bureau of Land Management Planning

Documents within the Range of the Northern Spotted Owl). This amendment required preparation of Watershed Analysis prior to initiating BLM activities. As a party to the *Northwest Forest Plan,* BLM, like USFS, is also required to ensure that projects are consistent with the Aquatic Conservation Strategy.

Federal Wild and Scenic Rivers Act

The Federal WSRA, enacted in 1968, established the National Wild and Scenic Rivers System "to preserve rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations." To be eligible for inclusion in the system, a river must be free-flowing and exhibit outstandingly remarkable values. Free-flowing means "existing or flowing in a natural condition without impoundment, diversion, straightening, rip-rapping, or other modification of the waterway" (16 U.S. Code Sec. 1286). outstandingly remarkable values are scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values (16 USC Sec. 1271). Depending on the specific attributes of a river, it may be designated as "wild," "scenic," or "recreation." Different segments of a single river can receive different designations; in other words, some segments can be designated wild, some scenic, and some recreation or combinations of these designations. Recreation rivers are defined as "rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past" (16 USC Sec. 1286).

State-designated rivers may be added to the Federal system upon the request of the state's governor and the approval of the Secretary of the Interior (16 USC Sec. 1286). Two sections of the American River were added to the federal system in 1981 under this method. These sections are the lower American River from Nimbus Dam to the river's confluence with the Sacramento River and the North Fork American River from its source to the Iowa Hill Bridge. The North Fork section is located above Nimbus, Folsom, and Lake Clementine dams many miles upstream from the confluence with Sacramento River. The North Fork is not regulated by Folsom Dam and would not be affected by hydraulic changes in the Sacramento River. The lower American River is designated as a recreational river.

17.2.2 State

California Public Resource Code, Division 6

The California Public Resource Code, Division 6, grants the State Lands Commission (SLC) jurisdiction over 4.5 million acres of land held in trust for Californians. The SLC's jurisdiction includes a 3-mile-wide section of tidal and submerged land adjacent to the coast and offshore islands, including bays, estuaries, and lagoons. It also includes the waters and beds of more than 120 rivers, lakes, streams, and sloughs. The State holds these lands for the public trust purposes of water-related commerce, navigation, fisheries, recreation, and open space. The SLC may grant dredging permits and issue land use leases for

activities within its jurisdiction. The SLC does not have a comprehensive use plan for these lands but manages them according to State and Federal laws and regulations. In the primary study area, the SLC's jurisdiction includes areas along the Sacramento River north of Red Bluff.

California Fire Plan

The *California Fire Plan* was prepared by the State Board of Forestry and the California Department of Forestry and Fire Protection to provide a comprehensive strategy for wildland fire protection and prevention in California. The plan provides recommendations for fire-safe land use planning. Preventive measures include using fire-resistant building materials, maintaining a defensible space around structures, vegetation management, and infrastructure planning.

Water Quality Control Plan

The *Water Quality Control Plan for the Sacramento River and San Joaquin River Basins* provides water quality objectives to protect beneficial uses of designated rivers and streams. *Water Quality Control Plan for the Sacramento River and San Joaquin River Basins* objectives are incorporated into county and city general plans, zoning ordinances, and subdivision ordinances.

California Public Resources Code, Sections 5093.50–5093.70

The California PRC Sections 5093.50 – 5093.70 were established through 1972 enactment of the Wild and Scenic Rivers Act, which was subsequently amended on several occasions, to preserve certain rivers that possess extraordinary scenic, recreational, fishery, or wildlife values in their free-flowing state. The State PRC identifies, classifies, and provides protection for specific rivers or river segments, as approved by the legislature. Rivers or river segments that are specifically identified and classified in the PRC comprise the State Wild and Scenic Rivers System. As described in PRC Section 5093.50, rivers or river segments included in the State system must possess "extraordinary scenic, recreational, fishery, or wildlife values"; however, the PRC does not define what constitutes "extraordinary."

Depending on the specific conditions of a river, it may be designated as "wild," "scenic," or "recreation." Different segments of a single river can receive different designations; in other words, some segments can be designated wild, some scenic, and some recreation or combinations of these designations. Recreation river segments are readily accessible by road or railroad, may have some development along their shorelines, and may have been impounded or diverted in the past (PRC Section 5093.53).

With its initial passage, the state system protected segments of eight rivers, including two sections of the American River. These sections include the lower American from Nimbus Dam to its confluence with the Sacramento River and the North Fork from its source to the Iowa Hill Bridge. The North Fork section is located above Nimbus, Folsom, and Lake Clementine dams many miles

upstream from the confluence with Sacramento River. The North Fork is not regulated by Folsom Dam and would not be affected by hydraulic changes in the Sacramento River. The lower American is designated as a recreational river.

17.2.3 Regional and Local

Shasta County General Plan

The *Shasta County General Plan* (2004) guides land use planning on non-Federal land for Shasta County through 2025. The Community Organization and Development Pattern element of the *Shasta County General Plan* establishes policies related to the organization and relationships of the community types present in Shasta County, the living environments these communities offer, and the locations of development in relation to these communities. These policies were developed to maintain and enhance the quality of their environments. The Community Organization and Development Pattern element includes several objectives that influence land use decisions in the project study area:

- To promote a development pattern that will accommodate, consistent with the other objectives of the plan, the growth that will be experienced by Shasta County
- To guide development in a pattern that will provide opportunities for present and future county residents to enjoy the variety of living environments that currently exist within the county
- To guide development in a pattern that will respect the natural resource values of county lands and their contributions to the county's economic base
- To guide development in a pattern that will minimize land use conflicts between adjacent land users
- To recognize that the major economic resources for achieving the development pattern will come from the private sector, rather than government, and that the general plan, as the expression of community values, will guide the use of these resources

Tehama County General Plan

The *Tehama County General Plan* is used to guide future development in unincorporated areas of the county. The county's current general plan was adopted in 1983 and is currently being updated. The updated *Draft General Plan and Background Report* were circulated to the public in May 2007. The Land Use element of the *Draft General Plan* establishes the goals, policies, and implementation measures that will help guide the growth and development of Tehama County for the next 20 years. This element also contains the General Plan Land Use Diagram, which delineates those areas of the county where

future residential development of varying densities and nonresidential growth is anticipated or will be directed (Tehama County 2007a and 2007b).

City of Shasta Lake General Plan

The planning boundaries for the *City of Shasta Lake General Plan* are within the Shasta Lake and vicinity study area, north of Keswick Dam, east of the Sacramento River, and west of I-5. This general plan was adopted in 1999 and is intended to guide land use planning within the city through the Year 2020 (City of Shasta Lake 1999). The following statement from the Land Use element of the general plan identifies some of the concerns surrounding land use decisions within the City of Shasta Lake:

> *The Land Use Element and the Land Use and Circulation Map constitute the physical framework for the general plan, which designates the proposed location, distribution, and extent of land uses. Land use was a specific area of concern identified as being key to the development of the City of Shasta Lake. Some of the major issues identified included an evaluation and establishment of urban, rural, and urban reserve boundaries. This was accomplished by identifying areas that currently lack infrastructure that would be required to develop in an orderly manner through the development of Area Plans.*

City of Redding General Plan

The planning boundaries for the *City of Redding General Plan* encompass areas within the city limits and the urban growth boundary. This plan was adopted in 2000 and is intended to guide land use planning through the year 2020 (City of Redding 2000). The Community Development and Design element of the general plan states the following about the role and effects of land use policies:

> *Land use policies and the General Plan Diagram affect every property in the City. They determine how people can use/develop their land and what they can reasonably expect to develop next door, down the street, or across town. They provide for overall consistency and compatibility between land uses and can be a determining factor in quality of life. The policies … also have a direct bearing on traffic, the feasibility of public transportation, and the quality of the air.*

City of Anderson General Plan

The planning boundaries of the *City of Anderson General Pla*n encompass areas within the city limits and the urban growth boundary. The City of Anderson released its updated general plan in May 2007 (City of Anderson 2007). The general plan is intended to guide land use planning within the city through the Year 2027. The following statement from the Land Use element of the general plan identifies some of the concerns surrounding land use decisions within the City of Anderson:

> *The Land Use Element describes the pattern of land development within the City of Anderson and the proposed expansion area and provides direction for the future development envisioned for the City. Also included in this Element are descriptions of geographic areas that are anticipated to be developed over the term of this General Plan and goals and policies to guide the City's decision makers in their review of development proposals. This Element also defines land use categories and provides supporting detail for the uses depicted upon the Anderson General Plan Land Use Diagram.*

Red Bluff General Plan

The planning boundaries for the *City of Red Bluff General Plan* encompass areas within the city limits and the urban growth boundary. The adopted General Plan elements are as follows: Circulation element (1991), Housing element (2004), and Land Use, Natural Environment, Noise, and Safety Elements (1993). The following statement from the Land Use element summarizes concerns relative to land use decisions in Red Bluff (City of Red Bluff 1993):

> *The land use element identifies the spatial arrangement of existing and proposed uses of land including public lands and facilities. It lays out the distribution of classes of land use, the intensity of those uses, and proposes a strategy of goals, objectives, policies and implementation measures to promote a wise use of land to promote the welfare of the community.*

17.3 Environmental Consequences and Mitigation Measures

17.3.1 Methods and Assumptions

To characterize existing land uses in the primary study area, pertinent planning documents were reviewed to identify objectives for the level, type, location, density, and intensity of development and to determine whether the alternatives would be in conflict with current plans and policies. Planning documents that were reviewed include the STNF LRMP (USFS 1995), the Management Guide for the NRA, and the general plans for the cities of Shasta Lake, Redding, Anderson, and Red Bluff and Shasta and Tehama counties. Land use maps and zoning maps were consulted to identify planned land uses. The analysis also included a review of aerial photography to determine existing land uses in the primary study area.

The impacts of each alternative are analyzed separately, starting with the analysis of the No-Action Alternative, followed by each of the action alternatives. The impact analysis includes a discussion of both direct and indirect impacts associated with each alternative.

17.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines and consider the context and intensity of the environmental effects as required under NEPA. An alternative was determined to result in a significant effect related to land use and planning if it would do any of the following:

- Create land uses that are incompatible with existing and planned land uses adjacent to actions described as part of the project
- Introduce substantial nuisance effects on sensitive land uses that would disrupt use over an extended time period
- Conflict with any applicable land use plan, policy, ordinance, or regulation of an agency with jurisdiction over the project (including general plans, specific plans, and zoning ordinances) adopted for the purpose of avoiding or mitigating an environmental effect
- Disrupt or divide the physical arrangement of an established community
- Conflict with any applicable habitat conservation or natural community conservation plan

17.3.3 Topics Eliminated from Further Consideration

Effects of the proposed enlargement of Shasta Lake on the listed segments of the American River have been eliminated from further consideration in this EIS. The listed segment of the North Fork American River has been eliminated because it is above any regulated reaches and is many miles from the confluence of the American and Sacramento rivers. The lower American River has been eliminated because none of the alternatives would adversely affect its designation as a recreational river under the Federal WSRA or State PRC. Under each of the action alternatives, releases from Shasta Dam would increase from late spring through early autumn. Increased releases from Shasta Dam during this period would reduce the volume of water released from Folsom Dam

during the primary recreation season on the lower American River (late spring through early autumn). Flow volumes and water levels within the lower American River would, however, remain substantially similar to existing conditions and would remain within the river's typical range of variation during the primary recreation season. During the secondary recreation season (autumn through spring), precipitation is greater, flows in the Sacramento River and Delta are higher, and releases from Shasta Dam would be reduced to increase storage in Shasta Lake. Reclamation may need to occasionally increase releases from Folsom Dam to accommodate demand and offset decreased releases from Shasta Dam. Flow volumes and water levels in the lower American River would, however, remain substantially similar to existing conditions and within the river's typical range of variation during the secondary recreation season.

17.3.4 Direct and Indirect Effects

No-Action Alternative

Shasta Lake and Vicinity, Upper Sacramento River (Shasta Dam to Red Bluff), Lower Sacramento River and Delta, and CVP/SWP Service Areas
The impact discussion for the No-Action Alternative addresses all three study areas together, because this alternative would not impact land use in either of the three study areas.

Impact LU-1 (No-Action): Disrupt Existing Land Uses No new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, there would be no impact. Mitigation is not required for the No-Action Alternative.

Impact LU-2 (No-Action): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions No new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, there would be no impact. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP1 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact LU-1 (CP1): Disrupt Existing Land Uses Project construction activities associated with enlarging Shasta Dam and relocating utilities, infrastructure, and public service and recreational facilities could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to certain lands. Construction activities that could disrupt land uses include the transport of project materials to and from project construction sites and the demolition and relocation of some utilities. This impact would be potentially significant.

It is anticipated that construction activities would be limited to the Shasta Lake and vicinity study area; therefore, no impacts associated with disruption of existing land uses would be expected to occur downstream from Shasta Dam.

Construction activities specific to enlarging Shasta Dam would be limited to the existing footprint of the Shasta Dam facilities and areas immediately adjacent. The project construction site would be accessed by existing roadways (I-5, Shasta Dam Boulevard, and Lake Boulevard). The access roads allow commercial truck use and are capable of supporting project-generated traffic. Road modifications would be necessary to accommodate project traffic en route to the construction sites and access restrictions would occur. Noise, air quality, and traffic impacts along these local roadways are evaluated in separate sections of the PDEIS. Equipment staging areas would be sited to avoid affecting or conflicting with existing land uses.

Project construction activities associated with relocating utilities, infrastructure, and public service and recreational facilities could result in temporary and localized disruptions of existing land uses. Lake inundation resulting from future dam operations could result in long-term disruptions of land uses in the primary study area. The Utilities and Miscellaneous Minor Infrastructure Technical Memorandum provides descriptions and detailed maps of the utilities and minor infrastructure that would be demolished or relocated in the ancillary areas near Shasta Lake (Reclamation 2007). Chapter 21 (Utilities and Service Systems) of this PDEIS evaluates the project's impacts on utilities and service systems, and the environmental impacts of utilities demolition and relocation are evaluated in the pertinent technical chapters of the EIS (e.g., Water Quality, Air Quality and Climate, and Noise and Vibration).

Construction activities would affect major features around Shasta Lake and vicinity and would require demolition, relocation, modification, or reconstruction to prevent inundation of the features caused by an increased reservoir elevation. The major features affected would include:

- Major roads and road segments (Lakeshore Drive realignment)
- Vehicle bridges (Charlie Creek, Doney Creek, McCloud River, Didallas Creek, and Second Creek)
- Railroad bridge
- Utilities and service systems infrastructure
- Campgrounds and picnic areas
- Buildings (resort/marina, residential, USFS facilities)

The communities of Lakeshore and Sugarloaf would be affected the most by transportation infrastructure relocation activities. Seventy-five small road segments (both paved and unpaved) would need to be modified. CP1 would result in the inundation of Lakeshore Drive at numerous locations south of Charlie Creek Bridge and in two locations between Charlie Creek and Doney Creek bridges. Relocation of Lakeshore Drive and the UPRR would occur near existing residences and businesses. Road construction activity could result in temporary and localized increases in dust, noise, and construction truck traffic and potential disruption of access.

Seven bridges would need to be replaced. Construction activities associated with bridge modifications and relocations, particularly in areas with existing development such as Bridge Bay Marina and the communities of Lakeshore and Sugarloaf, could result in short-term disruptions of nearby residential, commercial, and industrial land uses. Bridge construction activity could result in temporary and localized increases in dust, noise, and construction truck traffic and potential disruption of access.

Approximately 66,000 feet of power and telecommunications lines would need to be demolished and reconstructed in areas around Shasta Lake. Utilities infrastructure relocation activities could result in short-term disruptions of land uses in communities and recreation areas around Shasta Lake. Relocation activities could require partial or full road closures and other access restrictions to ensure public safety. Utilities relocation activities could also result in temporary and localized increases in dust, noise, heavy equipment traffic, and other project traffic.

An estimated 45 buildings would be affected under a 6.5-foot dam raise. The buildings have been categorized as residential (cottages, homes, etc.), commercial (resorts, marinas, stores, etc.), and USFS sites (work stations, campground buildings, recreation site restrooms, etc.). Buildings within the inundation area would be removed, and some would be relocated. Utilities associated with the removed buildings (water systems, septic systems, telecommunications and power facilities) would also require demolition or abandonment. Construction activity related to removal and/or relocation of buildings would result in temporary and localized increases in dust, noise, and construction truck traffic and potential disruption of access. Some existing marinas would need to be modified or relocated, which would disrupt existing commercial and recreational land uses. See the *Recreation and Public Access Technical Report* for details concerning marina relocations.

Reservoir dikes would be required in the areas of Antlers/Lakeshore and at the UPRR track at the south end of Bridge Bay for protection of existing infrastructure from increased full pool elevations. Additional sites for dike construction could be added in the future. Dike construction could serve to lessen long-term land use impacts resulting from the project by eliminating the need to remove and relocate a number of structures. Construction activities

associated with dike construction would result in temporary and localized increases in dust, noise, and construction truck traffic and potential disruption of access.

Project implementation could result in short-term disruptions of land uses of parcels around Shasta Lake and vicinity during construction and relocation activities; long-term disruptions of land use could also result from project operations. This impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Impact LU-2 (CP1): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation would result in inundating land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies. This impact would be potentially significant.

It is anticipated that construction activities would be limited to the Shasta Lake and vicinity study area; therefore, no conflicts with existing land use goals and policies would be expected to occur in planning jurisdictions downstream from Shasta Dam.

Project implementation would result in an increase in reservoir pool elevation during extreme storm events, which could result in the flooding of approximately 1,200 acres in the lower elevations around Shasta Lake. To prevent utilities and infrastructure damage, Reclamation would relocate roads, utilities and service systems, marinas, and other structures and would modify a number of bridges. Relocation plans are based on broad assumptions regarding optimum construction, operation, and environmental conditions. Areas planned for relocation activities could have land use designations that conflict with the land use proposed by the project. It is anticipated that some relocation activities would conflict with land use designations. Specific relocation sites are needed before a detailed analysis can be made. Once relocation sites are known, the proposed land use would be compared to the existing land uses and land use designations to determine consistency with the USFS LRMP and the *Shasta County General Plan* and the Shasta County Zoning Ordinance.

Areas that would be most affected by project implementation are located on the Sacramento Arm of Shasta Lake and include the communities of Sugarloaf and Lakeshore. A number of existing residential land uses would be inundated by a higher full pool elevation in Shasta Lake. Residences within 20 feet of the new full pool elevation will be demolished and most will be relocated.

Most recreation facilities that could be inundated by project implementation would be relocated; some recreation facilities would be relocated adjacent to existing recreation facilities. Sites proposed for the relocation of recreational facilities could be inconsistent with the current land use designations.

Reclamation would cooperate with USFS to find the most suitable relocation sites that would be consistent with the STNF LRMP and the NRA Management Guide.

Open space lands would be inundated. STNF LRMP land allocations that would be inundated include Riparian Reserve allocations. Loss of the use of NRA lands would be inconsistent with LRMP and NRA goals and policies. Reclamation would coordinate mitigation measures with USFS to minimize the impacts from losing the ability to use lands around Shasta Lake.

Vegetation clearing required for the relocation of structures, marinas, recreation facilities, and utilities could be inconsistent with the STNF LRMP, the *Shasta County General Plan*, and the Shasta County Zoning Ordinance. Many relocation activities would require vegetation clearing prior to construction. Specific clearing sites would be dependent on the sites chosen for utilities, building, and infrastructure relocation. The sites have not been determined at this time. Once specific relocation sites are known and the areas requiring vegetation clearance are determined, an analysis would be performed to determine whether the proposed action would be inconsistent with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan*, and the Shasta County Zoning Ordinance. Reclamation would obtain authorization and/or use permits from USFS for actions within the jurisdiction of USFS; Reclamation would also obtain authorization and/or use permits from Shasta County and the California Department of Forestry and Fire Protection for vegetation clearing activities within the jurisdiction of Shasta County.

It should be noted that even where site-specific land use designations in the NRA conflict with proposed relocation activities, the STNF LRMP identifies the following overarching goal for the STNF: “provide for continued use and new development of hydroelectric facilities.” This implies that specific USFS land allocations that may be inconsistent with relocation activities could be revised or amended for project purposes. However, Reclamation would cooperate with USFS to amend site-specific land use designations, which could require additional NEPA review.

Site-specific information is needed for all infrastructure, building, and utilities relocation plans to review completely for consistency with existing land use planning documents, primarily the STNF LRMP and the *Shasta County General Plan*. Given the magnitude of facilities that might be relocated, including existing marinas, it is anticipated that there would be some inconsistencies with existing planning policies. This impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact LU-3 (CP1): Disrupt Existing Land Uses Construction activities would be limited to the primary study area; therefore, there would be no disruption of

existing land uses in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP1): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area; therefore, no conflicts with existing land use goals and policies would occur in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP2 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact LU-1 (CP2): Disrupt Existing Land Uses Project construction activities associated with enlarging the Shasta Dam facilities and relocating utilities and infrastructure could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to land. Construction activities that could disrupt land uses include the transport of project materials to and from project construction sites. This impact would be potentially significant.

This impact would be similar to Impact LU-1 (CP1). A dam raise of 12.5 feet would result in a larger area of inundation than CP1, which would, in turn, result in additional relocation of existing structures, infrastructure, and utilities and a longer duration for the impact. Reclamation estimates the construction of CP2 would take 44 months, which would be 8 months longer than for CP1. CP2 would, therefore, result in longer term disruptions of land use than would CP1. Approximately 500 additional acres would be inundated by CP2, totaling 1,734 acres of land that would be inundated by Shasta Dam operations. Specific information regarding the location and number of structures that would permanently lost will be incorporated into the land use impact analysis.

Project implementation could result in short-term and long-term disruptions of existing land uses. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Impact LU-2 (CP2): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation could result in a permanent loss of inundated land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies. This impact would be potentially significant.

This impact would be similar to LU-2 (CP1). A dam raise of 12.5 feet would create a larger area of inundation than CP1, which, compared to CP1, would result in additional relocation of structures and infrastructure that would be subject to USFS and Shasta County land use goals and policies. A site-specific analysis would be conducted to determine where relocation activities and permanent land base losses resulting from project implementation would be inconsistent with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan*, and the Shasta County Zoning Ordinance.

Project implementation could result in short-term and long-term impacts that could conflict with existing land use goals and policies. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact LU-3 (CP2): Disrupt Existing Land Uses Construction activities would be limited to the primary study area; therefore, there would be no disruption of existing land uses in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP2): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area; therefore, no conflicts with existing land use goals and policies would occur in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply
Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP3 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact LU-1 (CP3): Disrupt Existing Land Uses Project construction activities associated with enlarging the Shasta Dam facilities and relocating utilities and infrastructure could result in short- and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to land. Construction activities that could disrupt land uses include the transport of project materials to and from project construction sites. This impact would be potentially significant.

This impact would be similar to LU-1 (CP1). A dam raise of 18.5 feet would result in a larger area of inundation than CP1, which would result in additional relocation of existing structures and infrastructure compared to CP1 and a longer duration for the impact. Reclamation estimates that construction of CP3 would take 46 months, which would be 10 months longer than for CP1. Approximately 2,500 acres of land would be inundated by CP3 and, according to the 2003 infrastructure inventory at Shasta Lake, an estimated 130 buildings

would be inundated under an 18.5-foot dam raise (Shasta County 2003). Specific information regarding the location and number of structures that would be permanently lost would be incorporated into the land use impact analysis. CP3 would require a more extensive (longer and wider) system of reservoir dikes than CP1 to accommodate increased Shasta Lake elevations resulting from Shasta Dam operations. A dam raise of 18.5 feet would result in the encroachment of 100 road segments. Lakeshore Drive could be inundated for nearly its entire length between Charlie Creek and Doney Creek.

Project implementation could result in short- and long-term disruptions of existing land uses. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Impact LU-2 (CP3): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation could result in a permanent loss of inundated land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies. This impact would be potentially significant.

This impact would be similar to LU-2 (CP1). A dam raise of 18.5 feet would result in a larger area of inundation than CP1, which, compared to CP1, would result in additional relocation of existing structures and infrastructure that would be subject to existing USFS and Shasta County land use goals and policies. A site-specific analysis would be conducted to determine where relocation activities and permanent land base losses resulting from project implementation would be inconsistent with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan*, and the Shasta County Zoning Ordinance.

Project implementation could result in short-term and long-term impacts that could conflict with existing land use goals and policies. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact LU-3 (CP3): Disrupt Existing Land Uses Construction activities would be limited to the primary study area; therefore, there would be no disruption of existing land uses in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP3): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area; therefore, no conflicts with existing land use goals and policies would occur in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP4 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact LU-1 (CP4): Disrupt Existing Land Uses Project construction activities associated with enlarging the Shasta Dam facilities and relocating utilities and infrastructure could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to land. Construction activities that could disrupt land uses include the transport of project materials to and from project construction sites. This impact would be potentially significant.

This impact would be similar to LU-1 (CP1). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Impact LU-2 (CP4): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation could result in a permanent loss of inundated land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies. This impact would be potentially significant.

This impact would be similar to LU-2 (CP1). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact LU-3 (CP4): Disrupt Existing Land Uses Construction activities would be limited to the primary study area. Gravel augmentation and the Reading Island habitat restoration along the upper Sacramento River could cause minor disruptions of existing land uses in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP4): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area. Gravel augmentation and the Reading Island habitat restoration along the upper Sacramento River would not alter land uses and would not be expected to conflict with existing land use goals and policies. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP5 addresses the Shasta Lake and

Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact LU-1 (CP5): Disrupt Existing Land Uses Project construction activities associated with enlarging the Shasta Dam facilities and relocating utilities and infrastructure could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to land. Construction activities that could disrupt land uses include the transport of project materials to and from project construction sites. This impact would be potentially significant.

This impact would be similar to LU-1 (CP1). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Impact LU-2 (CP5): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation could result in a permanent loss of inundated land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies. This impact would be potentially significant.

This impact would be similar to LU-2 (CP-1). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact LU-3 (CP5): Disrupt Existing Land Uses Construction activities would be limited to the primary study area. Gravel augmentation and the Reading Island habitat restoration along the upper Sacramento River could cause minor disruptions of existing land uses in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP5): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area. Gravel augmentation and the Reading Island habitat restoration along the upper Sacramento River would not alter land uses and would not be expected to conflict with existing land use goals and policies. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

17.3.5 Mitigation Measures

Table 17-1 presents a summary of mitigation measures for land use.

Table 17-1. Summary of Mitigation Measures for Land Use

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact LU-1: Disrupt Existing Land Uses (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	LU-1: Minimize and/or Avoid Temporary Disruptions to Local Communities.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact LU-2: Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	LU-2: Minimize and/or Avoid Conflicts with Land Use Goals and Policies.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact LU-3: Disrupt Existing Land Uses (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	NI	NI	NI	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	NI	NI	NI	LTS	LTS
Impact LU-4: Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	NI	NI	NI	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	NI	NI	NI	LTS	LTS

Notes:
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant
SU = significant and unavoidable

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts LU-3 and LU-4 for the extended study area. Mitigation is provided below for Impacts of CP1 on land uses in the primary study area.

Mitigation Measure LU-1 (CP1): Minimize and/or Avoid Temporary Disruptions to Local Communities To minimize and/or avoid temporary

disruption to local communities, the following measures will be implemented during project construction:

- Prior to construction, Reclamation and its contractor will develop a construction plan for each affected community (i.e., Lakeshore, Sugarloaf), consisting of the following:
  - Alternate access routes will be identified for local residences and businesses affected by project construction activities.
  - Construction and staging areas will be fenced, secured, and clearly marked. Security will be provided to ensure public safety.
  - Public parking areas outside of the construction staging areas will be kept clear of construction-related equipment of materials at all times.
  - Any open trenches will be covered or secured after daily activities to protect worker and public safety.
  - Construction activities near noise-sensitive land uses (e.g., near residences, campgrounds) or land uses that experience high levels of public activity (e.g., boat ramps, marinas) will be restricted to days and hours that minimize land use conflicts to the extent feasible.
- The contractor will provide advance notice of the construction activities schedule to the affected community members (e.g., residences, property owners, business owners, and public facilities operators), including posting of signs in the project area.
- The contractor will provide a phone number and community contact for inquiries about the project throughout the construction period.
- Reclamation and its contractor will coordinate with local jurisdictions and obtain all necessary permits (e.g., encroachment permit, utility excavation permit), will comply with permit conditions established to minimize construction impacts, and will assign an inspector to the project to oversee construction activities.

Implementing this mitigation measure would substantially reduce land use capability impacts generated by short-term construction activities, but might not reduce all impacts to a less than significant level. As a result, this impact would remain significant and unavoidable.

Mitigation Measure LU-2 (CP1): Minimize and/or Avoid Conflicts with Land Use Goals and Policies To reduce conflicts with land use goals and

policies of affected jurisdictions, Reclamation will implement the following measures:

- Reclamation will coordinate with USFS to find the most suitable relocation sites for recreation facilities with respect to consistency with the STNF LRMP and the NRA Management Guide.

- Reclamation will coordinate with USFS to identify measures to minimize the impacts of the loss of use of USFS lands around Shasta Lake (including open space and Riparian Reserve allocations) caused by inundation, and measures to offset inconsistencies with the LRMP and NRA goals and policies related to the loss of use of NRA lands.

- As utility and facility relocation sites are being refined, Reclamation will evaluate consistency of the relocated land uses with the USFS LRMP, the NRA Management Guide, the Shasta County General Plan, and the county zoning ordinance. To the degree possible, Reclamation will design the relocated utilities and facilities to comply with these plans and ordinances. If needed, Reclamation would seek permits, easements, and or plan amendments.

Implementing this mitigation measure would substantially reduce land use plan consistency impacts, but might not reduce all impacts to a less than significant level. As a result, this impact would remain significant and unavoidable.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts LU-3 and LU-4 for the extended study area. Mitigation is provided below for the impacts of CP2 on land uses in the primary study area.

Mitigation Measure LU-1 (CP2): Minimize and/or Avoid Temporary Disruptions to Local Communities This mitigation measure is identical to Mitigation Measure LU-1 (CP1).

Mitigation Measure LU-2 (CP2): Minimize and/or Avoid Conflicts with Land Use Goals and Policies This mitigation measure is identical to Mitigation Measure LU-2 (CP1).

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is required for impacts LU-3 and LU-4. Mitigation is provided below for the impacts of CP3 on land uses in the primary study area.

Mitigation Measure LU-1 (CP3): Minimize and/or Avoid Temporary Disruptions to Local Communities This mitigation measure is identical to Mitigation Measure LU-1 (CP1).

Mitigation Measure LU-2 (CP3): Minimize and/or Avoid Conflicts with Land Use Goals and Policies This mitigation measure is identical to Mitigation Measure LU-2 (CP1).

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is required for impacts LU-3 and LU-4 in the extended study area. Mitigation is provided below for the impacts of CP4 on land uses in the primary study area.

Mitigation Measure LU-1 (CP4): Minimize and/or Avoid Temporary Disruptions to Local Communities This mitigation measure is identical to Mitigation Measure LU-1 (CP1).

Mitigation Measure LU-2 (CP4): Minimize and/or Avoid Conflicts with Land Use Goals and Policies This mitigation measure is identical to Mitigation Measure LU-2 (CP1).

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for impacts LU-3 and LU-4 for the extended study area. Mitigation is provided below for the impacts of CP5 on land uses in the primary study area.

Mitigation Measure LU-1 (CP5): Minimize and/or Avoid Temporary Disruptions to Local Communities This mitigation measure is identical to Mitigation Measure LU-1 (CP1).

Mitigation Measure LU-2 (CP5): Minimize and/or Avoid Conflicts with Land Use Goals and Policies This mitigation measure is identical to Mitigation Measure LU-2 (CP1).

17.3.6 Cumulative Effects

The action alternatives could temporarily affect land use in the Shasta Lake and vicinity portion of the project area during construction, and some components might be inconsistent with the USFS LRMP, the NRA Management Guide, the Shasta County General Plan, and the county zoning ordinance. Only a few of the present or reasonably foreseeable future actions are located in the vicinity of Shasta Lake and have the potential to conflict with land uses that might also be affected by construction of the action alternatives. These actions include Antlers Bridge replacement, the Turntable Bay Master Development Plan, and the Iron Mountain Mine Restoration Plan. The Antlers Bridge replacement is currently under construction and would be completed before any of the action alternatives would begin. With respect to the Turntable Bay Master Development Plan and the Iron Mountain Mine Restoration Plan, it is unlikely these activities would occur simultaneously with the action alternatives, or would considerably and adversely affect use of the same land. Therefore, construction activities related to implementation of the proposed SLWRI alternatives would not contribute

considerably to significant cumulative impacts related to temporary land use impacts.

A few of the present or reasonably foreseeable future actions are located in the STNF, the NRA, or Shasta County. As with the action alternatives, some of these actions might not be consistent with the USFS LRMP, the NRA Management Guide, the Shasta County General Plan, and the county zoning ordinance. The cumulative effects of these actions on resources protected by these land use plans are addressed in other the pertinent technical chapters of the PDEIS.

This page left blank intentionally.

Chapter 18
Recreation and Public Access

18.1 Affected Environment

This section describes recreational facilities and opportunities and public access in the primary and extended study areas.

18.1.1 Recreation

Shasta Lake and Vicinity

Shasta Lake is the centerpiece of the Shasta Unit of the Shasta-Trinity National Recreation Area (NRA), which is administered by the USFS Shasta-Trinity National Forest, headquartered in Redding. The Shasta Unit has a total area of approximately 125,500 acres, of which 29,500 acres are currently inundated by Shasta Lake at full pool, leaving approximately 96,000 acres of land area (USFS 1996). Figure 18-1 shows the recreation facilities in the Shasta Unit of the NRA.

Recreation Setting and Activities The Shasta-Trinity National Forest manages the Shasta Unit of the NRA to be a showcase recreational area. Environmental factors such as a hot summer season, steep terrain, and sparse forest cover in some areas favor water-oriented recreation as the main attraction. The focal point of recreation in the Shasta Unit is Shasta Lake itself, with its large surface area and 370 miles of shoreline (USFS 1996). The lake has four major arms; three of the arms are more than 12 miles long at full pool, and all are a mile or more wide at their downstream ends. The main basin of the lake near the dam is about 2 miles across.

Because boating is the predominant recreation activity at Shasta Lake, the lake attracts all types and sizes of powerboats, including personal watercraft (jet skis); runabouts, ski boats, and fishing boats; and larger cabin cruisers, pontoon boats, deck boats, and houseboats (Graefe et al. 2005).

Most fishing at Shasta Lake is done by boat rather than from the shoreline. The summer stratification of the lake into an upper warm layer above a deep cold-water pool provides opportunities for anglers to catch both warmwater and cold-water fish species year-round (USFS 1996).

Because of the steep terrain around the lake, there are no suitable sites for developed beach facilities (USFS 1996), and most swimming is associated with boating. Shasta Lake is also a very popular camping destination.

The primary recreation season at Shasta Lake is the period of approximately 100 days from Memorial Day weekend to Labor Day weekend, although recreation uses occur year-round. Daytime high temperatures during the summer average in the mid to high 90s and in midwinter average in the mid 50s. Nearly all of the 30 to 70 inches of precipitation received by the lake area, mostly in the form of rain but occasionally as snowfall, occurs during late fall, winter, and spring (USFS 1996).

The Shasta Unit is bisected by Interstate 5, which provides easy access in 4 hours or less for more than five million residents of southern Oregon and Northern California (USFS 1996). The population of Shasta County was estimated to be about 181,000 in 2009 (U.S. Census Bureau 2011).

This combination of large size and plentiful water-based recreation opportunities, favorable climate, and easy access make Shasta Lake one of the most visited recreation destinations in the state and region. The Shasta Unit of the Shasta-Trinity NRA received approximately 2.4 million recreation visitor days of use in 1994 (USFS 1996). Use levels are reduced during low-water years. Boating use levels as high as 1,400 boats have been recorded on summer weekends in recent years. Houseboats have been found to compose 30–40 percent of boat traffic on summer weekends (Graefe et al. 2005).

Recreation Facilities The boating, fishing, camping, and other recreation activities enjoyed at Shasta Lake are supported by a diverse range of public, commercial, and private facilities. Table 18-1 summarizes the major types of recreation facilities present.

Recreational boating on Shasta Lake is dependent on access to the water via shoreline facilities such as boat ramps and marinas. Six USFS public boat ramps are dispersed around the lake (USFS 2010a). Total parking capacity at the six ramps is about 600 vehicles (USFS 2007). The three largest ramps also offer accessible boat loading platforms for use by disabled persons (USFS 2010a).

A two-lane low-water ramp is used only when the reservoir is at least 75 feet below full pool, making the other public ramp in that area unusable (USFS 2010a). Parking is on the lake bed, and vault toilets are provided when the ramp is in use.

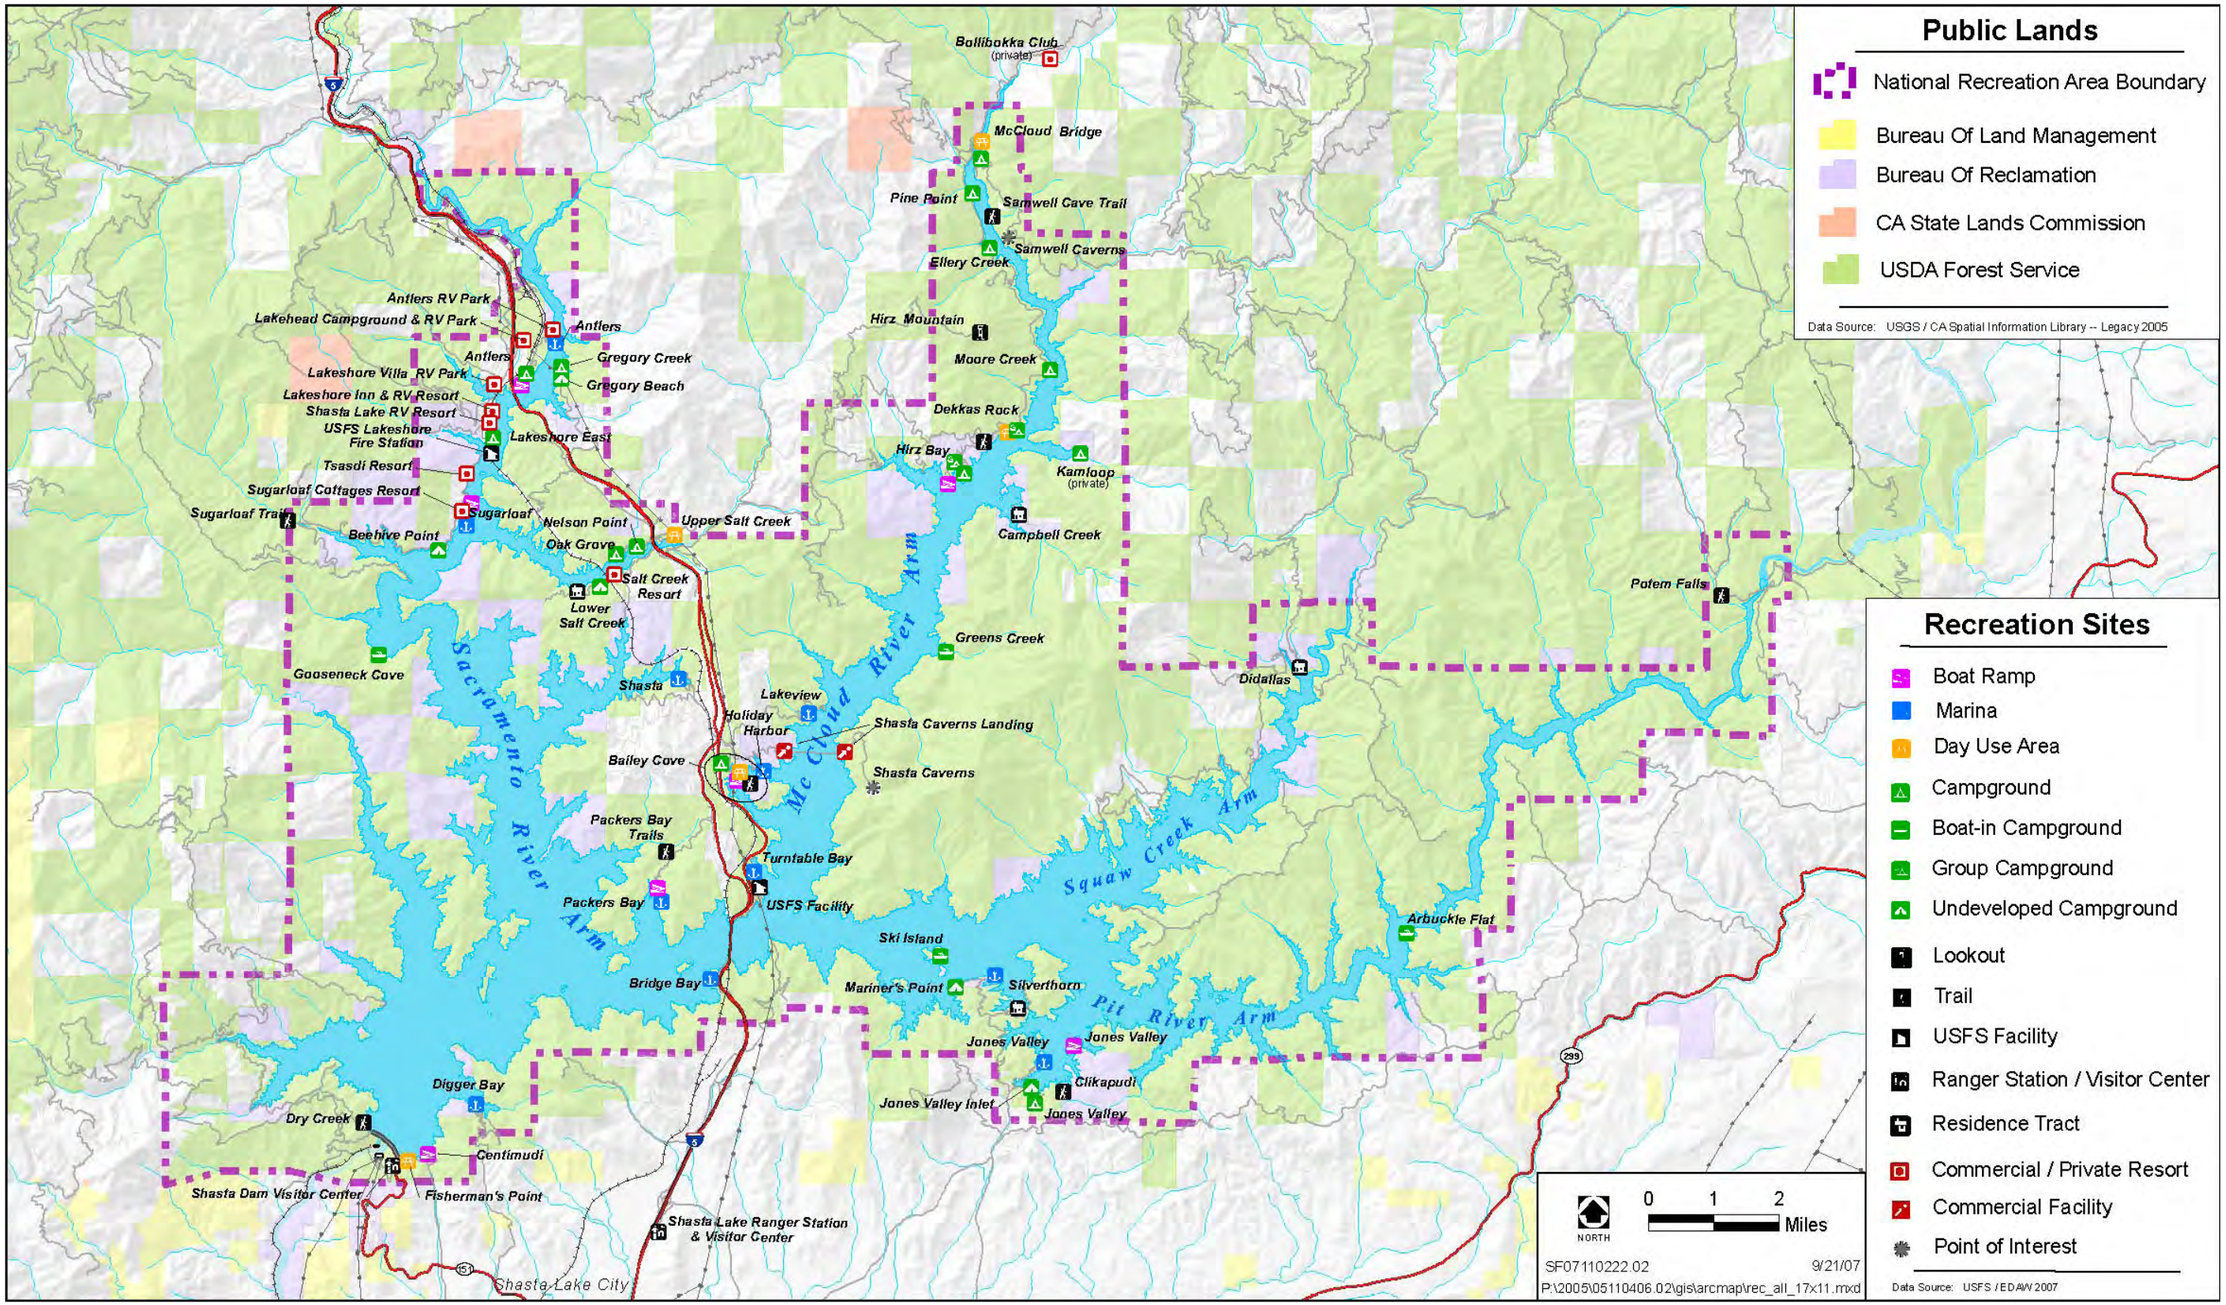

Figure 18-1. Recreation Facilities in the Shasta Unit of the NRA

This page left blank intentionally.

Ten commercial marinas and marina resorts, all of which operate under USFS special-use permits, are distributed around Shasta Lake. All of the marinas offer houseboats for rent, providing a combined rental fleet of several hundred houseboats. Some marinas also rent other types of powerboats, personal watercraft, and nonpowered boats. The other primary service offered by most of the marinas is short- and long-term moorage for private boats. In addition to the rental fleets, several hundred private houseboats are moored at these marinas, along with many other powerboats. Additional commercial services are offered at most marinas/marina resorts, such as boat launching, gas sales, stores, and restaurants. Some have tent and recreational vehicle (RV) campsites and cabin or motel accommodations (ShastaLake.com 2011).

Table 18-1. Summary of Public, Commercial, and Private Recreation Facilities on Shasta Lake

Type of Facility	Number	Description
Public Facilities		
Boat ramp	6	Each provides parking, restrooms, and two to four paved launch lanes at full pool; there is also a two-lane low-water ramp with parking on the lake bed.
Day-use area	4	Each provides parking, picnic sites with tables and grills, and restrooms.
Family or group campground	15	Twelve family campgrounds with eight to 59 sites per campground; all have flush and/or vault toilets, most have piped water. Three group campgrounds have water and vault toilets.
Shoreline camping area	5	No designated campsites; all are provided with vault toilets, some with piped water.
Boat access campground	4	Eight to 23 sites per campground, accessible only by boat; vault toilets are provided.
Trail/trailhead	12	Twelve trails from one-third mile to 8 miles in length; several trailheads are incorporated into boat ramp or day-use parking areas, while others are stand-alone facilities.

Table 18-1. Summary of Public, Commercial, and Private Recreation Facilities on Shasta Lake (contd.)

Type of Facility	Number	Description
Commercial Facilities		
Marina/marina resort	10	Wide range of sizes and services; most provide boat rentals, moorage, gas, groceries, etc.; some provide campsites and/or cabins.
Nonmarina resort/ RV park	7	Most provide cabins and/or RV and tent sites, moorage, and groceries/sundries. (Note: Five of these have shoreline infrastructure other than floating docks, two do not; additional resorts are nearby but not on the lake shoreline.)
Organization campground	1	Operated for members and the general public by California Kamloops, Inc.; tent camping, accessible only by boat, and boat dock/moorage provided for campers.
Other commercial facility	2	Shasta Lake Cavern tour; provides ferry and bus transport to caverns, moorage for private boats, and a gift shop.
		Bollibokka Club; offers lodging, meals, and guided trout fishing trips on the McCloud River upstream from the lake. (Note: this facility is not within the NRA, but is accessed via a USFS road)
Private Facilities		
Private cabin	~160	Located in four tracts, managed by USFS for individual recreation use with restrictions on improvements.

Source: USFS 1996

Key:
NRA = National Recreation Area
RV = recreational vehicle
USFS = U.S. Forest Service

Sixteen nonmarina resorts and RV parks are located on or near Shasta Lake. These typically provide some combination of tent and/or RV campsites and cabins with other ancillary amenities such as stores, game rooms, restaurants, and swimming pools (ShastaLake.com 2011). Some of the resorts have special-use permits from USFS for use of a segment of shoreline land and/or installation of a boat dock. Other resorts are situated a short distance from the shoreline but do not provide direct access to the lake.

Thirteen USFS-constructed and concessionaire-operated and maintained family and group campgrounds are located on the lake. These range in size from 8 to 59 sites and generally provide flush and/or vault restrooms and drinking water. Several of the campgrounds are adjacent to a public boat ramp or are served by a nearby ramp. Also available to campers are five shoreline camping areas with vault toilets but no designated sites; boaters may use one of four boat-access campgrounds ranging in size from eight to 23 sites, each with fire rings, picnic tables, and vault toilets (USFS 2010b). Four USFS day-use sites with views of the lake provide five to nine picnic sites each, along with restrooms and drinking water (USFS 2011). An additional day-use and swim area is at the upstream end of the Salt Creek inlet, but is not currently operational.

Twelve USFS hiking and mountain biking trails, totaling about 25 miles in length, are located on or near the shoreline of Shasta Lake. Several of these trails are accessed via trailheads located at boat ramp and day-use parking areas, while others are served by stand-alone trailheads (USFS 2010c).

A unique commercial recreation service offered at Shasta Lake is the Shasta Caverns Tour. The tour operator uses a parking area, gift shop, and ferry boarding facility on the west shore of the McCloud River Arm, and a similar staging area on the opposite shore, where visitors board buses for the short drive to the caverns.

Four USFS-managed "recreation residence" tracts are located on Shasta Lake, with numerous private cabins near the shoreline. USFS policy is to manage these facilities for the individual recreation use of the owners and to keep the areas in a primarily natural state (USFS 1996).

Reservoir Operations and Effects on Recreation Reclamation manages Shasta Lake primarily to provide water supply, which results in an annual cycle of major water level fluctuations at the lake. Such fluctuations affect access to water-based recreation facilities and services. In the typical annual cycle, the reservoir will reach its highest elevation for the year during late spring, then will be gradually drawn down through the summer peak recreation season and into fall. Refilling begins with the arrival of substantial winter rains in the watershed and continues through spring with additional rain and snowmelt. The highest annual reservoir pool level usually occurs between mid-April and mid-May. As the reservoir is drawn down during summer and fall, the lowest elevations are typically reached in November or December (DWR 2011a).

Boating facilities on the lake are generally designed to accommodate these expected and normal fluctuations in reservoir pool levels. All but one of the six primary public boat ramps extend to at least 75 feet below full pool; four extend from 95 feet to more than 200 feet below full pool (USFS 2010a).

Certain boating safety issues are related to pool level fluctuations. Reservoir drawdown places rocks, shoals, and islands just below the water surface where they may be struck by boats. Conversely, rising water levels may put obstacles that were easily seen and avoided one day just beneath the surface the next. Because the lake level varies considerably on a seasonal basis, the pattern of submerged obstacles varies as well.

Rising water levels may also increase the amount of floating debris in the lake, primarily woody debris that may include large tree limbs and logs. The larger debris can present a hazard to boating; even smaller debris can damage props or clog water intake ports in boat-engine cooling systems.

Campers are affected to some degree by falling pool levels because the distance from the campsites to the shoreline increases as the pool level decreases. The

sites nearest the shoreline at most public campgrounds will be within a few hundred feet of the water through most summers when the pool level is generally high, but they may be considerably farther from the water during the off-peak seasons or during the latter portion of the peak season in dry years. Because the shoreline terrain is steep in most areas, the drawdown zone is difficult for visitors to use. Drawdown of the reservoir also has aesthetic effects for lake users, with an expanding band of mostly bare earth and rock exposed as the pool level declines.

Upper Sacramento River (Shasta Dam to Red Bluff)

The Sacramento River corridor is an important recreation resource for the northern California region. Access and facilities are found on both public and private land. This section describes existing recreation and public access resources in the primary study area, beginning at and including the downstream side of Shasta Dam and extending to Lake Red Bluff/Red Bluff Diversion Dam (RBDD) that could be affected by the project. Figure 18-2 shows the recreation facilities in the upper Sacramento River portion of the primary study area.

Shasta Dam Reclamation controls public access at Shasta Dam. For security reasons, access was by permit only for several years; since 2010 visitors have been allowed to drive across the dam between 6 a.m. and 10 p.m. after producing a valid driver's license and vehicle registration and subjecting their vehicle and any trailer to inspection (Reclamation 2010).

The area immediately below the dam, where the Shasta Powerplant and associated infrastructure is located and where water is released from Shasta Dam and the powerplant, is closed to public use for safety and security reasons.

Shasta Dam to Keswick Dam Recreation facilities provided along this portion of the Sacramento River include the Chappie-Shasta Off Highway Vehicle (OHV) Area, Sacramento River Rail Trail and other trails, Shasta Campground, and Keswick Reservoir Boat Ramp.

Keswick Reservoir occupies nearly the full length of the narrow river gorge that stretches 9 miles from Keswick Dam to Shasta Dam. The reservoir has a healthy population of wild trout, including German browns and rainbows, and fish are occasionally planted by the DFG.

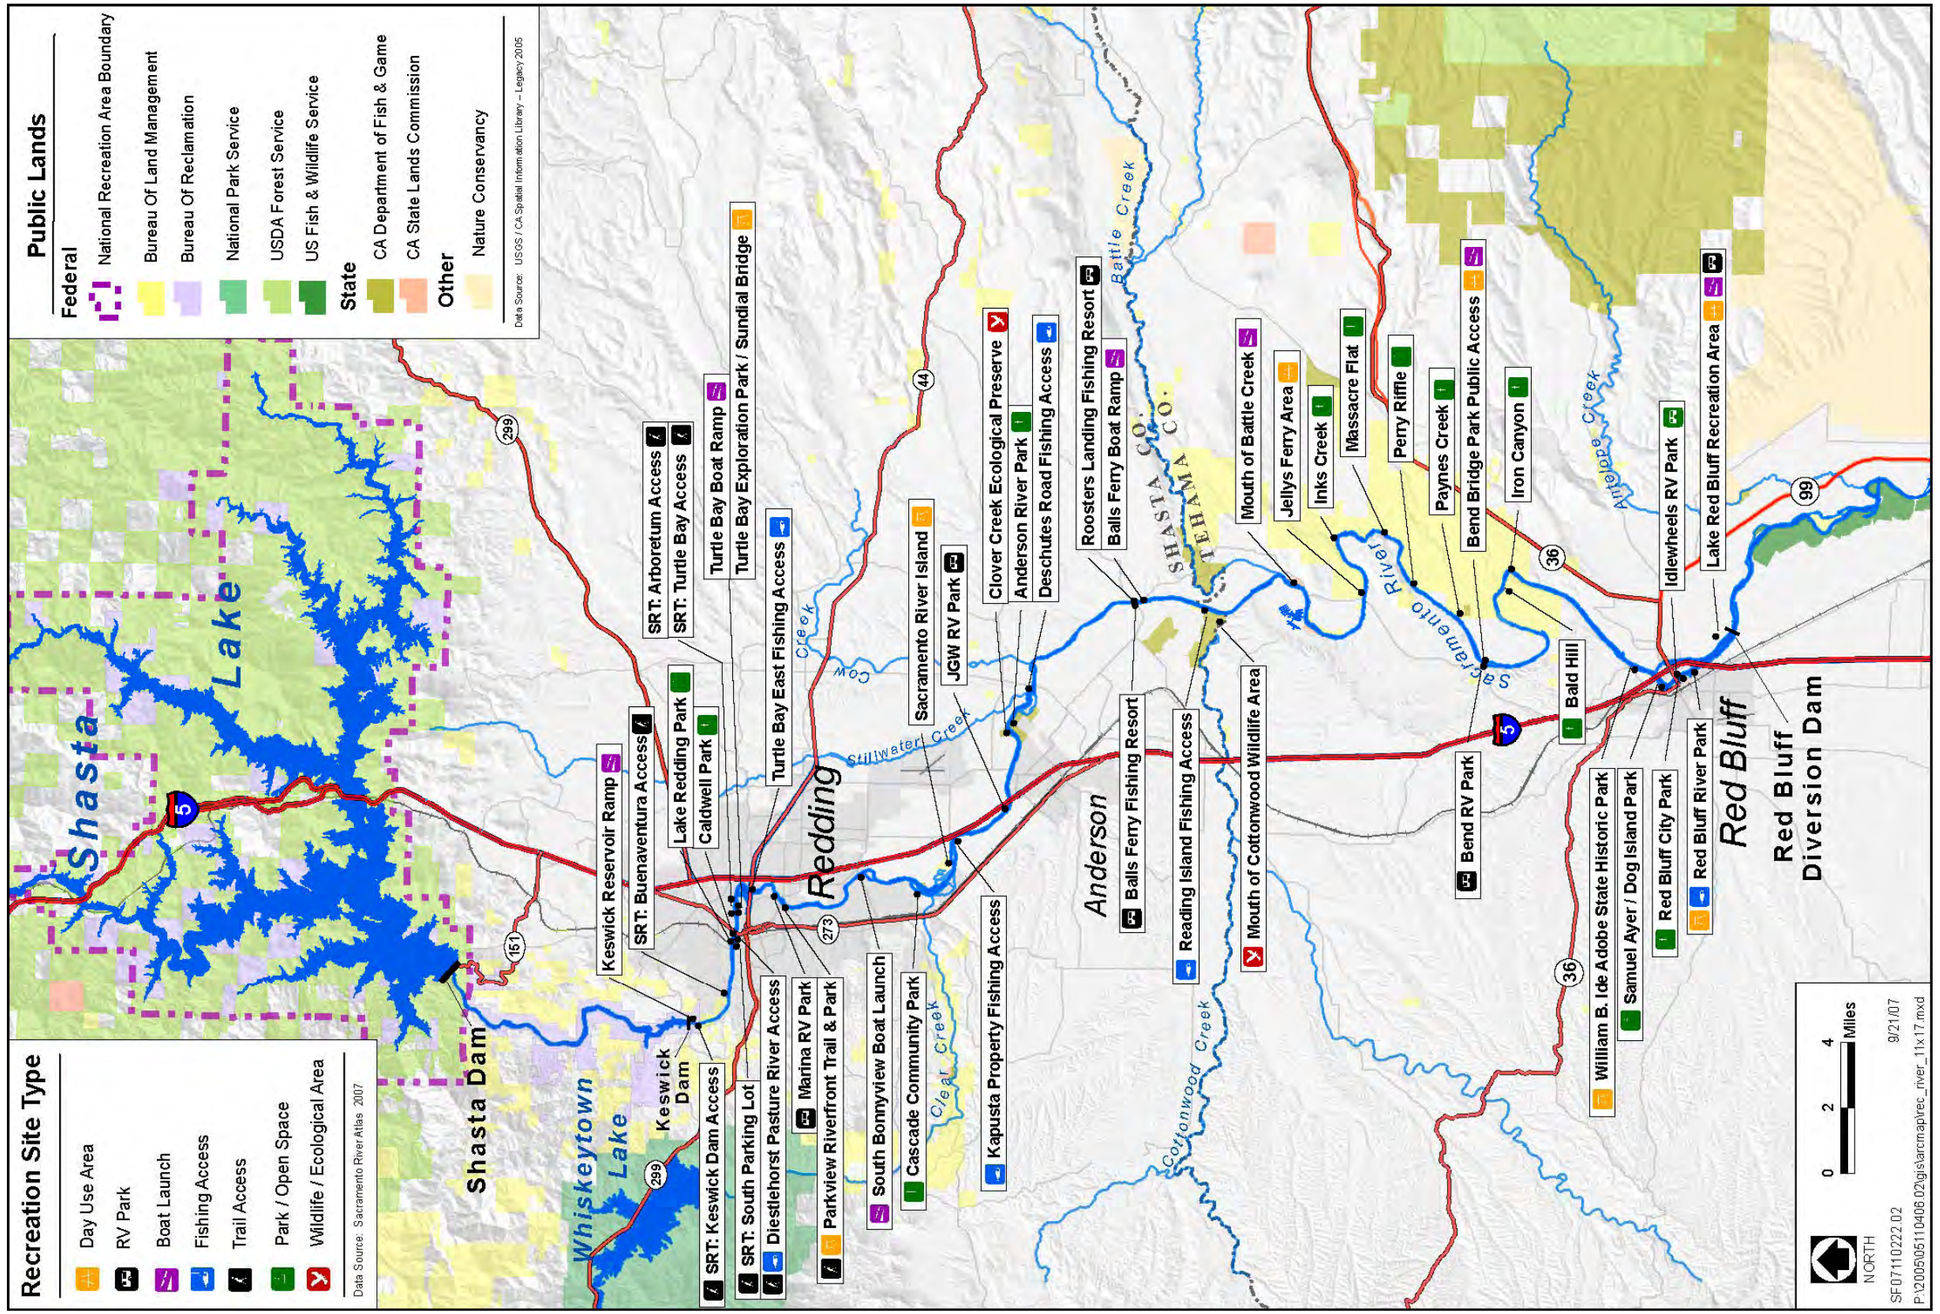

Figure 18-2. Recreation Facilities in the Upper Sacramento River Portion of the Primary Study Area

This page left blank intentionally.

The Chappie-Shasta OHV Area, managed by the U.S. Bureau of Land Management (BLM) Redding Field Office, provides opportunities for OHV use on 200 miles of roads throughout 52,000 acres of land. Two staging areas provide access to OHV roads and trails that are rated difficult and moderate, and that are open to two-wheeled motorcycles, all-terrain vehicles, and four-wheel-drive high-clearance vehicles (BLM 2006). The Shasta staging area and campground are situated close to the river about 1 mile below Shasta Dam. The campground has 30 campsites for tents and RVs. No water or electricity hook-ups are available (USFS 2010b).

The Sacramento River Rail Trail, a nonmotorized-use National Recreation Trail, extends more than 10 miles along an old railroad line and closely follows the west side of the river and of the shoreline of Keswick Reservoir. The wide and generally flat gravel-surface trail is open year-round to equestrians, hikers, and bicyclists. Trailheads are located at the Chappie-Shasta OHV Area, at Keswick Boat Ramp and Rock Creek, at the southern terminus of the trail, and at a location near the midpoint of the trail. The BLM lands above the east side of Keswick Reservoir have more than 20 miles of trails, primarily single-track nonmotorized trails with a dirt surface, connecting at the north end to Shasta Dam (Healthy Shasta 2009).

Keswick Dam to Red Bluff Diversion Dam This area encompasses about 60 miles of the Sacramento River and contains the majority of recreation resources and public access sites within the primary study area. Recreational activities are numerous within this area and include fishing, boating, hiking, horseback riding, biking, hunting, camping, picnicking, wildlife viewing/nature observation, viewing historic sites, and enjoying developed urban recreational activities such as soccer and baseball. The discussion below provides a brief overview of the activities supported by the Sacramento River and riverside recreation facilities, followed by additional details about recreation facilities.

Recreational Setting and Activities The Sacramento River between Keswick Dam and RBDD flows past cities and towns and both private and public lands. The riparian forests along the river, the oak woodlands and grasslands on higher ground, and riverside bluffs provide a scenic setting for river users at riverside recreation facilities and for boaters and anglers on the river. The riparian landscape between Redding and Red Bluff is described as the most unspoiled of the entire 375-mile river (DBW 2011a). BLM owns and manages much of the riverside lands between Balls Ferry and Red Bluff (approximately River Mile (RM) 250 to RM 276).

The climate of the northern Sacramento River valley is hot and dry during the summer, with daily high temperatures averaging in the upper 90s Fahrenheit and little or no precipitation. Winter climate can be described as moderate but wet, with average daily high temperatures in the mid 50s during December and January and an average of 4 to 8 inches of rain per month between November and March.

River use and the recreation opportunities available vary throughout the year with the highly variable flow of the river. During the winter and spring, the river may have short-term peak flows of 80,000 to 90,000 cubic feet per second (cfs) and is usually flowing above 20,000 to 30,000 cfs. Flows are less variable during the summer and fall, with typical summer flows of 10,000 to 15,000 cfs and typical fall flows of 5,000 to 10,000 cfs (DWR 2011b). BLM identifies flows of 6,000 to 12,000 cfs as optimal for boating (BLM no date). River temperature is cold year-round because of the release of water from the deep cold-water layers of Keswick Reservoir, and Shasta Lake upstream. Winter water temperatures are in the 40s Fahrenheit and summer water temperatures do not rise above the mid 50s.

The Sacramento River is known for good fishing opportunities. Species such as salmon, steelhead, rainbow trout, sunfish, largemouth bass, and striped bass can be found within the river. Fly fishing is popular, especially when flows are 5,000 to 8,000 cfs, which typically occurs during fall and early winter (Fly Fishing Connection 2003).

Boating opportunities are abundant along the Sacramento River from Keswick Dam to the seasonal Lake Red Bluff. Eight sites along the river provide public boat ramps and two additional sites permit car-top launch and retrieval. (Lake Red Bluff will no longer exist after 2012, when RBDD operations cease and are replaced by operation of a pumping plant that is currently under construction.)

Although the Sacramento River is not generally considered a whitewater river, there are two easy whitewater runs on this section of the river. The first is from Keswick Dam to the Anderson-Cottonwood Irrigation District Diversion Dam in Redding. The second run is from Anderson River Park to William B. Ide Adobe State Historic Park. This run is 22 miles long and rated Class I to Class II. The Class II China Rapid is a few miles upstream from Red Bluff (Tuthill 2005).

Opportunities for trail activities such as walking, jogging, bicycling, and horseback riding are available throughout this stretch of the river. There are 21 sites with trails or access to trails. The most notable trails along this section of river are the Sacramento River Trail and the trails that connect BLM lands below Balls Ferry.

Hunting opportunities are located primarily on BLM land along the Sacramento River. The main hunting areas along the river are Inks Creek, Massacre Flat, Perry Riffle, Paynes Creek, Bald Hill, and Iron Canyon. Hunting is permitted on BLM land unless posted as closed (e.g., along hiking trails and at developed recreation areas). Game species found on BLM lands include quail, dove, waterfowl, deer, pig, bear, and turkey (BLM 1992).

Opportunities for developed camping along or near the river are located mainly at privately operated RV parks and fishing resorts, and are also provided at the

public Lake Red Bluff Recreation Area. Most camping opportunities are for RVs, but a few tent and group camping sites are available. Primitive camping is available at five sites within the BLM Sacramento River Area, between about Battle Creek and Payne's Creek, about 10 miles upstream from RBDD. River visitors may also camp on undeveloped BLM land within the area. The mouth of Inks Creek and 0.75 mile above and below the mouth is closed to camping (BLM 1992).

The Sacramento River corridor provides a beautiful setting for picnickers. A total of 21 sites along this river reach provide picnicking facilities; these sites include municipal parks, RV parks and fishing resorts (private facilities), William B. Ide Adobe State Historic Park, boat ramps, and fishing access sites. Generally, facilities include picnic tables, shade structures (or trees), and barbeque pits.

Another recreation opportunity available along the Sacramento River is viewing historic sites. Historic sites or historical markers exist at a handful of sites.

The Sacramento River meanders through the small cities of Redding, Anderson, and Red Bluff. These cities' municipal parks along this section of the river provide developed urban recreation opportunities such as horseshoes, soccer, and baseball, as well as playgrounds and a swimming pool.

Recreational Facilities More than 40 recreation/public access sites are available along the Sacramento River between Keswick Dam and RBDD. For this analysis, these sites have been categorized by primary use as municipal parks, fishing access/day-use areas, boat launches, trail accesses, RV parks, wildlife areas, and undeveloped open space areas. Table 18-2 describes these facilities by type.

Municipal Parks Municipal parks in this river section include Lake Redding Park, Caldwell Park, Cascade Community Park (City of Redding); Anderson River Park (City of Anderson); and Samuel Ayer/Dog Island Park and Red Bluff City Park (City of Red Bluff) (CSUC 2006; City of Redding 2004; City of Anderson 2007). Most of the municipal parks provide facilities such as trails or trail access, restrooms, playgrounds, ball fields, swimming pools, horseshoe pits, and picnic sites. Lake Redding Park (Lake Redding is created by the Anderson-Cottonwood Irrigation District Diversion Dam) provides boating facilities, trails, picnic facilities, horseshoe pits, and restrooms. Anderson River Park provides a similar range of amenities, including a boat ramp.

Table 18-2. Summary of Recreation Sites along the Sacramento River between Keswick Dam and Red Bluff Diversion Dam

Type of Facility	Number	Description
Public Facilities		
Municipal park	6	Managed by the Cities of Redding, Anderson, and Red Bluff. All sites provide parking and picnic sites. Most have restrooms and trails. Several also have boat ramps and two sites have hand launching. Other amenities include horseshoe pits, sports fields, swimming pools, playgrounds, a skateboard park, a fish viewing area, and a bike riding area.
Boat launch	6	Managed by the City of Redding, Shasta County, Tehama County, the State Lands Commission, and the City of Red Bluff. All provide parking and most provide restrooms. One site is a Point of Historical Interest and one site provides raft rentals.
Trail access	6	Managed by Reclamation and the City of Redding. Primarily provide access to Sacramento River Trail. All provide parking, two provide picnic sites, and one provides restrooms. One site has a historical marker and one has a historic powerhouse.
Fishing access/ day-use area	7	Managed by the City of Redding, BLM, and Shasta County. Most provide parking and access to trails. Other amenities include ponds, boat ramps, day-use facilities, group camping, and a community garden.
Wildlife area/ ecological reserve	2	Both managed by DFG. Mouth of Cottonwood Creek Wildlife Area has parking facilities. Clover Creek Ecological Preserve has no facilities.
Open space area	6	All are managed by BLM. Most have trails, three have parking, and two have restrooms. Other amenities include hand launching, picnic sites, walk-in camping, fishing pond, and beaches. Three are trail or boat access only.
Other public park	2	Lake Red Bluff Recreation Area, administered by USFS, provides river access, day-use, and camping facilities; also includes the Sacramento River Discovery Center. William B. Ide Adobe State Historic Park is a small State Parks unit focused on a historic adobe and related structures.
Subtotal	35	
Private/Commercial Facilities		
Educational/nature Park	1	Turtle Bay Exploration Park; includes a museum, butterfly house, live animals, and parking, with access to a scenic pedestrian bridge over the river and the Sacramento River Trail.
RV park	7	The largest facility provides 174 RV sites, four other facilities provide from 44 to 85 RV sites; two “fishing resorts” provide 12 and 20 RV sites. Most provide a boat ramp and showers; other amenities include tent sites, restaurants, swimming pools, a store, a bar, and a group campground.
Subtotal	8	
Total – All Facilities	43	

Key:
BLM = U.S. Bureau of Land Management
DFG = California Department of Fish and Game
Reclamation = U.S. Department of the Interior, Bureau of Reclamation
RV = recreational vehicle
State Parks = California Department of Parks and Recreation
USFS = U.S. Forest Service

Fishing Access and Day-Use Sites There are four public fishing accesses in this reach of the Sacramento River: Turtle Bay East Fishing Access, Kapusta Property Fishing Access, Deschutes Road Fishing Access, and Reading Island Fishing Access. All of the fishing accesses provide parking and most provide trails as well. The sites are managed by the City of Redding, Shasta County, and BLM (CSUC 2006). Reading Island provides a cement boat ramp along a slough leading to the river, but sedimentation and dense aquatic vegetation limit use to small car-top boats. Primitive group camping is also available at Reading Island, under a special-use permit issued by BLM (BLM no date).

Three day-use sites are available on this stretch of the Sacramento River. These sites may provide both fishing and trail access, like that found at Diestlehorst Pasture River Access, managed by the City of Redding. Two BLM-managed day-use sites, Jellys Ferry and Sacramento River Island, are also available (CSUC 2006).

Boat Launch Facilities There are six sites on this river reach that are primarily for boat launching: Turtle Bay Boat Ramp and South Bonnyview Boat Launch, operated by the City of Redding; Balls Ferry Boat Ramp, operated by Shasta County; Mouth of Battle Creek Boat Launch, owned by the State Lands Commission; Bend Bridge Park Public Access, operated by Tehama County; and Red Bluff River Park, operated by the City of Red Bluff.

Trails and Trail Access Facilities The Sacramento River Trail is a 13-mile paved urban trail system along the riparian corridor on both sides of the river from Keswick Dam to Turtle Bay Park in Redding. Two pedestrian bridges cross the river to create a loop of about 5 miles. At least six sites provide primary access to the trail and a few other sites provide connections to the trail (Healthy Shasta 2008).

Unlike the boating and day-use facilities that occur throughout this river reach, the trail access sites are primarily on the portion of the river that flows through Redding. Six specific Sacramento River Trail access sites and five other sites, all provided by the City of Redding, also provide access to the Sacramento River Trail.

RV Parks There are seven privately operated RV parks along this reach: one in Redding (Marina RV Park), three in the Anderson area (JGW RV Park, Balls Ferry Fishing Resort, and Roosters Landing Fishing Resort), one near the community of Bend (Bend RV Park), and two in Red Bluff (Idlewheels RV Park and Durango RV Resort). The two largest parks offer 85 and 174 RV sites. Two of the parks also offer tent camping, and two parks offer group camping. All of the RV parks offer picnic facilities and most offer showers. Three of the parks offer boat launches. Two of the parks offer a restaurant and one offers a bar, swimming pool, and store. The largest park, a new facility in Red Bluff, offers a lap pool and spa, a lodge, two clubhouses for meetings, and 45 acres of surrounding land with walking trails (CSUC 2006).

Wildlife Areas There is one DFG-owned and managed area along this river reach, the Mouth of Cottonwood Creek Wildlife Area. A parking area is the only improvement at the site. The area is excellent habitat for Swainson's hawk, bald eagle, ringtail, and river otter and provides good wildlife viewing, birding, and photography opportunities (DFG 2011).

Undeveloped Public Lands There are six areas between Inks Creek and Iron Canyon that, for this analysis, are considered undeveloped open space areas: Inks Creek, Massacre Flat, Perry Riffle, Paynes Creek, Bald Hill, and Iron Canyon. All six areas are managed by the BLM Redding Field Office. Other than parking areas, few facilities are available at most of these areas; they are mainly large open areas available for general public use and enjoyment (CSUC 2006).

Other Public and Private Parks Turtle Bay Exploration Park in Redding is a privately operated facility that contains a museum, butterfly house, forest camp replica, arboretum, and gardens. The park provides access to the scenic Sundial pedestrian bridge over the river, and access to the Sacramento River Trail (Turtle Bay Exploration Park 2011). The 3-acre William B. Ide Adobe State Historic Park in Red Bluff focuses on several historical elements and provides parking, trails, picnic facilities, and restrooms (State Parks 1990).

Lower Sacramento River and Delta

Recreation opportunities on the Sacramento River downstream from RBDD include hunting, fishing, boating, RV/tent/group camping, birding, wildlife viewing, picnicking, hiking, and sports activities (softball, soccer, tennis, basketball, horseshoes). The 100-mile stretch of river down to Colusa includes many parcels of public conservation and recreation lands, as well as a few privately owned commercial recreation sites. Primary landowners on the river include the U.S. Fish and Wildlife Service, with more than two dozen units of the Sacramento River National Wildlife Refuge totaling more than 10,300 acres (many of which are closed to the public) (USFWS 2005), and DFG, with more than 15 units of the Sacramento River Wildlife Area totaling more than 3,700 acres (most open to the public but accessible only by boat) (DFG 2004). The California Department of Parks and Recreation (State Parks) operates three park units (one State park and two State recreation areas) on the river between Red Bluff and Colusa – one each near Corning (RM 218), Hamilton City (RM 193 – RM 200), and Colusa (RM 145) (CSUC 2006). An additional State recreation area is located on the Sacramento River in the Delta.

Recreation facilities are located primarily between Red Bluff and the Bidwell-Sacramento River State Park near Hamilton City, about 50 river miles downstream, because of the availability of the State park facilities and privately owned RV parks and resorts. Downstream from Bidwell–Sacramento River State Park, the variety and density of facilities are reduced. Facilities vary from boat ramps and marinas to campgrounds, picnic sites, and trails (CSUC 2006). Beyond Lake Red Bluff and RBDD, it is not expected that recreation or public

access would be affected with implementation of the project; therefore, an in-depth review of recreation activities and facilities south of Lake Red Bluff is not presented in this analysis.

CVP/SWP Service Areas

CVP and SWP facilities and service areas are widespread throughout much of California. Facilities include multiple dams, reservoirs, and canals that provide substantial water-based recreational activities. Releases from dams on major tributaries to the Sacramento River provide numerous recreational opportunities, especially boating and fishing. Reservoirs such as Folsom, Oroville, and New Melones provide boating, fishing, camping, and other recreational activities.

18.2 Regulatory Framework

18.2.1 Federal

U.S. Forest Service

Shasta Lake and the surrounding Federal lands compose the Shasta Unit of the Whiskeytown-Shasta-Trinity NRA, established by Congress in November 1965 to provide for public outdoor recreation use and enjoyment, among other purposes. Both the Shasta and Trinity units of the NRA are within the Shasta-Trinity National Forest and are administered by USFS as the Shasta-Trinity NRA. The act establishing the NRA specified that it was to be administered in a manner coordinated with other purposes of the CVP. Reclamation retained management of lands and waters needed for operating the CVP, and controls operation of Shasta Dam and reservoir pool levels. The lake surface and surrounding lands are administered by USFS (an exception is the area in the immediate vicinity of the dam, which is administered by Reclamation).

USFS management of recreation within the Shasta Unit occurs under the authority of the 1987 Master Interagency Agreement between Reclamation and USFS. Administration of the Shasta Unit of the NRA is coordinated with the administration and purposes of the CVP through a memorandum of agreement between Reclamation and USFS established December 31, 1986. The management of Shasta Lake is guided by the 1995 *Shasta-Trinity National Forest Land and Resource Management Plan* (Shasta-Trinity LRMP) and the 1996 *Shasta-Trinity NRA Management Plan*. The NRA Management Plan is currently being updated through a series of amendments.

Shasta-Trinity National Forest Land and Resource Management Plan (1995) The Shasta-Trinity LRMP (USFS 1995a) guides management of both the Shasta and Trinity national forests with the goals of integrating a mixture of management activities that protect forest resources and allow use, fulfill guiding legislation, and address local, regional, and national issues. The project is located within two management units—the Shasta Unit of the NRA, which

includes Shasta Lake and surrounding lands, and the Front Unit, which includes USFS lands south of the lake. As stated in the Shasta-Trinity LRMP, the Shasta Unit is managed according to the current NRA Management Plan. The portion of the Front Unit located within the primary study area (south of the lake) is managed under Matrix Prescription III, Roaded Recreation. This prescription "emphasizes recreational opportunities associated with developed road systems and dispersed and developed campsites" (USFS 1995a). The Shasta-Trinity LRMP states that this prescription is also the primary prescription for the Shasta Unit of the NRA. The plan provides relevant recreation-related standards and guidelines to ensure road, trail, and facility development and management activities consistent with a Roaded Natural setting.

Shasta-Trinity National Recreation Area Management Guide (1996) The *Shasta-Trinity National Recreation Area Management Guide* (USFS 1996) integrates management of the NRA with and implements the direction in the LRMP. The guide addresses key management concerns related to recreation and other resource management, such as the types and amounts of commercial and USFS recreation facilities to be provided. Desired future conditions for Shasta Lake are described, and management recommendations aimed at implementing the LRMP and achieving desired future conditions are detailed for both lake and land-based recreation and for commercial recreation operations within the NRA.

Mendocino National Forest Land and Resource Management Plan (1995) The *Mendocino National Forest Land and Resource Management Plan* (Mendocino National Forest LRMP) (USFS 1995b) guides management of the Mendocino National Forest with the goals of integrating a mixture of management activities that protect forest resources and allow use, fulfill guiding legislation, and address local, regional, and national issues. Management Area #38, Lake Red Bluff Recreation Area, is at the extreme downstream end of the primary study area. (The Lake Red Bluff Recreation Area was transferred from Reclamation ownership in the late 1980s and is isolated from the rest of the National Forest; all other lands are well to the west of the study area.)

The Mendocino National Forest LRMP states that management and development should conform to the record of decision for the Final Environmental Impact Statement for the Lake Red Bluff Recreational Development. Relevant recreation-related major aspects of this decision include a management direction emphasizing supplying quality water-oriented recreation experiences for the public, maintaining a safe setting for recreational users, and providing educational and interpretive opportunities. The management area is also managed under the Recreation Area prescription, which "provides direction for maintaining attractive landscapes and recreation quality around major lakes and within other areas of concentrated recreation use" (USFS 1995b). The area is to be managed to maintain a Recreation Opportunity Spectrum (ROS) class of "Roaded Natural."

U.S. Bureau of Land Management

Overview BLM administers most of the public lands along the Sacramento River between Shasta Dam and Keswick Dam, and additional lands between Keswick Dam and the city of Redding, as part of the 23,000-acre Interlakes Special Recreation Management Area. BLM also administers more than 17,000 acres of public lands on both sides of the river within the Sacramento River Management Area, which extends from just downstream from Redding downstream to the Tehama County/Glenn County boundary, about 25 miles south of Red Bluff. Most of the BLM lands are concentrated above Red Bluff, between Jellys Ferry and Iron Canyon. A few hundred additional acres of BLM lands are at two island parcels downstream from Red Bluff.

Proposed Redding Resource Management Plan and Final Environmental Impact Statement (1992) The proposed resource management plan (RMP) and Final Environmental Impact Statement (BLM 1992) for the Redding Resource Area (BLM 1992) identifies proposed management direction for BLM-administered public lands within the Redding Resource Area, totaling approximately 250,000 acres of land in north-central California. The RMP focuses on resolving four main issues: land tenure adjustment, recreation management, access, and forest management. BLM selected a preferred alternative for each of the seven management areas and collectively these preferred alternatives compose the proposed action of the RMP. The project is located within the Shasta and Sacramento River management areas. The Shasta Management Area includes the lands southwest of Lake Shasta within the Interlakes Special Recreation Management Area. General recreation management direction for the entire Redding Resource Area is also provided within the RMP and focuses on ROS designations and guidelines, camping limits, OHV designations, and wild and scenic rivers.

Recreation-related management direction for the Interlakes Special Recreation Management Area includes objectives to provide a regional opportunity for motorized recreation with a focus within the Gene Chappie/Shasta OHV Area and to enhance nonmotorized recreation opportunities within the area via a greenway connecting Redding to Shasta Dam along the Sacramento River. Motorized vehicle use is limited to designated roads and trails that may be closed between November 15 and April 15 to protect the wintering deer herd. The area is managed as Semi-Primitive, Non-Motorized, Semi-Urban, Semi-Primitive Motorized, and Roaded Natural (ROS Classes).

The Sacramento River Management Area includes the Sacramento Island area, between Redding and Anderson, a large block of contiguous parcels along the river between Balls Ferry (RM 276) and Iron Canyon (RM 250), and two islands downstream from Red Bluff. Recreation-related management direction for these areas includes management within the Semi-Primitive Motorized (ROS class), closure to motorized vehicles, and an emphasis on boat-in access and use. Because of the special value of the Valley oak riparian forest at Sacramento Island, the area has been designated as a Research Natural

Area/Area of Critical Environmental Concern, with special management plans to protect and improve the plant communities and habitat there.

The 25 miles of the Sacramento River between Balls Ferry and Iron Canyon have been determined to be eligible for inclusion in the National Wild and Scenic Rivers System, with recreational, scenic, and wild classifications for various segments. All public lands within one-quarter mile of normal high water will be managed to protect the outstandingly remarkable values and free-flowing character that led to their determination of eligibility.

18.2.2 State

California Department of Fish and Game

DFG manages the ecological reserve and the wildlife areas within the study area under Title 14 of the California Code of Regulations and the California Fish and Game Code. The regulations provide for various types of public uses on the wildlife areas. However, fish and wildlife protection and enhancement are the primary management purposes of the wildlife areas; recreation and public use is secondary to habitat preservation. Ecological reserves are established to provide rare, threatened, or endangered plants and wildlife and special habitat types; public entry may be restricted to protect wildlife or habitat.

The DFG-administered wildlife areas on the Sacramento River within the primary and extended study areas are designated by the California Fish and Game Code as "Type C" areas, which generally have no or minimal developed facilities. A "Type C" area designation does not require hunters to have a permit or pass (other than a valid California hunting license and any required stamps) for most areas. General "Type C" area regulations apply to all of the wildlife area within the study area; special regulations for each area prohibit camping and establish other restrictions on hunting and other uses (see Title 14 of the California Code of Regulations).

DFG interacts with other management agencies in the study area to ensure that hunting and fishing regulations are enforced on public and private lands and maintains authority over all activities that have the potential to affect wildlife or wildlife habitat. DFG administers the waterfowl hunting program on a number of Federal wildlife refuges, including the Sacramento River National Wildlife Refuge.

California Department of Parks and Recreation

State Parks manages the State park and recreation areas within the study area under Title 14 of the California Code of Regulations and the California Public Resources Code. Specific management direction and guidance is provided by general plans for individual parks. A preliminary draft general plan has recently been developed for the Bidwell-Sacramento River State Recreation Area. The plan provides specific goals and guidelines for a range of issues related to environmental resources, visitor use and opportunities, and park administration

and operations. Additional direction for facility development at each of the park's four subunits is also provided. The management recommendations contained in the 1990 general plan for William B. Ide Adobe State Historic Park are focused on protecting the historic integrity that is the primary value of the 3-acre site, as well as protection of the riparian forest in the riverbank area (State Parks 1990). No current park management plans were available for the two other small State Parks units on the river.

18.2.3 Regional and Local

Shasta County

The Open Space and Recreation Element of the *Shasta County General Plan* (Shasta County 2004) is intended to preserve open space for the economy, enjoyment of scenic beauty, recreation, and use of natural resources. The Open Space and Recreation Element addresses recreation as it relates to the tourist industry and recreation at the countywide level. Recreation is considered the active use of open space land. "Recreational areas are essentially open space lands which are designed to accommodate recreational activities such as hiking, picnicking, or camping" (Shasta County 2004). Several sites that fall under the recreation analysis herein are included under Shasta County's Open Space Inventory: the Shasta-Trinity National Forest, BLM holdings, Balls Ferry Fishing Access, Anderson River Park and Fishing Access, Lake Redding–Caldwell Memorial Park, Turtle Bay Regional Park, Turtle Bay East, privately owned and operated recreational facilities such as resorts and RV parks, and historic landmarks and points of interest (Shasta County 2004).

The Open Space and Recreation Element describes goals and objectives for protection of open space and recreation resources including the following (Shasta County 2004):

- Protection of open space through certain land-use classifications
- Coordination of parks and recreation systems planning, acquisition, development and operation among Federal, State, county, and city governments
- Using the National Resource Protection–Recreation Resources land use designation to protect the quality of recreation resource values of national parks and recreation areas, wilderness areas, and State parks
- Permitting commercial recreation uses
- Requirement of public access and easements provided by the Subdivision Map Act along the Sacramento River (Keswick Dam to the county line) and Battle Creek (downstream from Coleman Powerhouse)

- Provision of public access and easements for recreation if riparian habitat is not significantly affected, public access is not available within a reasonable distance, or the corridor is located near urban, town, and rural community centers

The Public Facilities Element contains a discussion of recreation at the community level. The element states that the "community recreation needs of Shasta County residents and the degree to which these needs are met by County government vary with the type of community in which they live" (Shasta County 2004). Recreation needs in urban areas are primarily for publicly owned parklands. The element identifies that "recreation officials in the unincorporated urban areas of the County indicate that a substantial portion of the recreation needs of the residents of these communities is not being met" (Shasta County 2004). An increase in recreational demand is expected as a result of the growth of urban areas over the 20-year planning period. County policy "will rely upon interagency planning efforts and providing long-term protection of resource and open space lands and features that exhibit future recreation potential" (Shasta County 2004). The objective in the Public Facilities Element related to recreation describes developing a land use pattern that adequately serves for community recreation. The policy that supports this objective relates to designation of the locations of existing and proposed large-scale community recreation facilities as Natural Resources Protection Parklands (Shasta County 2004).

Tehama County

The Open Space and Conservation Element of the *Tehama County General Plan Update 2009–2029* (March 2009) (Tehama County 2009) addresses several resource areas, including Natural Resource Land and Recreation. The element includes a brief description of national forests located within the county, Lassen Volcanic National Park, BLM lands, State parks, Black Butte Lake (USACE), and county parks. The element states one overarching Natural Resource Land and Recreation goal (Goal OS-9): "To protect and enhance resource lands in the County for the continued benefit of agriculture, timber, grazing, recreation, wildlife habitat, and quality of life" (Tehama County 2009). Supporting policies aim to do all of the following:

- Protect and enhance resource lands

- Protect reasonable access to resource lands and not unreasonably deprive users of enjoyment of previously accessible areas through closure

- Coordinate natural resource practices and recreation plans of different jurisdictions and assure cooperation

- Promote recreation opportunities including agritourism, nature tourism, and environmental learning tourism

The Public Services Element of the general plan includes goals and policies related to recreation facilities. The goals and policies aim to develop local services that meet local needs in a cost-effective manner, including supporting enhanced recreation services for existing and future residents, and obtaining dedicated lands for new schools, libraries, and recreational facilities when existing facilities are not adequate.

City of Redding

The Recreation Element of the City of Redding's general plan (City of Redding 2000) contains goals and objectives on natural and scenic open areas, development of a regional river parkway, archaeological and historic resources related to park and recreation sites, park planning and development, compatibility with adjacent land uses, facility funding and management, recreation programs, citywide trail system, and vandalism and user safety. Recreation-related goals and policies within the Recreation Element address natural and scenic open areas, a citywide trail system, and regional recreation opportunities, among others. The plan specifically recognizes the Sacramento River as "the backbone of the City's park system." Policies are established within the plan for a regional river parkway and for trails along the river, including continued development of the Sacramento River Trail.

The *City of Redding Parks, Trails, and Open Space Master Plan* (City of Redding 2004) includes as part of its parks strategy Goal PK4, "The Sacramento River and its major tributary streams will continue to be the focus and the organizing principle of the park, trail, and open space system." In addition, the plan establishes Goal TB1 within the Trails and Bikeway Strategy, "Promote and facilitate the development of a Citywide Trail System." A subgoal is to "continue development of the Sacramento River Trail to establish a common and continuous thread along the river corridor."

City of Anderson

The Recreation Element of the City of Anderson's general plan "addresses parks and recreation facilities throughout the Anderson Planning Area, including both those owned and maintained by the City of Anderson and those under the purview of other agencies or, selectively, private entities" (City of Anderson 2007). The element includes a description of the parks in the city, park classifications and standards, park issues, and a description of the recreation trails network. One of the identified additional park needs is to extend, enlarge, and protect Anderson River Park, which is located with the primary study area. Relevant recreation-related policies contained with the element aim to do all of the following:

- Allow for expanded and diverse recreational programs, areas, and opportunities
- Facilitate community and cultural opportunities

- Formalize and enhance walking trails in existing city parks
- Provide nonmotorized linkages between parks and open spaces
- Develop and promote community trails to provide health benefits for all residents
- Update the Parks and Recreation System Master Plan, incorporating appropriate provisions of the general plan (including the Trails-Sidewalks Network Concept Plan) into the master plan, and establish clear priorities and phasing plans as part of the master plan process

18.3 Environmental Consequences and Mitigation Measures

18.3.1 Methods and Assumptions

The project could affect recreation and public access resources through a variety of impact mechanisms. Primary effects on recreation facilities and recreation activities at Shasta Lake would be tied directly to the increased full pool elevation. Additional impacts could result from changes in reservoir operations that alter the magnitude, rate, or timing of reservoir drawdown; and from construction-related disruption of recreation access and activities at and near Shasta Dam. Primary conflicts with the use of recreation facilities and recreation-related activities on the Sacramento River and tributaries would be tied directly to the changes in flow regime of the rivers and the seasonal timing of those changes.

More specifically, this chapter evaluates the potential impacts on recreation and public access facilities and recreation activities resulting from the following mechanisms:

- Construction-related disruption of recreation access and activities at and near Shasta Dam
- Seasonal inundation of reservoir recreation facilities and shoreline access sites
- Changes in the magnitude, rate, or timing of reservoir drawdown
- Seasonal inundation of river recreation facilities or access sites
- Increased or decreased river flows during particular recreation use periods
- Disruption of recreation access and boating, or changes in river characteristics related to boating, caused by gravel deposition activities

The evaluation of impacts on Shasta Lake recreation facilities was based on several existing information sources. During previous phases of the project, a detailed inventory was prepared and high-resolution aerial photo–based mapping was completed for all recreation facilities on or near the shoreline of Shasta Lake. The inventory data included descriptions and elevations for the features of each facility up to an elevation 30 feet above the current full pool elevation of 1,067 feet above mean sea level including buildings, paved and unpaved roads, paved and unpaved areas, and miscellaneous objects. The inventory data include the lowest and highest elevations at which each feature would be affected (buildings excepted; only the lowest elevation was recorded for buildings). The inventory did not include buried infrastructure such as electric and water lines and septic systems. However, nearly all developed facilities on the lake are known to include these types of improvements, and these would also be among the features affected at most locations.

The CalSim-II computer model was used to aid in the evaluation of potential impacts of the project on water-related resources, including recreation resources. This computer modeling used historical California hydrology data to represent the variety of weather and hydrologic patterns, including wet periods and droughts, under which the project would be operated. Each model run represented a constant level of development (2005 for the existing case and 2030 for the future case), so that performance of the No-Action Alternative and other alternatives could be evaluated under both existing and future conditions.

For statements based on CalSim-II modeling results (e.g., statements regarding project impacts on mean monthly flow), “existing conditions” refers to modeling runs with 2005 facilities and demands; “future conditions” refers to modeling runs with forecasted 2030 demands and reasonably foreseeable future projects and facilities. The existing and future base cases are the without-project conditions in 2005 and 2030, respectively. The No-Action Alternative represents future conditions in 2030, including other reasonably foreseeable future projects and facilities.

The results of the CalSim-II modeling provide information on seasonal changes in Shasta Lake pool elevation associated with each dam-raise height. This information was used in combination with the inventory data described above to determine impacts of the alternatives on recreation facilities and activities. CalSim-II results also describe flow characteristics for the Sacramento River downstream from Shasta Dam, and for other rivers downstream from reservoirs within the CVP and SWP service areas whose operations may be affected by the project. These data were used to determine potential impacts on recreation and public access on the Sacramento River downstream from Shasta Dam and on tributary rivers and reservoirs within the CVP and SWP service areas. Both average increases and decreases in monthly pool elevation and mean monthly flows are considered with respect to impacts evaluated in this section. Preliminary assessments of impacts on public and commercial recreation

facilities at Shasta Lake were reviewed by USFS and revised based on comments received.

A detailed description of the CalSim-II model, the modeling methodology used to evaluate this project, and key assumptions are provided in the Modeling Appendix. Summaries of the analysis and modeling results are provided in Chapter 6, "Hydraulics, Hydrology, and Water Management."

18.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on recreation and public access would be significant if project implementation would do any of the following:

- Substantially affect the operability or seasonal use of or otherwise affect reservoir and river recreation facilities and access sites as a result of water level changes or flow regime modifications
- Substantially increase recreation use such that existing facilities would be used beyond their capacity and degraded
- Substantially reduce recreational opportunities or substantially degrade recreational experiences
- Create hazardous or unusual conditions for boaters, swimmers, waders, or other water-contact activities as a result of increased or decreased water levels related to flow regime modifications associated with the action alternatives

Significance statements are relative to both existing conditions (2005) and future conditions (2030) unless stated otherwise.

18.3.3 Topics Eliminated from Further Consideration

No topics related to recreation and public access that are included in the significance criteria listed above were eliminated from further consideration. All relevant topics are analyzed below.

18.3.4 Direct and Indirect Effects

No-Action Alternative

Under the No-Action Alternative, the existing Shasta Dam would be operated in the same manner as under current operations. Changes to the reservoir flow regime caused by changes in demand and other factors would be small, with a reduction in Shasta Lake storage of 2 – 4 percent during the fall of some years. Shasta Lake storage under the No-Action Alternative would be within -2 percent and 1 percent of Shasta Lake storage under existing conditions at most times. Also, no new project-related recreation facilities would be constructed and no existing facilities would be altered, expanded, or demolished.

It is anticipated that if the project alternatives were not implemented, CVP and SWP operations would continue under existing regulatory requirements. Analysis of flow modeling indicates that there would be no significant changes in flows with the potential to affect recreation between existing conditions and the future No-Action Alternative conditions.

Under the No-Action Alternative, changes to the flow regime of the upper Sacramento River as a result of changes in demand and other factors would be small; mean monthly flows in the Sacramento River would be within ±5 percent of flows under existing conditions at most times (flows could increase by a greater amount during late summer and early fall of below-normal, dry, and critical years). Also, no new recreation facilities would be constructed and no existing facilities would be altered, expanded, or demolished.

Under the No-Action Alternative, the flow regime in the lower Sacramento River and Delta and in the CVP/SWP service areas would not change as a result of Shasta Lake operations.

Shasta Lake and Vicinity

Impact Rec-1 (No-Action): Increased Use of Shasta Lake Recreation Facilities and Demand for Recreation Opportunities on Shasta Lake and in the Vicinity
Demand for recreation facilities at Shasta Lake and in the vicinity is expected to increase, but recreation opportunities would still be extensive and varied. This impact would be less than significant.

Recreational use at Shasta Lake and in the vicinity is expected to increase in the future simply based on population growth in Northern California and southern Oregon from now until 2030. The resulting increase in demands on all recreational facilities and opportunities could affect the quality of the recreational activity. Recreational opportunities would still be extensive and

varied in the area, however, and USFS management of the Shasta Unit of the Shasta-Trinity NRA would continue to respond to changing recreation needs. Because no substantial hydrologic changes are anticipated under the No-Action Alternative, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Rec-2 (No-Action): Increased Use and Demand for Recreation Opportunities on the Upper Sacramento River Demand for recreation facilities along the upper Sacramento River is expected to increase, but recreation opportunities would still be extensive and varied. This impact would be less than significant.

Recreational use in the upper Sacramento River portion of the primary study area is expected to increase in the future simply based on population growth in Northern California from now until 2030. The resulting increase in demands on all recreational facilities and opportunities could affect the quality of the recreational activity. Recreational opportunities would still be extensive and varied in the area, however. Because no substantial hydrologic changes are anticipated under the No-Action Alternative, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta
Impact Rec-3 (No-Action): Increased Use and Demand for Recreation Opportunities on the Lower Sacramento River and in the Delta Demand for recreation facilities along the lower Sacramento River and in the Delta is expected to increase, but recreation opportunities would still be extensive and varied. This impact would be less than significant.

Recreational use in the lower Sacramento River and Delta portions of the extended study area is expected to increase in the future simply based on population growth in Northern and Central California from now until 2030. The resulting increase in demands on all recreational facilities and opportunities could affect the quality of the recreational activity. Recreational opportunities would still be extensive and varied in the area, however. Because no substantial hydrologic changes are anticipated under the No-Action Alternative, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas
Impact Rec-4 (No-Action): Increased Use and Demand for Recreation Opportunities in the CVP and SWP Service Areas Demand for recreation facilities in the CVP/SWP service areas is expected to increase, but recreation opportunities in the CVP/SWP service areas would still be extensive and varied. This impact would be less than significant.

Recreational use in the CVP/SWP service areas within the extended study area is expected to increase in the future simply based on population growth in California from now until 2030. The resulting increase in demands on all recreational facilities and opportunities could affect the quality of the recreational activity. Recreational opportunities would still be extensive and varied in the area, however. Because no substantial hydrologic changes are anticipated under the No-Action Alternative, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

By increasing storage at Shasta Lake, this alternative would change the full pool elevation and seasonal pool elevations at Shasta Lake, and the flow regime downstream in the Sacramento River and potentially several other reservoirs and downstream waterways. In turn, these alterations to reservoir pool elevations and river flows could affect the usability of several types of recreation facilities on Shasta Lake and the downstream reservoirs and waterways, particularly marinas, boat ramps, and nearshore campgrounds and day-use areas. These alterations could also affect the ability of recreationists to use the reservoirs and waterways for boating, camping, fishing, and similar activities.

The full pool elevation of Shasta Lake would increase by 8.5 feet and the pool elevation would average as much as 6 to 10 feet higher than under existing (2005) and No-Action Alternative (2030) conditions at various times of the year. The greatest change would occur during the wettest years. The surface area of the reservoir at full pool would increase by about 1,100 acres (4 percent) with a 6.5-foot dam raise. The width of the water body would not increase substantially in most areas, and much of the increase would occur during spring rather than during the high-traffic summer boating period.

At most times, flows in the upper Sacramento River within the primary study area (between Shasta Dam and RBDD) would be within about ±5 percent of flows relative to existing (2005) and No-Action Alternative (2030) conditions.

Reservoir- and river-based recreation facilities and activities are similar in the primary and extended study areas downstream from Shasta Lake; thus potential effects on reservoir and river recreation would be similar. However, changes to the flow regime affecting reservoirs and rivers in the extended study area would be increasingly attenuated by flows from tributary waterways and other water sources and diversions that are unaffected by the project, reducing the level of effects downstream.

Shasta Lake and Vicinity

Impact Rec-1 (CP1): Seasonal Inundation of Shasta Lake Recreation Facilities or Portions of Recreation Facilities and Public Access at Pool Elevations Above the Current Full Pool Elevation Substantial effects from inundation of recreation facilities or portions of Shasta Lake facilities would result from the 8.5-foot increase in full pool elevation associated with the 6.5-foot dam raise. The reservoir would fill to the new full pool elevation of 1,075.5 feet in some years, and would fill to an elevation greater than the current full pool elevation of 1,067 feet in many years. In each case portions of existing recreation facilities on the shoreline would be inundated. However, construction activities would include relocation of affected recreation facilities. Replacement facilities would be of equivalent quality to affected facilities, provide comparable shoreline access, where applicable, and would comply with Americans with Disabilities Act (ADA) and Architectural Barriers Act (ABA) guidelines. Therefore, this impact would be less than significant.

Within each of the three arms of Shasta Lake with recreation development, effects on individual recreation facilities under CP1 would vary. These effects would range from no effect to effects on several of the facilities' inventoried and mapped features (e.g., roads, parking, and restrooms or other buildings) and on features not specifically inventoried (e.g., campsites and picnic sites). Anticipated effects of CP1 on inventoried and mapped (developed) recreation facilities are shown in Table 18-3.

On the Sacramento River Arm, one of the two boat ramps, one of the four campgrounds, and one of the four marinas would be subjected to effects on several features or a substantial portion of the facility's use area. Other facilities that would be subject to major effects are the USFS Lakeshore Fire Station and the Dry Creek trailhead and trail at the west side of Shasta Dam. The only operational day-use area and one campground would be subject to a somewhat lesser but still substantial effect, while several additional facilities would be subject to relatively minor effects.

On the McCloud River Arm, both marinas and both boat ramps would be subject to major effects, as would the USFS Station at Turntable Cove. At least two of the cabins in the recreation residence tract at Campbell Cove would be affected. Effects would be less but still substantial at several of the six public campgrounds and two of the three day-use areas.

On the Pit River Arm, both of the boat ramps and three of the four marinas would be subject to major effects, whereas the lower loop of the one campground would experience a lesser effect. On the Squaw Creek Arm, one private cabin in the Didallas recreation residence tract would be affected. (This is the only recreation facility on the Squaw Creek Arm, and is not listed in the table.)

Table 18-3. Effects of CP1 on Developed Recreation Facilities at Shasta Lake

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
Sacramento River Arm	
Boat Ramps	
1. Antlers Public Boat Ramp	Boat ramp length reduced but ramp usable; parking lot and restroom unaffected
2. Centimudi Public Boat Ramp	Boat ramp entirely affected, most of lower parking lot affected, access road to ramp and parking partly affected
Campgrounds	
1. Antlers Campground	No effect – all features are above full pool elevation
2. Gregory Creek Campground	One restroom affected and shoreline campsites affected
3. Lakeshore East Campground	One restroom, lower portion of access road, and some campsites affected
4. Nelson Point Campground	Campground access road and possibly some campsites affected
Day-Use Areas	
1. Fisherman's Point Day Use Area	Access road, parking, and restroom unaffected, but part of use area affected
2. Salt Creek Swim Area (nonoperational)	Restroom and portion of paved pathway affected
Marinas	
1. Antlers Resort and Marina	One building affected, boat ramp partially affected
2. Digger Bay Marina	Bottom portion of marina road/ramp affected, but effects appear minor
3. Shasta Marina Resort	Office and equipment shed affected, parking and access roads partially affected
4. Sugarloaf Resort and Marina	Electrical service building and associated structures affected, boat ramp and unpaved parking areas partially affected
Resorts (Nonmarina)	
1. Lakeshore Inn and RV Park	Shoreline campsites and walkway may be affected
2. Salt Creek Resort and RV Park	Resort unaffected; lower part of old road bed used as boat ramp affected, but usable
3. Shasta Lake RV Resort	No effect – entire facility is above full pool elevation
4. Sugarloaf Cottages Resort	Unpaved shoreline access roads affected but usable
5. Tsasdi Resort	Entrance and exit roads connecting to Lakeshore Drive affected; resort cabins appear to be unaffected
Other Facilities	
1. USFS Lakeshore Fire Station	Five buildings affected, entrance road partially affected
2. Dry Creek Trailhead and Trail	Trailhead and portion of trail along shoreline affected

Table 18-3. Effects of CP1 on Developed Recreation Facilities at Shasta Lake (contd.)

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
McCloud River Arm	
Boat Ramps	
1. Bailey Cove Boat Ramp and Day Use Area	Boat ramp entirely affected, parking area, day-use area, and access road partially affected
2. Hirz Bay Public Boat Ramp	Boat ramp entirely affected; some of lower parking area likely to be affected
Campgrounds	
1. Bailey Cove Campground	Campsites appear unaffected; access road may be affected
2. Dekkas Rock Campground	Lower part of loop road affected; possibly a portion of group camp affected
3. Ellery Creek Campground	Lower portion of loop road and shoreline campsites affected
4. Hirz Bay Campgrounds	No effect – entire facility is above full pool elevation
5. Kamloop Camp (private organization)	No effect – entire facility is above full pool elevation
6. McCloud Bridge Campground	Portion of access road affected; some campsites likely affected
7. Moore Creek Campground	Lower portion of loop road and shoreline campsites affected
8. Pine Point Campground	No effect – entire facility is above full pool elevation
Day-Use Areas	
1. Dekkas Rock Day Use Area	Lower portion of loop road and some parking affected
2. McCloud Bridge Day Use Area	Part of use area affected (no permanent infrastructure present)
Marinas	
1. Holiday Harbor Marina	Two marina buildings and boat ramp affected, overflow parking partially affected; RV park/campground likely to be partially affected
2. Lakeview Marina	Four buildings and tank affected, shoreline part of access road affected; access to buildings appears to be unaffected
Other Facilities	
1. Bollibokka Club	No effect – entire facility is above full pool elevation
2. Campbell Creek Cove cabins	At least two cabins affected, possibly others also affected
3. Shasta Caverns ferry landing	Access roads serving east and west shore landings partially affected; parking and building unaffected
4. USFS Station (Turntable Bay)	Four buildings affected and access road affected
Pit River Arm	
Boat Ramps	
1. Jones Valley Public Boat Ramp	Boat ramp entirely affected, access road from parking area partially affected
2. Packers Bay Public Boat Ramp	Boat ramp and information shelter affected, parking partially affected

Table 18-3. Effects of CP1 on Developed Recreation Facilities at Shasta Lake (contd.)

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
Campgrounds	
1. Lower Jones Valley Campground	Footbridge associated with trail affected; culverts and creek may back up into campground during high-water periods
2. Upper Jones Valley Campground	No effect – entire facility is above full pool elevation
Marinas	
1. Bridge Bay Resort and Marina	Seven buildings, boat ramp, parking lots, and roads affected
2. Jones Valley Resort	Three buildings and access road affected, parking area and resort roads partially affected
3. Packers Bay Marina	Boat ramp partially affected but usable
4. Silverthorn Marina Resort	Parking and ramp mostly affected, shoreline road partially affected
Other Facilities	
1. Clikapudi Trail

RV = recreational vehicle
USFS = U.S. Forest Service

It is important to note that effects on roads and bridges that are outside of the recreation facilities themselves but used to access the facilities would also affect recreation at Shasta Lake. (Effects on roads and bridges are discussed in more detail in Chapter 20, "Transportation and Traffic.") A prominent example is the effect on a long stretch of Lakeshore Drive, the primary route on the west side of the Sacramento River Arm providing visitors access to several commercial recreation facilities (marinas and nonmarina resorts) and a campground. Effects on the road would begin at a small segment near the north end of the Doney Creek Bridge and extend about 2 miles south to the Sugarloaf area. Two major bridges over inlets of the lake would be affected as well. (These roads and bridges are also used to access private homes and nonrecreation businesses.) Numerous segments of Shasta County and USFS roads that provide access to facilities or the shoreline on each of the lake's arms would also be affected.

In summary, the most prominent direct effects on recreation facilities and public access at Shasta Lake and in the vicinity from the 6.5-foot dam raise would be the major effects on five of six boat ramps, one of 13 public family campgrounds, six of 10 commercial marinas, and USFS stations on both the Sacramento River and McCloud River arms. A lesser but still substantial effect would occur at several day-use areas and two campgrounds and minor effects would occur at several additional facilities. Table 18-4 summarizes the number of recreation facilities of specific types substantially affected.

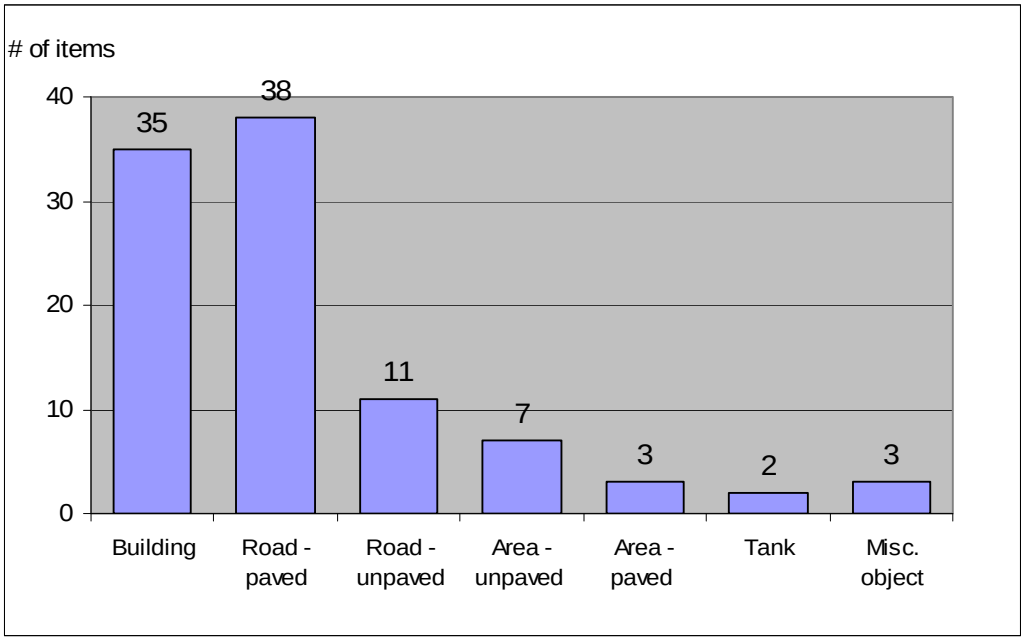

Table 18-4. Tally of Shasta Lake Recreation Facilities Substantially Affected by CP1

Type of Facility	Number of Facilities Affected
Boat ramp	5
Marina	6
Campground (family)	1
Day-use area	3
USFS operations	2
Trailhead	1
Recreation residence tract	1

Figure 18-3 depicts the total number of inventoried Shasta Lake recreation facility items, at all recreation facilities combined, that would be affected by inundation under CP1. A total of 99 facility and infrastructure elements would be affected, with nearly three-fourths of those being buildings and segments of paved roads. A lesser number of unpaved road segments, paved and unpaved areas (usually parking areas), tanks, and miscellaneous objects would also be affected.

Source: Reclamation 2003

Figure 18-3. Number of Recreation Facility Infrastructure Items Affected by a 6.5-Foot Dam Raise Under CP1

As described in Section 2.4.2 in Chapter 2, “Alternatives,” construction activities under all action alternatives would include relocation of affected

recreation facilities. This could include relocation of affected portions of facilities within existing use areas, in adjacent undeveloped areas, or at new sites in the same general vicinity of the lake. Because of consolidation of facilities, the total number of facilities of specific types may be reduced. However, all affected recreation capacity would be replaced. Replacement facilities would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable. With the relocation of affected facilities, this impact would be less than significant.

Recreation is highly important to the Shasta Lake area. Therefore, mitigation is included to uphold the completion of all actions related to the relocation of affected recreation facilities in order to maintain recreation capacity at Shasta Lake, as included in the project description.

Impact Rec-2 (CP1): Temporary Construction-Related Disruption of Recreation Access and Activities at and near Shasta Dam Construction activity at Shasta Dam that would be necessary to raise the dam and complete related modifications would prevent recreation visitors from crossing the dam, as is possible now with a permit from Reclamation, and thus could affect other recreation activities in the area. These effects are expected only during the construction period. However, this impact would be potentially significant.

One of the primary routes used by recreation visitors to the Chappie-Shasta OHV Area, situated below Shasta Dam on the west side of Keswick Reservoir, crosses Shasta Dam. It is assumed that public access to the road crossing the dam, which is available now with an annual permit issued by Reclamation, would be temporarily suspended during the construction phase of the project. An alternative route to the Chappie-Shasta OHV Area from the south exists, but that route requires several more miles of travel on unpaved roads than the route across the dam, and it may not be suitable for some visitors to the OHV area who bring OHVs to the area on trailers.

The road across the dam is also the primary access route to the Dry Fork Creek trailhead near the west end of Shasta Dam, used by hikers and anglers to access the Dry Fork Creek Trail, which follows the shoreline of Shasta Lake. Access to this trailhead and trail would be disrupted during the project construction period. (As noted under Impact Rec-1 (CP1) above, the trailhead itself would be destroyed by modifications to the dam and portions of the trail would be affected by the increased reservoir elevation.)

Construction at Shasta Dam would also result in a temporary cessation of Reclamation's public tours of the dam and powerhouse, and disturbance of recreation visits to the Shasta Dam Visitor Center (situated just below the east end of the dam), because of noise, dust, and aesthetic changes.

For the reasons described above, this impact would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

Impact Rec-3 (CP1): Effects on Boating and Other Recreation Use and Enjoyment of Shasta Lake as a Result of Changes in the Annual Drawdown of the Reservoir An increase in the magnitude or rate or changes in the timing of the annual summer and fall drawdown of Shasta Lake could adversely affect boating enjoyment and safety on the reservoir. Conversely, a reduced or slower drawdown could have beneficial effects. However, under CP1, reservoir operations would not change from existing operations, with little change in annual magnitude, rate, or timing of reservoir drawdown. Therefore, this impact would be less than significant.

Over the past decade, Shasta Lake has had an average drawdown of about 67 feet from the annual high pool. (The annual high pool is typically reached in April or May and the reservoir is drawn down during summer and fall, before the winter rains arrive.) During most of those years, the drawdown has been in the range of 50 to 85 feet but has been as large as 108 feet and as little as 38 feet. Total drawdown, as compared to the full pool elevation of 1,067 feet (which the reservoir does not reach every year), has averaged about 77 feet and has been as great as 130 feet. Both public launch ramps and commercial recreation facilities such as marinas and shoreline resorts on the lake are designed and operated to remain functional at a wide range of pool elevations, although some facilities are closed or have restricted use below certain pool elevations. Boaters familiar with the lake generally know to expect a substantial annual drawdown and are aware of the effects of drawdown on facilities and navigation on the lake. Signs at boat ramps and marinas warn boaters of the potential for rapidly changing conditions on the lake as a result of regular seasonal drawdowns.

Potential adverse effects of an increase in the magnitude or rate of drawdown include an increase in seasonally exposed shoals and other boating hazards, and increased navigation challenges as compared to what boaters have typically experienced in past years. Other potential adverse effects of such changes in drawdown include a need to more frequently adjust docks and moorings at boat launches and marinas and other locations, and an increase in the distance between developed shoreline campsites and day-use areas and the water's edge. Facilities that operate only above a certain pool level would be usable for a shorter period of time each year. Aesthetically, an increased drawdown would result in a less appealing recreation setting characterized by a wider unvegetated inundation zone. Conversely, a reduced drawdown or slower drawdown during the primary summer boating season could have beneficial effects by reducing the adverse effects described above, which normally occur to some degree each year under existing conditions and would continue under the No-Action Alternative.

Under CP1, storage would increase but reservoir operations would not change; therefore, the character of the annual reservoir drawdown would not be expected to change greatly. This conclusion is confirmed by CalSim-II modeling results, which indicate that the reservoir elevation would be as much

as 8 to 10 feet higher at various points in the year, but that the magnitude, rate, and timing of the annual drawdown would be essentially unchanged relative to the existing (2005) and No-Action Alternative (2030) conditions. The only exception to this would occur during some drier-than-average years: increased storage during spring would be followed by a smaller increase or a slight reduction in late summer and early fall, resulting in a slightly greater drawdown than under existing conditions. As a result, no effects related to drawdown changes are expected under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-4 (CP1): Increased Hazards to Boaters and Other Recreationists at Shasta Lake from Standing Timber and Stumps Remaining in Untreated Areas of the Inundation Zone At full pool, the increased pool elevation would result in approximately 730 acres of newly inundated area where the existing trees and other vegetation would not be removed. Anglers would generally benefit from the associated enhancement of fish habitat; however, the standing trees and stumps remaining in these areas would increase the number of areas and total acreage where this type of hazard to boaters and other recreation visitors would exist. Therefore, this impact would be significant.

Approximately 730 acres (66 percent) of the 1,100 acres of newly inundated area that would result from the 6.5-foot dam raise at full pool would receive no vegetation treatment (no vegetation removed), to maximize the habitat benefits of inundated and residual vegetation. The remaining 370 acres would be subject to either complete vegetation removal or overstory removal. In areas of overstory removal, all trees greater than 10 inches in diameter at breast height would be removed, with stumps cut to within 24 inches of the ground surface. The intent of these treatments would be to minimize the risk to boaters and other visitors from snags and water hazards. These treatments would be targeted for areas adjacent to developed recreation sites and houseboat mooring areas, and other areas where snags pose the greatest risk to boaters.

Because no vegetation would be removed from portions of the newly inundated area, the area at Shasta Lake where boaters would be exposed to potential hazards from standing timber and stumps would increase. The hazards may increase as the trees die and decay, leaving stumps that may be at or just below the water surface. The hazard represented by the standing timber and stumps would exist only when the reservoir surface elevation is above the current full pool elevation, which would occur only during the highest pool elevation period (generally late spring and early summer) of wetter-than-normal years.

Although the number and acreage of areas where this hazard would be present would expand, the hazard already exists on portions of the Pit River and Squaw Creek arms of the lake, where vegetation was not cleared when the reservoir was constructed and where numerous inundated trees still exist. The Shasta Lake Boating Safety brochure provided to Shasta Lake boaters by USFS warns that numerous underwater obstacles (as well as floating debris and shallows) are

present and not marked, and that responsibility for boating safety rests with each individual vessel operator. Also, the Shasta County ordinance that limits boat speeds on Shasta Lake to 5 mph within 100 feet or the shoreline would serve to reduce the hazard. Finally, the standing timber and other remaining vegetation would provide structural diversity that is attractive to fish; therefore, these areas are likely to be attractive to anglers who could benefit from the increase in uncleared areas and who may consider them a recreation enhancement rather than a hindrance.

Despite these factors, the untreated areas of the new inundation zone would represent an increased hazard to boaters and potentially other types of recreationists. For this reason, this impact would be significant. Mitigation for this impact is proposed in Section 18.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Rec-5 (CP1): Seasonal Inundation of Portions of Recreation Facilities or Informal River Access Sites as a Result of Increased River Flows Within the upper Sacramento River portion of the primary study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result from increased mean monthly river flows associated with project implementation and operation. In general, the increases in flow that would occur in some years would be expected to be small (5 percent or less); the area of inundation beyond that which would occur existing conditions or under the No-Action Alternative would be likewise small. As a result, the adverse effects are unlikely to be substantial. This impact would be less than significant.

Increased river flows associated with project implementation could temporarily inundate portions of developed recreation facilities used by boaters, anglers, and other recreationists to access the upper Sacramento River between Shasta Dam and Red Bluff. Any of the more than 15 boat ramps at public and privately operated parks on the river would be affected if increased river flow were to cause the ramps, which are generally designed to be used at a range of river elevations, to be overtopped. These facilities are often associated with picnic areas, shoreline fishing access areas, and similar day-use facilities, as well as campgrounds. The portions of these areas nearest to the riverbank could also be affected. Many of these facilities are used year-round, but the peak period for boating on the river is late spring through fall (May–November), when river flows are most likely to be in the optimum range of 6,000 to 12,000 cfs. Although existing average monthly flows are within this range year-round, in most winter and spring seasons the river experiences much higher peak flows of 30,000 to 50,000 cfs or more that may last several weeks.

Many of the locations that recreationists use to access the river and to hand-launch watercraft are informal sites where conditions such as gradually sloping and sandy riverbanks create beaches that are conducive to recreation

use. Like developed sites, these undeveloped and informal use areas may be affected by increased river flows if increased flows were to result in temporary inundation of the area.

CalSim-II model simulations indicate that at nearly all times, Sacramento River flow below Keswick Dam under CP1 would be within about ±5 percent of flows relative to existing (2005) and No-Action Alternative (2030) conditions. (The only exception suggested by the model results is the potential for a flow increase of up to 30 percent during midwinter of critically dry years.) Regarding increases to river stage, the CalSim-II model simulations indicate that, during late summer (July and August) of some years, mean monthly river stage below Keswick Dam could increase as much as 2 to 5 feet relative to existing (2005) and No-Action Alternative (2030) conditions. (River stage during the summer below Keswick Dam is typically 13 to 14.5 feet under existing conditions.) The model simulations also indicate that in some years, the mean monthly river stage could be up to 2 feet higher during late fall and early winter (October to January) and up to 4 feet higher during late winter and spring (February to May). (The model results also indicate the potential for lower river levels during some of these seasons in some years. Effects of decreased river flows are addressed below under Impact Rec-7 (CP1).)

Although river stage information for points within the primary study area downstream from Keswick Dam was not assessed, the effects of the project on river stage at those locations would be expected to be moderated by inflows from tributaries, and would therefore be less than the potential changes below Keswick Dam. As a result, potential effects of the project on recreation facilities would be progressively less as one moves downstream from Keswick Dam.

Because most recreation facilities are designed to be used well above the river stage elevations that commonly occur during late summer and spring, the stage increases cited above would not affect the functionality of those facilities. The small summer and fall increases in river stage would be likewise unlikely to have noticeable adverse effects on informal use sites, because those sites exist at a range of elevations and at many river locations. During periods of very high flows that may occur during winter and spring, boat ramps and other recreation facilities on the river may close, and safety warnings may be issued to boaters to stay off the river until the flow subsides.

It is important to note that for this assessment of environmental consequences, specific information was not available regarding how specific river stages affect specific recreation facilities. The assessment has also not considered the riverbank slope in specific river reaches, which would determine how much increased inundation would result from river stage increases at undeveloped recreation sites. Additional analysis would be required to provide accurate projections of effects at specific recreation sites or specific stretches of riverbank. Overall, however, the hydrologic changes in the Sacramento River

high flows resulting from CP1 would be relatively small and within the variability of flows that already occur in the river.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-6 (CP1): Increased Difficulty for Boaters in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the primary study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River. Depending on the time of year and base river flows, increased flow may also have beneficial effects. Because the magnitude of flow increases associated with CP1 would be small (generally less than 5 percent), adverse effects on boaters within the primary study area are unlikely. This impact would be less than significant.

Increased river flows associated with project implementation could affect boating conditions on the upper Sacramento River between Shasta Dam and Red Bluff. Increased flows can make boating on the river more difficult, particularly for nonmotorized boats such as canoes and dories or "drift boats." Drift boats are controlled by oars; these boats are commonly used by anglers and commercial angling guide services, primarily during summer, before lower flows during fall make their use more difficult. Canoeing, kayaking, and similar forms of nonmotorized boating are also most common on the river during summer, but are less affected by low flows than drift boating. Boating activity occurs on the river year-round, but the peak period for boating is late spring through fall (May–November), when river flows are most likely to be in the optimum range.

As described above under Impact Rec-4 (CP1), CalSim-II model simulations indicate that at nearly all times, Sacramento River flow below Keswick Dam under CP1 would be within about ±5 percent of flows relative to existing (2005) and No-Action Alternative (2030) conditions. However, CalSim-II model simulations indicate that mean monthly river stage below Keswick Dam could increase by as much as 2 to 5 feet relative to existing (2005) and No-Action Alternative (2030) conditions during late summer (July and August) of some years, and could increase by as much as 2 to 4 feet during other seasons. Changes in flows farther downstream within the primary study area would be expected to be progressively smaller as the influence of tributary streams increases.

The generally small flow increases that would occur as a result of the project in some years would be unlikely to adversely affect boating, which occurs primarily during summer and fall, and may have small beneficial effects during dry years by reducing exposed sand bars and shallows and thus increasing navigability on the river. Although boating activity is lower during winter, particularly during peak-flow periods when facilities may be closed and

conditions are hazardous, increased flows during dry years and decreased flows during wet years could have similarly minor beneficial effects during those months.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-7 (CP1): Increased Difficulty for Swimmers and Waders in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the upper Sacramento River, particularly during summer when swimming activity is most likely, and during fall and winter nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming and wading conditions. Increased flows can make swimming and wading more challenging and potentially more hazardous. The magnitude of flow increases associated with CP1 would be small (generally less than 5 percent), and the timing of the increases would be such that adverse effects on angling waders within the primary study area are unlikely. Swimming is not a common activity on the main channel of the river because of cold-water temperatures. As a result, this impact would be less than significant.

Increased river flows associated with project implementation could affect swimming and wading conditions on the upper Sacramento River between Shasta Dam and Red Bluff. Increased flows can make swimming and wading more difficult. Because of cold-water temperatures (a maximum of less than 60 degrees during summer), swimming is not a major activity on the Sacramento River, but it does occur, particularly in association with other activities like tubing and nonmotorized boating. Anglers commonly wade in the river; their use is particularly focused on the months of September and October, when flows typically decrease substantially from summer levels and the opportunities for wading correspondingly increase.

As described above under Impact Rec-4 (CP1), CalSim-II model simulations indicate that at nearly all times, Sacramento River flow below Keswick Dam under CP1 would be within about ±5 percent of flows relative to existing (2005) and No-Action Alternative (2030) conditions. However, CalSim-II model simulations indicate that mean monthly river stage below Keswick Dam could increase by as much as 2 to 5 feet relative to existing (2005) and No-Action Alternative (2030) conditions during July and August of some years, and could increase by as much as 2 to 4 feet during other seasons. Changes in flows farther downstream within the primary study area would be expected to be progressively smaller as the influence of tributary streams increases.

The generally small increases in summer flows throughout the primary study area that would occur as a result of the project in some years would be unlikely to adversely affect the limited amount of swimming that occurs during those months. The CalSim-II model simulations suggest that little or no change in river stage is likely during September, relative to existing (2005) and No-Action

Alternative (2030) conditions, and that only very small increases are likely in October and November of some years. The absence or very small magnitude of river stage increases during the fall peak period for wading by anglers indicates that adverse effects of the project on wading anglers are unlikely.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-8 (CP1): Increased Usability of the Sacramento River for Boating and Water-Contact Recreation as a Result of Decreased River Flows
Decreased mean monthly flows within the primary study area, particularly during summer when boating and swimming activity is most likely and during fall and winter low-flow periods when wade angling activity is most likely, could result in enhanced boating, swimming, and wading conditions. Decreased flows during normally high-flow periods can make boating less challenging and potentially less hazardous. The magnitude of flow decreases associated with the project would be small (generally less than 10 percent), and the timing of the decreases (fall and winter months) would be such that effects on boaters, swimmers, and waders within the primary study area are unlikely. As a result, this impact would be less than significant.

Decreased river flows associated with project implementation could benefit boating conditions on the Sacramento River in the primary study area, between Shasta Dam and Red Bluff. Decreased flows can make boating on the river easier, particularly for nonmotorized boats such as canoes and dories or “drift boats.” BLM has identified an optimum range of 6,000 to 12,000 cfs for boating on the Sacramento River in the primary study area. Boating may benefit if the decrease lowers flows below the high end of the optimum range. Under existing conditions, average monthly flows below Keswick Dam and below Cottonwood Creek are above the optimum level during midsummer most years and during much of the winter and early spring of wet years.

Decreased river flows associated with project implementation could also benefit conditions for swimming and wading, although boating conditions may be adversely affected if flow were to fall below the low end of the optimum range of 6,000 cfs. Decreased flow could make swimming and wading easier and may lengthen the period when these activities are best pursued. For example, wading anglers typically concentrate their activity in the fall months, when flows are lowest, whereas fishing from a boat is more common in summer, when flows are higher. Reduced flows in late summer or early fall may extend the wading season.

As described above under Impact Rec-4 (CP1), CalSim-II model simulations indicate that at nearly all times, Sacramento River flow below Keswick Dam under CP1 would be within about ±5 percent of flows relative to existing (2005) and No-Action Alternative (2030) conditions. However, CalSim-II model simulations indicate that mean monthly river stage below Keswick Dam could

decrease by as much as 2 to 6 feet relative to existing (2005) and No-Action Alternative (2030) conditions during the late fall and early winter (November to January) of wetter-than-normal years, and could decrease by as much as 2 to 4 feet during April and May in some years. Again, changes in flows farther downstream within the primary study area would be expected to be progressively smaller as the influence of tributary streams increases.

The reduction in mean monthly flows during fall and early-winter months of wetter-than-normal years would have minimal effects on boating because the existing mean flows during those months are usually within the optimum range. However, the decreased flow could have a beneficial effect on boating during the winter months of wet years, when the existing mean flows are above the optimum range.

The small reduction in flows and the corresponding decrease in river stage during some spring months during both wetter-than-normal and drier-than-normal years could have a beneficial effect on wading, because it could reduce flows to a level that is similar to existing fall conditions, when wading by anglers is most popular. However, given that the spring months are not the period when most wading anglers are present, and that swimming activity is low in the spring months, the effects are likely to be minimal.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-9 (CP1): Enhanced Angling Opportunities in the Upper Sacramento River as a Result of Improved Flows and Reduced Water Temperatures Project operation would result in improved flow and water temperature conditions in the upper Sacramento River, which would benefit all four Chinook salmon runs. This would result in enhanced populations of these game fish in the river, which would provide enhanced sport angling opportunities. This impact would be beneficial.

Chinook salmon contribute to the popular sport fishery in the upper Sacramento River. (The salmon season has been closed on the upper Sacramento River in recent years, but may be reopened if the health of the runs improves.) With increased flows and cooler water temperature resulting from project operation, salmon populations would benefit from reduced mortality. These beneficial effects on Chinook salmon could result in enhanced angling opportunities on the upper Sacramento River, which would have a beneficial effect on recreation. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-10 (CP1): Disruption of Sacramento River Boating and Access Resulting from the Gravel Augmentation Program The proposed gravel augmentation program would not be implemented under CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-11 (CP1): Changes in Usability of Reading Island Fishing Access Boat Ramp and Enhanced Recreation at Reading Island The proposed restoration of Sacramento River flow through Anderson Slough at Reading Island, rehabilitation of the Reading Island boat ramp for use by motorized boats, and construction of a handicap fishing access area would not be implemented under CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Rec-12 (CP1): Seasonal Inundation of Portions of River Recreation Facilities or Informal River Access Sites on the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Within the extended study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result if increased mean monthly river flows were to occur in some months of some years as a result of project implementation and operation under CP1. However, even with the increases, flows on the Sacramento, American, and Feather rivers would remain moderate and well below normal winter and spring high flows. As a result, adverse effects on river facilities or informal use areas within the extended study area are unlikely. This impact would be less than significant.

Increases in Sacramento River stage (elevation) within the extended study area associated with increased flows under CP1 would be small (only occasionally more than 1 foot, and no more than about 1.3 feet). The area of inundation beyond that which would occur under existing conditions and the No-Action Alternative would be likewise small. Also, the largest increases would occur during late summer and early fall and primarily during drier-than-normal years, when river flow and stage would be below average. On the Feather River below Thermalito Afterbay and on the lower American River (at the H Street Bridge), the increase in flows would be larger during some months of some years (with some increases greater than 25 percent), and these increases would occur during wetter-than-normal as well as drier-than-normal years. Yet here, too, the largest increases would occur during late summer and early fall, when flows are generally moderate. On both rivers, flows would remain moderate and well below winter and spring high flows experienced in most years. Therefore, adverse effects on river recreation facilities and informal use areas appear unlikely.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-13 (CP1): Increased Difficulty for Boaters in Using the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly flows within the extended study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River and other rivers affected by the project. Depending on

the time of year and base river flows, increased flow may also have beneficial effects on boating by reducing shallow bars and riffles, thus improving navigability. However, the timing and flow conditions under which the flow increases are likely to occur on the Sacramento, Feather, and American rivers under CP1 and the continuation of moderate flows even with the increase suggest that adverse effects on boaters within the extended study area are unlikely. This impact would be less than significant.

CalSim-II modeling results indicate that the magnitude of flow increases in the Sacramento River associated with CP1 may be as large as about 29 percent at Verona and 23 percent below Wilkins Slough and below Freeport. However, the largest changes would occur primarily during mid- and late summer and early fall (July to September), and primarily during drier-than-normal years, when flows are normally relatively low. Thus, even with the flow increases, flows would remain moderate (12,000 to 15,000 cfs at Verona and 15,000 to 20,000 cfs below Freeport).

CalSim-II modeling results indicate that the magnitude of flow increases in the Feather River below Thermalito Afterbay associated with CP1 may be as large as 43 percent. However, the largest increases would occur during mid- and late summer and early fall and primarily during drier-than-normal years, when flows are often lower than average. Flows would remain moderate (2,200 to 7,600 cfs) with the increases. CalSim-II modeling results also indicate that flows in the American River at the H Street Bridge (below Folsom Lake) would also be substantially increased during some months of some years, but would remain moderate. Although some of the potential flow increases in the Sacramento, Feather, and American rivers would be substantial, adverse effects on boating appear to be unlikely.

Hydrologic changes in more distant areas of the CVP and SWP service areas resulting from CP1 cannot be accurately predicted but would be small. Such slight changes occur on a dynamic and daily basis under existing conditions as water is moved throughout California. Other CVP and SWP reservoir elevations, canal flows, and flows below the reservoirs could be slightly modified, but any resulting effects on recreation would be negligible and speculative.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-14 (CP1): Increased Difficulty for Swimmers and Waders in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly river flows within the extended study area during some months of some years, particularly during summer when swimming activity is most likely and nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming and wading conditions. These activities could become more hazardous, and thus

less attractive to river users. However, given the timing of the likely flow increases under CP1, the conditions under which such increases would occur, and the continuation of moderate flows even with the increase, adverse effects on swimmers and waders in the extended study area are unlikely. This impact would be less than significant.

Even during the lowest flow months of late summer and early fall, average flow in the more downstream portions of the Sacramento River is around 10,000 cfs; average flow is much higher at other times of the year. As a result, swimming and wading are not common activities on the river in much of the extended study area, where the most common uses are boating and bank angling.

CalSim-II modeling results indicate that, during some months of some years, the magnitude of flow increases in the Sacramento River associated with CP1 may be as large as about 29 percent at Verona and 23 percent below Wilkins Slough and below Freeport. However, the largest changes would occur primarily during mid- and late summer and early fall (July to September), and primarily during drier-than-normal years, when flows are normally relatively low. Thus, even with the flow increases, flows would remain moderate (12,000 to 15,000 cfs at Verona and 15,000 to 20,000 cfs below Freeport).

CalSim-II modeling results indicate that the magnitude of flow increases in the Feather River below Thermalito Afterbay associated with CP1 may be as large as 43 percent. However, the largest increases would occur during mid- and late summer and early fall and primarily during drier-than-normal years, when flows are often lower than average. Flows would remain moderate (2,200 to 7,600 cfs) with the increases. CalSim-II modeling results also indicate that flows in the American River at the H Street Bridge (below Folsom Lake) would also be substantially increased during some months of some years, but would remain moderate. Some of the potential flow increases in the Sacramento, Feather, and American rivers would be substantial; however, adverse effects on swimming and wading appear to be unlikely. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-15 (CP1): Increased Difficulty for Boaters and Anglers in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Decreased River Flows Reduced mean monthly flows during fall and winter low-flow periods when wade angling activity is most common, and during summer and fall when boating and river floating is popular in some areas, could have adverse effects if reduced flows were to reduce fishing success or boating navigability. Given the modest flow decreases in the Sacramento River associated with CP1 and the timing of the changes, effects on these recreation uses of the Sacramento River in the extended study area are unlikely. However, given the magnitude and timing of the largest flow decreases during some years on the Feather and American rivers below CVP and SWP reservoirs in the extended study area, adverse effects may occur. This impact would be potentially significant.

CalSim-II results indicate that the magnitude of mean monthly flow decreases that would occur in some years in the Sacramento River below Wilkins Slough, at Verona, and below Freeport associated with CP1 is small (generally less than 8 percent) and equate to elevation (stage) decreases of no more than about 6 inches. The largest changes would occur during mid- and late fall and early winter (October through December) rather than in the summer months, when boating activity is highest. Wade angling is not common on most of the river in the extended study area, because of the depth and volume of the river, among other factors. As a result of these factors, adverse effects on boating or angling from the flow decreases appear to be unlikely.

CalSim-II results indicate that mean monthly flows in the Feather River below Thermalito Afterbay would be reduced in some years by as much as 31 percent during late fall through spring (November through May), particularly during drier-than-normal years. Use is generally lower during that period than during the summer and early and mid-fall; however, some boating and angling activity occurs on the Feather River during those months, and that activity could be adversely affected if navigability or angling success were to be hampered by reduced flow and shallower water.

CalSim-II results indicate that mean monthly flows in the American River at the H Street Bridge (below Folsom Lake) would also be reduced by as much as 10 to 32 percent in some months of some years, primarily during summer to mid-fall (June through October). In general, the effect would be to reduce flows during periods when the flows are already below average. This may adversely affect boating and angling on the river if navigability or angling success is hampered by reduced flow and shallower water.

For the reasons described above, this impact would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Like CP1, by increasing storage at Shasta Lake, CP2 would change the full pool elevation at Shasta Lake, and the seasonal pool elevations and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. In turn, these alterations to reservoir pool elevations and river flows could affect the usability of some types of recreation facilities on the lake and downstream waterways, particularly marinas, boat ramps, and nearshore campgrounds and day-use areas. These alterations could also affect the ability of recreationists to use the reservoirs and waterways for boating, camping, fishing, and similar activities.

The full pool elevation of Shasta Lake would increase by 14.5 feet and the pool elevation would average as much as 12 to 17 feet higher than under existing (2005) and No-Action Alternative (2030) conditions at various times of the year. The greatest change would occur during the wettest years.

Raising the dam by 12.5 feet would increase the surface area of the reservoir at full pool by about 1,750 acres (6 percent). The width of the water body would not increase substantially in most areas, and much of the increase would occur during spring rather than during the high-traffic summer boating period.

In general, the proposed changes in flow and river stage on the upper Sacramento River associated with CP2 are similar to but slightly greater than the changes associated with CP1, as outlined above.

Reservoir- and river-based recreation facilities and activities in the primary and extended study areas downstream from Shasta Lake are similar; thus potential reservoir and river recreation impacts would be similar. However, changes to the flow regime affecting reservoirs and rivers in the extended study area would be increasingly attenuated by flows from tributary waterways and other water sources and diversions that are unaffected by the project, reducing the level of impacts.

Shasta Lake and Vicinity

Impact Rec-1 (CP2): Seasonal Inundation of Shasta Lake Recreation Facilities or Portions of Recreation Facilities and Public Access at Pool Elevations Above the Current Full Pool Elevation Substantial effects from inundation of recreation facilities or portions of Shasta Lake facilities would result from the 14.5-foot increase in full pool elevation associated with the 12.5-foot dam raise. The reservoir would fill to the new full pool elevation of 1,081.5 feet in some years, and would fill to an elevation greater than the current full pool elevation of 1,067 feet in many years. In each case portions of existing recreation facilities on the shoreline would be inundated. However, construction activities would include relocation of affected recreation facilities. Replacement facilities would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable, and would comply with ADA and ABA guidelines. Therefore, this impact would be less than significant.

Within each of the three arms of Shasta Lake with recreation development, effects on individual recreation facilities under CP2 would vary. These effects would range from no effect to effects on several of the facilities' inventoried and mapped features (e.g., roads, parking, and restrooms or other buildings) and on features not specifically inventoried (e.g., campsites and picnic sites). Anticipated effects of CP2 on inventoried and mapped (developed) recreation facilities are shown in Table 18-5.

Table 18-5. Effects of CP2 on Developed Recreation Facilities at Shasta Lake

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
Sacramento River Arm	
Boat Ramps	
1. Antlers Public Boat Ramp	Boat ramp length shortened but usable; courtesy dock and rail would also be affected
2. Centimudi Public Boat Ramp	Boat ramp and lower parking entirely affected, part of access road to ramp and lower parking affected
Campgrounds	
1. Antlers Campground	All features are above full pool elevation; shoreline erosion may threaten portions of site
2. Gregory Creek Campground	One restroom, part of campground road, and shoreline campsites affected
3. Lakeshore East Campground	One restroom, lower half of campground road, and several campsites affected
4. Nelson Point Campground	Campground road and some campsites affected
Day-Use Areas	
1. Fisherman's Point Day Use Area	Parking and restroom unaffected but most picnic sites affected; also loss of access to shoreline trail
2. Salt Creek Swim Area (nonoperational)	Restroom and portion of paved pathway affected
Marinas	
1. Antlers Resort and Marina	Generator/pumphouse building and boat ramp/dock access road affected
2. Digger Bay Marina	Bottom portion of marina access road/ramp affected, but appears to remain usable
3. Shasta Marina Resort	Two buildings (office and equipment shed) affected, most of parking and access roads affected
4. Sugarloaf Resort and Marina	Electrical service building and associated structures affected, boat ramp and unpaved parking areas partially affected
Resorts (Nonmarina)	
1. Lakeshore Inn and RV Park	Shoreline campsites and walkway, and underground septic system may be affected
2. Salt Creek Resort and RV Park	Resort unaffected; old road bed used as boat ramp (outside resort) affected
3. Shasta Lake RV Resort	Entire facility appears to be unaffected
4. Sugarloaf Cottages Resort	Four cottages and large portion of unpaved shoreline access roads affected
5. Tsasdi Resort	Three cabins and entrance and exit roads connecting to Lakeshore Drive affected

Table 18-5. Effects of CP2 on Developed Recreation Facilities at Shasta Lake (contd.)

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
1. USFS Lakeshore Fire Station	Five buildings and entrance road affected (entire facility)
2. Dry Creek Trail and Trailhead	Beginning of trail and access road/trailhead parking entirely affected
McCloud River Arm	
Boat Ramps	
1. Bailey Cove Boat Ramp and Day Use Area	Boat ramp entirely affected, parking area, day-use area, and access road partially affected
2. Hirz Bay Public Boat Ramp	Boat ramp and lower parking area, restroom, entirely affected
Campgrounds	
1. Bailey Cove Campground	No effects – entire facility is above full pool elevation
2. Dekkas Rock Campground	Lower part of loop road and portion of group camp affected
3. Ellery Creek Campground	Lower portion of loop road and shoreline campsites affected
4. Hirz Bay Campgrounds	No effects – entire facility is above full pool elevation
5. Kamloop Camp (private organization)	No effects – entire facility is above full pool elevation
6. McCloud Bridge Campground	One restroom, lower part of camp loop and shoreline campsites affected
7. Moore Creek Campground	Lower portion of loop road, shoreline campsites likely affected
8. Pine Point Campground	Possible that some shoreline campsites affected
Day-Use Areas	
1. Dekkas Rock Day Use Area	Lower portion of loop road and parking affected
2. McCloud Bridge Day Use Area	Most of picnic sites affected
Marinas	
1. Holiday Harbor Marina	Three buildings, boat ramp, and tank affected, some overflow parking affected; RV park and road to RV park affected
2. Lakeview Marina	Five buildings and tank affected, access to buildings affected
Other Facilities	
1. Bollibokka Club	No effects – entire facility is above the full pool elevation
2. Campbell Creek Cove cabins	At least five cabins affected; possibly others also affected
3. Shasta Caverns ferry landing	Two buildings at east landing affected, access roads serving east and west shore landings partially affected
4. USFS Station (Turntable Bay)	Four buildings and access road affected

Table 18-5. Effects of CP2 on Developed Recreation Facilities at Shasta Lake (contd.)

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
Pit River Arm	
Boat Ramps	
1. Jones Valley Public Boat Ramp	Boat ramp and turnaround area at top of ramp entirely affected, access road to parking lot partially affected
2. Packers Bay Public Boat Ramp	Boat ramp and restroom, information shelter, and pump house buildings affected, portion of parking affected
Campgrounds	
1. Lower Jones Valley Campground	One restroom building and trail footbridge affected, camp loop road and campsites partially affected
2. Upper Jones Valley Campground	No effects – entire facility is above full pool elevation
Marinas	
1. Bridge Bay Resort and Marina	Most of facility – Including eight buildings, boat ramp, parking lots, and roads – affected
2. Jones Valley Resort	Three buildings, parking area, ramp, and shoreline access roads affected
3. Packers Bay Marina	Access road from public ramp affected, boat ramp partially affected
4. Silverthorn Resort	Parking and ramp affected, shoreline access road partially affected

Source: Reclamation 2003; data provided by EDAW (now AECOM) in 2007

Key:
RV = recreational vehicle
USFS = U.S. Forest Service

Under CP2, the recreation facilities on the Sacramento River Arm that would be subject to effects on several features or a substantial portion of the facility's use area are one of the two boat ramps, one of the four campgrounds, two of the four marinas, three of the five nonmarina resorts, and the two day-use areas. The USFS Lakeshore Fire Station and the Dry Creek trailhead would also be subject to major effects.

On the McCloud River Arm, many of the major facilities would be subject to effects on several features or on a substantial portion of the facility's use area: both public boat ramps, all three day-use areas, both marinas, and one of seven campgrounds. Other facilities affected to a similar degree are the USFS station at Turntable Cove, the Shasta Caverns Tour facilities on the east and west shores, and several of the cabins within the recreation residence tract on the east shore at Campbell Creek Cove.

All but one of the public and commercial recreation facilities on the Pit River Arm would be subject to major effects under CP2 – both boat ramps, all four

marinas, and one of the two campgrounds. On the Squaw Creek Arm, one private cabin within the Didallas recreation residence tract would be affected. Although they are not included in the table because of a lack of permanent infrastructure, shoreline camping areas at Beehive Point (Sacramento River Arm) and Mariner Point (Pit River Arm) would also be subject to substantial effects with the inundation of unpaved access roads and use areas. The four boat-in camps on Shasta Lake could also be affected, but the only permanent infrastructure at the boat-in camps is vault toilets. Information about the location of the campsites and vault toilets at the boat-in camps is not available.

Thus, the most prominent direct effects on recreation facilities and public access at Shasta Lake and in the vicinity under CP2 would be the major effects on five of six boat ramps, eight of 10 marinas, two of five resorts, three of 13 public campgrounds, and four of five day-use areas. Other facilities subject to major effects are USFS stations on the Sacramento River and McCloud River arms, the Dry Creek and Clickapudi trailheads near Shasta Dam and on the Pit River Arm, and the Shasta Caverns ferry landing and several private cabins on the McCloud River Arm. Table 18-6 summarizes the number of recreation facilities of specific types substantially affected.

Table 18-6. Tally of Shasta Lake Recreation Facilities Substantially Affected by CP2

Type of Facility	Number of Facilities Affected
Boat ramp	5
Marina	8
Resort	2
Campground (family)	3
Group campground	1
Day-use area	4
USFS operations	2
Trailhead	2
Recreation residence tract	1
Commercial tour	1

Key:
USFS = U.S. Forest Service

Somewhat lesser effects would occur at several campgrounds and one marina. Minor effects would occur at additional facilities of several types.

Figure 18-4 depicts the total number of inventoried Shasta Lake recreation facility items, at all recreation facilities combined, that would be affected by inundation under CP2. A total of 122 facility and infrastructure elements would be affected, with more than three-fourths of those being buildings and segments of paved roads. A lesser number of unpaved road segments, paved and unpaved

areas (usually parking areas), tanks, and miscellaneous objects would also be affected.

Source: Reclamation 2003

Figure 18-4. Number of Recreation Facility Infrastructure Items Affected by a 12.5-Foot Dam Raise Under CP2

As described in Section 2.4.2 in Chapter 2, "Alternatives," construction activities under all action alternatives would include relocation of affected recreation facilities. This could include relocation of affected portions of facilities within existing use areas, in adjacent undeveloped areas, or at new sites in the same general vicinity of the lake. Because of consolidation of facilities, the total number of facilities of specific types may be reduced. However, all affected recreation capacity would be replaced. Replacement facilities would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable. With the relocation of affected facilities, this impact would be less than significant.

Recreation is highly important to the Shasta Lake area. Therefore, mitigation is included to uphold the completion of all actions related to the relocation of affected recreation facilities in order to maintain recreation capacity at Shasta Lake, as included in the project description.

Impact Rec-2 (CP2): Temporary Construction-Related Disruption of Recreation Access and Activities at and near Shasta Dam Construction activity at Shasta Dam that would be necessary to raise the dam and complete related modifications would prevent recreation visitors from crossing the dam, as is possible now with a permit from Reclamation, and thus could affect other recreation activities in the area. These effects are expected only during the construction period. However, this impact would be potentially significant.

This impact would be similar to Impact Rec-2 (CP1). If the increased dam-raise height relative to CP1 (12.5 feet versus 6.5 feet under CP1) would substantially lengthen the period during which construction would occur or otherwise increase construction-related disruption in the dam area, the effects described under CP1 could be increased. This impact would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

Impact Rec-3 (CP2): Effects on Boating and Other Recreation Use and Enjoyment of Shasta Lake as a Result of Changes in the Annual Drawdown of the Reservoir An increase in the magnitude or rate or changes in the timing of the annual summer and fall drawdown of Shasta Lake could adversely affect boating enjoyment and safety on the reservoir. Conversely, a reduced or slower drawdown could have beneficial effects. However, under CP2, reservoir operations would mimic existing operations, with little change in annual magnitude, rate, or timing of reservoir drawdown. Therefore, this impact would be less than significant.

This impact would be similar to Impact Rec-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-4 (CP2): Increased Hazards to Boaters and Other Recreationists at Shasta Lake from Standing Timber and Stumps Remaining in Untreated Areas of the Inundation Zone At full pool, the increased pool elevation would result in approximately 1,167 acres of newly inundated area where the existing trees and other vegetation would not be removed. Anglers would generally benefit from the associated enhancement of fish habitat; however, the standing trees and stumps that would remain in these areas would increase the number of areas and total area where this type of hazard to boaters and other recreation visitors would exist. Therefore, this impact would be significant.

Approximately 1,167 acres (67 percent) of the 1,750 acres of newly inundated area that would result from the 12.5-foot dam raise at full pool would receive no vegetation treatment (no vegetation removed), to maximize the habitat benefits of inundated and residual vegetation. In general, this impact would be similar to Impact Rec-4 (CP1), although the total area where the potential hazard from remaining trees and stumps would be greater under CP2. Because the untreated areas of the new inundation zone would represent an increased hazard to boaters and potentially other types of recreationists, this impact would be significant. Mitigation for this impact is proposed in Section 18.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Rec-5 (CP2): Seasonal Inundation of Portions of Recreation Facilities or Informal River Access Sites as a Result of Increased River Flows Within the upper Sacramento River portion of the primary study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result from increased mean monthly river flows associated with

project implementation and operation. In general, the increases in flow that would occur in some years would be expected to be small (5 percent or less); the area of inundation beyond that which would occur under existing conditions and the No-Action Alternative would be likewise small. As a result, the adverse effects are unlikely to be substantial. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Rec-5 (CP1), because the alteration of the flow regime of the Sacramento River under CP2 would be more substantial than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-6 (CP2): Increased Difficulty for Boaters in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the primary study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River. Depending on the time of year and base river flows, increased flow may also have beneficial effects. Because the magnitude of flow increases associated with CP2 would be small (generally less than 5 percent), adverse effects on boaters within the primary study area are unlikely. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Rec-6 (CP1), because the alteration of the flow regime of the Sacramento River under CP2 would be more substantial than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-7 (CP2): Increased Difficulty for Swimmers and Waders in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the upper Sacramento River, particularly during summer when swimming activity is most likely and during fall and winter nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming and wading conditions. Increased flows can make swimming and wading more challenging and potentially more hazardous. The magnitude of flow increases associated with CP2 would be small (generally less than 5 percent), and the timing of the increases would be such that adverse effects on angling waders within the primary study area are unlikely. Swimming is not a common activity on the main channel of the river because of cold-water temperatures. As a result, this impact would be less than significant.

This impact would be similar to but slightly greater than Impact Rec-7 (CP1), because the alteration of the flow regime of the Sacramento River under CP2 would be more substantial than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-8 (CP2): Increased Usability of the Sacramento River for Boating and Water-Contact Recreation as a Result of Decreased River Flows Decreased mean monthly flows within the primary study area, particularly

during summer when boating and swimming activity is most likely and during fall and winter low-flow periods when wade angling activity is most likely, could result in enhanced boating, swimming, and wading conditions. Decreased flows during normally high-flow periods can make boating less challenging and potentially less hazardous. The magnitude of flow decreases associated with CP2 would be small (generally less than 10 percent), and the timing of the decreases (fall and winter months) would be such that effects on boaters, swimmers, and waders within the primary study area are unlikely. As a result, this impact would be less than significant.

This impact would be similar to but slightly greater than Impact Rec-8 (CP1), because the alteration of the flow regime of the Sacramento River under CP2 would be more substantial than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-9 (CP2): Enhanced Angling Opportunities in the Upper Sacramento River as a Result of Improved Flows and Reduced Water Temperatures Project operation would result in improved flow and water temperature conditions in the upper Sacramento River, which would benefit all four Chinook salmon runs. This would result in enhanced populations of these game fish in the river, which would provide enhanced sport angling opportunities. This impact would be beneficial.

This impact would be similar to Impact Rec-9 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-10 (CP2): Disruption of Sacramento River Boating and Access Resulting from the Gravel Augmentation Program The proposed gravel augmentation program would not be implemented under CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-11 (CP2): Changes in Usability of Reading Island Fishing Access Boat Ramp and Enhanced Recreation at Reading Island The proposed restoration of Sacramento River flow through Anderson Slough at Reading Island, rehabilitation of the Reading Island boat ramp for use by motorized boats, and construction of a handicap fishing access area would not be implemented under CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Rec-12 (CP2): Seasonal Inundation of Portions of River Recreation Facilities or Informal River Access Sites on the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Within the extended study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result if increased mean

monthly river flows were to occur in some months of some years as a result of project implementation and operation under CP2. However, even with the increases, flows on the Sacramento, Feather, and American rivers would remain moderate and well below normal winter and spring high flows. As a result, adverse effects on river facilities or informal use areas within the extended study area are unlikely. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Rec-12 (CP1), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be more substantial than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-13 (CP2): Increased Difficulty for Boaters in Using the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly flows within the extended study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River and other rivers affected by the project. Depending on the time of year and base river flows, increased flow may also have beneficial effects on boating by reducing shallow bars and riffles, thus improving navigability. However, the timing and flow conditions under which the flow increases are likely to occur on the Sacramento, Feather, and American rivers under CP2 and the continuation of moderate flows even with the increase suggest that adverse effects on boaters within the extended study area are unlikely. This impact would be less than significant.

Hydrologic changes in more distant areas of the CVP/SWP service areas resulting from CP2 cannot be accurately predicted but would be small. Such slight changes occur on a dynamic and daily basis under existing conditions as water is moved throughout California. Other CVP and SWP reservoir elevations, canal flows, and flows below the reservoirs could be modified slightly, but any resulting impacts on recreation would be negligible and speculative.

This impact would be similar to but slightly greater than Impact Rec-13 (CP1), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be more substantial than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-14 (CP2): Increased Difficulty for Swimmers and Waders in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly river flows within the extended study area during some months of some years, particularly during summer when swimming activity is most likely and nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming

and wading conditions. These activities could become more hazardous and thus less attractive to river users. However, given the timing of the likely flow increases under CP2, the flow conditions under which such increases would occur, and the continuation of moderate flows even with the increase, adverse effects on swimmers and waders within the extended study area are unlikely. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Rec-14 (CP1), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be more substantial than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-15 (CP2): Increased Difficulty for Boaters and Anglers in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Decreased River Flows Reduced mean monthly flows during fall and winter low-flow periods when wade angling activity is most common, and during summer and fall when boating and river floating is popular in some areas, could have adverse effects if reduced flows were to reduce fishing success or boating navigability. Given the modest flow decreases in the Sacramento River associated with CP2 and the timing of the changes, effects on these recreation uses of the Sacramento River within the extended study area are unlikely. However, given the magnitude and timing of the largest flow decreases during some years on the Feather and American rivers below CVP and SWP reservoirs in the extended study area, adverse effects may occur. This impact would be potentially significant.

This impact would be similar to but slightly greater than Impact Rec-15 (CP1), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be more substantial than under CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

Like each of the alternatives discussed above, by altering storage and operations at Shasta Lake, CP3 would change the full pool elevation at Shasta Lake, and the seasonal pool elevations and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. In turn, these alterations to reservoir pool elevations and river flows could affect the usability of some types of recreation facilities on the lake and downstream waterways, particularly marinas, boat ramps, and nearshore campgrounds and day-use areas. These alterations could also affect the ability of recreationists to use the reservoirs and waterways for boating, camping, fishing, and similar activities.

The full pool elevation of Shasta Lake would increase by 20.5 feet and the pool elevation would average as much as 18 to 24 feet higher than under existing (2005) and No-Action (2030) conditions at various times of the year. The

greatest change would occur during the wettest years. Raising the dam by 18.5 feet would increase the surface area of the reservoir at full pool by about 2,570 acres (9 percent). The width of the water body would not increase substantially in most areas, and much of the increase would occur during spring rather than during the high-traffic summer boating period.

In general, the changes in flow and river stage on the upper Sacramento River associated with CP3 are more substantial than the changes associated with CP1 and CP2. However, these changes are still within a few percentage points of the changes associated with CP1 and CP2, as outlined above.

Reservoir- and river-based recreation facilities and activities in the primary and extended study areas downstream from Shasta Lake are similar; thus potential reservoir and river recreation impacts would be similar. However, changes to the flow regime affecting reservoirs and rivers in the extended study area would be increasingly attenuated by flows from tributary waterways and other water sources and diversions that are unaffected by the project, reducing the level of impacts.

Shasta Lake and Vicinity

Impact Rec-1 (CP3): Seasonal Inundation of Shasta Lake Recreation Facilities or Portions of Recreation Facilities and Public Access at Pool Elevations Above the Current Full Pool Elevation Substantial effects from inundation of recreation facilities or portions of Shasta Lake facilities, such as boat launch ramps, campgrounds, marinas, and day-use areas, would result from the 20.5-foot increase in full pool elevation associated with the 18.5-foot dam raise. The reservoir would fill to the new full pool elevation of 1,087.5 feet in some years, and would fill to an elevation greater than the current full pool elevation of 1,067 feet in many years. In each case, portions of existing recreation facilities on the shoreline would be inundated. However, construction activities would include relocation of affected recreation facilities. Replacement facilities would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable, and would comply with ADA and ABA guidelines. Therefore, this impact would be less than significant.

Within each of the three arms of Shasta Lake with recreation development, effects on individual recreation facilities under CP3 would vary. These effects would range from no effect to effects on several of the facilities' inventoried and mapped features (e.g., roads, parking, and restrooms or other buildings) and on features not specifically inventoried (e.g., campsites and picnic sites). Anticipated effects of CP3 on inventoried and mapped (developed) recreation facilities are shown in Table 18-7.

Table 18-7. Effects of CP3 on Developed Recreation Facilities at Shasta Lake

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
Sacramento River Arm	
Boat Ramps	
1. Antlers Public Boat Ramp	Boat ramp entirely affected; courtesy dock and rail would also be affected; restroom may be affected; parking lot is primarily unaffected
2. Centimudi Public Boat Ramp	Boat ramp and lower parking entirely affected, part of access road to ramp and lower parking affected
Campgrounds	
1. Antlers Campground	Amphitheater may be affected; shoreline erosion may threaten portions of site
2. Gregory Creek Campground	Two restrooms, lower half of campground road, and associated campsites affected
3. Lakeshore East Campground	One restroom and majority of campground road and campsites affected
4. Nelson Point Campground	Most of campground road and several campsites affected
Day-Use Areas	
1. Fisherman's Point Day Use Area	Parking and restroom unaffected but most picnic sites affected; also loss of access to shoreline trail
2. Salt Creek Swim Area (nonoperational)	Two restrooms, bathhouse, and paved pathways affected
Marinas	
1. Antlers Resort and Marina	Generator/pumphouse building and boat ramp/dock access road affected
2. Digger Bay Marina	One building affected; lower portion of marina access road/ramp affected, but appears to remain usable
3. Shasta Marina Resort	Three buildings (office, equipment shed, residence) affected; most parking and access roads affected
4. Sugarloaf Resort and Marina	Electrical service building and associated structures affected, boat ramp and unpaved parking areas partially affected

Table 18-7. Effects of CP3 on Developed Recreation Facilities at Shasta Lake (contd.)

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
Resorts (Nonmarina)	
1. Lakeshore Inn and RV Park	Shoreline campsites and walkway, storage building, cabin, covered patio area affected; underground septic system may be affected
2. Creek Resort and RV Park	Resort unaffected; old road bed used as boat ramp (outside resort) affected
3. Shasta Lake RV Resort	Resort office affected
4. Sugarloaf Cottages Resort	Seven cottages and large portion of unpaved cabin and shoreline access roads affected
5. Tsasdi Resort	Five cabins and entrance and exit roads connecting to Lakeshore Drive affected
Other Facilities	
1. USFS Lakeshore Fire Station	Five buildings and entrance road affected (entire facility)
2. Dry Creek Trail and Trailhead	Beginning of trail and access road/trailhead parking entirely affected
McCloud River Arm	
Boat Ramps	
1. Bailey Cove Boat Ramp and Day Use Area	Boat ramp, parking area, day-use area, and access road entirely affected
2. Hirz Bay Public Boat Ramp	Boat ramp and lower parking area, restroom entirely affected
Campgrounds	
1. Bailey Cove Campground	Access road from ramp/day-use area affected
2. Dekkas Rock Campground	Loop road and associated portion of group camp affected
3. Ellery Creek Campground	Most of loop road and associated campsites affected
4. Hirz Bay Campgrounds	No effect – entire facility is above full pool elevation
5. Kamloop Camp (private organization)	One building affected
6. McCloud Bridge Campground	Entire facility – two restrooms, camp loop road, and associated campsites – affected
7. Moore Creek Campground	Lower portion of loop road and shoreline campsites appear to be affected
8. Pine Point Campground	Possible that some shoreline campsites affected

Table 18-7. Effects of CP3 on Developed Recreation Facilities at Shasta Lake (contd.)

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
Day-Use Areas	
1. Dekkas Rock Day Use Area	Loop road and associated picnic sites and parking affected
2. McCloud Bridge Day Use Area	Entire facility, including picnic sites and restroom, affected
Marinas	
1. Holiday Harbor Marina	Entire facility, including three buildings, boat ramp, and tank affected; most parking, RV park, and road to RV park affected
2. Lakeview Marina	Entire facility, including five buildings, tank, paved access roads affected
Other Facilities	
1. Bollibokka Club	Facility appears to be unaffected; McCloud River Arm would extend near one building and one miscellaneous object, which may be affected
2. Campbell Creek Cove cabins	At least seven cabins affected; possibly others also affected
3. Shasta Caverns ferry landing	Most of east and west side landings affected; two buildings at east landing, and access roads serving east and west shore landings also affected
4. USFS Station (Turntable Bay)	Entire facility, including four buildings and access road, affected
Pit River Arm	
Boat Ramps	
1. Jones Valley Public Boat Ramp	Boat ramp and turnaround area at top of ramp entirely affected, access road to parking lot partially affected
2. Packers Bay Public Boat Ramp	Boat ramp and restroom, information shelter, and pump house buildings affected; large portion of parking affected
Campgrounds	
1. Lower Jones Valley Campground	One restroom building, trail footbridge, and large portion of camp loop road and associated campsites affected
2. Upper Jones Valley Campground	No effects – entire facility is above full pool elevation

Table 18-7. Effects of CP3 on Developed Recreation Facilities at Shasta Lake (contd.)

Facility Name	Explanation of Effects on Facility at Full Pool Elevation
Marinas	
1. Bridge Bay Resort and Marina	Nearly entire facility – eight buildings, boat ramp, parking lots, and access roads – affected
2. Jones Valley Resort	Most of facility – five buildings, parking area, ramp, and shoreline access roads – affected
3. Packers Bay Marina	Access road from public ramp and marina ramp affected
4. Silverthorn Resort	Most of facility – resort office and restaurant building, parking, ramp, and shoreline access road – affected

Source: Reclamation 2003; data provided by EDAW (now AECOM) in 2007

Key:
RV = recreational vehicle
USFS = U.S. Forest Service

Under CP3, nearly all of the public and commercial recreation facilities on the Sacramento River Arm would be subject to effects on several features or a substantial portion of the facility's use area. One of the two boat ramps, three of the four campgrounds, two of the four marinas, three of the five nonmarina resorts, and the one operational day-use area would all be subject to these major effects. The USFS Lakeshore Fire Station and the Dry Creek trailhead and trail would also be subject to a major effect, as would the Salt Creek Swim Area, which is currently not operational but used on occasion for overflow camping and as a base camp for firefighting crews. One marina and one nonmarina resort would be subject to lesser but still substantial effects and several of the remaining facilities would be subject to minor effects.

On the McCloud River Arm, both public boat ramps, all three day-use areas, both marinas, and two of seven campgrounds would be subject to major effects. Other facilities that would experience major effects are the USFS station at Turntable Cove, the Shasta Caverns Tour facilities on the east and west shores, and at least seven cabins on the east shore within the Campbell Creek Cove recreation residence tract.

Effects on recreation facilities on the Pit River Arm under CP3 are similar to those that would occur under CP2. All but one of the public and commercial recreation facilities – both boat ramps, all four marinas, and one of the two campgrounds – would be subject to major effects. On the Squaw Creek Arm, one cabin within the Didallas recreation residence tract would be affected.

Shoreline camping areas at Beehive Point (Sacramento River Arm) and Mariner Point (Pit River Arm) would also be subject to substantial effects, with the unpaved access roads and use areas mostly inundated. The four boat-in camps

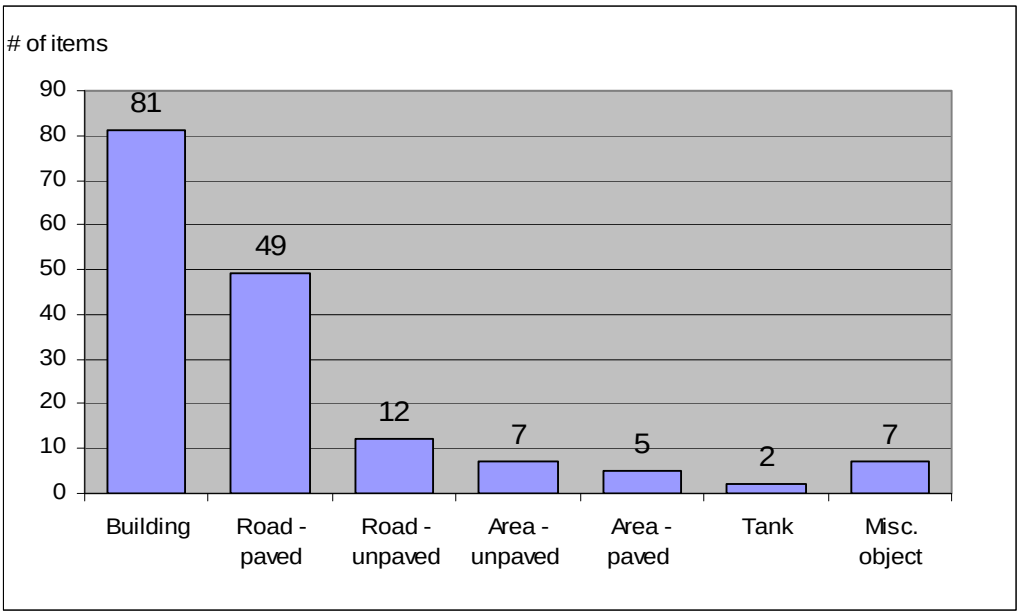
on Shasta Lake would most likely also be affected. However, as noted previously, the only permanent infrastructure at the boat-in camps is vault toilets, and information about the locations of the campsites and vault toilets at the boat-in camps is not available. Thus, the most prominent direct effects on recreation facilities and public access at Shasta Lake and in the vicinity under CP3 would be the major effects on all six boat ramps, nine of 10 marinas, four of five nonmarina resorts, all five day-use areas, six of 13 public campgrounds, and one private campground. Other facilities subject to major effects are USFS stations on the Sacramento River and McCloud River arms, the Dry Creek Trail and trailhead near the dam, and the Shasta Caverns ferry landing and seven private cabins on the McCloud River Arm. Many of these facilities would be entirely or nearly inundated at the new full pool elevation associated with CP3. Table 18-8 summarizes the number of recreation facilities of specific types affected.

Table 18-8. Tally of Shasta Lake Recreation Facilities Substantially Affected by CP3

Type of Facility	Number of Facilities Affected
Boat ramp	6
Marina	9
Resort	4
Campground (family)	6
Group campground	1
Private campground	1
Day-use area	5
USFS operations	2
Trailhead	2
Recreation residence tract	2
Commercial tour	1

Source: Reclamation 2003; data provided by EDAW (now AECOM) in 2007

Key:
USFS = U.S. Forest Service



Somewhat lesser but still considerable effects would occur at one campground and one marina while relatively minor effects would occur at additional facilities of several types. Additional effects would occur at trailheads (most located at day-use areas or boat ramps addressed above) and at numerous segments of trail near the present shoreline.

Figure 18-5 depicts the total number of inventoried Shasta Lake recreation facility items, at all recreation facilities combined, that would be affected by inundation under CP3. A total of 163 facility and infrastructure elements would be affected, with more than three-fourths of those being buildings and segments of paved roads. A lesser number of unpaved road segments, paved and unpaved

areas (usually parking areas), tanks, and miscellaneous objects would also be affected.

As described in Section 2.4.2 in Chapter 2, "Alternatives," construction activities under all action alternatives would include relocation of affected recreation facilities. This could include relocation of affected portions of facilities within existing use areas, in adjacent undeveloped areas, or at new sites in the same general vicinity of the lake. Because of consolidation of facilities, the total number of facilities of specific types may be reduced. However, all affected recreation capacity would be replaced. Replacement facilities would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable. With the relocation of affected facilities, this impact would be less than significant.

Recreation is highly important to the Shasta Lake area. Therefore, mitigation is included to uphold the completion of all actions related to the relocation of affected recreation facilities in order to maintain recreation capacity at Shasta Lake, as included in the project description.

Source: Reclamation 2003

Figure 18-5. Number of Recreation Facility Infrastructure Items Affected by an 18.5-Foot Dam Raise Under CP3

Impact Rec-2 (CP3): Temporary Construction-Related Disruption of Recreation Access and Activities at and near Shasta Dam Construction activity at Shasta Dam that would be necessary to raise the dam and complete related modifications would prevent recreation visitors from crossing the dam, as is possible now with a permit from Reclamation, and thus could affect other

recreation activities in the area. These effects are expected only during the construction period. However, this impact would be potentially significant.

This impact would be similar to Impact Rec-2 (CP1). If the increased dam raise height relative to CP1 (18.5 feet versus 6.5 feet under CP1) would substantially lengthen the period during which construction would occur or otherwise increase construction-related disruption in the dam area, the effects described under CP1 could be increased. This impact would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

Impact Rec-3 (CP3): Effects on Boating and Other Recreation Use and Enjoyment of Shasta Lake as a Result of Changes in the Annual Drawdown of the Reservoir An increase in the magnitude or rate or changes in the timing of the annual summer and fall drawdown of Shasta Lake could adversely affect boating enjoyment and safety on the reservoir. Conversely, a reduced or slower drawdown could have beneficial effects. However, under CP3, reservoir operations would mimic existing operations, with little change in annual magnitude, rate, or timing of reservoir drawdown. Therefore, this impact would be less than significant.

This impact would be similar to Impact Rec-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-4 (CP3): Increased Hazards to Boaters and Other Recreationists at Shasta Lake from Standing Timber and Stumps Remaining in Untreated Areas of the Inundation Zone At full pool, the increased pool elevation would result in approximately 1,738 acres of newly inundated area where the existing trees and other vegetation would not be removed. Anglers would generally benefit from the associated enhancement of fish habitat; however, the standing trees and stumps that would remain in these areas would increase the number of areas and total area where this type of hazard to boaters and other types of recreation visitors would exist. Therefore, this impact would be significant.

Approximately 1,738 acres (68 percent) of the 2,570 acres of newly inundated area that would result from the 18.5-foot dam raise at full pool would receive no vegetation treatment (no vegetation removed), to maximize the habitat benefits of inundated and residual vegetation. In general, this impact would be similar to Impacts Rec-4 (CP1) and Rec-4 (CP2), although the total area where the potential hazard resulting from remaining trees and stumps would be greater under CP3. Because the untreated areas of the new inundation zone would represent an increased hazard to boaters and potentially other types of recreationists, this impact would be significant. Mitigation for this impact is proposed in Section 18.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Rec-5 (CP3): Seasonal Inundation of Portions of Recreation Facilities or Informal River Access Sites as a Result of Increased River Flows Within the

upper Sacramento River portion of the primary study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result from increased mean monthly river flows associated with project implementation and operation. In general, the increases in flow that would occur in some years would be expected to be small (5 percent or less); the area of inundation beyond that which would occur under existing conditions and the No-Action Alternative would be likewise small. As a result, the adverse effects are unlikely to be substantial. This impact would be less than significant.

This impact would be similar to but greater than Impacts Rec-5 (CP1) and Rec-5 (CP2), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be greater than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-6 (CP3): Increased Difficulty for Boaters in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the primary study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River. Depending on the time of year and base river flows, increased flow may also have beneficial effects. Because the magnitude of flow increases associated with CP3 would be small (generally less than 5 percent), adverse effects on boaters within the primary study area are unlikely. This impact would be less than significant.

This impact would be similar to but greater than Impacts Rec-6 (CP1) and Rec-6 (CP2), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be greater than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-7 (CP3): Increased Difficulty for Swimmers and Waders in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the upper Sacramento River, particularly during summer when swimming activity is most likely and during fall and winter nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming and wading conditions. Increased flows can make swimming and wading more challenging and potentially more hazardous. The magnitude of flow increases associated with CP3 would be small (generally less than 5 percent), and the timing of the increases would be such that adverse effects on angling waders within the primary study area are unlikely. Swimming is not a common activity on the main channel of the river because of cold-water temperatures. As a result, this impact would be less than significant.

This impact would be similar to but greater than Impacts Rec-7 (CP1) and Rec-7 (CP2), because the alteration of flow regimes of the lower Sacramento River

and rivers below CVP and SWP reservoirs would be greater than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-8 (CP3): Increased Usability of the Sacramento River for Boating and Water-Contact Recreation as a Result of Decreased River Flows Decreased mean monthly flows within the primary study area, particularly during summer when boating and swimming activity is most likely and during fall and winter low-flow periods when wade angling activity is most likely, could result in enhanced boating, swimming, and wading conditions. Decreased flows during normally high-flow periods can make boating less challenging and potentially less hazardous. The magnitude of flow decreases associated with CP3 would be small (generally less than 10 percent), and the timing of the decreases (fall and winter months) would be such that effects on boaters, swimmers, and waders within the primary study area are unlikely. As a result, this impact would be less than significant.

This impact would be similar to but greater than Impacts Rec-8 (CP1) and Rec-8 (CP2), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be greater than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-9 (CP3): Enhanced Angling Opportunities in the Upper Sacramento River as a Result of Improved Flows and Reduced Water Temperatures Project operation would result in improved flow and water temperature conditions in the upper Sacramento River, which would benefit all four Chinook salmon runs. This would result in enhanced populations of these game fish in the river, which would provide enhanced sport angling opportunities. This impact would be beneficial.

This impact would be similar to Impact Rec-9 (CP1) and would be beneficial. Mitigation for this impact is not required.

Impact Rec-10 (CP3): Disruption of Sacramento River Boating and Access Resulting from the Gravel Augmentation Program The proposed gravel augmentation program would not be implemented under CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-11 (CP3): Changes in Usability of Reading Island Fishing Access Boat Ramp and Enhanced Recreation at Reading Island The proposed restoration of Sacramento River flow through Anderson Slough at Reading Island, rehabilitation of the Reading Island boat ramp for use by motorized boats, and construction of a handicap fishing access area would not be implemented under CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Rec-12 (CP3): Seasonal Inundation of Portions of River Recreation Facilities or Informal River Access Sites on the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows

Within the extended study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result if increased mean monthly river flows were to occur in some months of some years as a result of project implementation and operation under CP3. However, even with the increases, flows on the Sacramento and Feather rivers would remain moderate and well below normal winter and spring high flows. As a result, adverse effects on river facilities or informal use areas within the extended study area are unlikely. This impact would be less than significant.

This impact would be similar to but greater than Impacts Rec-12 (CP1) and Rec-12 (CP2), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be greater than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-13 (CP3): Increased Difficulty for Boaters in Using the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly flows within the extended study area, particularly during summer and fall when boating activity is most likely, could result in more difficult boating launching and boating conditions on the Sacramento River and other rivers affected by the project. Depending on the time of year and base river flows, increased flow may also have beneficial effects on boating by reducing shallow bars and riffles, thus improving navigability. However, the timing and flow conditions under which the flow increases are likely to occur on the Sacramento, Feather, and American rivers under CP3 and the continuation of moderate flows even with the increase suggest that adverse effects on boaters within the extended study area are unlikely. This impact would be less than significant.

Hydrologic changes in more distant areas of the CVP and SWP service areas resulting from CP3 cannot be accurately predicted but would be small. Such slight changes occur on a dynamic and daily basis under existing conditions as water is moved throughout California. Other CVP and SWP reservoir elevations, canal flows, and flows below the reservoirs could be modified slightly, but any resulting effects on recreation would be negligible and speculative.

This impact would be similar to but greater than Impacts Rec-13 (CP1) and Rec-13 (CP2), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be greater than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-14 (CP3): Increased Difficulty for Swimmers and Waders in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly river flows within the extended study area during some months of some years, particularly during summer when swimming activity is most likely and during nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming and wading conditions. These activities could become more hazardous and thus less attractive to river users. However, given the timing of the likely flow increases under CP3, the conditions under which such increases would occur, and the continuation of moderate flows even with the increase, adverse effects on swimmers and waders in the extended study area are unlikely. This impact would be less than significant.

This impact would be similar to but greater than Impacts Rec-14 (CP1) and Rec-14 (CP2), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be greater than under CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-15 (CP3): Increased Difficulty for Boaters and Anglers in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Decreased River Flows Reduced mean monthly flows during fall and winter low-flow periods when wade angling activity is most common, and during summer and fall when boating and river floating is popular in some areas, could have adverse effects if reduced flows were to reduce fishing success or boating navigability. Given the modest flow decreases in the Sacramento River associated with CP3 and the timing of the changes, effects on these recreation uses of the Sacramento River in the extended study area are unlikely. However, given the magnitude and timing of the largest flow decreases during some years on the Feather and American rivers below CVP and SWP reservoirs in the extended study area, adverse effects may occur. This impact would be potentially significant.

This impact would be similar to but greater than Impacts Rec-15 (CP1) and Rec-15 (CP2), because the alteration of flow regimes of the lower Sacramento River and rivers below CVP and SWP reservoirs would be greater than under CP1 and CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

Like each of the alternatives discussed above, by increasing storage at Shasta Lake, CP4 would change the full pool elevation at Shasta Lake, and the seasonal pool elevations and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. In turn, these alterations to reservoir pool elevations and river flows could affect the usability of some types of recreation facilities on the lake and downstream waterways,

particularly marinas, boat ramps, and nearshore campgrounds and day-use areas. These alterations could also affect the ability of recreationists to use the reservoirs and waterways for boating, camping, fishing, and similar activities.

As under CP3, under CP4 the full pool elevation of Shasta Lake would increase by 20.5 feet and the pool elevation would average as much as 18 to 24 feet higher than under existing (2005) and No-Action Alternative (2030) conditions at various times of the year. The greatest change would occur during the wettest years. However, the dedicated Shasta Lake storage of 378 thousand acre-feet (TAF) is unique to CP4 and would result in a different drawdown scenario than under CP3. In general, Shasta Lake storage would be 100–140 TAF greater under CP4 than under CP3 at various times of the year, with the greatest difference occurring during October and November. This equates to an increase in pool elevation of about 3 to 5 feet throughout the year.

Raising the dam by 18.5 feet would increase the surface area of the reservoir at full pool by about 2,570 acres (9 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years. Also, the increase in acreage would be distributed around the several hundred miles of the reservoir's rim. The width of the water body would not increase substantially in most areas, and much of the increase would occur during spring rather than during the high-traffic summer boating period.

The changes in flow and river stage on the upper Sacramento River associated with CP4 would be the same as the changes associated with CP1, as outlined above, in that the operated storage of 256 TAF would be the same for CP1 and CP4.

Reservoir- and river-based recreation facilities and activities are similar in the primary and extended study areas downstream from Shasta Lake; thus potential reservoir and river recreation impacts would be similar. However, changes to the flow regime affecting reservoirs and rivers in the extended study area would be increasingly attenuated by flows from tributary waterways and other water sources and diversions that are unaffected by the project, reducing the level of effects.

Shasta Lake and Vicinity

Impact Rec-1 (CP4): Seasonal Inundation of Shasta Lake Recreation Facilities or Portions of Recreation Facilities and Public Access at Pool Elevations Above the Current Full Pool Elevation Substantial effects from inundation of recreation facilities or portions of Shasta Lake facilities, such as boat launch ramps, campgrounds, marinas, and day-use areas, would result from the 20.5-foot increase in full pool elevation associated with the 18.5-foot dam raise. The reservoir would fill to the new full pool elevation of 1,087.5 feet in some years, and would fill to an elevation greater than the current full pool elevation of 1,067 feet in many years. In each case portions of existing recreation

facilities on the shoreline would be inundated. However, construction activities would include relocation of affected recreation facilities. Replacement facilities would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable, and would comply with ADA and ABA guidelines. Therefore, this impact would be less than significant.

As described in Section 2.4.2 in Chapter 2, "Alternatives," construction activities under all action alternatives would include relocation of affected recreation facilities. This could include relocation of affected portions of facilities within existing use areas, in adjacent undeveloped areas, or at new sites in the same general vicinity of the lake. Because of consolidation of facilities, the total number of facilities of specific types may be reduced. However, all affected recreation capacity would be replaced. Replacement facilities would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable. With the relocation of affected facilities, this impact would be less than significant.

Recreation is highly important to the Shasta Lake area. Therefore, mitigation is included to uphold the completion of all actions related to the relocation of affected recreation facilities in order to maintain recreation capacity at Shasta Lake, as included in the project description.

Impact Rec-2 (CP4): Temporary Construction-Related Disruption of Recreation Access and Activities at and near Shasta Dam Construction activity at Shasta Dam that would be necessary to raise the dam and complete related modifications would prevent recreation visitors from crossing the dam, as is possible now with a permit from Reclamation, and could affect other recreation activities in the area. These effects are expected only during the construction period. However, this impact would be potentially significant.

This impact would be similar to Impact Rec-2 (CP1). If the increased dam-raise height relative to CP1 (18.5 feet versus 6.5 feet under CP1) would substantially lengthen the period during which construction would occur or otherwise increase construction-related disruption in the dam area, the effects described under CP1 could be increased. This impact would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

Impact Rec-3 (CP4): Effects on Boating and Other Recreation Use and Enjoyment of Shasta Lake as a Result of Changes in the Annual Drawdown of the Reservoir An increase in the magnitude or rate or changes in the timing of the annual summer and fall drawdown of Shasta Lake could adversely affect boating enjoyment and safety on the reservoir. Conversely, a reduced or slower drawdown could have beneficial effects. However, under CP4 reservoir operations would mimic existing operations, with little change in annual magnitude, rate, or timing of reservoir drawdown. Therefore, this impact would be less than significant.

This impact would be similar to Impact Rec-3 (CP1) and would be significant. Mitigation for this impact is proposed in Section 18.3.5.

Impact Rec-4 (CP4): Increased Hazards to Boaters and Other Recreationists at Shasta Lake from Standing Timber and Stumps Remaining in Untreated Areas of the Inundation Zone At full pool, the increased pool elevation would result in approximately 1,738 acres of newly inundated area where the existing trees and other vegetation would not be removed. Anglers would generally benefit from the associated enhancement of fish habitat; however, the standing trees and stumps that would remain in these areas would increase the number of areas and total area where this type of hazard to boaters and other types of recreation visitors would exist. Therefore, this impact would be significant.

This impact would be the same as Impact Rec-4 (CP3) and would be significant. Mitigation for this impact is proposed in Section 18.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Rec-5 (CP4): Seasonal Inundation of Portions of Recreation Facilities or Informal River Access Sites as a Result of Increased River Flows Within the upper Sacramento River portion of the primary study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result from increased mean monthly river flows associated with project implementation and operation. In general, the increases in flow that would occur in some years would be expected to be small (5 percent or less); the area of inundation beyond that which would occur under existing conditions and the No-Action Alternative would be likewise small. As a result, the adverse effects are unlikely to be substantial. This impact would be less than significant.

This impact would be the same as Impact Rec-5 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-6 (CP4): Increased Difficulty for Boaters in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the primary study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River. Depending on the time of year and base river flows, increased flow may also have beneficial effects. Because the magnitude of flow increases associated with CP4 would be small (generally less than 5 percent), adverse effects on boaters within the primary study area are unlikely. As a result, this impact would be less than significant.

This impact would be the same as Impact Rec-6 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-7 (CP4): Increased Difficulty for Swimmers and Waders in Using the Sacramento River as a Result of Increased River Flows Increased mean

monthly flows within the upper Sacramento River, particularly during summer when swimming activity is most likely and during fall and winter nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming and wading conditions. Increased flows can make swimming and wading more challenging and potentially more hazardous. The magnitude of flow increases associated with CP4 would be small (generally less than 5 percent), and the timing of the increases would be such that adverse effects on angling waders within the primary study area are unlikely. Swimming is not a common activity on the main channel of the river because of cold-water temperatures. As a result, this impact would be less than significant.

This impact would be the same as Impact Rec-7 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-8 (CP4): Increased Usability of the Sacramento River for Boating and Water-Contact Recreation as a Result of Decreased River Flows Decreased mean monthly flows within the primary study area, particularly during the summer months when boating and swimming activity is most likely and during fall and winter low-flow periods when wade angling activity is most likely, could result in enhanced boating, swimming, and wading conditions. Decreased flows during normally high-flow periods can make boating less challenging and potentially less hazardous. The magnitude of flow decreases associated with CP4 is small (generally less than 10 percent), and the timing of the decreases (fall and winter months) is such that effects on boaters, swimmers, and waders within the primary study area are unlikely. As a result, this impact would be less than significant.

This impact would be the same as Impact Rec-8 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-9 (CP4): Enhanced Angling Opportunities in the Upper Sacramento River as a Result of Improved Flows and Reduced Water Temperatures Project operation would result in improved flow and water temperature conditions in the upper Sacramento River, which would benefit all four Chinook salmon runs, as well as steelhead, American shad, and striped bass. This would result in enhanced populations of these game fish in the river, which would provide enhanced sport angling opportunities. This impact would be beneficial.

Chinook salmon, steelhead, American shad, and striped bass all contribute to the popular sport fishery in the upper Sacramento River. (The salmon season has been closed on the upper Sacramento River in recent years, but may be reopened if the health of the runs improves.) With increased flows and cooler water temperature resulting from project operation, salmon populations would benefit from reduced mortality. Cooler water temperatures would also create more suitable conditions in the river for steelhead, American shad, and striped bass. These beneficial effects on game fish species could result in enhanced angling opportunities on the upper Sacramento River, which would have a

beneficial effect on recreation. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-10 (CP4): Disruption of Sacramento River Boating and Access Resulting from the Gravel Augmentation Program Access to and boating on the upper Sacramento River may be temporarily affected while gravel is placed in the river under the proposed gravel augmentation program. However, gravel placement would occur during only a 1-month period and most augmentation sites would not be adjacent to public river access sites; further, the method of gravel deposition would have little effect on boating. The program could increase the number of shallows encountered by boaters, but shallows are normal characteristics of the targeted river reaches. Therefore, this impact would be less than significant.

The proposed gravel augmentation program could affect boating on the upper Sacramento River by increasing the number of shallow riffles where boating could be made more difficult or hazardous, or where boats may drag the bottom during low-water periods. In the short term, river access and boating may be affected while the gravel is being placed in the river. However, the program would affect only a few sites between Keswick Dam and Clear Creek each year, and the sites under consideration are well distributed along more than 10 miles of the river. Gravel placement would most likely occur only during an approximately 1-month period of late summer (late August to late September), limiting the time during which access or boating could be disrupted. Only a few of the gravel augmentation sites under consideration are adjacent to public river access sites, where access could be disrupted for 1 or 2 days during gravel placement. Deposition of gravel at most sites would occur using a talus cone or lateral berm method, which would use dump trucks or conveyors to place gravel near the riverbank, and would have little effect on boating. Only a few sites would use a direct placement method, which would use front-end loaders to deposit gravel directly in the river channel, and which could conflict with boating during the 1 or 2 days of gravel deposition.

The gravel augmentation program would increase the number of shallows that boaters on the river could encounter. However, shallows as well as rocks and other obstructions are normal characteristics of the targeted reaches of the river (Tuthill 2005). As a result, the boats most commonly used on the upper river (e.g., shallow-draft prop and jet-driven power boats, canoes, kayaks, and rafts) are able to navigate shallow waters, and published boating guides warn boaters of depth changes caused by shifting sands and silts, shallowness, snags, and other obstructions they may encounter (DBW 2011b). For these reasons, both short- and long-term effects on river access and boating are likely to be minimal. As a result, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-11 (CP4): Changes in Usability of Reading Island Fishing Access Boat Ramp and Enhanced Recreation at Reading Island Restoring Sacramento

River flow through Anderson Slough at Reading Island would increase boating and fishing access and opportunities for day-use visitors to the park. This impact would be beneficial.

Several options for restoring Sacramento River flow through Anderson Slough at Reading Island are under consideration, with the primary purpose of recreating habitat for anadromous salmonid fish species. This restoration would deepen the slough and flush out the aquatic vegetation that now clogs the waterway and renders the Reading Island boat ramp on the slough nearly unusable. Also under consideration are rehabilitation of the boat ramp for motorized boat use and construction of a handicap fishing access area. These actions to restore habitat and rehabilitate and enhance recreation facilities would increase boating and fishing access and opportunities for day-use visitors to the park. They would also make the park more functional and attractive for river float trip groups that occasionally camp at the island under BLM special-use permits. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Rec-12 (CP4): Seasonal Inundation of Portions of River Recreation Facilities or Informal River Access Sites on the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows

Within the extended study area, inundation of recreation facilities or portions of recreation facilities such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities could result if increased mean monthly river flows were to occur in some months of some years as a result of project implementation and operation under CP4. However, even with the increases, flows on the Sacramento, Feather, and American rivers would remain moderate and well below normal winter and spring high flows. As a result, adverse effects on river facilities or informal use areas within the extended study area are unlikely. This impact would be less than significant.

This impact would be the same as Impact Rec-12 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-13 (CP4): Increased Difficulty for Boaters in Using the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows

Increased mean monthly flows within the extended study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River and other rivers affected by the project. Depending on the time of year and base river flows, increased flow may also have beneficial effects on boating by reducing shallow bars and riffles, thus improving navigability. However, the timing and flow conditions under which the flow increases are likely to occur on the Sacramento, Feather, and American rivers under CP4 and the continuation of moderate flows even with the increase

suggest that adverse effects on boaters within the extended study area are unlikely. This impact would be less than significant.

Hydrologic changes in more distant areas of the CVP/SWP service areas resulting from CP4 cannot be accurately predicted but would be small. Such slight changes occur on a dynamic and daily basis under existing conditions as water is moved throughout California. Other CVP and SWP reservoir elevations, canal flows, and flows below the reservoirs could be slightly modified, but any resulting impacts on recreation would be negligible and speculative.

This impact would be the same as Impact Rec-13 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-14 (CP4): Increased Difficulty for Swimmers and Waders in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly river flows within the extended study area during some months of some years, particularly during summer when swimming activity is most likely and during nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming and wading conditions. These activities could become more hazardous and thus less attractive to river users. However, given the timing of the likely flow increases under CP1, the conditions under which such increases would occur, and the continuation of moderate flows even with the increase, adverse effects on swimmers and waders within the extended study area are unlikely. This impact would be less than significant.

This impact would be the same as Impact Rec-14 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-15 (CP4): Increased Difficulty for Boaters and Anglers in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Decreased River Flows Reduced mean monthly flows during fall and winter low-flow periods when wade angling activity is most common, and during summer and fall when boating and river floating is popular in some areas, could have adverse effects if reduced flows were to reduce fishing success or boating navigability. Given the modest flow decreases in the Sacramento River associated with CP4 and the timing of the changes, effects on these recreation uses of the Sacramento River in the extended study area are unlikely. However, given the magnitude and timing of the largest flow decreases during some years on the Feather and American rivers below CVP and SWP reservoirs in the extended study area, adverse effects may occur. This impact would be potentially significant.

This impact would be the same as Impact Rec-15 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Like each of the alternatives discussed above, by increasing storage at Shasta Lake, CP5 would increase the full pool elevation at Shasta Lake, and the seasonal pool elevations and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. In turn, these alterations to reservoir pool elevations and river flows could affect the usability of some types of recreation facilities on the lake and downstream waterways, particularly marinas, boat ramps, and nearshore campgrounds and day-use areas. These alterations could also affect the ability of recreationists to use the reservoirs and waterways for boating, camping, fishing, and similar activities.

The full pool elevation of Shasta Lake would increase by 20.5 feet and the pool elevation would average as much as 18 to 24 feet higher than under existing (2005) and No-Action Alternative (2030) conditions at various times of the year. The greatest change would occur during the wettest years. Raising the dam by 18.5 feet would increase the surface area of the reservoir at full pool by about 2,570 acres (9 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years. Also, the increase in acreage would be distributed around the several hundred miles of the reservoir's rim. The width of the water body would not increase substantially in most areas, and much of the increase would occur during spring rather than during the high-traffic summer boating period.

Changes in flow and river stage on the upper Sacramento River associated with CP5 would be the same as those associated with CP3, as outlined above.

Reservoir- and river-based recreation facilities and activities in the primary and extended study areas downstream from Shasta Lake are similar; thus potential reservoir and river recreation impacts would be similar. However, changes to the flow regime affecting reservoirs and rivers in the extended study area would be increasingly attenuated by flows from tributary waterways and other water sources and diversions that are unaffected by the project, reducing the level of impacts.

Shasta Lake and Vicinity

Impact Rec-1 (CP5): Seasonal Inundation of Shasta Lake Recreation Facilities or Portions of Recreation Facilities and Public Access at Pool Elevations Above the Current Full Pool Elevation Substantial effects from inundation of recreation facilities or portions of Shasta Lake facilities, such as boat launch ramps, campgrounds, marinas, and day-use areas, would result from the 20.5-foot increase in full pool elevation associated with the 18.5-foot dam raise. The reservoir would fill to the new full pool elevation of 1,087.5 feet in some years, and would fill to an elevation greater than the current full pool elevation of 1,067 feet in many years. In each case portions of existing recreation facilities on the shoreline would be inundated. However, construction activities would include relocation of affected recreation facilities. Replacement facilities

would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable, and would comply with ADA and ABA guidelines. Therefore, this impact would be less than significant.

As described in Section 2.4.2, construction activities under all action alternatives would include relocation of affected recreation facilities. This could include relocation of affected portions of facilities within existing use areas, in adjacent undeveloped areas, or at new sites in the same general vicinity of the lake. Because of consolidation of facilities, the total number of facilities of specific types may be reduced. However, all affected recreation capacity would be replaced. Replacement facilities would be of equivalent quality to affected facilities and provide comparable shoreline access, where applicable. With the relocation of affected facilities, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Recreation is highly important to the Shasta Lake area. Therefore, mitigation is included to uphold the completion of all actions related to the relocation of affected recreation facilities in order to maintain recreation capacity at Shasta Lake, as included in the project description.

Impact Rec-2 (CP5): Temporary Construction-Related Disruption of Recreation Access and Activities at and near Shasta Dam Construction activity at Shasta Dam that would be necessary to raise the dam and complete related modifications would prevent recreation visitors from crossing the dam, as is possible now with a permit from Reclamation, and could affect other recreation activities in the area. These effects are expected only during the construction period. However, this impact would be potentially significant.

This impact would be similar to Impact Rec-2 (CP1). If the increased dam-raise height relative to CP1 (18.5 feet versus 6.5 feet under CP1) would substantially lengthen the period during which construction would occur or otherwise increase construction-related disruption in the dam area, the effects described under CP1 could be increased. This impact would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

Impact Rec-3 (CP5): Effects on Boating and Other Recreation Use and Enjoyment of Shasta Lake as a Result of Changes in the Annual Drawdown of the Reservoir An increase in the magnitude or rate or changes in the timing of the annual summer and fall drawdown of Shasta Lake could adversely affect boating enjoyment and safety on the reservoir. Conversely, a reduced or slower drawdown could have beneficial effects. However, under CP5, reservoir operations would mimic existing operations, with little change in annual magnitude, rate, or timing of reservoir drawdown. Therefore, the impact would be less than significant.

This impact would be the same as Impact Rec-3 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-4 (CP5): Increased Hazards to Boaters and Other Recreationists at Shasta Lake from Standing Timber and Stumps Remaining in Untreated Areas of the Inundation Zone At full pool, the increased pool elevation would result in approximately 1,738 acres of newly inundated area where the existing trees and other vegetation would not be removed. Anglers would generally benefit from the associated enhancement of fish habitat; however, the standing trees and stumps that would remain in these areas would increase the number of areas and total area where this type of hazard to boaters and other recreation visitors would exist. Therefore, this impact would be significant.

This impact would be the same as Impact Rec-4 (CP3) and would be significant. Mitigation for this impact is proposed in Section 18.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Rec-5 (CP5): Seasonal Inundation of Portions of Recreation Facilities or Informal River Access Sites as a Result of Increased River Flows Within the upper Sacramento River portion of the primary study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result from increased mean monthly river flows associated with project implementation and operation. In general, the increases in flow that would occur in some years would be expected to be small (5 percent or less); the area of inundation beyond that which would occur under existing conditions and the No-Action Alternative would be likewise small. As a result, the adverse effects are unlikely to be substantial. This impact would be less than significant.

This impact would be the same as Impact Rec-5 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-6 (CP5): Increased Difficulty for Boaters in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the primary study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River. Depending on the time of year and base river flows, increased flow may also have beneficial effects. Because the magnitude of flow increases associated with CP5 would be small (generally less than 5 percent), adverse effects on boaters within the primary study area are unlikely. This impact would be less than significant.

This impact would be the same as Impact Rec-6 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-7 (CP5): Increased Difficulty for Swimmers and Waders in Using the Sacramento River as a Result of Increased River Flows Increased mean monthly flows within the upper Sacramento River, particularly during summer when swimming activity is most likely and during fall and winter nonpeak-flow periods when wade angling activity is most likely, could result in more difficult

swimming and wading conditions. Increased flows can make swimming and wading more challenging and potentially more hazardous. The magnitude of flow increases associated with CP5 would be small (generally less than 5 percent), and the timing of the increases would be such that adverse effects on angling waders within the primary study area are unlikely. Swimming is not a common activity on the main channel of the river because of cold-water temperatures. As a result, this impact would be less than significant.

This impact would be the same as Impact Rec-7 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-8 (CP5): Increased Usability of the Sacramento River for Boating and Water-Contact Recreation as a Result of Decreased River Flows Decreased mean monthly flows within the primary study area, particularly during summer when boating and swimming activity is most likely and during fall and winter low-flow periods when wade angling activity is most likely, could result in enhanced boating, swimming and wading conditions. Decreased flows during normally high-flow periods can make boating less challenging and potentially less hazardous. The magnitude of flow decreases associated with CP5 would be small (generally less than 10 percent), and the timing of the decreases (fall and winter months) would be such that effects on boaters, swimmers, and waders within the primary study area are unlikely. As a result, this impact would be less than significant.

This impact would be the same as Impact Rec-8 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-9 (CP5): Enhanced Angling Opportunities in the Upper Sacramento River as a Result of Improved Flows and Reduced Water Temperatures Project operation would result in improved flow and water temperature conditions in the upper Sacramento River, which would benefit all four Chinook salmon runs. This would result in enhanced populations of these game fish in the river, which would provide enhanced sport angling opportunities. This impact would be beneficial.

This impact would be similar to Impact Rec-9 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-10 (CP5): Disruption of Sacramento River Boating and Access Resulting from the Gravel Augmentation Program Access to and boating on the upper Sacramento River may be temporarily affected while gravel is placed in the river under the proposed gravel augmentation program. However, gravel placement would occur during only a 1-month period and most augmentation sites would not be adjacent to public river access sites; further, the method of gravel deposition would have little effect on boating. The program could increase the number of shallows encountered by boaters, but shallows are

normal characteristics of the targeted river reaches. Therefore, this impact would be less than significant.

This impact would be the same as Impact Rec-10 (CP4) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-11 (CP5): Changes in Usability of Reading Island Fishing Access Boat Ramp and Enhanced Recreation at Reading Island Restoring Sacramento River flow through Anderson Slough at Reading Island would increase boating and fishing access and opportunities for day-use visitors to the park. This impact would be beneficial.

This impact would be the same as Impact Rec-11 (CP4) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Rec-12 (CP5): Seasonal Inundation of Portions of River Recreation Facilities or Informal River Access Sites on the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Within the extended study area, inundation of recreation facilities or portions of recreation facilities, such as boat launch ramps and unimproved riverbank sites used for boat launching and other activities, could result if increased mean monthly river flows were to occur in some months of some years as a result of project implementation and operation under CP5. However, even with the increases, flows on the Sacramento, Feather, and American rivers would remain moderate and well below normal winter and spring high flows. As a result, adverse effects on river facilities or informal use areas within the extended study area are unlikely. This impact would be less than significant.

This impact would be the same as Impact Rec-12 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-13 (CP5): Increased Difficulty for Boaters in Using the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly flows within the extended study area, particularly during summer and fall when boating activity is most likely, could result in more difficult conditions for boat launching and boating on the Sacramento River and other rivers affected by the project. Depending on the time of year and base river flows, increased flow may also have beneficial effects on boating by reducing shallow bars and riffles, thus improving navigability. However, the timing and flow conditions under which the flow increases are likely to occur on the Sacramento, American, and Feather rivers under CP5 and the continuation of moderate flows even with the increase suggest that adverse effects on boaters within the extended study area are unlikely. This impact would be less than significant.

This impact would be the same as Impact Rec-13 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-14 (CP5): Increased Difficulty for Swimmers and Waders in Using the Sacramento River and Rivers below CVP and SWP Reservoirs as a Result of Increased River Flows Increased mean monthly river flows within the extended study area during some months of some years, particularly during summer when swimming activity is most likely and during nonpeak-flow periods when wade angling activity is most likely, could result in more difficult swimming and wading conditions. These activities could become more hazardous and thus less attractive to river users. However, given the timing of the likely flow increases under CP5, the conditions under such increases would occur, and the continuation of moderate flows even with the increase, adverse effects on swimmers and waders in the extended study area are unlikely. This impact would be less than significant.

This impact would be the same as Impact Rec-14 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Rec-15 (CP5): Increased Difficulty for Boaters and Anglers in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Decreased River Flows Reduced mean monthly flows during fall and winter low-flow periods when wade angling activity is most common, and during summer and fall when boating and river floating is popular in some areas, could have adverse effects if reduced flows were to reduce fishing success or boating navigability. Given the modest flow decreases in the Sacramento River associated with CP5 and the timing of the changes, effects on these recreation uses of the Sacramento River within the extended study area are unlikely. However, given the magnitude and timing of the largest flow decreases during some years on the Feather and American rivers below CVP and SWP reservoirs in the extended study area, adverse effects may occur. This impact would be potentially significant.

This impact would be the same as Impact Rec-15 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 18.3.5.

18.3.5 Mitigation Measures

Table 18-9 presents a summary of mitigation measures for recreation and public access.

Table 18-9. Summary of Mitigation Measures for Recreation and Public Access

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Rec-1 (No-Action): Increased Use of Shasta Lake Recreation Facilities and Demand for Recreation Opportunities on Shasta Lake and in the Vicinity Impact Rec-1 (CP1 – CP5): Seasonal Inundation of Shasta Lake Recreation Facilities or Portions of Recreation Facilities and Public Access at Pool Elevations Above the Current Full Pool Elevation	LOS before Mitigation	LTS	LTS	LTS	LTS	LTS	LTS

Key:
B = beneficial
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant
S = significant

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impact Rec-3 (CP1) and Impacts Rec-5 (CP1) through Rec-14 (CP1). Mitigation is provided below for Impacts Rec-2 (CP1), and Rec-4 (CP1), which would affect recreation at Shasta Lake recreation facilities, and for Impact Rec-15 (CP1), which would affect recreation on rivers in the extended study area.

Mitigation Measure Rec-1 (CP1): Modify and Relocate Recreation Facilities Inundated by Increases in Shasta Lake Full Pool Elevation

Recreation is highly important to the Shasta Lake area. This mitigation measure is included to uphold the completion of all actions related to the relocation of affected recreation facilities in order to maintain recreation capacity at Shasta Lake, as included in the project description.

To avoid physical impacts of an increase in Shasta Lake's full pool elevation on recreation facilities, Reclamation will protect such facilities from inundation, modify existing facilities to replace affected areas, or endon existing facilities and replace them at other suitable sites (i.e., relocate facilities). Facilities will be protected, modified, or relocated as described below.

Where feasible, Reclamation will protect recreation facilities from seasonal high-water levels by installing berms, dikes, retaining walls, or similar structures to prevent inundation. The surface level of affected paved and unpaved areas (most used for parking) will be raised if that would prevent inundation. In areas where this is not feasible or is impractical, new facilities to replace lost parking areas will be constructed in adjacent unaffected areas. Reclamation will mitigate effects on parking areas in conjunction with mitigation for effects on boat ramps served by the parking areas.

Affected buildings and other facilities will be relocated. Such buildings and facilities include boat ramps, campgrounds, and day-use area restrooms, and marina and resort buildings (restrooms, cabins, offices, retail stores, storage facilities, and restaurants).

Effects on boat ramps may be difficult to mitigate on existing sites, given the need to have ample ramp space above the full pool level for the facility to function properly and the need to consider parking for vehicles and boat trailers in mitigation plans. Therefore, the elevation of both the ramp and parking area will be raised as on-site mitigation, or boat ramp facilities will be replaced with new facilities in the same general area of the lake that would serve launching needs for that local area.

Affected segments of hiking and biking trails will be relocated upslope in order to restore the continuity of the affected trails.

All capacity of recreation facilities (e.g., boat launching, campsites, picnic sites, marina moorage and related services, resort lodging) lost as a result of inundation will be replaced. Decisions about whether individual affected facilities will be modified or relocated will be addressed in conjunction with USFS, based on overall effects on the features of individual facilities as well as operational needs. Some relocated facilities may be consolidated within other existing facilities, rather than being relocated at a currently undeveloped area. All plans for replacement of facilities will be evaluated and approved by USFS.

Preliminary mitigation plans for effects of an 18.5-foot dam raise on Shasta Lake recreation facilities have been developed with the cooperation of USFS. The proposed mitigation for Impact Rec-1 under CP3 (which also applies to this impact under CP4 and CP5) is summarized by facility type in Table 18-10 (presented under "CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply" below). Under CP1, fewer facilities would be affected than under CP3, and effects on other recreation facilities would be less than under CP3; therefore, the amount of mitigation required under CP1 would also be less than the amount shown in Table 18-10, although required mitigation for effects of CP1 would still be substantial.

Reclamation's mitigation plans for recreation facilities will include mitigation of project effects on roads and bridges, many of which are used for access to recreation facilities. Facility access roads may be relocated, raised, or abandoned. If abandoned roads serve a substantial recreation-access purpose, mitigation may take the form of upgrading alternative access routes that serve the same areas.

Implementation of this mitigation measure would maintain Impact Rec-1 (CP1) at a less than significant level.

Mitigation Measure Rec-2 (CP1): Provide Information About and Improve Alternate Recreation Access and Opportunities to Mitigate the Temporary Loss of Recreation Access and Opportunities During Construction at Shasta Dam Reclamation will inform recreation users of the Chappie-Shasta OHV Area about an alternate route to the area from the south, and will improve this alternative route (e.g., by grading unpaved portions) if necessary for vehicles pulling trailers to use the road. To mitigate the temporary disruption in public tours of Shasta Dam during construction, Reclamation will develop and provide enhanced information about the dam and its operation at the Reclamation Visitor Center at the dam, which would remain open. Mitigation for temporary loss of access to the trailhead at the west end of Shasta Dam is not necessary because the trailhead itself would be affected by construction.

Implementation of this mitigation measure would reduce Impact Rec-2 (CP1) to a less than significant level.

Mitigation Measure Rec-4 (CP1): Provide Information to Shasta Lake Visitors About Potential Safety Hazards in Newly Inundated Areas from Standing Timber and Stumps To mitigate impacts on visitor safety from remaining trees and stumps in untreated areas of the newly inundated zone, Reclamation will work with USFS to provide maps, bulletins, informational postings, and other media as deemed appropriate by USFS at boat ramps, marinas, and other developed Shasta Lake recreation sites. Similar information could be provided at public meetings and events and at USFS and other Web sites used by Shasta Lake visitors to learn about conditions at the lake. The information provided will identify the general areas of the shoreline where the hazard exists, and will inform boaters or the nature of the hazard, the periods of time when the hazard is of concern (i.e., when the reservoir elevation is above the current full pool elevation), and best practices to avoid the hazard while recreating on the lake.

Mitigation Measure Rec-15 (CP1): Implement Mitigation Measure Aqua-15 (CP1): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements This measure is identical to Mitigation Measure Aqua-15 (CP1), described in Chapter 11, "Fisheries and Aquatic Ecosystems."

This measure will also protect recreation uses on these rivers by ensuring that any potential changes in flow would be within the current range of variability. Implementation of this mitigation measure would reduce Impact Rec-15 (CP1) to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impact Rec-3 (CP2), and Impacts Rec-5 (CP1) through Rec-14 (CP2). Mitigation is provided below for Impacts Rec-2 (CP2) and Rec-4 (CP2), which would affect recreation at Shasta Lake recreation facilities, and for Impact Rec-15 (CP2), which would affect recreation on rivers in the extended study area.

Mitigation Measure Rec-1 (CP2): Modify and Relocate Recreation Facilities Inundated by Increases in Shasta Lake Full Pool Elevation This mitigation measure is identical to Mitigation Measure Rec-1 (CP1). Implementation of this mitigation measure would maintain Impact Rec-1 (CP2) at a less than significant level.

Mitigation Measure Rec-2 (CP2): Provide Information About and Improve Alternate Recreation Access and Opportunities to Mitigate the Temporary Loss of Recreation Access and Opportunities During Construction at

Shasta Dam This mitigation measure is identical to Mitigation Measure Rec-2 (CP1). Implementation of this mitigation measure would reduce Impact Rec-2 (CP2) to a less than significant level.

Mitigation Measure Rec-4 (CP2): Provide Information to Shasta Lake Visitors About Potential Safety Hazards in Newly Inundated Areas from Standing Timber and Stumps This mitigation measure is identical to Mitigation Measure Rec-4 (CP1). Implementation of this mitigation measure would reduce Impact Rec-4 (CP2) to a less than significant level.

Mitigation Measure Rec-15 (CP2): Implement Mitigation Measure Aqua-15 (CP2): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements This mitigation measure is identical to Mitigation Measure Aqua-15 (CP2). Implementation of this mitigation measure would reduce Impact Rec-15 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impact Rec-3 (CP3) and Impacts Rec-5 through Rec-14 (CP3). Mitigation is provided below for Impacts Rec-2 (CP3), and Rec-4 (CP3), which would affect recreation at Shasta Lake recreation facilities, and for Impact Rec-15 (CP3), which would affect recreation on rivers in the extended study area.

Mitigation Measure Rec-1 (CP3): Modify and Relocate Recreation Facilities Inundated by Increases in Shasta Lake Full Pool Elevation This mitigation measure is identical to Mitigation Measure Rec-1 (CP1). Implementation of this mitigation measure would maintain Impact Rec-1 (CP3) at a less than significant level.

Mitigation Measure Rec-2 (CP3): Provide Information About and Improve Alternate Recreation Access and Opportunities to Mitigate the Temporary Loss of Recreation Access and Opportunities During Construction at Shasta Dam This mitigation measure is identical to Mitigation Measure Rec-2 (CP1). Implementation of this mitigation measure would reduce Impact Rec-2 (CP3) to a less than significant level.

Mitigation Measure Rec-4 (CP3): Provide Information to Shasta Lake Visitors About Potential Safety Hazards in Newly Inundated Areas from Standing Timber and Stumps This mitigation measure is identical to Mitigation Measure Rec-4 (CP1). Implementation of this mitigation measure would reduce Impact Rec-4 (CP3) to a less than significant level.

Mitigation Measure Rec-15 (CP3): Implement Mitigation Measure Aqua-15 (CP3): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements This mitigation measure is identical to

Mitigation Measure Aqua-15 (CP3). Implementation of this mitigation measure would reduce Impact Rec-15 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

No mitigation is needed for Impact Rec-3 (CP4), and Impacts Rec-5 through Rec-14 (CP4). Mitigation is provided below for Impacts Rec-2 (CP4) and Rec-4 (CP4), which would affect recreation at Shasta Lake recreation facilities, and for Impact Rec-15 (CP4), which would affect recreation on rivers in the extended study area.

Mitigation Measure Rec-1 (CP4): Modify and Relocate Recreation Facilities Inundated by Increases in Shasta Lake Full Pool Elevation This mitigation measure is identical to Mitigation Measure Rec-1 (CP1). Implementation of this mitigation measure would maintain Impact Rec-1 (CP4) at a less than significant level.

Mitigation Measure Rec-2 (CP4): Provide Information About and Improve Alternate Recreation Access and Opportunities to Mitigate the Temporary Loss of Recreation Access and Opportunities During Construction at Shasta Dam This mitigation measure is identical to Mitigation Measure Rec-2 (CP1). Implementation of this mitigation measure would reduce Impact Rec-2 (CP4) to a less than significant level.

Mitigation Measure Rec-4 (CP4): Provide Information to Shasta Lake Visitors About Potential Safety Hazards in Newly Inundated Areas from Standing Timber and Stumps This mitigation measure is identical to Mitigation Measure Rec-4 (CP1). Implementation of this mitigation measure would reduce Impact Rec-4 (CP4) to a less than significant level.

Mitigation Measure Rec-15 (CP4): Implement Mitigation Measure Aqua-15 (CP4): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements This mitigation measure is identical to Mitigation Measure Aqua-15 (CP1). Implementation of this mitigation measure would reduce Impact Rec-15 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impact Rec-3 (CP5), and Impacts Rec-5 (CP5) through Rec-14 (CP5). Mitigation is provided below for Impacts Rec-2 (CP5) and Rec-4 (CP5), which would affect recreation at Shasta Lake recreation facilities, and for Impact Rec-15 (CP5), which would affect recreation on rivers in the extended study area.

Mitigation Measure Rec-1 (CP5): Modify and Relocate Recreation Facilities Inundated by Increases in Shasta Lake Full Pool Elevation This mitigation measure is identical to Mitigation Measure Rec-1 (CP1).

Implementation of this mitigation measure would maintain Impact Rec-1 (CP5) at a less than significant level.

Mitigation Measure Rec-2 (CP5): Provide Information About and Improve Alternate Recreation Access and Opportunities to Mitigate the Temporary Loss of Recreation Access and Opportunities During Construction at Shasta Dam This mitigation measure is identical to Mitigation Measure Rec-2 (CP1). Implementation of this mitigation measure would reduce Impact Rec-2 (CP5) to a less than significant level.

Mitigation Measure Rec-4 (CP5): Provide Information to Shasta Lake Visitors About Potential Safety Hazards in Newly Inundated Areas from Standing Timber and Stumps This mitigation measure is identical to Mitigation Measure Rec-4 (CP1). Implementation of this mitigation measure would reduce Impact Rec-4 (CP5) to a less than significant level.

Mitigation Measure Rec-15 (CP5): Implement Mitigation Measure Aqua-15 (CP5): Maintain Flows in the Feather River , American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements This mitigation measure is identical to Mitigation Measure Aqua-15 (CP1). Implementation of this mitigation measure would reduce Impact Rec-15 (CP5) to a less than significant level.

18.3.6 Cumulative Effects

A diverse variety of programs that have been developed or are under development by Federal, State, and local agencies – individually and in conjunction with other agencies – are among the other past, present, and reasonably foreseeable future projects that may affect environmental conditions in the primary and extended study areas and therefore may contribute to cumulative effects.

These projects include construction and operation of projects or implementation of programs that may have the potential to adversely affect both land- and water-based recreation and, in combination, cause an existing significant cumulative effect. For example, construction of some projects or implementation of programs may temporarily constrain boat navigation. Some of these project's facilities may displace recreation facilities or activities, or may cause a long-term impediment to navigation on waterways. Water-based recreation may also be indirectly affected because of changes in reservoir water storage or changes in river flows downstream from reservoirs attributable to these projects. To the extent possible, foreseeable actions have been incorporated in the CalSim-II model and data developed for analysis of operational impacts on reservoir elevations and river flows under the project alternatives.

Several programs provide only general plans or frameworks for potential future projects or actions; no construction or other implementation of the programs has

yet occurred, and no site-specific projects have been identified or undergone environmental analysis. Therefore, there are no effects of past or present projects associated with these programs, and future projects that may occur are uncertain. Some of the programs or projects may result in temporary construction effects; however, the exact locations of these projects are unknown at this time. Many ongoing and future programs include public access or recreation objectives or measures, or would protect or enhance water quality, fisheries, wildlife habitat, and other biological resources that support recreation uses. These programs have the potential to result in beneficial effects on recreation, which could help reduce potentially significant cumulative effects.

The effects of climate change on operations at Shasta Lake could potentially affect water-based recreation opportunities both at the lake and downstream. As described in the Climate Change Projection Appendix, climate change could result in higher reservoir releases in the future because of an increase in winter and early-spring inflow into the lake from high-intensity storm events. The change in reservoir releases could be necessary to manage for flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in downstream channel equilibrium, which could affect the Sacramento River's ease of use for water-based recreation.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As described in Section 18.3.4 above, without mitigation, CP1 could cause significant and potentially significant effects on recreation and public access. These effects would result from seasonal inundation of recreational facilities and public access routes, temporary construction-related disruption of recreation access and activities at and near Shasta Dam, and increased difficulty for boaters and anglers in using the Sacramento River and rivers below CVP and SWP reservoirs as a result of decreased river flows. These contributing adverse effects from CP1 would be cumulatively considerable. With implementation of Mitigation Measures Rec-2 (CP1), Rec-4 (CP1), and Rec-15 (CP1), adverse effects from CP1 would be reduced to a less than significant level and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on recreation and public access. This would not be a cumulatively significant effect.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to water-based recreation opportunities downstream. As described in the Climate Change Projection Appendix, climate warming could result in more intense rainstorms, an increased occurrence of high-intensity rainfall, earlier melting of seasonal snowpack, and more events of rain or snow. These expected consequences of climate change may create more frequent and severe flooding associated with lakes and rivers, and thus greater challenges to water-based recreation in the Sacramento River in the primary and extended study areas.

However, as noted in the Climate Change Projection Appendix, studies also generally predict that climate change may cause Shasta Lake to be unable to stay above the 550-TAF dead pool in some critically dry years. With the lake at such a low level, an increase in adverse effects on recreation on the lake could result in critically dry years. Implementation of CP1 could potentially diminish the effects of increased flows and potential flooding on downstream recreation in the Sacramento River by providing additional reservoir storage capacity after construction; however, it would not likely increase the anticipated adverse effects on recreation on Shasta Lake in critically dry years. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The cumulative effects of CP2 would be similar to those of CP1, but greater in magnitude. With implementation of Mitigation Measures Rec-2 (CP2), Rec-4 (CP2), and Rec-15 (CP2), adverse effects from CP2 would be reduced to a less than significant level and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on recreation and public access. This would not be a cumulatively significant effect.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

The cumulative effects of CP3 would be similar to those of CP1, but greater in magnitude. With implementation of Mitigation Measures Rec-2 (CP3), Rec-4 (CP3), and Rec-15 (CP3), adverse effects from CP3 would be reduced to a less than significant level and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on recreation and public access. This would not be a cumulatively significant effect.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

The cumulative effects of CP4 would be similar to those of CP1, but greater in magnitude. With implementation of Mitigation Measures Rec-2 (CP4), Rec-4 (CP4), and Rec-15 (CP4), adverse effects from CP4 would be reduced to a less than significant level and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on recreation and public access. This would not be a cumulatively significant effect.

CP5 – 18.5-Foot Dam Raise, Combination Plan

The cumulative effects of CP5 would be similar to those of CP1, but greater in magnitude. With implementation of Mitigation Measures Rec-2 (CP5), Rec-4 (CP5), and Rec-15 (CP5), adverse effects from CP5 would be reduced to a less than significant level and would no longer result in a cumulatively considerable incremental contribution to cumulative effects on recreation and public access. This would not be a cumulatively significant effect.

Chapter 19
Aesthetics and Visual Resources

19.1 Affected Environment

This chapter describes the affected environment related to aesthetics and visual resources for the dam and reservoir modifications proposed under the SLWRI.

Because of the potential influence of the proposed modification of Shasta Dam on water deliveries over a large geographic area, the SLWRI includes both a primary study area and an extended study area. The primary study area has been further divided into Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). The extended study area consists of the lower Sacramento River and Delta and the CVP/SWP service areas.

19.1.1 Visual Environment

Both natural and artificial landscape features contribute to perceived visual images and the aesthetic value of a view. The value is determined by contrasts, forms, and textures exhibited by the natural environment (e.g., geology, hydrology, vegetation, and wildlife), as well as human-made features. The aesthetic value of an area is a measure of its visual character and quality combined with the viewer's response to the area (DOT 1981). In general terms, the visual landscape is considered to be a vital component of an area's overall resource value. The ability of the landscape to undergo alteration without losing its visual character is considered important for the maintenance of high scenic value. As development deviates from the natural landscape, visual impacts increase. The visual impacts of a project are determined by a number of factors, including effects on the visual character and quality (e.g., form, line, color, and texture), visual exposure, viewer sensitivity, and the number of viewers who are expected to see the project.

People respond differently to changes in the physical environment, depending on their prior experiences and expectations, their proximity to the views, and the length of time the view is visible to them. Visual effects analyses tend to be highly subjective. For this reason, aesthetics and visual resources are addressed qualitatively rather than quantitatively.

This section focuses on the primary study area consisting of Shasta Lake and vicinity and the upper Sacramento River from Shasta Dam downstream to the Red Bluff Diversion Dam. The focus is on the primary study area because implementation of the project would have virtually no effect on aesthetic values and visual resources in the extended study area.

The visual environment, or character, is a function of both the natural and artificial landscape features that make up a view. The character of any given area is influenced by geologic, hydrologic, botanical, wildlife, recreational, and urban features. The perception of visual character can vary significantly as season, hour, light, shadow, weather, and the other elements of a view change. Form, line, color, and texture are the basic components used to describe visual character and quality for most visual assessments (DOT 1981). The dominance of each of these components on the landscape forms the viewer's impression of the landscape and, therefore, the aesthetic value of the landscape. The aesthetic value of an area is a measure of its visual character and scenic quality combined with the viewer response.

The overall sensitivity and response of a viewer to the quality of a view is based on a combination of viewer exposure and viewer sensitivity. Viewer exposure refers to the visibility of resources in the landscape, the proximity of the vantage point to the view, the elevation of the viewer relative to the view, the frequency and duration of the viewing, the number of observers, and preconceived expectations of individual viewers or groups. Viewer sensitivity refers to the extent of the public's concern for particular landscapes. Judgments of visual quality and viewer response should be based on a regional frame of reference The geographical setting and nature of the visual resource will significantly influence the degree of visual quality and sensitivity experienced by the viewer. For example, the presence of a small hill in an otherwise flat landscape may be considered a significant visual element, but a hill of the same size may have very little significance when located in mountainous terrain.

For purposes of this report, a viewshed is defined as the surface area visible from a particular location (e.g., a highway pull-out, campground, or marina) or sequence of locations (e.g., along a highway or trail). The scenic attractiveness and distance zones also influence the aesthetic value of a viewshed.

Scenic Attractiveness

Scenic attractiveness is classified as:

- **Class A "distinctive" –** Areas where landform, vegetation patterns, water characteristics, and cultural features combine to provide unusual, unique, or outstanding scenic quality. These landscapes have strong positive attributes of variety, unity, vividness, mystery, intactness, order, harmony, uniqueness, pattern, and balance.

- **Class B "typical" –** Areas where landform, vegetation patterns, water characteristics, and cultural features combine to provide ordinary or common scenic quality. These landscapes generally have positive, yet common, attributes of variety, unity, vividness, mystery, intactness, order, harmony, uniqueness, pattern, and balance.

- **Class C "indistinctive" –** Areas where landform, vegetation patterns, water characteristics, and cultural features have low scenic quality. Water and rock forms of any consequence are often missing in Class C landscapes. These landscapes have weak or missing attributes of variety, unity, vividness, mystery, intactness, order, harmony, uniqueness, pattern, and balance.

Class A and B visual resources typically are found in State or Federal parks, recreation areas, and wilderness areas, including rivers and lakes. Class C resources generally are areas that have low scenic quality and consist of more common landscapes.

Distance Zones

In addition to scenic attractiveness, three primary distance zones are used, as appropriate, to characterize the viewsheds described in the following sections. These distance zones, described below, are foreground, middle ground, and background.

- **Foreground (0 to 0.5 mile) –** At a foreground distance, people can distinguish small boughs or leaf clusters, tree trunks and large branches, individual shrubs, clumps of wildflowers, medium-sized animals, and medium to large birds.

- **Middle ground (0.5 to 4 miles) –** At a middle ground distance, people can distinguish individual tree forms, large boulders, flower fields, small openings in the forest or tree line, and small rock outcrops. Form, texture, and color remain dominant and pattern is important.

- **Background (4 miles to horizon) –** At a background distance, people can distinguish groves or stands of trees, large openings in the forest, and large rock outcrops. Texture is not detectable and color has flattened, but large patterns of vegetation or rocks are still distinguishable, and landform ridgelines and horizon lines are the dominant visual characteristics.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

For purposes of the aesthetics and visual resources assessment, the primary study area encompasses Shasta Lake and vicinity and the upper Sacramento River in Northern California. Shasta Dam is located about 9 miles northwest of Redding, and the dam and the entire reservoir are in Shasta County. The Shasta Lake and vicinity portion of the primary study area is composed of Shasta Dam and Shasta Lake and the lower reaches of the tributaries draining into Shasta Lake. The upper Sacramento River portion includes dam-related infrastructure downstream from the dam, Keswick Reservoir, and watersheds that are tributary to the Sacramento River downstream to Red Bluff.

The terrain of the primary study area is extremely diverse and includes the mountainous terrain surrounding Shasta Lake as well as the landscapes of the Central Valley below Keswick Reservoir. Upstream from Keswick Reservoir, slopes are characterized by a mix of pine and oak forests and, to varying degrees, chaparral and rock outcrops. The landscape includes topographic features of the Klamath Mountains, the southern Cascade Range, and the Central Valley. Two volcanic features – Mount Shasta and Mount Lassen – can be seen from numerous vantage points throughout the area.

Shasta Lake is the central visual attraction of the primary study area. It is the largest lake in the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). The Shasta-Trinity Unit of the NRA is managed by the USFS, Shasta-Trinity National Forest (STNF) to provide high-quality recreational experiences and visual perceptions to the public. Shasta Lake offers the public a variety of outdoor recreational experiences and activities, including boating, water-skiing, swimming, fishing, camping, picnicking, hiking, hunting, and mountain biking. Recreation at the lake is managed by the USFS consistent with the STNF *Land and Resource Management Plan* (LRMP) and guidelines established for the Whiskeytown-Shasta-Trinity NRA.

Shasta Lake has a surface area of 29,500 acres, with a shoreline of about 420 miles. Currently, there are 10 marinas on Shasta Lake, most of which are located in coves. Although numerous campgrounds provide facilities for land-based recreation, the primary recreational use of the lake is water-based. Many types of boats use the lake, including private and commercial houseboats, powerboats, and personal watercraft.

The construction of Shasta Dam inundated the canyons of the Sacramento, Pit, and McCloud rivers, as well as numerous tributaries. The diversity of visual experiences at Shasta Lake and the surrounding slopes is influenced by fluctuating water levels, compounded by human-made features such as Interstate 5 (I-5), the Union Pacific Railroad (UPRR), and electrical transmission facilities. A variety of commercial and residential uses occurs in, on, or near Shasta Lake.

Shasta Lake is crossed from north to south by I-5 via the Pit River Bridge at the western end of the Pit Arm and the Antlers Bridge near the northern end of the Sacramento Arm. Views from both of these bridges are dominated by Shasta Lake and the surrounding landscapes; the views encompass minimal development, although Bridge Bay Resort can be clearly seen from the southbound lanes of the Pit River Bridge and some commercial and residential development can be seen from the Antlers Bridge.

The STNF LRMP classifies National Forest System (NFS) lands based on visual quality objectives (VQO). VQOs identify how much a management activity can contrast visually with the character of the landscape. The Shasta-Trinity Unit of the NRA includes lands managed by the STNF to meet the

following VQOs: modification, partial retention, and retention. Areas designated as "modification" are typically developed areas, such as campgrounds, marinas, and boat launch ramps, with management activities in the foreground and a natural appearance in the middle ground. "Partial retention" refers to those areas where management activities remain visually subordinate on the landscape. "Retention" areas are those where management activities are not visually evident.

The LRMP defines three principal criteria to classify VQOs: (1) sensitivity levels, (2) scenic quality of the landscape, and (3) distance from the main viewing areas. Table 19-1 compares the acreage of VQOs (as defined in the LRMP) to the total area of NFS lands managed by USFS in the Shasta-Trinity Unit of the NRA.

Table 19-1. Shasta-Trinity National Forest Inventoried Visual Quality Objectives

Inventoried VQO	NFS Lands (2,705,234 acres)		NRA Lands (Shasta-Trinity Unit) (121,505 acres)	
	Acres[1]	Percent[2]	Acres[3]	Percent[4]
Preservation	498,700	18	28,095	23
Retention	175,000	6	92,387	76
Partial Retention	590,600	22	0	0
Modification	597,600	22	1,112	1
Maximum Modification	259,100	10	0	0

Notes:

[1] Number of acres of lands of the VQO type in the LRMP management area (NFS land only)

[2] Percentage of lands of the VQO type in the LRMP management area (NFS land only)

[3] Number of acres of land by VQO type in the NRA (Shasta-Trinity Unit) management area (NFS land only)

[4] Percentage of lands by VQO type in the LRMP management area (NFS land only)

Key:

NFS = National Forest System

VQO = visual quality objective

In the NRA, Shasta Dam and Shasta Lake are the dominant components of the visual environment. The lake, combined with constructed facilities (e.g., Shasta Dam, Pit River Bridge, Bridge Bay Resort) and natural features (e.g., mountains, rivers, canyons, vegetation) observable from various locations have a substantial influence on the visual character of the existing landscape.

The remaining parts of this section describe the visual resources in the primary study area. Much of the content of these descriptions was taken from reconnaissance-level data gathered during the SLWRI by Reclamation and its consultants. The STNF also provided information used to characterize these

visual resources. Visual resources are described in terms of visual sensitivity and viewer response.

Viewsheds A number of factors can influence the aesthetic value of viewsheds in the primary study area, which are dominated by constructed features and natural landscapes. Although exposed surfaces associated with grading and barren shoreline may be obvious, factors such as vegetation, lighting, and glare can also substantially influence these viewsheds both spatially and temporally. The viewshed types that occur in the primary study area are listed below and described in the following sections:

- Panoramic views
- Vista points
- Landscape features
- Distinctive built features
- Built features (detractions)
- Exposed shoreline of Shasta Lake
- External views

Panoramic Views A panoramic view is defined as the unbroken view of an entire surrounding area. In the Shasta Dam and Shasta Lake area, panoramic viewing opportunities are governed by the elevation, aspect, and location of the viewer. The steep, mountainous topography around Shasta Lake largely influences the degree to which any given area can be seen from a particular vantage point. Vegetation, lighting, and glare also influence a panoramic view. For example, panoramic views as seen from the lake level vary greatly from those seen from the I-5 corridor higher up the slope.

The contrast between Shasta Lake and the surrounding mountains affords visitors a diversity of views from various locations around the lake. The length and configuration of the shoreline of Shasta Lake coupled with the mountainous terrain represent an important visual and scenic resource in the region.

Panoramic viewsheds are plentiful throughout the primary study area. Among the most dramatic and high-quality views is that of the so-called “Three Shastas,” consisting of Shasta Dam, Shasta Lake, and Mount Shasta. The photograph in Figure 19-1, taken from the State Route (SR) 151 vista point above the Shasta Dam Visitor Center, illustrates the Three Shastas with the dam in the foreground, the lake in the middle ground, and Mount Shasta in the background. This view is a widely publicized panorama that draws large numbers of visitors to the area annually. Class A and B views extend for miles to the north, east, and west from the SR 151 vista point.

Figure 19-1. Panoramic view of the Three Shastas (Shasta Dam, Shasta Lake, and Mount Shasta) as seen from the State Route 151 Vista Point

For purposes of this assessment, panoramic viewsheds consist primarily of views visible from locations immediately adjacent to or above Shasta Dam that are subject to heavy use (e.g., Bridge Bay Resort, Shasta Dam Visitor Center, the I-5 corridor). However, some less accessible, but nonetheless important, locations such as residences, campgrounds, marinas, and other facilities may also provide opportunities for panoramic views and thus have been included in the assessment of potential impacts on panoramic views.

Vista Points Vista points differ from panoramic views in the level of visible expanse. Panoramic views encompass an entire surrounding area, whereas views from vista points are limited by what can be seen through an opening, such as between rows of trees or buildings. Shasta Lake and the surrounding area offer almost limitless viewing opportunities. Viewsheds have been assessed based on sites that are representative of popular use areas such as marinas, residences, and other recreational features.

Figure 19-2. Typical View of Shasta Lake from a Lakeside Campsite (taken from the Dekkas Rock Campground, McCloud Arm)

Most of the shoreline around the lake (above the ordinary high-water line) is heavily vegetated and its topography varies significantly. Views from most onshore recreation areas are limited by stands of trees and undulating banks. Figure 19-2 shows a view of the lake from a typical lakeside campsite, in this case the Dekkas Rock Campground located on the McCloud Arm. Views of the shoreline from the water are also influenced by topography and vegetation. Although large expanses of the shoreline may be visible to boaters, lake elevation and bank topography ultimately determine what can be seen by boaters.

Landscape Features
"Landscape feature" is a term used to describe the land characteristics of a particular area, such as a forested or mountainous site. Several landscape features characterize the primary study area, including forest, rocky outcrops, and urban development. Well-known landscape features in the primary study area include Shasta Dam, Mount Shasta, the Sundial Bridge, and the Sacramento River. The distance of the feature upstream from Shasta Dam, coupled with variations in lake levels, influences the view of landscape features. As the lake level falls, the various arms look more like rivers (e.g., channelized, boulder-strewn) and less like a lake. Figure 19-3 illustrates some of the distinctive landscape features visible from the Bridge Bay Resort, including the marina, the Pit River Bridge, and limestone outcrops located along the McCloud Arm.

Figure 19-3. Some of the Distinctive Landscape Features Visible from the Bridge Bay Resort, Including a Portion of the Bridge Bay Marina, the Pit River Bridge, and Dramatic Limestone Outcrops Along the McCloud Arm

Distinctive Built Features The aesthetic quality of a distinctive built feature is subject to individual interpretation. This subjective interpretation is influenced by the contrast of these features with their setting. For example, engineered features such as Shasta Dam and its infrastructure (Figure 19-4) can be considered to detract from the "natural" character of the setting, because some viewers might argue that the natural character of the features inundated by Shasta Lake is its greatest strength. The dam, which was completed in 1945, is a curved concrete gravity-type dam containing 6.5 million cubic yards of concrete weighing 15 million tons. It is the second largest dam in mass in the United States. (Grand Coulee Dam on the Columbia River in Washington State is the largest.)

The 3,460-foot-long dam is 602 feet high, 543 feet thick at the bottom, and 30 feet thick at the top (Reclamation 2005). The face of the dam covers 31 acres,

Figure 19-4. Shasta Dam and Infrastructure

equal to six football fields and their stadiums, and the 487-foot spillway is the largest built waterfall in the world – three times the height of Niagara Falls. The spillway, as seen from the west, measures 375 feet in width with three drum gates, each 110 feet wide, 28 feet tall, and weighing 500 tons. There are 18 outlets on the face of the dam, each 8½ feet in diameter (large enough to drive a pickup truck through) with a maximum spillage capacity of 186,000 cubic feet per second.

With 420 miles of shoreline, Shasta Lake is the largest human-made lake in California. The water storage capacity is more than 4.5 million acre-feet. The surface area of the lake is 29,740 acres, and the lake drains 6,665 square miles (Reclamation 2005). The lake is one of the major landmarks in Northern California.

Built Features (Detractions) An opinion concerning the attractiveness of a built feature is formed by the viewer's perception, biases, and personal preferences. A feature seen as an eyesore by one viewer may very well be considered attractive by another. Built features such as bridges, structures, roads, power transmission lines, and water storage tanks are generally visible only from site-specific locations (e.g., the visitor center, marinas, sections of I-5) in the primary study area. Figure 19-5 shows an example of built features found in the primary study area (in this case, a railroad bridge in the foreground and the Antlers/I-5 Bridge in the background, as seen from Lakeshore Drive).

Figure 19-5. Examples of Built Features in the Primary Study Area

Additional built features of interest in the primary study area include bridges, roads, utilities, and commercial, administrative, and residential structures.

Exposed Shoreline of Shasta Lake Currently, Shasta Lake reaches or nearly reaches full-pool levels about once every 5 years. Because it is a reservoir, water levels fluctuate in response to climatic conditions and operational requirements. Typical operational scenarios involve drawing the reservoir down during the demand period (May through October) and storing runoff during the winter/spring period. By its nature, the amount of shoreline exposed below the 1,070-foot elevation fluctuates daily. In extremely dry years, more than 200 vertical feet of shoreline may be exposed for extended periods through the fall.

Unlike bodies of water that are influenced by tides or other natural fluctuations, Shasta Lake does not support habitats that can adapt to large changes in

environmental conditions. Therefore, the exposed shoreline below the ordinary high water line is essentially devoid of vegetation (Figure 19-6). The relatively gradual slope to the lake bottom results in a greater area of exposed shoreline with lower water levels, resulting in the "bathtub ring" effect common to California reservoirs (Reclamation 2006). As the elevation of the water level decreases, the viewing quality changes spatially and temporally. Erosional processes, primarily wave erosion, exacerbate this situation. The seasonal fluctuations in water levels and, consequently, the amount of exposed shoreline greatly affect the visual quality of Shasta Lake.

External Views A number of factors may affect the viewsheds described in the preceding section. Exposed surfaces associated with barren shoreline and activities such as grading may be obvious, but factors such as vegetation, lighting, and glare could also substantially affect these viewsheds both spatially and temporally.

Figure 19-6. The "Bathtub Ring" Effect

Topography and property boundaries influence the public's external views of the primary study area. Views of the lake from private property are infrequent. Most private properties are located some distance from the lake, and views of the lake are buffered by vegetation and the topography of NFS lands surrounding the lake. Nevertheless, some of the private properties in the vicinity of Shasta Lake have views of the lake, although the quality of these views varies. Figure 19-7 shows a view of Shasta Lake from a nearby residence (the McCloud Arm is seen in the middle ground and the Pit Arm in the background).

Figure 19-7. View of Shasta Lake from a Residence Located off Northwoods Road, Lakehead, California

Light and Glare A majority of the lands surrounding Shasta Lake are densely vegetated and undeveloped. As a result, there are relatively few sources of artificial light and glare in the Shasta

Lake and vicinity portion of the primary study area. The reaches of the upper Sacramento River that pass through developed communities, such as Redding and Anderson, do have substantial sources of light and glare, and, to a lesser degree, light and glare are observable between the City of Shasta Lake and Lakehead. Vehicle traffic and roadway lighting along the I-5 corridor, scattered residential and commercial development, and reflective surfaces such as boats and marinas are among the primary sources of light and glare. The Shasta Dam compound has a variety of sources of light and glare. The backdrop of Shasta Dam at night is nonetheless an attraction for visitors and residents.

Exposed bare mineral soils, which characterize the "bathtub ring" around the perimeter of the lake during periods of drawdown, are a potential source of glare (Figure 19-6). The chroma of these soils is generally light, and the contrast of the bathtub ring with upslope vegetation and downslope water is readily apparent from various distances.

Vegetation Vegetation is an important variable in characterizing visual conditions. The type, location, diversity, and distribution of vegetation influence form and texture, depending on the vantage point of the viewer. The diverse assemblage of vegetation and barren areas in and adjacent to the primary study area varies seasonally. As mentioned previously, forestlands surround Shasta Lake. The transition from chaparral/montane hardwood–dominated habitat at the southern end of the lake to a conifer-dominated forest to the north and east is apparent to travelers on I-5 as well as to people viewing the area from the lake level or a vista point.

Typically, vegetation extends from the ordinary high-water line of Shasta Lake into the adjacent uplands. Changes in vegetation type are apparent as the viewer's eye is drawn upward from lake level to surrounding ridgelines. Because there is no vegetation below the ordinary high-water line, a distinct demarcation is visible between upland vegetation and water levels as the reservoir fluctuates.

Viewer Groups The perceptions of viewers are influenced by their location, specific activities in which they are engaged, personal degree of awareness, and individual values and goals. Activities associated with the project could affect three distinct viewer groups: motorists, residents, and recreationists.

Motorists For the purposes of this report, motorists are people who view the primary study area from a moving vehicle. Motorists can be drivers or passengers. This group typically consists of commuters, local residents, business travelers, and tourists.

Tourists are often acutely aware of viewsheds. Business travelers, commuters, and local residents who travel the same routes frequently may become inured to a view but, at the same time, are more likely to be aware of visual changes than occasional passersby. In general, views of Shasta Lake from motorists on I-5 are

of short duration but relatively frequent from Bridge Bay north to Lakehead. The longest duration and most expansive panoramic view of Shasta Lake from I-5 occurs as the roadway approaches and crosses Shasta Lake over the Pit River Bridge from both the north and the south. Traveling this route at a speed of 55 miles per hour, the viewer would be able to observe the lake and its vicinity for approximately 1 minute. Other I-5 views may vary from 4 to 16 seconds, depending on the direction and speed of travel.

Less traveled roads in the vicinity of Shasta Lake, such as SR 151, Salt Creek Road, and Gilman Road, also offer views of the lake. Most views of the lake from these roads are limited to vistas (views framed by trees or structures) and are, therefore, of short duration. However, one of the best vantage points from which to view the Three Shastas is at an overlook along SR 151, a state scenic highway (Figure 19-1). Motorists traveling north who do not stop at the overlook also see a spectacular view of the Three Shastas while traveling, although the view is of short duration.

Residents For the purposes of this report, residents are people whose homes, businesses, and/or property are near, and have a view of, a portion of the primary study area. The sensitivity of residents to aesthetic values and changes to a viewshed is highly individual. In addition, the sensitivity of residents to changes in a viewshed is influenced, in part, by the location and the length of time that the view from a particular location appears altered from its previous condition (e.g., temporary changes during construction or long-term modifications to the landscape).

Views of Shasta Lake from private properties are limited by land ownership patterns – most of the lands surrounding Shasta Lake are Federally owned – as well as access, vegetation, and topography. Homes on nearby ridges, such as those on the ridgeline between Packers Bay and Turntable Bay, typically have partial views of Shasta Lake. Similarly, homes clustered along the Sacramento Arm near Lakehead have views upstream and downstream from the arm, although the views are limited by the steep topography.

Recreationists For the purposes of this report, recreationists are people who use the lands in the NRA for recreation. Like residents, recreational users of Shasta Lake are highly sensitive to the visual character of Shasta Lake and the surrounding environment.

Recreationists are people who participate in land-based activities, such as hiking along the shoreline, camping in the NRA's many campgrounds, or water-based activities, such as boating, fishing, or rafting. Several commercial facilities offer overnight accommodations adjacent to the shoreline. Recreational users often have a unique perspective on the surrounding environment.

Visual Assessment Units and Key Observation Points Visual assessment units (VAU) are areas of distinct visual character in a viewshed that provide a

framework for comparing the visual effects of alternatives. Key observation points (KOP) are commonly traveled routes or other likely observation points in a VAU from which a representative group (motorists, residents, and recreationists) can observe a viewshed.

VAUs are defined by areas where the features or activities associated with the project would occur in the line of sight of a KOP and represent foreground or middle ground views (i.e., within 4 miles of a KOP in the VAU). KOPs were established at locations from which portions of the primary study area can clearly be seen by members of the various viewer groups. Table 19-2 lists the KOPs established in the primary study area. Locations of VAUs and KOPs are shown in Figures 19-8a through 19-8h. Photographs taken from each KOP are provided after each figure.

Photographs for Figure 19-8h

The locations of VAUs were determined using the following steps:

- **Identification of Visually Sensitive Areas** – A determination of sensitivity was made by considering the level of use that a particular view receives by the public. Driving routes, recreational areas, and designated scenic corridors subject to heavy to moderate use represented the numerous sites in the primary study area that could be considered visually sensitive. Examples of visually sensitive areas include the I-5 corridor over the Pit River Bridge, the Shasta Dam Visitor Center, and Bridge Bay Resort.

- **Definition of the Landscape Character** – The landscape character is shaped by the physical, biological, and cultural attributes that combine to make a landscape identifiable or unique. The diverse terrain of the region coupled with the unique attributes of Shasta Lake and the Sacramento River are examples of the landscape character of the primary study area.

- **Identification of Visually Sensitive Observation Points** – This step was used to identify visually sensitive observation points throughout the primary study area that could be adversely affected by changes to the visual environment resulting from project implementation. Important examples of visually sensitive observation points include the vista point located on SR 151 and residences overlooking portions of Shasta Lake. Views from such points would be affected by changes in water levels, as well as the changes to infrastructure associated with raising Shasta Dam and enlarging Shasta Lake.

- **Identification of Visually Affected KOPs** – Key observation points are determined by the extent of observable visual impacts from a specific location, and would depend on the location and distance of the affected area relative to the visually sensitive observation point. The analysis of impacts at such sites considered whether or not project activities would be in the direct line of sight or would occur in the foreground (0 to 0.5 mile) or middle ground (0.5 to 4 miles) view. The distinctiveness of features begins to diminish beyond 3 miles. Key observation points represent observation points in the primary study area having a direct line of sight to, or a view of, the foreground or middle ground of affected areas. The KOPs selected for the analysis of project impacts are identified in Table 19-2 and are further described in the following section.

- **Classification of Scenic Attractiveness** – Scenic attractiveness refers to a classification system used to distinguish unique or remarkable views from those that are more mundane. As described previously, the classification system consists of the following categories: Class A “distinctive,” Class B “typical,” and Class C “indistinctive.”

Following is a discussion of the VAUs and associated KOPs that were identified for the primary study area. Because the primary study area is so large and much of it is remote, VAUs were established at locations subject to relatively high levels of use where changes to the visual environment would be most apparent.

Shasta Dam VAU The Shasta Dam VAU was established to illustrate the views of Shasta Dam from the SR 151 overlook, the Shasta Dam Visitor Center, and the Main Body of Shasta Lake. All of these locations draw numerous visitors annually and receive widespread publicity in regional tour guides. Shasta Dam and the adjacent Visitor Center provide a unique setting from which the public's visual impression of the overall impact of the project (i.e., raising of water levels, increased dam elevation) would be made. A popular attraction in the Shasta Dam VAU is to walk across the dam. (Unregulated vehicle traffic is restricted because of homeland security concerns.) In addition, boaters and other water-based recreationists have expansive views of the waterside face of the dam.

KOP 1 Views from the Shasta Dam overlook on SR 151 capture the essence of the region by offering unobstructed views of the Three Shastas (Shasta Dam in the foreground, Shasta Lake in the middle ground, and Mount Shasta in the background). Situated on the mountainside above the southeast side of the dam, the overlook offers viewers the opportunity to observe not only the Three Shastas, but also the upper Sacramento River as it flows from the dam spillway and miles of mountainous, forested terrain in most directions. The unique and outstanding scenic quality of this view makes it a Class A visual resource that also contains components of the more typical Class B views (e.g., forest, ridgelines).

KOP 1 (Photo 1a) illustrates the Class A panoramic views from the SR 151 overlook to the north/northeast. The dam, the southern end of the Main Body of the lake, and the forested landscape are prominent, with Mount Shasta, about 50 miles away, dominant in the background. Also clearly visible, but less remarkable than the dam, is the dam's infrastructure, including the powerhouse and maintenance roads. The uniqueness of the dam and its infrastructure set against a dramatic landscape of forest and mountains makes this view a Class A visual resource.

KOP 1 (Photo 1b) illustrates the limited Class B views of the upper Sacramento River channel downstream from the spillway from the SR 151 overlook. The Sacramento River, regulated by Keswick Reservoir, flows through a steep canyon and is obscured from view by topography and vegetation. The Chappie-Shasta Off-Highway Vehicle (OHV) Area, managed by the U.S. Bureau of Land Management, along with sections of County Road 5G011 (which is accessed via the dam) and an abandoned railroad line, are visible on the north side of the river, but the river channel itself is not visible from this KOP.

KOP 2 KOP 2 (Photo 2a) illustrates the Class A and B views of the southern end of the lake as seen from the center of the roadway crossing over Shasta Dam. A panoramic view of the southern end of the lake, which occupies the foreground and the middle ground with Mount Shasta on the horizon, is seen from this area. Centimudi Boat Ramp is clearly visible in the middle ground to the east (KOP 2, Photo 2c).

Turning to the west (KOP 2, Photo 2b), the Shasta Dam compound and the Sacramento River below the dam form the primary focal point from this viewpoint. The river meanders out of sight about 1 mile downstream from the dam. This spectacular view of the spillway is a Class A visual resource.

KOP 3 Downstream from the dam, on the right (north) side of the Sacramento River, the U.S. Bureau of Land Management maintains the Chappie-Shasta OHV Area. KOP 3 was established to illustrate the limited views of the downstream face of Shasta Dam from the OHV main staging area. As shown in Photo 3a (KOP 3), the middle ground of the view is dominated by a Class B view of the upper part of Shasta Dam. Vegetation and topography limit the extent of views of the dam from this location and, as illustrated by Photo 3b, also effectively block views of the river channel south toward the river from the staging area.

KOP 4 A public campground at the OHV staging area provides views for OHV recreationists. Although Shasta Dam is not visible from the campground, the Sacramento River dominates the middle ground view to the north, east, and south. KOP 4, photos 4a and 4b, respectively, show the Class B views of the river upstream and downstream.

KOPs 5, 6, 7, and 8 Approximately 0.25 mile downstream from the OHV staging area, south of the NRA boundary, is the historic mining community of Coram and the Coram Ranch, a privately owned recreation resort. KOPs 5, 6, 7, and 8 were established to illustrate the varying degrees of river views (and at one location (KOP 7, Photo 7a) a view of Shasta Dam) from the Coram Ranch cabins. Views from the River House (KOP 5, photos 5a and 5b), the Dogwood House (KOP 6, photos 6a and 6b), and the modular cabins (KOP 8, Photo 8) are considered Class B, offering views of the Sacramento River approximately 1 mile downstream from the dam. The most remarkable view of the primary study area from the ranch is the view of Shasta Dam from the ranch's main house (KOP 7, Photo 7a). Although distance places the dam in the middle ground, as seen from the main house, it is nonetheless impressive. Foreground vegetation serves to frame the dam and draw the viewer's focus to the feature. Photos 7b and 7c (KOP 7) illustrate the views of the Sacramento River from the main ranch house. The views from KOP 7 of Shasta Dam and the Sacramento River are considered to be Class A.

KOP 9 KOP 9 was established to demonstrate the view of Shasta Dam and the Sacramento River from Coram Road, upslope of the OHV staging area.

The Class A view of the river and dam from KOP 9 (Photo 9a) shows the foreground, middle ground, and background landscape. Although most of the dam is visible, its base and a portion of the right abutment (north end) are obscured by topography. The narrowing of the river channel toward the background draws the viewer's eye toward the dam and the mountains in the background. The Class B view looking downstream (Photo 9b) offers partial views of the river, limited by vegetation and topography.

KOP 10 KOP 10 was established to illustrate the view afforded motorists traveling on Lake Boulevard. Coming into the NRA from the south, approximately 0.5 mile of the extreme northern end of Lake Boulevard follows the shoreline of Shasta Lake before ending at the Visitor Center. Similar to views from SR 151 (KOP 1), the elevation of the roadway above the lake allows for expansive vistas from pullouts along the route. Photo 10a shows the Class A vista point view of the lakeside face of Shasta Dam, the Main Body of Shasta Lake in the middle ground, and the forested mountain terrain that dominates the background. Vegetation and topography in the foreground frame the view but also restrict it. The full extent of the view from KOP 10 cannot be fully appreciated by viewers unless they stop at a roadside pullout; otherwise, they will quickly pass it by when traveling on Lake Boulevard.

Views of Shasta Lake, the surrounding mountains, and Mount Shasta (in the distant background) looking north from KOP 10 (Photo 10b) are impressive but more typical of views around Shasta Lake. The Class B view of the lake and its vicinity from this location would be most noticed by motorists traveling east on Lake Boulevard, but the view would be of short duration because the road turns abruptly south away from the lake a short distance beyond this point.

KOP 11 KOP 11 (Photo 11) illustrates the panoramic view that boaters and other water-based recreationists in the Main Body of the lake have of Shasta Dam. The attractiveness of a distinctive built feature, such as the dam, in contrast to the natural character of its surroundings (e.g., water and mountains) is subjective; nonetheless, it is an impressive sight. The uniqueness of the dam set against a dramatic landscape of water and mountains makes this view a Class A visual resource.

Dry Creek Trail VAU The proximity of the Dry Creek Trail area to Shasta Dam makes it a prominent part of the landscape when viewed from the Main Body of Shasta Lake. Most of the Dry Creek Trail shoreline is not visible from the dam, the Chappie-Shasta OHV Area staging area and campground, or other areas frequented by the public because it is obstructed by topography and has limited public access. Although the Dry Creek Access Road meanders through the uplands adjacent to the shoreline, the road is primitive and used only by OHV recreationists, mountain bikers, and the occasional hiker.

KOP1 Most views of the shoreline from the road are obstructed by vegetation and distance. KOP 1 (Photo 1) shows the lakeside view, which is the

most common vantage from which visitors to Shasta Lake would see the Dry Creek Trail shoreline. This Class B view is common throughout the Shasta Lake portion of the primary study area.

Little Backbone Inlet VAU The Little Backbone Inlet VAU was established to illustrate the more typical views that boaters and other water-based recreationists would have of the western side of Shasta Lake. Much of this area has been previously disturbed by mining, wildfire, and OHV activities. Because most of the western shoreline is remote and undeveloped, few people visit the area.

KOP 1 As with much of the western shoreline, the distance from the more populated parts of the primary study area makes it difficult to discern specific details of the landscape. KOP 1 (photos 1a and 1b) illustrate the Class B views in this part of the lake.

Digger Bay VAU The Digger Bay Marina is one of the most difficult marinas on Shasta Lake to access by car. Although it is only 3 miles from the City of Shasta Lake, the road is narrow and extremely winding and the surrounding terrain is very steep. Nonetheless, this USFS-managed marina offers a variety of amenities that make it a popular destination, including the only source of gas in the western part of the lake, a small store, and boat rentals.

KOPs 1, 2, and 3 Views of Shasta Lake from the upper parking area are limited by vegetation and topography (KOP 1, Photo 1, and KOP 2, Photo 2). Similarly, views of Shasta Lake (KOP 3, Photo 3a) and the uplands adjacent to the marina (KOP 3, photos 3b and 3c) are also extremely limited by vegetation and topography. These views are a Class C, indistinctive visual resource.

Packers Bay VAU

KOP 1 Although smaller than nearby Bridge Bay Resort, Packers Bay is a popular destination for water-based recreationists. In addition to a boat ramp managed by USFS, the Packers Bay Marina features amenities such as gas, houseboat rentals, and a small store that is open on a seasonal basis in a less congested environment than at other recreational facilities around the lake. Scenery in and around the Packers Bay Marina is not terribly dramatic, but rather is typical of the region. KOP 1 (Photo 1) shows the Class B view from the Packers Bay Boat Ramp.

Bridge Bay VAU The Bridge Bay Resort and Marina is the largest and one of the most popular marinas on the lake. Its close proximity to I-5 and amenities such as a restaurant, lodging, a store, and a full-service boat marina with houseboat rentals draw a large number of visitors annually. Tourists and motorists, particularly those traveling along the I-5 corridor, are attracted to Bridge Bay by its accessibility. It is from Bridge Bay that most visitors to the region are likely to derive their initial visual perception of Shasta Lake and the surrounding area.

KOP 1 KOP 1 (Photos 1a and 1b) was established to illustrate the view of Shasta Lake from the main parking area adjacent to the Bridge Bay store. During full-pool or nearly full-pool periods, this parking area is used heavily by visitors, boat owners, and other recreationists accessing the lake from Bridge Bay. As the water recedes, marina users and other recreationists tend to follow it downslope, thus lessening the level of use received by this parking area and subsequently altering the viewing perspective. Photo 1a illustrates the Class B view of the Bridge Bay Marina as seen from KOP 1. Landscape features in this photo as well as Photo 1b, taken from the same KOP but from a slightly different perspective, are generally typical for the area—that is, positive yet common.

KOP 2 KOP 2 (Photo 2) illustrates the striking view of the I-5 Pit River Bridge and the UPRR trestle that is located on the lower deck of the bi-level bridge structure, as seen from the northern part of the Bridge Bay Marina. This view is available not only from the parking lot and northern marina, but from the resort's restaurant and hotel as well. As a result of its strong positive attributes (e.g., uniqueness, pattern, balance, mystery), the bridge, which is a Class A visual resource, dominates the middle ground of the scene.

KOP 3 South of Bridge Bay's Marina 4, which is located in the extreme southeast corner of the main body of the lake adjacent to the UPRR tracks, is the Bridge Bay Marina maintenance area. From this location there is a view of the train tunnels adjacent to the east side of the maintenance area. KOP 3, Photo 3a, shows the northern end of the southernmost tunnel, and Photo 3b (taken from the same location) shows the southern end of the northernmost tunnel. Both perspectives would be apparent only to people working in the maintenance area or those who purposely access the area to view the trains. The track and its features are set back against the hillside; therefore, distance, shadow, and topography would obscure most views of this location from the lake, and viewers passing through the primary study area on the train would not have much opportunity to view the lake. Photo 3c, taken from the same location as the previous two photos, demonstrates the distance of the tracks from the Main Body of the lake and illustrates the site's Class B view.

KOP 4 KOP 4 was established to document the initial impression that visitors accessing Bridge Bay's Marina 4 would experience from the stairway. Similar to views from KOP 1, photos 4a and 4b (KOP 4) show the Class B views of the lake from this location.

Sacramento Arm VAU The Sacramento Arm is the busiest and most developed arm of Shasta Lake. For purposes of this assessment, the Sacramento Arm VAU consists of the northern portion of the Sacramento Arm from the Sugarloaf Creek inlet north.

KOPs 1 and 2 In the Pollock area, the Sacramento Arm begins to display characteristics of a river channel more than a lake. Banks on either side of the

channel become increasingly narrow as one travels upstream. KOPs 1 and 2 were established to illustrate the limited views from Riverview Drive, a local road running parallel to the east side of I-5 that is primarily used by residents and recreationists to access Shasta Lake. Photos 1 and 2 illustrate views available to motorists traveling along Riverview Drive. Despite being less than 350 feet from the lake, the elevation of Riverview Drive and adjacent vegetation obscure most views that motorists would have from this roadway. The indistinctive views from both of these KOPs are best characterized as Class C, having low scenic quality.

KOP 3 The community of Lakeshore, which stretches along the west (right) side of the Sacramento Arm, is composed primarily of permanent and vacation homes, and a few commercial resorts. Proceeding south on Lakeshore Drive, along the western (right) shoreline, the first inlet that is crossed (Doney Creek) allows for extended views upstream and a complex view of the Sacramento Arm downstream (Photo 3). The complexity of the latter view stems from the presence of a UPRR trestle, which parallels the roadway in the foreground, and the I-5 Antlers Bridge in the middle ground. Although these structures contribute to an interesting view, neither is unique; therefore, both aspects from this KOP are best characterized as having a Class B scenic quality. Assuming a speed of 45 miles per hour (mph), motorists passing over the Doney Creek inlet would be exposed to the views on either side of the roadway for approximately 9 seconds.

KOP 4 Continuing south on Lakeshore Drive, the USFS's Lakeshore East Campground offers views of the Sacramento Arm. Although these views are somewhat obscured by trees, views both upstream and downstream from the campground's main entrance are fairly broad (KOP 4, photos 4a and 4b, respectively). Photo 4a illustrates the distance upstream that can be seen from this KOP. The features in this view, such as the Antlers Bridge in the background, are not unique or remarkable. Similarly, the downstream view (Photo 4b) is typical for the area. Thus, views of the lake from the campground entrance are best characterized as having a Class B scenic quality.

KOP 5 Lakeshore Drive crosses the lake for the second time to the south of I-5 at the Charlie Creek inlet. Similar to the views described for KOP 5, views from the Charlie Creek Bridge, both to the northwest (Photo 5a) and southeast (Photo 5b), are expansive, but common to the area (Class B scenic quality): the lake in the foreground, vegetation in the middle ground, and mountains in the background. Assuming a speed of 45 mph, motorists passing over the Charlie Creek inlet would be exposed to the views on either side of the roadway for approximately 8 seconds.

KOP 6 The Beehive Campground managed by USFS as a dispersed campground typifies the nature of the views afforded visitors to the parts of the lake west of I-5. As shown by KOP 6 (photos 6a, 6b, and 6c), views are

expansive but generally unremarkable. There are no features unique to the area to distinguish it from other nearby Class B vantage points.

KOP 7 Sugarloaf Cove is located in one of the most remote parts of the Sacramento Arm. Aside from a narrow road in the uplands that leads into the rugged Backbone Ridge region, there are no recreational improvements in the cove. Photos 7a and 7b illustrate the narrowness of the cove, where a broad bathtub ring of soils are exposed during periods of drawdown. Views in the Sugarloaf Cove area are indistinctive and are best characterized as Class C, having low scenic quality.

KOPs 8, 9, and 10 Sugarloaf Resort Marina is situated adjacent to a residential and commercial area. KOPs 8, 9, and 10 were established to show the view of the marina and its features from several aspects including homes (KOP 8, Photo 8), the marina access road (KOP 9, photos 9a through c), and the public boat ramp (KOP 10, Photo 10). The broad expanse of views from the Sugarloaf shoreline, coupled with the attributes of the marina's structure (e.g., pattern, balance, intactness), is somewhat unusual in the area but typical for Shasta Lake (thus, a Class B distinction).

KOP 11 The Tsasdi Resort, a privately owned recreation facility located on Lakeshore Drive, offers guests a variety of outdoor activities, including hiking, fishing, and boating. Cabins and other resort buildings are situated on the hillside overlooking the lake. The resort maintains its own boat dock, which is accessed from a small parking area immediately adjacent to Lakeshore Drive. The view shown in Photo 11a, looking east from this parking area, is somewhat distinctive but not unique. A railroad trestle crossing the lake in the middle ground creates diversity of pattern in the view, but because the feature is not unique, it is best characterized as having a Class B scenic quality. Similarly, the view to the south from the same KOP is fairly typical for the area and is also best described as having a Class B scenic quality.

KOP 12 Located on the uplands above the east (right) side of the lake is the Lakeshore Resort Campground. This privately owned resort is near the community of Lakeshore (less than 0.25 mile) and I-5 (approximately 0.5 mile), which makes it a popular recreation destination. Although scenic, neither the upstream view (to the east) (Photo 12a) nor the downstream view (to the southeast) (Photo 12b) is unique for the area (thus, Class B). The I-5/Antlers Bridge in the middle ground of the upstream view is prominent and creates a sense of balance between the foreground and background, but the view is not distinct (i.e., unusual, unique, or outstanding) in the context of the project area and is best characterized as having a Class B scenic quality.

KOP 13 One of the most significant inlets branching off of the Sacramento Arm is the Salt Creek Inlet. USFS campgrounds (Nelson Point and Oak Grove) and a day use area (Oak Grove) on the north (right) side of this inlet are inaccessible by boat because the water in the inlet is shallow. As shown in

Photo 13, taken from the Oak Grove Day Use Area, land-based recreation facilities are a fair distance from water (this photo was taken in May 2008). Steep topography below the ordinary high-water line significantly restricts the view from this KOP. The lake's bathtub ring dominates the Class C, indistinctive view. The quality of the view during periods in which the lake is full or nearly full would be more typical of the project area and would thus be better characterized as having a Class B scenic quality.

KOP 14 The south (left) shore of the Salt Creek Inlet supports a variety of residences, including privately owned cabins on National Forest System lands. Access via Salt Creek Lodge Road parallels much of the inlet's shoreline. KOP 14, established at the intersection of Salt Creek Lodge Road and Lower Salt Creek Road, illustrates the Class A views available to motorists, residents, and recreationists passing through the area. Features that set views from this KOP apart from the more typical views previously described for many of the KOPs in the primary study area are the presence of Mount Shasta in the background (albeit the mountain is difficult to distinguish because of haze at the time Photo 14a was taken) and the distinctiveness of the UPRR trestle in the middle ground of Photo 14b. As viewed from KOP 14, the trestle imparts a sense of mystery; its northern end draws the viewer's eye to the background, where the trestle seemingly disappears into the mountainside.

KOP 15 KOP 15 illustrates a typical view from the residential development along Lower Salt Creek Road. The area is relatively steep and densely forested. The dominance of vegetation in the foreground of photos 15a and 15b is indicative of the nature of views from residences, which have scenic quality (Class B) that is common for the region.

KOP 16 The Antlers Public Boat Ramp is located immediately east of I-5 and directly faces the Antlers Bridge, which spans the Sacramento Arm. As seen from the boat ramp, vegetation frames the bridge in the middle ground of the view (Photo 16). Built features (the boat ramp, Antlers Bridge, I-5) dominate the view, whereas unique landscape features, such as the river that meanders through the foreground and middle ground and the rugged mountains in the background, add to the uniqueness, pattern, and mystery of the view. The scenic quality of this view make it a Class A visual resource that also includes components of the more typical Class B views (e.g., forest, ridgelines).

KOP 17 KOP 17 was established to illustrate views from the Antlers Picnic Area located at the top of the Antlers Public Boat Ramp. Several picnic tables and benches allow the public the opportunity to sit and view both the upland parking area (Photo 17a) and the lake (Photo 17b). As shown by Photo 17a, the view of the public parking area is indistinctive; thus, a Class C view. The view of the lake from the picnic area (Photo 17b) is somewhat more distinctive than the view toward the parking lot, but it is fairly typical of views from the Shasta Lake shoreline. Vegetation and topography often limit views of the water. This view would be a Class B, typical visual resource.

KOP 18 KOP 18 (photos 18a through c) was established to illustrate the views that campers staying at one of the public resorts or campgrounds around Shasta Lake would typically see (in this case the Antlers Resort). Visual resources associated with the uplands (Photo 18a), lake (Photo 18b), and campground facilities (Photo 18c) are a combination of Class C indistinctive and Class B typical.

McCloud Arm VAU The McCloud Arm of Shasta Lake is notable for the towering gray limestone mountains that line the eastern shore of the arm. Large, naturally formed caverns in the limestone are popular tourist and spelunking destinations. Lake Shasta Caverns, a commercial operation, operates out of Bailey Cove and ferries visitors across the lake. In fact, boats provide the only access to the right bank of most of the McCloud Arm. Although parts of the lower reach of the McCloud Arm are visible from I-5, topography, including a gradual narrowing of the arm toward its upstream end and heavily forested uplands, limits most views to areas immediately surrounding the scattered residences, campgrounds, boat ramps, and small resorts along the arm.

KOP 1 Located near the confluence of the McCloud and Pit arms, Turntable Bay currently houses administrative facilities, including USFS boat docks. As demonstrated by KOP 1 (Photo 1), Turntable Bay and vicinity can be seen by ridgeline homes overlooking the lake. Transitory views from the area in and around Turntable Bay (such as those available to motorists and boaters) are dependent on water levels, which in turn would determine the quality of the view (i.e., Class B or, subjectively, Class C).

KOP 2 KOP 2 (Photo 2) was established near one of the most heavily used and visible areas on Shasta Lake: the confluence of the McCloud and Pit arms, on the east side of the I-5 Pit River Bridge. Boaters accessing the various arms of the lake east of Bridge Bay will pass through this area. As seen from the lake, views of the shoreline are panoramic; however, the quality of the view varies widely depending on the middle ground and background features (e.g., the presence of a distinctive built feature such as the Pit River Bridge or a snow-covered Mount Shasta). Photo 2 showing Turntable Bay is an example of the Class B typical view that is predominant around Shasta Lake. This photo also illustrates the conspicuous bathtub ring that is seen along the entire perimeter of the lake as water levels draw down.

KOPs 3 and 4 Bailey Cove is a USFS recreational facility that includes a public picnic area, campground, and boat ramp easily accessible from I-5. KOP 3 (Photo 3) shows the narrow inlet in which the boat ramp is located. From the south-facing perspective of the boat ramp and its adjoining parking lot, little of the main body of the McCloud Arm can be seen. Class B views are typical for the area. North of the boat ramp, Bailey Cove, including a portion of Holiday Harbor, can be seen from the Bailey Cove Day Use/Picnic Area. Although Bailey Cove proper is separated from the inlet into which the boat ramp extends

by the peninsular shape of the area, the quality of the views is similar. KOP 4 (Photo 4) shows the limited Class B view to the east from the picnic area.

KOP 5 Farther upstream is the Holiday Harbor Resort and Marina. This facility includes a campground, a marina, and a small store. KOP 5 (Photo 5) shows the distinctive, Class A view of the Holiday Harbor Marina as viewed from the Holiday Harbor Campground. Although the marina is nested in a small inlet, the view from this location draws the viewer's eye to the main body of the McCloud Arm framed by the limestone outcrops and the mountains in the background.

KOP 6 Lake Shasta Caverns is a popular regional tourist destination located approximately 1.5 miles east of I-5. The west (right) shore public reception area includes a parking area, a store, restrooms, a play area, and a boat dock, which houses the privately owned ferry used to transport visitors across the lake to the caverns. With the exception of the boat dock, all public areas are located in uplands, and, as shown by KOP 6 (Photo 6), the lake and eastern limestone outcrops are not readily apparent from the caverns parking lot. The aesthetic value of the lake and surrounding scenery is an important component of the experience offered by the Lake Shasta Caverns tour, which exposes visitors to a variety of Class A and B views during its various tours. Recently, the proprietor expanded the site-seeing tour options to include dinner cruises during the summer that depart from the Lake Shasta Caverns reception center.

KOPs 7 and 8 KOP 7 (Photo 7) was established to show the view of the lake and the Lakeview Marina from the Lakeview Resort's caretaker residence. This destination is one of the most remote marinas and boat ramps on the McCloud Arm, located about 3 miles east of I-5. The dramatic background of mountains and limestone outcrops rising out of the lake makes the view from KOP 7 a Class A view, although the view available to the general public from this location is somewhat blocked by the caretaker's house and surrounding vegetation. Better opportunities for public views of the lake and vicinity from the Lakeview Resort property are available farther up the shoreline at the boat ramp. As viewed from KOP 8, the boat ramp extends south into the main body of the McCloud Arm, where people are exposed to expansive views looking south toward the Pit Arm (Photo 8a). The contrast and landscape features of the foreground, middle ground, and background create Class A views of the lake from this location. Turning to the north (Photo 8b), the Class A views continue. Views from the boat ramp looking west toward the Lakeview Marina and the caretaker's residence (Photo 8c) are somewhat more common (i.e., Class B) for Shasta Lake.

KOPs 9 and 10 KOPs 9 and 10 were established to illustrate shoreline views midway along the McCloud Arm. The north/south alignment of the arm results in noticeable changes in vegetation and terrain. Although the southerly parts of the arm tend to support a more shrub-dominated habitat, views begin to become more scenic moving north up the arm as conifers and significant rocky

outcrops become more evident. The conspicuous bathtub ring that is visible along the entire perimeter of the lake as water levels draw down is just as evident in this part of the lake as it is elsewhere, and the forested mountains in the uplands in the middle ground and background settings (KOP 9, Photo 9) are relatively common Class B visual resources. However, vivid rock outcrops, such as those around Shasta Caverns (KOP 10, Photo 10), add a level of mystery to the upper part of the McCloud Arm. KOP 10 (Photo 10) shows an example of the distinctive Class A visual resources found along the McCloud Arm.

KOP 11 The McCloud Arm's trend toward the north/northeast routes it away from the I-5 corridor and into largely undeveloped, publicly managed and privately owned lands. Visually, a majority of the views of the upper reach of the McCloud Arm are limited primarily to boaters on the lake, a few homes scattered throughout the uplands adjacent to Gilman Road, and an assortment of USFS campgrounds and day use areas that extend along the increasingly narrow channel.

Hirz Bay is a boat launch and group camping facility managed by USFS on the McCloud Arm. Although Hirz Bay is approximately 10 miles from I-5, it is a popular destination for campers, boaters, and hikers. The Hirz Bay Trail, a gently sloping walking trail that extends from Hirz Bay to Dekkas Rock, is mentioned in regional travel guides as offering views of the lake and spectacular limestone outcrops (Soares 1992, Trails.com 2007).

Although views of the lake from the campground and surrounding lakeshore are limited by topography and vegetation, the boat ramp, closer to the shoreline, affords a wider expanse of views of the water. Progressive narrowing of the channel is apparent when looking from downstream to upstream (KOP 11, Photos 11a and 11b, respectively). The expansiveness of the views from Hirz Bay, although somewhat typical for the region, could be characterized as Class A bordering on Class B.

KOP 12 KOP 12 was established to illustrate views of the Hirz Bay and vicinity shoreline from Shasta Lake. As shown by Photo 12, the view looking west from the lake evokes a sense of wilderness beyond the shoreline and does not hint at the level of development that lies between the middle ground and background (i.e., I-5). Although this view is somewhat typical for the northern part of the McCloud Arm, it could be considered a Class A visual resource because of the sense of intactness it conveys.

KOP 13 Campbell Creek, located on the east shore of the McCloud Arm directly across from Hirz Bay, is a residential recreation tract consisting of 28 privately owned cabins on National Forest System lands. The only practicable access to the area is by boat. Overland access is via a primitive (at best) jeep trail. Therefore, visitors to the area would form their initial impression of the visual resources afforded by the Campbell Creek inlet from the lake. Photo 13a

looks toward the south bank of the inlet, where most of the cabins are located beyond the tree line. In many cases, the cabins are difficult to see from the lake because of their colors, which are meant to blend with the natural environment, and the dense forest that surrounds them. Similarly, a few cabins are also located on the eastern shore, but these cabins also have been designed to be unobtrusive to the natural environment (Photo 13b). The expansiveness of the views from the Campbell Creek inlet, although somewhat typical for the region, could be characterized as Class A bordering on Class B.

KOP 14 Similar to views of the lake from Hirz Bay, Class B views from Dekkas Rock Campground widen downstream and narrow upstream (KOP 14, photos 14a and 14b, respectively). Unlike the Hirz Bay camping facilities, which are located some distance from the actual shoreline, the Dekkas Rock Campground offers sites overlooking the lake and near the ordinary high-water line. KOP 14 was established to illustrate views of the progressively narrowing channel from Dekkas Rock Campground (photos 14a and 14b, respectively). Similar to views from Hirz Bay (KOP 11), views from KOP 14 could also be characterized as Class A bordering on Class B.

KOP 15 The McCloud River Bridge is located at the extreme north end of the McCloud Arm approximately 19 miles east of I-5. Despite its relative remoteness, the bridge has frequent traffic, primarily created by recreationists fishing the river, staying in the nearby campground, or exploring the back roads. KOP 15 shows that unobstructed views of the McCloud Arm are available both upstream and downstream from the bridge (photos 15a and 15b, respectively). Although topography eventually interrupts these Class A views, a relatively long stretch of the entire channel width is visible from either direction.

KOP 16 Views of the McCloud River Bridge from the west approach are partially obscured by seasonal roadside vegetation, and the alignment of the eastern approach (KOP 16, Photo 16) prevents any views of the reservoir or the bridge until the road turns onto the bridge. Thus, the indistinctive or low scenic quality of the view from this KOP is characteristic of a Class C designation.

KOPs 17 and 18 Immediately south of the McCloud River Bridge on the east side of the McCloud Arm is the USFS McCloud River Campground. Scenic views from the campground are, in general, remarkable as a result of the surrounding topography and landscape features, such as the bridge, mountains, and the upper end of the McCloud Arm. KOP 17, which is located in Campsite 10, is typical of the Class A views available from campsites in the campground. As demonstrated by KOP 18 (photos 18a through c), views from areas around the campsites broaden as the viewer moves closer to the river channel.

Pit Arm VAU

KOPs 1, 2, 3, and 4 KOPs 1 through 4 were established to illustrate the gentle shoreline topography of the Pit Arm in the vicinity of Jones Valley, upstream from Silverthorn Resort. Beyond the Jones Valley inlet, there is only

one developed campsite accessible by boat. The increasing narrowness of the arm and the potential hazard to boats posed by the remnants of standing dead trees (snags) below the lake's ordinary high-water line make the Jones Valley area a popular destination for people who want to fish or who seek a quieter, more secluded recreational experience than activities such as waterskiing offer.

Expansive views of the lake and surrounding mountains (as viewed from KOP 1, photos 1a and 1b; KOP 2, Photo 2; KOP 3, Photo 3; and KOP 4, Photo 4) are somewhat typical and common to the area and thus would be characterized as having a Class B scenic quality. Although it is not apparent because of weather conditions at the time the photo was taken (October 26, 2007) (Photo 1b), on a clear day Mount Shasta is visible in the background. This factor would enhance the quality of the view from the Jones Valley Public Boat Ramp parking lot looking north, making it a Class A scenic designation.

KOP 5 KOP 5 illustrates a typical view from the houses and cabins in the residential development adjacent to the Silverthorn Resort. The dominance of vegetation in the foreground of Photo 5 is indicative of the nature of views from area homes and cabins. The neighborhood is built on a densely vegetated and steep peninsula with residences on the north side of the ridge facing the Silverthorn Marina and Resort; however, topography and dense vegetation obscure most views of the marina and resort facilities (Photo 5). Views from KOP 5 are typical Class B. Houses and cabins on the south side of the ridge face toward undeveloped areas around Jones Valley.

KOP 6 KOP 6 (photos 6a through c) shows views of the lake from the Silverthorn Resort boat ramp. Silverthorn Resort is a full-service commercial development offering cabin rentals, restaurants, houseboat rentals, a boat ramp, and a marina. Photo 6a illustrates the Class B view of the Silverthorn Marina as seen from KOP 6. Landscape features in this photo and in photos 6b and 6c, taken from the same KOP (but from a different aspect), are generally typical for the area; that is, positive yet common.

KOP 7 As seen from Shasta Lake, it is difficult to determine the level of development associated with the Silverthorn Resort and marina (Photo 7). A peninsula obscures most of the marina and boat ramp from view, as is apparent from KOP 7. Silverthorn Resort is an example of a built feature that may not be considered particularly attractive by viewers. The surrounding environment (i.e., vegetation, topography) is fairly typical for this part of the Pit Arm and would be considered a Class B, and possibly even a Class C, visual resource.

KOP 8 Ski Island is one of the most popular destinations in the Pit Arm. Close to Silverthorn Resort, Ski Island offers primitive campsites and easy access. KOP 8 (Photo 8) was established to illustrate the view that boaters have as they approach the island from the west. The presence of mature conifers adds to the scenic attractiveness of Ski Island, making it a Class B visual resource.

Squaw Creek Arm

KOPs 1 and 2 The Bully Hill (KOP 1, Photo 1) and Monday Flat (KOP 2, Photo 2) areas in the Squaw Creek Arm of Shasta Lake are among the flatter, more easily accessible areas of the lake for boaters looking for a place to land. The bathtub-ring effect is exacerbated by the relatively flatter topography of the area. As water levels drop, a greater expanse of unvegetated shoreline is exposed than appears in many other parts of the lake, and the distance to vegetated uplands is greater than in steeper areas. Although the middle ground and background of the views in this part of the lake include a variety of patterns (water, exposed bright soils, vertical vegetation), the view is typical for the Squaw Creek Arm, making it a Class B visual resource.

I-5 Corridor VAU The Pit River Bridge (also known as the Veterans of Foreign Wars Memorial Bridge) is a nearly 3,600-foot-long bi-level structure that conveys I-5 traffic over the Pit Arm of Shasta Lake, northeast of the Bridge Bay Resort. Vehicle traffic passes across the top level of the structure, and a UPRR track is located on the lower level. Views from the bridge are restricted to motorists or those traveling via train; pedestrians are not authorized to use the bridge for safety reasons.

KOP 1 Class A views experienced by motorists from the Pit River Bridge are of relatively long duration from either direction (up to a minute at normal highway speeds of 55 mph). From the I-5 northbound lanes, the lower ends of both the Pit and McCloud arms east of the bridge are clearly visible in the foreground to middle ground, with mountains in the background (KOP 1, Photo 1a). Views from the southbound lanes look west of the bridge toward the Sacramento Arm. Some features of Bridge Bay Marina can be seen from I-5 southbound (Photo 1b). The elevation of the Pit River Bridge above the existing surface elevation of the lake (full pool and lower) makes it difficult for parts of the lake that are visible from the northbound lanes to be seen from the southbound lanes, and vice versa. Views from either lane may also be partially obstructed by the bridge railing (depending on the height of the vehicle).

KOP 2 KOP 2 was established near one of the most heavily used and visible areas on Shasta Lake: the confluence of the McCloud and Pit arms, on the east side of the I-5 Pit River Bridge. Boaters accessing the various arms of the lake east of Bridge Bay pass through this area. The panoramic view of the lake, bridge, and surrounding mountains is distinctive and unique to the area. The balance and harmony of the patterns (i.e., water in the foreground leads the viewer's eye to the bridge in the middle ground, and from there to the mountains in the background) make this a Class A visual resource.

KOPs 3 and 4 Although not as readily visible, and of far less extent and shorter in duration than those seen from I-5 over the Pit River Bridge, additional views of Shasta Lake (specifically the Sacramento Arm) are available to motorists traveling on I-5 over the Antlers Bridge, located in the community of Lakehead at the north end of the lake. The lake is constricted by topography and

is considerably narrower at this point (KOP 3, Photo 3a). Consequently, Class B views from I-5 are of fairly short duration (approximately 15 seconds assuming a speed of 65 mph). Northbound motorists will notice the Antlers Campground boat launch, which extends from the north shore downslope into the lake (KOP 3, Photo 3b). Southbound motorists have a limited view of the portion of the lake located on the west side of the bridge (KOP 4, Photo 4). Steep topography to the south of the Antlers Bridge makes it difficult to see much more than a small, open body of water and the adjacent forested shoreline.

KOP 5 Located near the confluence of the McCloud and Pit arms, Turntable Bay currently houses administrative facilities, including USFS boat docks. As demonstrated by KOP 5 (Photo 5), transitory views of Turntable Bay and vicinity can be seen from I-5 by northbound motorists. The panoramic extent of the views, although of short duration as vehicles typically pass through this part of I-5 at high speeds, is typical for the Shasta Lake area but nonetheless impressive. As seen from KOP 5, the view would be a Class B or, subjectively, a Class A visual resource.

Visual Quality Objectives The Shasta-Trinity Unit of the NRA includes lands classified as modification, partial retention, and retention. Areas designated as "modification" in the LRMP are typically developed areas, such as campgrounds, marinas, and boat launch ramps; management activities in the foreground and middle ground in these areas have a natural appearance. "Partial retention" refers to those areas in which management activities remain visually subordinate on the landscape. "Retention" areas are those where management activities are not visually evident. The acres of lands categorized under each of these classifications are provided in Table 19-1.

The LRMP also includes a series of management prescriptions for various land allocations. The primary prescription for lands in the NRA is "limited roaded motorized recreation." The objective of this prescription is to provide for semi-primitive motorized recreation opportunities, while maintaining predominately natural-appearing areas with some modifications (USFS 1995a).

Scenic Highways Many state highways are located in areas of outstanding natural beauty. California's Scenic Highway Program was created by the Legislature in 1963 to preserve and protect scenic highway corridors from changes that would diminish the aesthetic value of lands adjacent to highways. The State laws governing the Scenic Highway Program are found in the Streets and Highways Code, Section 260 et seq. A highway may be designated as "scenic," depending on how much of the natural landscape can be seen by travelers, the scenic quality of the landscape, and the extent to which development intrudes on the traveler's enjoyment of the view. The State Scenic Highway System consists of a list of highways that are either eligible for designation as scenic highways or have been so designated. Shasta County scenic highways are listed in California Department of Transportation (Caltrans) 1992 (see Chapter 28, "Bibliography").

In Shasta County, and more specifically the primary study area, I-5 north of the City of Shasta Lake is recognized as a corridor in which the natural environment is dominant. In the primary study area, both I-5 and SR 151 are designated as State routes eligible for official scenic highway designation, although they contain contrasting elements of the natural and built environment (Shasta County 1984). I-5 between Redding (at the SR 299 East intersection) and Anderson is also designated as a corridor in which natural and man-made environments contrast; however, this section of roadway is not eligible for scenic highway designation (Shasta County 1984).

Lower Sacramento River and Delta and CVP/SWP Service Areas

The extended study area offers a wide and diverse array of landscapes and features that constitute visual resources. None of these landscapes and features would be affected by activities associated with the project.

19.2 Regulatory Framework

19.2.1 Federal

Aesthetic values and scenic resources in the Whiskeytown-Shasta-Trinity NRA are managed for the conservation of scenic values that contribute to public enjoyment of the NRA. The Forest Service Manual (2380.11 – 2380.19) addresses the management of landscape aesthetics and scenery in the NFS, as well as the NRA (36 Code of Federal Regulations, part 292, subpart B). Included in this directive are standards for the protection of the natural scenic qualities of public travel routes and shoreline protections. Aesthetic values and visual resources are also generally addressed in the environmental review of Federal projects through the NEPA. Some Federal agencies, such as USFS, provide guidelines for the management of visual resources in larger management areas. In response to increasing environmental concerns, USFS developed The Visual Management System to inventory, classify, analyze, and manage its visual resources. The primary objective of the system is to maintain and enhance the natural appearance of the characteristic landscape while actively managing various resources such as timber, grazing, wildlife, and recreation. The Visual Management System measures and evaluates two main elements: the natural and built features of the land and the public's concern for scenic quality.

The following describes the regulatory setting for lands managed by USFS.

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF LRMP contains goals, standards, and guidelines designed to guide the management of the STNF. The following goals, standards, and guidelines related to aesthetic issues associated with the primary study area were excerpted from the LRMP (USFS 1995a).

Visual Quality
Goals (LRMP, p. 4-5):

- Develop or expand opportunities for scenic drives and vista points.

- Maintain a diversity of scenic quality throughout the forest, particularly along major travel corridors, in popular dispersed recreation areas, and in highly developed areas.

Standards and Guidelines (LRMP, pp. 4-27 through 4-28):

- Manage activities and projects to meet adopted VQOs of (1) preservation, (2) retention, (3) partial retention, (4) modification, or (5) maximum modification. On rare occasions, the adopted VQO may not meet management's objectives (e.g., as a result of catastrophic events). Any proposed modification to an adopted VQO must go through the NEPA process and be approved by the forest supervisor.

- In the following sensitive travel corridors, the foreground portions (areas located up to ¼ to ½ mile from the road viewer) will be managed primarily to meet the adopted VQO of Retention:

  – I-5

- In the following sensitive travel corridors, the middle ground portions (areas between ¼ to ½ mile and 3 to 5 miles from the road viewer) will be managed primarily to meet the adopted VQO of Partial Retention:

  – I-5

- In the following sensitive travel corridors, the foreground portions (areas located from ¼ to ½ mile from the road viewer) will be managed primarily to meet the adopted VQO of Partial Retention:

  – Gilman Road (35N60/County 7HOI from I-5 East to McCloud River Bridge)

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area The Management Guide for the Whiskeytown-Shasta-Trinity NRA (USFS 1996) contains management strategies intended to achieve or maintain a desired condition. These strategies take into account opportunities, management recommendations for specific projects, and mitigation measures needed to achieve specific goals. The following strategies related to aesthetic issues associated with the primary study area were excerpted from the Management Guide.

Visual Resources (Management Guide, p. IV-19) All developments and long-term activities in the NRA will be designed with the intent of meeting VQOs. Those objectives include areas designated as retention, partial retention, and

modification. Retention is a VQO that in general means human activities are not evident to the casual forest visitor. The partial retention objective means human activities may be evident but must remain subordinate to the characteristic landscape. Modification means human activity may dominate the characteristic landscape but must follow established guidelines.

- Management activities that can be seen from developed recreation sites will meet a VQO of retention in the foreground and partial retention in the middle ground.

19.2.2 State

In 1963, the California legislature created the Scenic Highway Program to preserve and protect scenic highway corridors from changes that would diminish the aesthetic value of lands adjacent to the highways. The State regulations and guidelines governing the Scenic Highway Program are found in the Streets and Highways Code, Section 260 et seq. A highway may be designated as scenic depending on how much of the natural landscape can be seen by travelers, the scenic quality of the landscape, and the extent to which development intrudes on the travelers' enjoyment of the view.

Currently, only a short section of I-5 extending from its intersection with SR 97 in the City of Weed to its intersection with SR 89 near the City of Mount Shasta is a designated scenic highway (a part of the Volcanic Legacy Scenic Byway/All American Road). However, there has been interest in obtaining official scenic highway designation for the stretch of I-5 north of Shasta Lake to the Oregon border. Continuing efforts may be made to incorporate this segment of I-5 into the State's Master Plan for officially designated highways.

19.2.3 Regional and Local

The Scenic Highways Element of the Shasta County General Plan (Shasta County 1994) is intended to establish and protect highways (including both State and county roads) with scenic value. "Scenic highways" refers to any freeway, highway, road, street, boulevard, or other vehicular right-of-way that traverses an area of unusual scenic quality. An "official scenic highway" is a scenic highway that has been so designated by the State of California. The visible land area outside the actual right-of-way is generally described as the "viewshed" or the "scenic corridor." The corridor encompasses the land easily visible from the highway. Virtually every highway in Shasta County is a scenic highway; however, some scenic highways are more important than others, based on the visual quality of their scenic corridors, the degree to which the highways are used, and the vulnerability of the corridors to degradation of visual quality (Shasta County 1994).

19.3 Environmental Consequences and Mitigation Measures

This section identifies potential environmental effects on aesthetics and visual resources that could result from the project. Examples of proposed activities, common to all project action alternatives that could have an impact on visual resources and aesthetic values, include changes to inundation levels, raising Shasta Dam, dike construction, creation of borrow areas, abandonment and relocation of infrastructure, and vegetation clearing.

19.3.1 Methods and Assumptions

Analysis of potential impacts to aesthetic and visual resources is based on guidance provided by USFS and the significance criteria described in the CEQA Guidelines. To comply with CEQA, significance thresholds are used to evaluate the project's potential impacts on the visual character of the study areas, particularly the visual character of areas observable from KOPs. All assessments are qualitative, evaluating potential impacts of the project on the viewshed in relation to the local aesthetic context.

The fact that USFS manages a high proportion of the Federal lands above the current full pool elevation of Shasta Lake supports use of the USFS Visual Management System for this assessment. Under the USFS Visual Management System, the landscape is composed of a diversified variety of landforms, rock forms, and vegetative colors and textures. The widely diversified and unique landscape, and the setting of the study area within the NRA—designated as such in part because of its scenic quality of national importance—makes the overall scenic attractiveness a variety class "A" (see the bulleted list below for a description of the classes of scenic attractiveness). To provide some continuity with other Reclamation visual resources assessments, certain aspects of the USFS Scenery Management System are also used in this analysis, as appropriate, namely, the concepts of scenic attractiveness and primary distance zones.

A field assessment of the primary study area was conducted to identify areas of visual sensitivity and scenic resources, and to assess the character and quality of the aesthetic resources associated with the primary study area. Because no changes are anticipated to the aesthetic values and visual resources in the extended study area, a field assessment was performed only in the primary study area. This assessment emphasizes the potential relationship between the project and sensitive receptors associated with recreation areas, roadways, and commercial and residential development. Visual assessment units were mapped based on the distinct visual character of the landscape. Key observation points were identified in each VAU and photograph points were established. Despite the NRAs class A overall scenic attractiveness, the assessment of visual quality presented in this PDEIS is based on the quality of the scenic resources and the visual sensitivity of the most likely viewer group at a particular KOP. Assessment methods were applied to the project alternatives using the following steps:

- **Identify visually sensitive areas** – Areas rated highest for sensitivity are those having views seen by people driving to or from recreational activities or along routes designated as scenic corridors. Stationary views from relatively moderate- to high-use recreation areas and commercial/residential areas are also considered to be sensitive.

- **Define the landscape character** – Landscape character refers to the visual and cultural image of a geographic area. It is composed of the combination of physical, biological, and cultural attributes that make each landscape identifiable or unique. Landscape character embodies distinct landscape attributes that exist throughout an area.

- **Identify visually sensitive observation points** – Analysis of the impacts to visual resources from the implementation of any project alternative should consider both construction and postconstruction views. This step identifies visually sensitive observation points in the primary study area. Identification of visually sensitive observation points allows a comparison of existing views and areas of potential visual impact resulting from one or more alternative.

- **Identify visually affected key observation points** – Based on the location and distance of potential visual impact areas from the visually sensitive observation points, only a portion of the observation points may be significantly affected. This analysis further evaluates observation points to determine whether visual impact areas would occur (1) in the direct line of sight and (2) in the foreground (0 to 0.5 mile) and/or middle ground (0.5 to 4 miles) views. Observation points with visual impact areas in the direct line of sight or in the foreground, middle ground, or background view are referred to as KOPs, which are described in Section 19.1.

- **Classify scenic attractiveness** – Scenic attractiveness classifications are used to categorize visual features as follows: Class A “distinctive,” Class B “typical,” and Class C “indistinctive.” These classifications are described in Section 19.1.

19.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a project. A “[s]ignificant effect on the environment” means a substantial, or potentially substantial, adverse change in any of the physical conditions in the area affected by the project (CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially

reduce significant environmental effects (CEQA Guidelines, Section 15126.4(a)).

The criteria used to determine the significance of impacts for this analysis are based primarily on the CEQA Guidelines and other associated criteria, including regulatory agency standards. Federal criteria and NEPA guidance were also considered. The following significance criteria were developed based on guidance established in the CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts on aesthetic values and visual resources would be significant if they would result in any of the following:

- Have a substantial adverse effect on a scenic vista
- Substantially damage scenic resources, including trees, rock outcroppings, and historic buildings adjacent to a State scenic highway
- Substantially degrade the existing visual character or quality of the project site and its surroundings
- Create a new source of substantial light or glare that would adversely affect day or nighttime views in the project area

19.3.3 Topics Eliminated from Further Consideration

No significant topics related to aesthetics and visual resources have been eliminated from discussion.

19.3.4 Direct and Indirect Effects

The McCloud River upstream from the McCloud River Bridge is eligible for listing as a Wild and Scenic River under the Federal Wild and Scenic Rivers Act. In lieu of recommending Wild and Scenic designation, USFS and other stakeholders entered into a *Coordinated Resource Management Plan* with the primary objective of managing the river to protect its pristine resources. The State Public Resources Code, Section 5093.542, established through enactment of the Wild and Scenic Rivers Act, as amended (Sections 5093.50 – 5093.70), provides protection to the reach between the McCloud Reservoir and the McCloud River Bridge. A detailed discussion of the importance of the Federal Wild and Scenic Rivers Act and State Public Resources Code protections for the McCloud River north of the McCloud River Bridge is presented in Chapter 25 in the PDEIS.

No-Action Alternative

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Vis-1 (No-Action): Consistency with Guidelines for Visual Resources in the STNF LRMP Under the No-Action Alternative, there would be no inconsistencies with the guidelines for visual resources provided in the STNF

LRMP because the project would not be constructed. The visual setting would remain the same as existing conditions. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Vis-2 (No-Action): Degradation and/or Obstruction of a Scenic View from Key Observation Points Under the No-Action Alternative, scenic views would not be degraded and/or obstructed because the project would not be constructed. The visual setting would remain the same as existing conditions. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Vis-3 (No-Action): Generation of Increased Daytime Glare and/or Nighttime Lighting Under the No-Action Alternative, daytime and/or nighttime glare would not increase because the project would not be constructed. The visual setting would remain the same as existing conditions. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Vis-4 (No-Action): Consistency with Federal and State Scenic Highway Requirements Under the No-Action Alternative, there would be no inconsistencies with Federal and State Scenic Byway requirements because the project would not be constructed. The visual setting would remain the same as existing conditions. There would be no impact. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta, and CVP/SWP Service Areas None of the landscapes and features in the extended study area would be affected by the No-Action Alternative. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Vis-1 (CP1): Consistency with Guidelines for Visual Resources in the STNF LRMP The effects of the construction and operational elements of CP1 would be inconsistent with some of the VQOs established by the STNF LRMP. The LRMP calls for management activities that would be visible from the I-5 corridor and SR 151 to remain visually subordinate on the landscape and not be noticeable to the casual observer (a VQO of "retention"). Foreground views from KOPs most often used by the public, such as campgrounds and boat launches, are also managed according to the VQO of retention, whereas middle ground views are managed according to the "modification" VQO (management activities in the middle ground having a natural appearance). The construction and operational elements of CP1 would be more visible from some viewpoints than others. In addition, what might be considered short-term impacts to visual resources and aesthetics for some viewer groups, such as tourists, might be considered long-term impacts for other viewer groups, such as residents. The

LRMP does not distinguish between short-term and long-term VQOs nor between classes of viewers. Therefore, this impact is considered significant.

USFS VQOs for the Shasta-Trinity Unit of the NRA allow for some active land management. The LRMP calls for a VQO of retention along the Shasta Lake shoreline and modification in developed recreation sites. Vegetation removal along the shoreline and in some developed recreation sites in CP1 would exceed the definitions of retention and modification, better fitting the VQO of "maximum modification" (management activities are dominant, but appear natural when seen as background). Although affected areas could, over time, regain the attributes of the retention or modification VQOs, noticeable changes to aesthetic values and visual resources along the shoreline and in affected developed recreation sites resulting from CP1 would be apparent during and for an undetermined period after construction.

The LRMP calls for the foregrounds and middle grounds of State- and county-designated scenic highways that pass through the Shasta-Trinity Unit of the NRA, including portions of the I-5 corridor and SR 151, to be managed for the retention VQO. However, the effects of CP1 on aesthetic values and visual resources as seen from the highways would be visible in some areas during and after project construction. The appearance of areas that are visible from these highways could become similar to existing conditions when the project is completed.

Implementation of CP1 would result in impacts to visual resources that are inconsistent with LRMP VQOs. These impacts cannot be effectively mitigated or avoided, and the CP1 would not be consistent with the LRMP VQOs without amending the STNF LRMP. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-2 (CP1): Degradation and/or Obstruction of a Scenic View from Key Observation Points Under CP1, the "bathtub ring" that is apparent during less than full-pool conditions would become larger. Existing scenic views of areas where utilities and infrastructure would be relocated could be obstructed or degraded. Views, including those of the renowned "Three Shastas," would be obstructed or degraded from some KOPs during construction. Throughout the primary study area, vegetation retention or removal activities (proposed activities would vary by relocation area) would also degrade scenic views. Although project-related changes to the landscape could become less visible over time, these changes would be highly visible during construction. This impact is considered significant.

Under CP1, changes to the scenic views of Shasta Lake and the surrounding landscape would be most apparent when the lake is not full. From KOPs with panoramic views of Shasta Lake, the appearance of the expanded bathtub ring would be only minimally changed, given the overall size of the affected area. As the pool fluctuates, changes to the bathtub ring may not be apparent to

transitory viewers. For some groups such as residents, however, changes to the size of the bathtub ring would be more apparent and of longer duration. For all viewer groups, the effect of leaving vegetation in-place below the inundation level or removing vegetation from the shoreline would be readily apparent in all VAUs.

Scenic views of areas where utilities and infrastructure would be relocated would be at least temporarily degraded or obstructed during and after construction. Changes to these views could be highly visible from some KOPs.

Construction activities and materials associated with CP1 could also be highly visible. In particular, views from KOPs in the Shasta Dam VAU (e.g., the SR 151 scenic overlook, the Shasta Dam Visitor Center, the Coram Ranch House, and the lake) would be highly affected by construction activities and materials, including the movement of heavy equipment and the construction of scaffolding and framing.

Implementation of CP1 would degrade and obstruct scenic views from key observation points. These impacts cannot be effectively mitigated or avoided. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-3 (CP1): Generation of Increased Daytime Glare and/or Nighttime Lighting The increased area of light-colored soils around the Shasta Lake shoreline that are exposed during periods of drawdown and, conversely, the increased area of water surface associated with CP1 would increase the potential for daytime glare. The relocation of roads and infrastructure could also create new sources of reflective daytime glare. In addition, construction equipment could be a temporary source of reflective daytime glare. Extensive construction activities at night requiring the use of vehicle and perimeter lighting, particularly in the vicinity of Shasta Dam, would be necessary for several years. New sources of permanent nighttime lighting would also be required for some locations, such as relocated roads and recreational facilities. This impact is considered significant.

CP1 would increase the area of bare mineral soil exposed along the Shasta Lake shoreline during periods of drawdown. The light color of these soils is a significant source of unavoidable daytime glare. Water also serves as a source of substantial glare. The increased water surface area created by a 6.5-foot dam raise would increase the potential for unavoidable daytime glare being encountered by sensitive receptors around the lake. Changes in water surface elevations, particularly water level increases, would change the refractive angle of the water surface, thus potentially exposing sensitive receptors, such as campgrounds or residences, to a new source of significant glare. The intensity and duration of daytime glare would vary with changes in the angle of the sun and the elevation of the water surface.

Relocation of roads and infrastructure could create a source of both daytime and nighttime glare. Guardrails and other roadway fixtures, such as retaining walls, safety barriers, light standards, and other structures, have the potential to be reflective under natural and artificial light. In addition, nighttime lighting may be required at some locations, including roadways and recreation facilities, for safety purposes.

Construction activities associated with CP1 would generate daytime glare at various locations in the primary study area, most noticeably in areas where equipment would be operated, such as Shasta Dam. The potential for glare caused by light reflecting off construction equipment would vary with changes in the angle of the sun. This impact is considered significant and unavoidable. Mitigation for this impact is proposed in Section 19.3.5.

Impact Vis-4 (CP1): Consistency with Federal and State Scenic Highway Requirements State Route 151 is the only State-designated Scenic Highway in the primary study area. There are no federally designated scenic roadways in the primary study area. Under CP1, project construction activities around Shasta Dam would be visible from SR 151. The distance between the SR 151 vista point, high on the mountainside overlooking Shasta Dam, and the other proposed construction/relocation areas around the lake would make it very difficult for most viewers to differentiate changes resulting from CP1. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas None of the landscapes and features in the extended study area would be affected by activities associated with CP1. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Vis-1 (CP2): Consistency with Guidelines for Visual Resources in the STNF LRMP This impact would be similar to Impact Vis-1 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Construction and operational elements of CP2 would be inconsistent with some of the VQOs established by the STNF LRMP. The larger inundation area proposed under CP2 would result in an increased opportunity for management activities to be visible from the I-5 corridor, SR 151, and other areas managed according to retention and modification VQOs. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-2 (CP2): Degradation and/or Obstruction of a Scenic View from Key Observation Points This impact would be similar to Impact Vis-2 (CP1) for Shasta Lake and vicinity, and the upper Sacramento River (Shasta Dam to

Red Bluff). Under CP2, the "bathtub ring" that is apparent during less than full-pool conditions would become larger than what would be exposed under CP1. CP2 would also require the relocation of more utilities and infrastructure and more vegetation retention or removal than CP1. In addition, the timeframe for construction and implementation of the project would increase, which would prolong the period that scenic views are degraded by the project. Although project-related changes to the landscape could become less visible over time, these changes would be highly visible during construction. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-3 (CP2): Generation of Increased Daytime Glare and/or Nighttime Lighting This impact would be similar to Impact Vis-3 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Under CP2, more light-colored soils would be exposed, which would expand the amount of daytime glare. Construction and implementation of the project would take place over a longer period of time, which would prolong the requirement for nighttime lighting during construction and daytime glare from construction equipment. More roads and other infrastructure would be relocated, which would increase the amount of related daytime glare and nighttime lighting. The impact is considered significant and unavoidable. Mitigation for this impact is proposed in Section 19.3.5.

Impact Vis-4 (CP2): Consistency with Federal and State Scenic Highway Requirements This impact would be similar to Impact Vis-4 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Although the scale of vegetation removal and other activities associated with the construction at the proposed relocation sites would be larger under CP2 than under CP1, the distance of most construction activities from SR 151—the only designated scenic highway in the primary study area—would prevent CP2 from being inconsistent with State Scenic Highway requirements. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas None of the landscapes and features in the extended study area would be affected by activities associated with CP2. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Vis-1 (CP3): Consistency with Guidelines for Visual Resources in the STNF LRMP This impact would be similar to Impact Vis-1 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Construction and operational elements of CP3 would be inconsistent with some

of the VQOs established by the STNF LRMP. The larger inundation area proposed under CP3 would result in an increased opportunity for management activities to be visible from the I-5 corridor, SR 151, and other areas managed according to retention and modification VQOs. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-2 (CP3): Degradation and/or Obstruction of a Scenic View from Key Observation Points This impact would be similar to Impact Vis-2 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Under CP3, the "bathtub ring" that is apparent during less than full-pool conditions would become larger than what would be exposed under CP1 or CP2. CP3 would also require the relocation of more utilities and infrastructure and more vegetation retention or removal than CP1 or CP2. In addition, the timeframe for construction and implementation of the project would increase, which would prolong the period that scenic views are degraded by the project. Although project-related changes to the landscape could become less visible over time, these changes would be highly visible during construction. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-3 (CP3): Generation of Increased Daytime Glare and/or Nighttime Lighting This impact would be similar to Impact Vis-3 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Under CP3, more light-colored soils would be exposed, which would expand the amount of daytime glare. Construction and implementation of the project would take place over a longer period of time, which would prolong the requirement for nighttime lighting during construction and daytime glare from construction equipment. More roads and other infrastructure would be relocated, which would increase the amount of related daytime glare and nighttime lighting. The impact is considered significant and unavoidable. Mitigation for this impact is proposed in Section 19.3.5.

Impact Vis-4 (CP3): Consistency with Federal and State Scenic Highway Requirements This impact would be similar to Impact Vis-4 (CP1) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Although the scale of vegetation removal and other activities associated with the construction at the proposed relocation sites would be larger under CP3 than under CP1 or CP2, the distance of most construction activities from SR 151—the only designated scenic highway in the primary study area—would prevent CP3 from being inconsistent with State Scenic Highway requirements. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas None of the landscapes and features in the extended study area would be affected by activities associated with CP3. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Vis-1 (CP4): Consistency with Guidelines for Visual Resources in the STNF LRMP This impact would be similar to Impact Vis-1 (CP1) and similar to Impact Vis-1 (CP3) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Construction and operational elements of CP4 would be inconsistent with some of the VQOs established by the STNF LRMP. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-2 (CP4): Degradation and/or Obstruction of a Scenic View from Key Observation Points This impact would be similar to Impact Vis-2 (CP1) and similar to Impact Vis-2 (CP3) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff) with the exception of the proposed gravel augmentation and Reading Island channel clearing and habitat restoration actions included in CP4. Although talus cones, lateral berms, and the direct placement of gravel into the river channel would initially be noticeable to viewers in the immediate vicinity of such actions, project-related changes to the landscape would become less visible over time as gravels are dispersed by natural means. Similarly, channel clearing and habitat restoration activities at Reading Island would affect the existing views of the island, but these changes would become increasingly less noticeable over time as vegetation becomes reestablished. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-3 (CP4): Generation of Increased Daytime Glare and/or Nighttime Lighting This impact would be similar to Impact Vis-3 (CP1) and similar to Impact Vis-3 (CP3) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff) with the exception of the proposed gravel augmentation and Reading Island channel clearing and habitat restoration actions included in CP4. Gravel is typically light colored and reflective; therefore, gravel augmentation would create a temporary source of daytime glare. Over time, as the gravel disperses along the river channel, its potential to be a source of glare would diminish. Channel clearing and habitat restoration activities proposed for Reading Island under CP4 could also create a source of temporary daytime glare by the removal of vegetation, exposure of soils, and expansion of water surface. However, the potential for vegetation removal and exposed soils to be a source of daytime glare would be temporary, fading as new vegetation becomes established. The impact is considered significant and unavoidable. Mitigation for this impact is proposed in Section 19.3.5.

Impact Vis-4 (CP4): Consistency with Federal and State Scenic Highway Requirements This impact would be similar to Impact Vis-4 (CP1) and similar to Impact Vis-4 (CP3) for Shasta Lake and vicinity and the upper Sacramento

River (Shasta Dam to Red Bluff). This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas None of the landscapes and features in the extended study area would be affected by activities associated with CP4. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise Combination Plan, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Vis-1 (CP5): Consistency with Guidelines for Visual Resources in the STNF LRMP This impact would be similar to Impact Vis-1 (CP1) and similar to Impact Vis-1 (CP3) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Construction and operational elements of CP5 would be inconsistent with some of the VQOs established by the STNF LRMP. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-2 (CP5): Degradation and/or Obstruction of a Scenic View from Key Observation Points This impact would be similar to Impact Vis-2 (CP1) and nearly similar to Impact Vis-2 (CP4) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Additional enhancements to relocation areas associated with CP5 could result in a slightly greater level of degradation and/or obstruction of a view from a particular KOP than might occur under CP3 or CP4. This impact is considered significant and unavoidable. Mitigation for this impact is not available.

Impact Vis-3 (CP5): Generation of Increased Daytime Glare and/or Nighttime Lighting This impact would be similar to Impact Vis-3 (CP1) and nearly similar to Impact Vis-3 (CP4) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). Additional enhancements to relocation areas associated with CP5 could result in a slightly greater level of glare than might occur under CP3 or CP4. The impact is considered significant and unavoidable. Mitigation for this impact is proposed in Section 19.3.5.

Impact Vis-4 (CP5): Consistency with Federal and State Scenic Highway Requirements This impact would be similar to Impact Vis-4 (CP1) and similar to Impact Vis-4 (CP3) for Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas None of the landscapes and features in the extended study area would be affected by activities associated with CP5. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

19.3.5 Mitigation Measures

Table 19-3 presents a summary of mitigation measures for land use.

Table 19-3. Summary of Mitigation Measures for Aesthetics

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Vis-1: Consistency with Guidelines for Visual Resources in the STNF LRMP (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	SU	SU	SU	SU	SU
	Mitigation Measure	None required.	None available.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact Vis-2: Degradation and/or Obstruction of a Scenic View from Key Observation Points (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	SU	SU	SU	SU	SU
	Mitigation Measure	None required.	None available.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact Vis-3: Generation of Increased Daytime Glare and/or Nighttime Lighting (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	Vis-3: Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact Vis-4: Consistency with Federal and State Scenic Highway Requirements (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS

Notes:
LOS = level of significance
LTS = less than significant
NI = no impact
S = significant
SU = significant and unavoidable

No-Action Alternative

No mitigation is required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is available for impacts Vis-1 and Vis-2, and no mitigation is required for Impact Vis-4. Partial mitigation is provided below for Impact Vis-3.

Mitigation Measure Vis-3 (CP1): Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting Reclamation will do the following to minimize or avoid potential impacts to visual resources and aesthetics from daytime glare and nighttime lighting:

- Avoid constant nighttime lighting and overly bright lighting to the extent possible. The location of lighting will respond to the anticipated use and should not exceed the amount of light actually required by users.

- Lights will be screened and directed away from residences to the highest degree possible, and the amount of nighttime light used will be minimized to the highest degree possible. Lighting will include shielding to minimize offsite light spill and glare. In addition, the following measures will apply:

  – The spacing of luminaire lamps (or comparable vandal-resistant lighting) should be the maximum allowable for traffic safety.

  – Luminaires (or comparable vandal-resistant lighting) should be cutoff-type fixtures that cast low-angle illumination to minimize incidental spillover of light onto adjacent private properties and undeveloped open space. Fixtures that project upward or horizontally will not be used.

  – Luminaire lamps (or comparable vandal-resistant lighting) will be directed toward the roadway or lighted feature (e.g., campground restrooms, sidewalks) and away from adjacent residences and open space areas.

  – Luminaire lamps (or comparable vandal-resistant lighting) will provide good color rendering and natural light qualities. Low-pressure and high-pressure sodium fixtures that are not color corrected will not be used.

  – Luminaire lamps (or comparable vandal-resistant lighting) intensity will be the minimum allowable for traffic safety.

  – Luminaire lamp (or comparable vandal-resistant lighting) mountings will be downcast and the height of the poles minimized to reduce potential for backscatter into the nighttime sky and incidental spillover of light into adjacent private properties and open space.

  – Luminaire lamp (or comparable vandal-resistant lighting) mountings will have nonglare finishes.

- Guardrails and other roadway fixtures, including retaining walls, safety barriers, light standards, and other structures, will be limited to the minimum length, height, and bulk necessary to adequately provide for the safety of the roadway user. Earthtone colors in dark shades and flat finishes will be used on all roadway fixtures. New and replacement guardrails will not have a shiny, reflective finish. (These features are typically galvanized steel, which weathers naturally to a non-glare finish, typically within a year or so.) Retaining walls and other erosion control devices or structures will be constructed of natural materials whenever possible and will, to the maximum extent possible, be designed and sited to avoid detracting from the scenic quality of the corridor. Such structures will incorporate heavy texture or articulated plane surfaces that create heavy shadow patterns.

Implementation of this mitigation measure would reduce the impacts of the project related to daytime glare and nighttime lighting, but would not reduce them to a less than significant level. The impact is considered significant and unavoidable.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is available for impacts Vis-1 and Vis-2, and no mitigation is required for Impact Vis-4. Partial mitigation is provided below for Impact Vis-3.

Mitigation Measure Vis-3 (CP2): Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting This mitigation measure is identical to Mitigation Measure Vis-3 (CP1). Implementation of this mitigation measure will reduce the impacts of the project related to daytime glare and nighttime lighting. However, the impact will be significant and unavoidable.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is available for impacts Vis-1 and Vis-2, and no mitigation is required for Impact Vis-4. Partial mitigation is provided below for Impact Vis-3.

Mitigation Measure Vis-3 (CP3): Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting This mitigation measure is identical to Mitigation Measure Vis-3 (CP1). Implementation of this mitigation measure will reduce the impacts of the project related to daytime glare and nighttime lighting. However, the impact will be significant and unavoidable.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is available for impacts Vis-1 and Vis-2, and no mitigation is required for Impact Vis-4. Partial mitigation is provided below for Impact Vis-3.

Mitigation Measure Vis-3 (CP4): Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting This mitigation measure is identical to Mitigation Measure Vis-3 (CP1). Implementation of this mitigation measure will reduce the impacts of the project related to daytime glare and nighttime lighting. However, the impact will be significant and unavoidable.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is available for impacts Vis-1 and Vis-2, and no mitigation is required for Impact Vis-4. Partial mitigation is provided below for Impact Vis-3.

Mitigation Measure Vis-3 (CP5): Minimize or Avoid Visual Impacts of Daytime Glare and Nighttime Lighting This mitigation measure is identical to Mitigation Measure Vis-3 (CP1). Implementation of this mitigation measure will reduce the impacts of the project related to daytime glare and nighttime lighting. However, the impact will be significant and unavoidable.

19.3.6 Cumulative Effects

Cumulative effects are the impacts on the environment that result from the incremental impacts of the project alternative when added to the impacts of other past, present, and reasonably foreseeable future actions (14 California Code of Regulation 15355[b], 40 Code of Federal Regulations 1508.7), regardless of what agency (Federal or non-Federal) or entity undertakes such other actions. These impacts can result from individually minor, but collectively significant, actions taking place over time.

The President's Council on Environmental Quality NEPA regulations and the State CEQA Guidelines require that the cumulative impacts of a project be addressed in an environmental document when the cumulative impacts are expected to be significant (40 Code of Federal Regulations 1508.25[a][2], 14 California Code of Regulation 15130[a]). When a lead agency assesses a project having an incremental effect that is not "cumulatively considerable," the lead agency need not consider that effect significant. However, the lead agency will briefly describe its basis for concluding that the incremental effect is not cumulatively considerable.

Methods and Assumptions

The analysis of cumulative impacts in this chapter addresses the cumulative impacts of the various project alternatives. According to the CEQA Guidelines, the cumulative impacts discussion "should be guided by the standards of practicality and reasonableness." The CEQA Guidelines require that a

cumulative impacts analysis identify related projects, summarize the expected environmental impacts of those related projects, and analyze the cumulative impacts of the proposed and related projects. Past, present, and reasonably foreseeable projects affecting the same viewsheds as those associated with the primary study area are too numerous to list. Because no construction activities associated with the project would occur outside of the primary study area, the geographic scope of the area examined for cumulative impacts is the primary study area identified for this project. Antlers Bridge Replacement is an example of the types of projects that may contribute to cumulative impacts associated with aesthetics and visual resources in the primary study area.

Antlers Bridge Replacement Caltrans, in cooperation with the Federal Transit Administration, is currently in the process of replacing the I-5 Antlers Bridge over Shasta Lake (in the primary study area), near the community of Lakehead. This project includes construction of a 1,942-foot, five-lane segmental bridge with deep pile foundations that are 12 feet in diameter. In addition, it includes realignment of a 0.4-mile-long segment of I-5, requiring hillside excavation, construction of a five-lane freeway section and demolition of the existing 1,500 feet of steel deck truss bridge. The new bridge is being constructed next to the existing bridge, which remains open to traffic until the new bridge is completed. Although not considered to be a significant impact on visual resources and aesthetics (Caltrans and DOT 2007), the project is highly visible from surrounding public areas (I-5 corridor, Antlers Public Boat Ramp, and Lakehead). Construction is expected to be completed in 2012.

Cumulative Effects

Past, present, and reasonably foreseeable projects such as bridge reconstructions and highway modifications along the I-5 corridor, changes to marinas and resorts, and mine reclamation on the surrounding hillsides in addition to the effects of climate change could all affect the impression that viewers have of the region. In addition, as described in the Climate Change Projection Appendix, climate change could result in reduced end-of-September carryover storage volumes, thus resulting in lower lake levels for a portion of the year. Lower lake levels would increase the period of time that the “bathtub ring” would be visible.

Most of the impacts on aesthetics and visual resources resulting from implementation of the proposed SLWRI alternatives assessed in this chapter would be significant and unavoidable. Implementation of the proposed SLWRI alternatives would result in impacts to visual resources that are inconsistent with LRMP VQOs, and would degrade or obstruct scenic views from key observation points. These impacts are considered significant and unavoidable, and when assessed with other projects that could change the character and quality of the visual resources and aesthetics in Shasta Lake and vicinity and the upper Sacramento River, would be considered cumulatively significant. Implementation of the proposed SLWRI alternatives would also generate daytime glare at construction locations, and is considered significant and

unavoidable. However, this impact is temporary in nature, and would not be considered cumulatively significant.

None of the project alternatives would have a cumulatively considerable effect on aesthetics and visual resources in the extended study area.

Chapter 20
Transportation and Traffic

20.1 Affected Environment

This section describes the existing transportation network in the primary and extended study areas – specifically those roads, highways, bridges, railroads, ports, transit, navigation, and airports that could be affected by the SLWRI project alternatives.

20.1.1 Roadways

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

The primary study area includes Shasta Dam, Shasta Lake, and the upper Sacramento River between Shasta Dam and Red Bluff Diversion Dam in Shasta and Tehama counties. The surface transportation network in the primary study area consists of an interstate freeway, State highways, and smaller connector roads. Traffic in the area is generally moderate to light, except that heavy traffic in the Shasta Lake Unit of the Whiskeytown-Shasta-Trinity National Recreation Area is not unusual during weekends and holidays between May 1 and Labor Day (Reclamation 2004).

Figures 1-1 and 1-2 in Chapter 1, "Introduction," show the roadways in the primary study area. Interstate 5 (I-5) is the main north-south interstate freeway in the region. Several major arterials run north-south, generally parallel to the Sacramento River. State Route (SR) 99 and SR 70 run north-south; certain sections of both of these routes are expressways. SR 273 runs north-south from Redding, generally paralleling the Sacramento River before it intersects with I-5 several miles north of the Shasta/Tehama county line.

Every 3 years, the California Department of Transportation (Caltrans) collects traffic at the I-5/Turntable Bay Road and I-5/Bridge Bay Road interchanges for an 8-day period between April and June. Table 20-1 shows the average daily traffic counts for these interchanges in 2000, 2003, and 2006. These data provide a general sense of the amount of traffic accessing the Shasta Lake area from I-5.

Table 20-1. Average Daily Traffic Volume at the I-5/Turntable Bay Road and I-5/Bridge Bay Road Interchanges

Location	Average Daily Traffic Volumes		
	2000	2003	2006
Turntable Bay Road northbound off-ramp	130	170	145
Turntable Bay Road northbound on-ramp	90	65	110
Turntable Bay Road southbound off-ramp	60	35	38
Turntable Bay Road southbound on-ramp	120	85	80
Bridge Bay Road northbound off-ramp	470	310	302
Bridge Bay Road northbound on-ramp	90	60	54
Bridge Bay Road southbound off-ramp	110	150	145
Bridge Bay Road southbound on-ramp	490	350	331

Source: Caltrans 2006

SR 299 is the major east-west route. This route traverses Trinity, Shasta, Lassen, and Modoc counties north of Shasta Dam. SR 44 is another major east-west route farther south that traverses Shasta County near the city of Redding. SR 36, which also runs generally east-west, intersects with SR 99 and I-5, and this route crosses the Sacramento River near the city of Red Bluff.

There are 317 bridges in Shasta County, 231 of which have bridge spans of 20 feet or more, making them eligible for Federal aid. Ninety-four bridges are beyond their design lives, functionally obsolete, or structurally deficient (Shasta County RTPA 2004).

Lower Sacramento River and Delta

SR 45 follows the Sacramento River north from SR 113 in Knights Landing, north of Sacramento. I-5 parallels SR 45 and the Sacramento River to the west. On the west side of the Sacramento Valley, SR 29 runs north-south through Napa and Lake counties. East-west highways include SR 20 in Lake County, SR 162 in Glenn County, and SR 36 in Tehama and Trinity counties. Major east-west routes on the east side of the Sacramento Valley include SRs 70, 49, and 88; U.S. Highway 50; and Interstate 80.

The Delta region is served by several major freeways. I-5 and SR 99 run north-south and Interstate 80 and U.S. Highway 50 run east-west through Sacramento. Other highways extend from the cities of Sacramento and Stockton to small cities and towns in the region. New roadways have facilitated growth and urbanization along their corridors and within the upper watersheds of major inflowing rivers. Local roads in the Delta are often narrow and winding; during peak travel times, traffic in this area often includes slow, oversized farm equipment.

The two major north-south freeways in the San Joaquin River area are I-5 and SR 99, which pass through the San Joaquin Valley from Sacramento through

Stockton and continue on to Bakersfield and its vicinity. SR 41 runs in a north-south direction south of Fresno. Several east-west routes traverse the San Joaquin River basin: SR 152 is an expressway that connects Los Banos and Chowchilla in Madera County, SR 180 terminates in Yosemite National Park, SR 168 is a primary east-west route in Fresno County, and SRs 190 and 198 are primary routes in Tulare County.

CVP/SWP Service Areas

Numerous freeways and expressways serve portions of the CVP and SWP service areas not discussed above. U.S. 101 extends north and south near the coast from San Luis Obispo south to Los Angeles, and I-5 runs north-south through the Central Valley to Los Angeles and on to San Diego. An extensive, intricate freeway system serves the Los Angeles area. I-10 runs east from Los Angeles to Arizona, while I-8 runs east-west from San Diego to Arizona.

20.1.2 Public Transit

Public transit service in the primary study area is provided by the Redding Area Bus Authority (RABA), which provides fixed-route and demand-responsive (paratransit) service. RABA operates 12 fixed routes within the cities of Redding, Shasta Lake, and Anderson. Shasta County contracts with RABA for a rural commuter bus service. This commuter service offers express transportation into Redding from the outlying community of Burney. The RABA demand/response system provides complimentary transportation to disabled residents of the fixed-route service area. The service area is generally within 0.75 mile of the fixed routes, complying with the minimum mandates of the Federal Americans with Disabilities Act.

Most urban areas in the extended study area provide public transit. These transit systems generally provide both fixed-route and paratransit service. Transit services in the extended study area are not discussed further because they would not be affected by any of the alternatives.

20.1.3 Railroads

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

The Union Pacific Railroad (UPRR) and Western Pacific Railroad both have rail lines serving the vicinity of Shasta Lake and the upper Sacramento River area. The UPRR main line follows the I-5 alignment.

Lower Sacramento River and Delta

UPRR is the main rail line serving the Sacramento River region. The UPRR alignment approximates the alignment of I-5. The Western Pacific rail lines extend farther east through the cities of Marysville and Oroville.

Rail lines serving the Delta are the UPRR, the Western Pacific Railroad, and the Atchison, Topeka, and Santa Fe Railway.

The UPRR and Atchison, Topeka, and Santa Fe lines provide primary rail service connecting the Delta region to the San Joaquin River basin. The alignments of these rail lines generally follow the I-5 alignment through the San Joaquin Valley.

CVP/SWP Service Areas

The UPRR line runs north-south near the coast, from the San Francisco Bay Area through Los Angeles, then southeast toward the Arizona/Mexico border.

20.1.4 Water Navigation

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Water travel and navigation in the primary study area consists of smaller watercraft such as kayaks, canoes, and motorboats for fishing, water-skiing, and boating. Shasta Lake is a popular destination for houseboats. A 65-foot-long catamaran provides ferry service to the Shasta Caverns on the east side of the McCloud Arm of Shasta Lake. Water flows and depths in this segment of the Sacramento River limit river navigation to smaller watercraft.

Lower Sacramento River and Delta

The Port of Sacramento is located in West Sacramento in the southeastern part of Yolo County. Ship access to the port is provided from San Francisco Bay up the Sacramento River and through the Sacramento Deep Water Ship Channel. San Francisco Bay is approximately 80 nautical miles southwest of the Port of Sacramento. This route provides direct and unrestricted passage to the port (City of Sacramento 2005).

Two ports are located along the Sacramento River between Sacramento and Walnut Grove. Another commercial port is located on the Sacramento River at Isleton. A commercial port is located near Terminous and two ports are located adjacent to each other on Old and Middle rivers, northeast of Brentwood (CALFED 2000a). The Port of Stockton is on the San Joaquin River. A deep-water ship channel runs from Cache Slough in the Delta to West Sacramento, where the Port of Sacramento is located.

There are no commercial ports or shipping routes on the San Joaquin River upstream from the Port of Stockton.

CVP/SWP Service Areas

The Los Angeles-Long Beach installation on San Pedro Bay is one of the leading ports of California. The growth of Los Angeles led to the creation of its artificial harbors. Other harbors in this area serving commercial shipping are the San Luis Obispo, Santa Barbara, Carpinteria, Port Hueneme, El Segundo, Los Angeles, Long Beach, and San Diego harbors (CALFED 2000b).

20.1.5 Airports

There are four airports in the primary study area: Redding Municipal Airport, Benton Airpark, Shingletown Airport, and Fall River Mills Airport. Redding Municipal Airport, the closest airport to the project site, is located 20 miles southeast of Shasta Dam in Redding. More than 120 other airports exist in the extended study area; these airports are not relevant to the environmental analysis and thus are not discussed further.

20.2 Regulatory Framework

20.2.1 Federal

Several statutes and regulations include provisions specific to the interstate system in California and transportation projects in general. Title 23 of the U.S. Code and the Code of Federal Regulations govern highways; the laws for transportation are included in U.S. Code Title 23 and Code of Federal Regulations Title 49.

The following Federal legislative statutes may also apply to surface transportation and transportation aspects of the project:

- Federal Clean Air Act
- Federal Transit Act
- Americans with Disabilities Act
- Civil Rights Act
- Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users

The Federal Highway Administration issues directives and policy memoranda in the form of technical advisories, orders, and notices for Federally funded roadway and transit projects in California.

20.2.2 State

Caltrans plans, designs, constructs, and maintains State-owned roadways. Caltrans's standard specifications (Caltrans 2006) establish uniform design and construction procedures for California highways and local roads. The highway design criteria and policies in the standard specifications ensure minimum design, contract, and construction standards for projects.

The primary study area is in Caltrans District 2, headquartered in Redding. Caltrans Division of Transportation Planning, System Planning Branch, conducts long-range transportation plans in cooperation with local agencies to identify future highway improvements; the Division of Transportation Programming sets priorities for various Federal and State transportation funding programs.

20.2.3 Regional and Local

The circulation elements in the general plans of California cities and counties are concerned with the movement of people and goods. Section 65302(b) of the California Government Code requires that circulation elements address the general location and extent of existing and proposed major thoroughfares, transportation routes, terminals, and other local public utilities and facilities (Shasta County 2004).

Circulation elements establish goals and policies that pertain to transportation-related activities on city- or county-maintained roads. Most general plans contain circulation goals related to levels of service. Level of service describes the efficiency of road segments and intersections in terms of traffic delays. Level of service guidelines address long-term planning objectives rather than temporary conditions related to temporary, short-term traffic delays resulting from construction activities.

Counties in California classify county-maintained roads according to their intended function and linkage to land uses. Major roads are generally defined as primary carriers of intercity and intracounty travel. Collector roads are intended to provide subregional access and circulation by linking major roads with residential streets.

The Shasta County Regional Transportation Planning Agency is the congestion management agency in Shasta County. In 2004, the agency issued the *Regional Transportation Plan for Shasta County* in accordance with California Government Code Section 65080 et seq. and 23 U.S. Code 134–135 et seq. The plan discusses regional transportation issues, problems, and solutions and includes goals and objectives for each transportation mode and area of concern.

The Tehama County Transportation Commission is the regional transportation planning agency. It develops policies and allocates transportation funds in Tehama County. The commission published the 2005 *Tehama County Regional Transportation Plan* and is responsible for updating the plan.

Local agencies administer various transportation-related revenues that are sent directly to the agencies. The funds provide for the planning, design, operation, and maintenance of roadways and bridges. The Federal government provides matching funds under local assistance programs established under the Surface Transportation Improvement Program and Highway Bridge Rehabilitation and Replacement Program.

20.3 Environmental Consequences and Mitigation Measures

This section evaluates the environmental consequences of each project alternative related to traffic and transportation. The methods of evaluation are explained and the assumptions used to conduct the evaluation are listed below,

and the criteria used to determine the significance of impacts are described. Mitigation measures are recommended to avoid or reduce any potentially significant impacts to less than significant levels.

20.3.1 Methods and Assumptions

Level of service standards are typically used to evaluate long-term (operational) traffic impacts resulting from residential, employment-generating, industrial, and institutional development projects. The SLWRI is not a land use development project. Long-term operation of the project alternatives would not generate additional residential, employment-related, industrial, or institutional vehicular trips (other than a potential slight increase in trips from additional recreation use); therefore, this analysis focuses on construction-related traffic effects. Level of service standards were not used in this analysis because such standards are typically used to evaluate long-term traffic congestion resulting from operations under a proposed action.

Figures 20-1a through 20-1g (beginning on page 20-11) show the locations of transportation facilities that would be relocated under the project alternatives. Table 20-2 lists the named roads and bridges that would require relocation and identifies the map figure where the facility is shown. The facilities that would be relocated under each alternative are described with greater specificity in the associated impact evaluation that follows.

Table 20-2. Named Road and Bridge Facilities that Would Require Relocation Under the SLWRI

Roads and Bridges	Map Figure	CP1	CP2	CP3	CP4	CP5
Lakeshore Drive	20-1f	X	X	X	X	X
Doney Creek Bridge	20-1f	X	X	X	X	X
Charlie Creek Bridge	20-1f	X	X	X	X	X
Silverthorn Road	20-1c	X	X	X	X	X
Gillman Road	20-1g		X	X	X	X
Salt Creek Road	20-1d		X	X	X	X

Source: Data compiled by AECOM in 2011

Key:
CP = Comprehensive Plan
SLWRI = Shasta Lake Water Resources Investigation

The following project-related assumptions were used in the analysis of construction-related traffic that would result from needed roadway and bridge relocations and the dam raise:

- Excluding gravel augmentation, the estimated duration of proposed construction activities would be 36 months for CP1, 48 months for CP2, and 60 months for CP3–CP5. Under CP4 and CP5, gravel augmentation would continue to occur annually for an additional 5 years, for a total construction period of 10 years.

- On average, 5,000 to 10,000 tons of gravel would be installed per year.

- Gravel would be inserted at up to three sites per year.

- Gravel would be obtained from local commercial sources in Redding.

- Construction activities would occur concurrently.

- Excluding gravel augmentation, import of fill and construction materials (aggregate, cobble, sand, and concrete) and export of construction waste would result in 58 truck trips per day, with a maximum haul route distance of up to 20 miles. Export of vegetation cleared from the primary study area would result in approximately 23 round trips per day, with a maximum haul route distance of up to 20 miles.

- Gravel augmentation would result in up to 18 truck trips per day, with a maximum haul route distance of up to 40 miles.

- Restoration at Reading Island would result in up to 25 haul trips per day.

- The estimated construction labor force for CP1–CP5 would be 350–1,350 people over the total construction period, resulting in an approximate average of 900 daily round trips.

- The increase in recreational opportunities and additional visitor days would generate an approximate average of 148 one-way trips to Shasta Lake and its tributaries under CP1, 251 one-way trips per day under CP2, and 398 one-way trips under CP3–CP5.

- No railroad bridges would require relocation because the project design includes the construction of protective dikes and fortification of railroad embankments.

- Typical construction would occur during daylight hours Monday through Friday, but the construction contractor may extend the hours and may schedule construction work on weekends if necessary to complete aspects of the work within a given time frame. The average workday would be 8 hours.

20.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an environmental impact statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)) to less than significant levels.

Thresholds for determining the significance of transportation and traffic effects were based on the environmental checklist form in Appendix G of the State CEQA Guidelines and Federal, State, and local guidance. These thresholds consider the context and intensity of the environmental effects as required under NEPA.

Impacts of an alternative on transportation and traffic would be significant if project implementation would do any of the following:

- Conflict with an applicable plan, ordinance, or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation, including mass transit and nonmotorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit.

- Conflict with an applicable congestion management program, including but not limited to level of service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways.

- Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks.

- Substantially increase hazards as a result of a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment).

- Result in inadequate emergency access.

In accordance with NEPA, the methods for determining the significance of effects on traffic and transportation are based on the intensity of the effect within the context of the existing transportation facility.

The following screening criterion is recommended by the Institute of Transportation Engineers (ITE) (1989) for assessing the effects of construction projects that create temporary traffic increases. To account for the large percentage of heavy trucks associated with typical construction projects, ITE recommends a threshold level of 50 or more new peak-direction trips. Therefore, an alternative would cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system, and thus would result in a significant effect related to traffic and transportation, if it would result in 50 or more new truck trips during the a.m. peak hours or the p.m. peak hours.

20.3.3 Topics Eliminated from Further Consideration

Several categories of effects would not result from the No-Action Alternative or any of the action alternatives. These categories are described below. An analysis of potential effects in applicable categories for the No-Action Alternative and action alternatives follows this discussion.

None of the airports (Redding Municipal, Benton Airpark, Shingletown, or Fall River Mills) in the primary study area are located near the project site; therefore, project construction and operation would not affect air traffic patterns. For this reason, air traffic patterns are not discussed further in this analysis.

None of the alternatives would interfere with RABA services or affect transit service. Therefore, transit is not discussed further in this analysis.

None of the alternatives propose any facility that is in conflict with adopted policies, plans, or programs supporting alternative transportation. Therefore, this issue is not discussed further in this analysis.

The alternatives do not propose any changes in land use; however, under the action alternatives there could be minor changes in land uses throughout the study area because of increased water supply reliability. These indirect effects would be extremely minor and spread over a wide geographic area (i.e., throughout the CVP and SWP service areas). Therefore, none of the action alternatives would increase transportation hazards because of incompatible uses. This issue is not discussed further in this analysis.

20.3.4 Direct and Indirect Effects

No-Action Alternative

Under the No-Action Alternative, no improvements to Shasta Dam would be constructed and none of the associated road and bridge relocations would be

needed. It is expected that over time, as population and traffic levels increase, roads and bridges would be maintained and improvements would be constructed throughout the study area when needed to ensure safety and meet current engineering-design requirements. Also, growth occurring under the No-Action Alternative would likely be consistent with city and county general plans, resulting in effects on California's transportation network. The effects on and impact conclusions for the primary study area and extended study area are essentially the same.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Trans-1 (No-Action): Short-Term and Long-Term Increases in Traffic in the Primary Study Area in Relation to the Existing Traffic Load and Capacity of the Street System Traffic levels would not increase above levels anticipated in local general plans and regional transportation plans. This impact would be less than significant.

Traffic would be expected to increase compared to existing conditions under the No-Action Alternative. Traffic in the primary study area would increase by amounts anticipated in local general plans and regional transportation plans, and no construction-related truck trips would occur. Planned growth under the No-Action Alternative, including development of residential and recreational uses, has the potential to result in temporary, short-term increases in construction traffic. It is reasonable to assume, however, that necessary improvements to roads, bridges, and other transportation facilities would be made in response to increased traffic levels associated with increased population growth over time. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Trans-2 (No-Action): Adverse Effects on Access to Local Streets or Adjacent Uses in the Primary Study Area Access to local streets and adjacent uses would remain generally unchanged. This impact would be less than significant.

Access to local streets and adjacent uses in the primary study area would be maintained under the No-Action Alternative. No adverse construction-related effects on access would occur. Planned growth under the No-Action Alternative has the potential to impede access to local streets and adjacent uses. It is reasonable to assume, however, that road and bridge improvements needed to maintain access would be made in accordance with city and county regulations and policies. For this reason, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Trans-3 (No-Action): Hazards in the Primary Study Area Caused by a Design Feature No design hazards or incompatible uses would be introduced. This impact would be less than significant.

No design hazards or incompatible uses would be introduced in the primary study area under the No-Action Alternative. No construction-related effects would occur. Planned growth under the No-Action Alternative has the potential to introduce design hazards or incompatible uses. It is reasonable to assume, however, that necessary actions would be taken in accordance with city and county policies and design standards. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Trans-4 (No-Action): Adverse Effects on Emergency Access in the Primary Study Area Emergency access would remain unchanged. This impact would be less than significant.

Emergency access in the primary study area would remain unchanged under the No-Action Alternative. No construction-related effects would occur. Planned residential and recreation growth under the No-Action Alternative has the potential to affect emergency access during construction of roadway improvements to accommodate that growth. It is reasonable to assume, however, that necessary actions would be taken in accordance with city and county standards. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Trans-5 (No-Action): Accelerated Degradation of Surface Transportation Facilities in the Primary Study Area No increase in road degradation would occur because no trucks would transport materials to and from the project site. This impact would be less than significant.

Because construction would not occur, the No-Action Alternative would not require trucks to transport construction materials to and from the primary study area. Therefore, road degradation would not increase as a result of construction. Planned growth under the No-Action Alternative has the potential to result in increased truck trips, with the secondary effect of road degradation. It is reasonable to assume, however, that necessary actions would be taken to accommodate planned growth over time. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Trans-6 (No-Action): Temporary Increase in Traffic in the Extended Study Area in Relation to the Existing Traffic Load and Capacity of the Street System Traffic levels would not increase above levels anticipated in local general plans and regional transportation plans. This impact would be less than significant.

This impact is similar to Impact Trans-1 (No-Action) for the primary study area. For the same reasons as described under Impact Trans-1 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Trans-7 (No-Action): Adverse Effects on Access to Local Streets or Adjacent Uses in the Extended Study Area Access to local streets and adjacent uses would remain generally unchanged because no construction would occur. This impact would be less than significant.

This impact is similar to Impact Trans-2 (No-Action) for the primary study area. For the same reasons as described under Impact Trans-2 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Trans-8 (No-Action): Hazards in the Extended Study Area Caused by a Design Feature No design hazards or incompatible uses would be introduced. This impact would be less than significant.

This impact is similar to Impact Trans-3 (No-Action) for the primary study area. For the same reasons as described under Impact Trans-3 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Trans-9 (No-Action): Adverse Effects on Emergency Access in the Extended Study Area Emergency access would remain unchanged. This impact would be less than significant.

This impact is similar to Impact Trans-4 (No-Action) for the primary study area. For the same reasons as described under Impact Trans-4 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Trans-10 (No-Action): Accelerated Degradation of Surface Transportation Facilities in the Extended Study Area No increase in road degradation would occur because no trucks would transport materials to and from the project site. This impact would be less than significant.

This impact is similar to Impact Trans-5 (No-Action) for the primary study area. For the same reasons as described under Impact Trans-5 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 consists of raising Shasta Dam by 6.5 feet, which would increase the surface water elevation and acreage of the inundation area. Under CP1, transportation facilities in the proposed inundation area would be relocated to sites outside that area. Transportation facilities include road infrastructure and vehicular bridges. Construction would involve installing bank fortification to preserve road segments and dike/abutment protection for bridge structures that do not require relocation. The construction period would be approximately 36 months. As shown in Table 20-2 and Figures 20-1c and 20-1f, the following

transportation facilities would need to be relocated to accommodate construction under CP1:

- Four segments of Lakeshore Drive beginning in the Lakeshore area west of I-5, extending south to the Sugarloaf Area and along the Sugarloaf Creek Inlet. Shasta County owns and maintains the first segment extending from the Lakeshore area to the Sugarloaf area, the most populated areas around the lake. The Doney Creek and Charlie Creek bridges in this segment would also require relocation. The USFS owns and maintains the segments that extend from the Sugarloaf area along Sugarloaf Creek Inlet. A total of 8,075 feet of Lakeshore Drive would require relocation. No segment of Lakeshore Drive would need to be closed during construction.

- Three road segments in the Turntable Bay area northeast of the north end of the Pit River Bridge. These road segments are owned and maintained by USFS. The segments provide access to the Shasta Yacht Club. A total of 6,190 feet of roadway would require relocation. Given the terrain along these segments, these roadways would need to be closed during construction.

- Silverthorn Road and segments of USFS roads in the Jones Valley area, on the south side of the Pit River Arm of Shasta Lake. Owned and maintained by Shasta County, Silverthorn Road provides access to a residential area composed of permanent and seasonally occupied dwelling units. A total of 1,950 feet of roadway would be relocated. These roadways would need to be closed during construction.

- Additional road segments in the primary study area totaling 229 linear feet. None of these road segments would need to be closed during construction.

Potential impacts on access roads to and internal loop roads at campsites and other recreation facilities are evaluated in Chapter 18, “Recreation and Public Access.”

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Trans-1 (CP1): Short-Term and Long-Term Increases in Traffic in the Primary Study Area in Relation to the Existing Traffic Load and Capacity of the Street System Construction activities would temporarily increase traffic. This short-term, temporary impact would be potentially significant. In the long term, increased recreational opportunities and visitor days would result in additional traffic on area roadways; however, the long-term impact would be less than significant.

Existing traffic in the primary study area is generated by residents living and working in the area, living in the area and working elsewhere, and living elsewhere and working in the area; and by tourists who come to visit the dam, picnic, hike, camp, fish, and go boating. Because Shasta Lake is a tourist destination, traffic is seasonally heavier from the middle of spring to the middle of fall (Reclamation 2004).

Project construction activities would require numerous truck trips to move materials to and from the project site, as well as trips in personal vehicles by construction crew members commuting to and from the site. Traffic would temporarily increase on Shasta Dam Boulevard, Lake Boulevard, Lakeshore Drive, and other roads during the CP1 construction period. Commute trips by construction workers would add vehicles to the road system during the a.m. and p.m. peak periods. Haul truck trips would increase traffic on designated haul routes during peak and off-peak hours.

Approximately 58 round-trip haul trips per day are anticipated for trucking materials to the dam site over a 36-month construction period. Approximately 23 round trips per day are anticipated for trucking materials cleared from the land over the same period. The total number of truck trips, 81 round trips per day, would not exceed the ITE threshold of 50 new truck trips in the a.m. and p.m. peak hours because the truck trips would be distributed over an 8-hour workday; approximately 10 truck trips would occur during the peak-hour period. This impact would be less than significant.

Approximately 900 round trips per day by workers are anticipated. Although specific staging areas have not been identified, the work areas are expected to be distributed throughout the primary study area. Some areas would employ greater workforces than others. The total number of worker trips may temporarily exceed the existing traffic loads and capacities on the roads where substantial numbers of workers are located at any one time. This impact would be potentially significant.

Traffic slowdowns may also result from temporary obstruction of roadway access because of lane closures or heavy equipment entering and exiting the road. Circulation patterns would change if detours were to be required during replacement of transportation facilities. Detours may add traffic that could exceed the capacity of the facility being relocated. This impact would be potentially significant.

In the long term, increased recreational opportunities and visitors would increase traffic on area roads by an estimated average of 148 one-way trips per day. This small number of additional trips would be distributed throughout the primary study area. The additional trips are not expected to exceed the existing traffic loads and capacities of the street system. Growth in the primary study area that is generated through implementation of city and county general plans would increase traffic in the area. The regional transportation planning

documents identify roadway projects needed to accommodate expected traffic increases. Therefore, the long-term impact of traffic increases on area roads would be less than significant.

In summary, in the short term, construction activities under CP1 are expected to result in a potentially significant impact on traffic; but in the long term, the impact of traffic increases resulting from expected growth and additional recreational opportunities would be less than significant. Mitigation for this short-term impact is proposed in Section 20.3.5.

Impact Trans-2 (CP1): Adverse Effects on Access to Local Streets and Adjacent Uses in the Primary Study Area Relocation of transportation facilities would require either road closures and detours or partial road closures, or a combination of both. This temporary direct impact would be potentially significant. Indirect impacts on air quality, noise, and recreation resulting from extended travel lengths, increased traffic near sensitive land uses, and limiting or restricting access to recreational facilities are evaluated in the corresponding chapters of this Environmental Impact Statement (EIS).

CP1 would raise the elevation and increase the surface acreage of Shasta Lake. Several existing roads and bridges at the lake would require relocation to avoid potential inundation as the elevation of the lake's full pool increases.

It is anticipated that most of the new roadway alignments or bridges would be constructed and connected to existing road facilities before demolition of the existing facilities in the proposed inundation area. In some cases, work in the road relocation areas may require a road closure with detours, lane closures, or a combination of both. Road closures would temporarily impede access to local connector roads and recreational land uses, affecting residents, local recreational and nonrecreational businesses, and visitors to Shasta Lake. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

Detours and alternate routes resulting from road and bridge relocations could cause longer trip lengths and increase traffic in areas of sensitive land uses. The following potential indirect impacts are evaluated in the corresponding chapters of this EIS:

- Effects on air quality caused by extended trip lengths - Chapter 5, "Air Quality and Climate"
- Effects on sensitive receptors resulting from increased traffic on connector roads caused by detours - Chapter 8, "Noise and Vibration"
- Effects on recreation caused by restrictions to facility access - Chapter 18, "Recreation and Public Access"

Impact Trans-3 (CP1): Hazards in the Primary Study Area Caused by a Design Feature Relocated road segments and vehicular and railroad bridges would be designed to current engineering design standards. This impact would be beneficial.

Road segments, vehicular bridges, and railroad bridges must be designed to current engineering and seismic standards. Current engineering standards ensure that hazards are minimized to the maximum amount practicable. Replacing functionally and structurally obsolete bridges with functionally and structurally sound bridges is a beneficial aspect of CP1. Because relocated road segments and vehicular bridges would be designed to current engineering design standards, design features would not increase hazards but would actually decrease the potential for hazards. Because the replacement of obsolete bridges would be accelerated under CP1, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Trans-4 (CP1): Adverse Effects on Emergency Access in the Primary Study Area Road closures may result in increased response times for emergency vehicles. This direct impact would be potentially significant. Indirect impacts on air quality resulting from extended driving lengths, increased emergency vehicle response times, and potential noise impacts on sensitive receptors are discussed in the respective chapters of this EIS.

As discussed under Impact Trans-2 (CP1), temporary road closures and lane closures would be needed for construction of the relocated road alignments and bridges. Road and lane closures may restrict emergency vehicle access. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

The following potential indirect impacts are evaluated in the corresponding chapters of this EIS:

- Effects on air quality caused by extended trip lengths - Chapter 5, “Air Quality and Climate”
- Effects on sensitive receptors - Chapter 8, “Noise and Vibration”
- Effects of increased emergency vehicle response times - Chapter 22, “Public Services”

Impact Trans-5 (CP1): Accelerated Degradation of Surface Transportation Facilities in the Primary Study Area Trucks used to import fill material and export construction waste would accelerate degradation of surface transportation facilities used as haul routes. This impact would be potentially significant.

As noted in the discussion of Impact Trans-1 (CP1), CP1 would generate approximately 81 round trips per day for the length of the 36-month construction period. Degradation of road surfaces would result in a significant impact if truck trips associated with the project would substantially shorten the life of the facility so that the owner of the right-of-way would need to repair or rehabilitate the road surface before it is scheduled for repair. The significance determination is based on several factors, including the existing condition of road surfaces and the road's normal repair or rehabilitation schedule. Given the total number of anticipated trips and expected weight of the payloads, the impact of CP1 on existing road surfaces in relation to the anticipated utility of the road surfaces would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on traffic or transportation are expected to occur in the lower Sacramento River and Delta or the CVP/SWP service areas; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP2 consists of raising Shasta Dam by 12.5 feet, which would result in a greater increase in the surface water elevation and acreage of inundation area than under CP1. A larger number of transportation facilities would be relocated under CP2 than under CP1. CP2 would have a 48-month construction period, compared to 36 months under CP1. As shown in Table 20-2 and Figures 20-1c, 20-1d, 20-1f, and 20-1g, the following transportation facilities would need to be relocated to accommodate construction under CP2:

- Two segments of Lakeshore Drive in addition to the four road segments that would be relocated under CP1, for a total of six segment relocations along Lakeshore Drive totaling 13,063 feet. As under CP1, no segment of Lakeshore Drive would need to be completely closed during construction.

- The same three road segments in the Turntable Bay area (with a total roadway length of 6,190 feet) that would require relocation under CP1. As under CP1, these roadways would need to be closed during construction.

  Three segments of Gillman Road that run along the west side of the McCloud River Arm of Shasta Lake, totaling 1,246 feet. Owned and maintained by Shasta County, the road is used primarily by logging trucks. Gillman Road would need to be closed during construction.

- The same segments of Silverthorn Road and other USFS roads in the Jones Valley area that would require relocation under CP1 (with a total

roadway length of 1,950 feet). As under CP1, these roadways would need to be closed during construction.

- Four segments of Salt Creek Road that run along the west side of the Squaw Creek Arm of Shasta Lake, totaling 4,325 feet. Salt Creek Road is a dirt and gravel road owned and maintained by USFS. Its primary use is for USFS access. Didallas Creek Bridge crosses one of the segments and would also require relocation under CP2. Salt Creek Road would need to be closed during construction.

- An additional two road segments besides the two other road segments that would be relocated under CP1. The total length of the four roadway segments that would be relocated under CP2 is 2,280 feet. As under CP1, none of these road segments would need to be closed during construction.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Trans-1 (CP2): Short-Term and Long-Term Increases in Traffic in the Primary Study Area in Relation to the Existing Traffic Load and Capacity of the Street System Construction activities would temporarily increase traffic. This short-term, temporary impact would be potentially significant. In the long term, increased recreational opportunities and visitor days would result in additional traffic on area roadways; however, the long-term impact would be less than significant.

This impact is similar to Impact Trans-1 (CP1), but the impact would be greater than under CP1, as described below.

Approximately 58 round-trip haul trips per day are anticipated for trucking materials to the dam site over a 48-month construction period. Approximately 23 round trips per day are anticipated for trucking materials cleared from the land over the same period. The total number of truck trips, 81 round trips per day, would not exceed the ITE threshold of 50 new truck trips because the trips would be distributed over an 8-hour workday; approximately 10 truck trips would occur in the a.m. and p.m. peak hours. This is the same number of daily truck trips as under CP1, but these trips would be borne on the transportation network for a longer duration than under CP1; therefore, the impact would be greater than under CP1. Because the ITE threshold would not be exceeded, this impact would be less than significant.

Approximately 900 round trips per day by workers are anticipated over a 48-month period under CP2. Although specific staging areas have not been identified, the work areas are expected to be distributed throughout the primary study area. Some areas would employ greater workforces than others. The total number of worker trips may temporarily exceed the existing traffic loads and capacities on the roads where substantial numbers of workers are located at any

one time. The worker trips would occur over a longer construction period than under CP1; therefore, the impact would be greater than under CP1. This impact would be potentially significant.

As under CP1, traffic slowdowns also may result from temporary obstruction of roadway access because of lane closures or heavy equipment entering and exiting the road. Interference would occur over a longer period than under CP1; therefore, the impact would be greater than under CP1. This impact would be potentially significant.

In the long term, under CP2, traffic on area roads would increase by an estimated average of 251 one-way trips per day, more than under CP1; however, for the same reasons as described in CP1, this impact would be less than significant.

In summary, in the short term, construction activities under CP2 are expected to result in a potentially significant impact on traffic that would be greater than under CP1; but in the long term, the impact of traffic increases resulting from expected growth and additional recreational opportunities would be less than significant. Mitigation for this short-term impact is proposed in Section 20.3.5.

Impact Trans-2 (CP2): Adverse Effects on Access to Local Streets or Adjacent Uses in the Primary Study Area Relocation of transportation facilities would require either road closures and detours or partial road closures, or a combination of both. This temporary direct impact would be potentially significant. Indirect impacts on air quality, noise, and recreation resulting from extended travel lengths, increased traffic near sensitive land uses, and limiting or restricting access to recreational facilities are evaluated in the corresponding chapters of this EIS.

This impact would be similar to Impact Trans-2 (CP1); however, because CP2 would require more roads to be closed for a longer duration than CP1, the impact would be greater than under CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5. Potential indirect effects are evaluated in Chapter 5, “Air Quality and Climate;” Chapter 8, “Noise and Vibration;” and Chapter 18, “Recreation and Public Access.”

Impact Trans-3 (CP2): Hazards in the Primary Study Area Caused by a Design Feature Relocated road segments and vehicular and railroad bridges would be designed to current engineering design standards. This impact would be beneficial.

This impact would be similar to Impact Trans-3 (CP1); however, CP2 would result in a greater beneficial effect than CP1 because more obsolete bridges would be replaced under CP2 than under CP1. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Trans-4 (CP2): Adverse Effects on Emergency Access in the Primary Study Area Road closures may result in increased response times for emergency vehicles. This direct impact would be potentially significant. Indirect impacts on air quality resulting from extended driving lengths, increased emergency vehicle response times, and potential noise impacts on sensitive receptors are discussed in the respective chapters of this PDEIS.

This impact would be similar to Impact Trans-4 (CP1). However, the construction period for CP2 would be 48 months, 12 months longer than the construction period for CP1. Because road closures under CP2 would occur for a longer period than under CP1, the impact would be greater under CP2 than under CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5. Potential indirect effects are evaluated in Chapter 5, "Air Quality and Climate;" Chapter 8, "Noise and Vibration;" and Chapter 22, "Public Services."

Impact Trans-5 (CP2): Accelerated Degradation of Surface Transportation Facilities in the Primary Study Area Trucks used to import fill material and export construction waste would accelerate degradation of surface transportation facilities used as haul routes. This impact would be potentially significant.

This impact would be similar to Impact Trans-5 (CP1). As noted in the discussion of Impact Trans-1 (CP2), CP2 would generate approximately 81 round trips per day for the length of the 48-month construction period. This is the same number of round trips per day as under CP1; however, because the construction period for CP2 would be longer than the construction period for CP1, the impact on road surfaces under CP2 would be greater than under CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on traffic or transportation are expected to occur in the lower Sacramento River and Delta or the CVP/SWP service areas; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP3 consists of raising Shasta Dam by 18.5 feet, which would result in a greater increase in the surface water elevation and acreage of inundation area than would occur under CP1 or CP2. A larger number of transportation facilities would be relocated under CP3 than under CP1 and CP2. CP3 would have a 60-month construction period, compared to 36 and 48 months under CP1 and CP2, respectively. As shown in Table 20-2 and Figures 20-1c, 20-1d, 20-1f, and 20-1g, the following transportation facilities would need to be relocated to accommodate construction under CP3:

- Two road segments of Lakeshore Drive in addition to the six road segments that would be relocated under CP2, for a total of eight segment relocations along Lakeshore Drive totaling 13,743 feet. As under CP1 and CP2, no segment of Lakeshore Drive would need to be completely closed during construction.

- The same three segments in the Turntable Bay area (with a total roadway length of 6,190 feet) that would require relocation under CP1 and CP2. As under CP1 and CP2, these roadways would need to be closed during construction.

- The same three segments of Gillman Road that would require relocation under CP2. As under CP2, Gillman Road would need to be closed during construction.

- An additional three road segments of Silverthorn Road and/or other USFS roads in the Jones Valley area besides the segments that would require relocation under CP1 and CP2. The total length of roadway that would be relocated under CP3 is 3,562 feet. As under CP1 and CP2, these roadways would need to be closed during construction.

- An additional road segment of Salt Creek Road that runs along the west side of the Squaw Creek Arm of Shasta Lake, besides the four roadway segments that would be relocated under CP2. The total length of roadways that would be relocated under CP3 is 5,108 feet. As under CP2, Salt Creek Road would need to be closed during construction.

- Three additional road segments besides the four other road segments that would be relocated under CP1 and CP2. The total length of the seven roadway segments that would be relocated under CP3 is 3,939 feet. As under CP1 and CP2, none of these road segments would need to be closed during construction.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Trans-1 (CP3): Short-Term and Long-Term Increase in Traffic in the Primary Study Area in Relation to the Existing Traffic Load and Capacity of the Street System Construction activities would temporarily increase traffic. The short-term, temporary impact would be potentially significant. In the long term, increased recreational opportunities and visitor days would result in additional traffic on area roadways; however, the long-term impact would be less than significant.

This impact would be similar to Impacts Trans-1 (CP1) and Trans-1 (CP2), but the impact would be greater than under CP1 and CP2, as described below.

Approximately 58 round-trip haul trips per day are anticipated for trucking materials to the dam site over a 60-month construction period. Approximately 23 round trips per day are anticipated for trucking materials cleared from the land over the same period. The total number of truck trips, 81 round trips per day, would not exceed the ITE threshold of 50 new truck trips because the trips would be distributed over an 8-hour workday; approximately 10 trips would occur during the a.m. and p.m. peak hours. Although this is the same number of daily truck trips as under CP1 and CP2, these daily truck trips would occur for a longer duration than under CP1 and CP2; therefore, the impact would be greater than under CP1 and CP2. Because the number of truck trips during the peak hours would not exceed the ITE threshold, this impact would be less than significant.

Approximately 900 round trips per day by workers are anticipated over a 60-month period. Although specific staging areas have not been identified, the work areas are expected to be distributed throughout the primary study area. Some areas would employ greater workforces than others. The total number of worker trips may temporarily exceed the existing traffic loads and capacities on the roads where substantial numbers of workers are located at any one time. The worker trips would occur over a longer construction period than under CP1 or CP2; therefore, the impact would be greater than under CP1 and CP2. This impact would be potentially significant.

As under CP1 and CP2, traffic slowdowns may also result from temporary obstruction of roadway access because of lane closures or heavy equipment entering and exiting the road. Interference would occur over a longer period than under CP1 or CP2; therefore, the impact would be greater than under CP1 and CP2. This impact would be potentially significant.

In the long term, under CP3, traffic on area roads would increase by an estimated average of 398 one-way trips per day, more than under CP1 and CP2; however, for the same reasons as described in CP1, this impact would be less than significant.

In summary, in the short term, construction activities under CP3 are expected to result in a potentially significant direct impact on traffic that would be greater than under CP1 or CP2; however, the impact of traffic increases resulting from expected growth and additional recreational opportunities would be less than significant. Mitigation for this short-term impact is proposed in Section 20.3.5.

Impact Trans-2 (CP3): Adverse Effects on Access to Local Streets and Adjacent Uses in the Primary Study Area Relocation of transportation facilities would require either road closures and detours or partial road closures, or a combination of both. This temporary direct impact would be potentially significant. Indirect impacts on air quality, noise, and recreation resulting from extended travel lengths, increased traffic near sensitive land uses, and limiting

or restricting access to recreational facilities are evaluated in the corresponding chapters of this PDEIS.

This impact would be similar to Impacts Trans-2 (CP1) and Trans-2 (CP2); however, because CP3 would require more roads to be closed for a longer duration than CP1 and CP2, the impact would be greater than under CP1 or CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5. Potential indirect effects are evaluated in Chapter 5, "Air Quality and Climate;" Chapter 8, "Noise and Vibration;" and Chapter 18, "Recreation and Public Access."

Impact Trans-3 (CP3): Hazards in the Primary Study Area Caused by a Design Feature Relocated road segments and vehicular and railroad bridges would be designed to current engineering design standards. This impact would be beneficial.

This impact would be similar to Impacts Trans-3 (CP1) and Trans-3 (CP2); however, CP3 would result in a greater beneficial effect than CP1 or CP2 because more obsolete bridges would be replaced under CP3 than under CP1 or CP2. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Trans-4 (CP3): Adverse Effects on Emergency Access in the Primary Study Area Road closures may result in increased response times for emergency vehicles. This direct impact would be potentially significant. Indirect impacts on air quality resulting from extended driving lengths, increased emergency vehicle response times, and potential noise impacts on sensitive receptors are discussed in the respective chapters of this PDEIS.

This impact would be similar to Impacts Trans-4 (CP1) and Trans-4 (CP2). However, the construction period for CP3 would be 60 months, 12 months longer than the construction period for CP2 and 24 months longer than the construction period for CP1. Because road closures under CP2 would occur for a longer period than under CP1 or CP2, the impact would be greater under CP3 than under CP1 or CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5. Potential indirect effects are evaluated in Chapter 5, "Air Quality and Climate;" Chapter 8, "Noise and Vibration;" and Chapter 22, "Public Services."

Impact Trans-5 (CP3): Accelerated Degradation of Surface Transportation Facilities in the Primary Study Area Trucks used to import fill material and export construction waste would accelerate degradation of surface transportation facilities used as haul routes. This impact would be potentially significant.

This impact would be similar to Impacts Trans-5 (CP1) and Trans-5 (CP2). As noted in the discussion of Impact Trans-1 (CP3), CP3 would generate

approximately 81 round trips per day for the length of the 60-month construction period. This is the same number of round trips per day as under CP1 and CP2; however, because the construction period for CP3 would be longer than the construction periods for CP1 and CP2, the impact on road surfaces would be greater under CP3 than under CP1 or CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on traffic or transportation are expected to occur in the lower Sacramento and Delta area or the CVP/SWP service areas; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus

CP4 consists of raising Shasta Dam by 18.5 feet. The same transportation facilities would be relocated under this alternative as under CP3. CP4 would also have an approximately 60-month construction period like CP3, compared to 36 and 48 months under CP1 and CP2, respectively.

In addition to constructing the dam raise and relocating transportation facilities described for CP3, CP4 involves augmenting locations along the Sacramento River with gravel. The locations of those sites are shown in Figure 2-4 in Chapter 2, "Alternatives." As noted previously, gravel augmentation would be conducted at up to three of the identified sites annually for a 10-year period, commencing with construction of CP4. For purposes of this analysis, the following analysis evaluates, as the maximum intensity option, gravel augmentation at the three sites located the farthest from the city of Redding where gravel is known to be available from commercial sources. All other combinations of gravel augmentation sites would have lesser impacts than the combination of sites evaluated herein.

In addition to the dam construction, relocation of transportation facilities, and gravel augmentation, CP4 includes habitat and recreational resources improvements at Reading Island as described in Chapter 2, "Alternatives," and shown in Figure 2-5.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Trans-1 (CP4): Short-Term and Long-Term Increases in Traffic in the Primary Study Area in Relation to the Existing Traffic Load and Capacity of the Street System Construction activities would temporarily increase traffic. This short-term, temporary impact would be potentially significant. In the long term, increased recreational opportunities and visitor days would result in additional traffic on area roadways; however, the long-term impact would be less than significant.

This impact would be similar to but greater than Impacts Trans-1 (CP1), Trans-1 (CP2), and Trans-1 (CP3) because additional haul trips would be required for gravel augmentation and habitat restoration. Using the Redding Riffle site as the maximum-intensity option in terms of haul truck trips affecting traffic, approximately 800 round trips would be made during the September and August construction term under CP4. This is based on placing 19,000 tons of gravel at the site and the capacity of the haul trucks being 25 tons per load. With a total of 44 8-hour workdays (2 months excluding weekends), the number of daily haul trips would be 18 haul trips per day. This would not exceed the ITE threshold of 50 new truck trips in the peak-hour period even if all of the truck trips occurred during the peak-hour period. Distributed over an 8-hour work day, two truck trips would occur during the a.m. peak hour period and two truck trips would occur during the p.m. peak hour period.

In addition to the haul trips for gravel augmentation, there would be haul trips for removing approximately 15,650 cubic yards of fill material from Reading Island. Haul trucks can carry 14 cubic yards. Therefore, a total of approximately 1,118 haul trips would be required to remove the fill material. With a total of 44 8-hour workdays (2 months excluding weekends), the number of daily haul trips would be 25 haul trips per day. This would add approximately three truck trips in both the a.m. and p.m. peak hour periods.

Combining the three truck trips during the peak-hour period resulting from removing the fill material from Reading Island with gravel augmentation and the 18.5-foot Shasta Dam raise and related activities, approximately 15 peak-hour trips would occur. This is substantially below the ITE threshold of 50 new truck trips during the a.m. and p.m. peak hours.

In the long term, traffic increases on area roads would be similar to CP3.

In the short term, construction activities under CP4 are expected to result in a potentially significant impact on traffic; but in the long term, for the same reasons as described in CP1, the impact of traffic increases resulting from expected growth and additional recreational opportunities would be less than significant. Mitigation for this short-term impact is proposed in Section 20.3.5.

Impact Trans-2 (CP4): Adverse Effects on Access to Local Streets and Adjacent Uses in the Primary Study Area Relocation of transportation facilities would require either road closures and detours or partial road closures, or a combination of both. This temporary direct impact would be potentially significant. Indirect impacts on air quality, noise, and recreation resulting from extended travel lengths, increased traffic near sensitive land uses, and limiting or restricting access to recreational facilities are evaluated in the corresponding chapters of this PDEIS.

This impact would be the same as Impact Trans-2 (CP3) and similar to but greater than Impacts Trans-2 (CP1) and Trans-2 (CP2) because the duration of

project construction under CP4 would be longer than under CP1 or CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5. Potential indirect effects are evaluated in Chapter 5, "Air Quality and Climate;" Chapter 8, "Noise and Vibration;" and Chapter 18, "Recreation and Public Access."

Impact Trans-3 (CP4): Hazards in the Primary Study Area Caused by a Design Feature Relocated road segments and vehicular and railroad bridges would be designed to current engineering design standards. This impact would be beneficial.

This impact would be the same as Impact Trans-3 (CP3) and similar to Impacts Trans-3 (CP1) and Trans-3 (CP2); however, like CP3, CP4 would result in a greater beneficial effect than CP1 and CP2 because more obsolete bridges would be replaced under CP4 than under CP1 or CP2. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Trans-4 (CP4): Adverse Effects on Emergency Access in the Primary Study Area Road closures may result in increased response times for emergency vehicles. This direct impact would be potentially significant. Indirect impacts on air quality resulting from extended driving lengths, increased emergency vehicle response times, and potential noise impacts on sensitive receptors are discussed in the respective chapters of this PDEIS.

This impact would be the same as Impact Trans-4 (CP3) and similar to Impacts Trans-4 (CP1) and Trans-4 (CP2). For the same reasons as described under Impact Trans-4 (CP3), the impact would be greater under CP4 than under CP1 or CP2, and this impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5. Potential indirect effects are evaluated in Chapter 5, "Air Quality and Climate;" Chapter 8, "Noise and Vibration;" and Chapter 22, "Public Services."

Impact Trans-5 (CP4): Accelerated Degradation of Surface Transportation Facilities in the Primary Study Area Trucks used to import fill material and export construction waste would accelerate degradation of surface transportation facilities used as haul routes. This impact would be potentially significant.

This impact would be similar to Impacts Trans-5 (CP1), Trans-5 (CP2), and Trans-5 (CP3) but greater because gravel augmentation would affect more roadways for a longer duration. For the same reasons as described under Impact Trans-5 (CP3), the impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on traffic or transportation are expected to occur in the lower

Sacramento River and Delta or the CVP/SWP service areas; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 consists of raising Shasta Dam by 18.5 feet. The same transportation facilities would be relocated under this alternative as under CP3 and CP4. CP5 would have an approximately 60-month construction period like CP3 and CP4, compared to 36 and 48 months under CP1 and CP2, respectively.

Like CP4, CP5 involves augmenting locations along the Sacramento River with gravel as shown in Figure 2-4 in Chapter 2, "Alternatives." The assumptions stated for CP4 gravel augmentation are the same for CP5.

Also like CP4, in addition to the construction of the dam raise, relocation of transportation facilities, and gravel augmentation, CP5 includes habitat and recreational resources improvements at Reading Island as described in Chapter 2, "Alternatives," and shown in Figure 2-5.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Trans-1 (CP5): Short-Term and Long-Term Increases in Traffic in the Primary Study Area in Relation to the Existing Traffic Load and Capacity of the Street System Construction activities would temporarily increase traffic. This short-term, temporary impact would be potentially significant. In the long term, increased recreational opportunities and visitor days would result in additional traffic on area roadways, similar to CP3 and CP4; however, for the same reasons as described in CP1, the long-term impact would be less than significant.

This impact would be similar to but greater than Impacts Trans-1 (CP1), Trans-1 (CP2), Trans-1 (CP3), and Trans-1 (CP4) because very limited additional construction-related trips associated with enhancements to shoreline and tributary aquatic habitat and recreational trails would be needed. For the same reasons as described under Impact Trans-1 (CP3) and Trans-1 (CP4), the impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

Impact Trans-2 (CP5): Adverse Effects on Access to Local Streets and Adjacent Uses in the Primary Study Area Relocation of transportation facilities would require either road closures and detours or partial road closures, or a combination of both. This temporary direct impact would be potentially significant. Indirect impacts on air quality, noise, and recreation resulting from extended travel lengths, increased traffic near sensitive land uses, and limiting or restricting access to recreational facilities are evaluated in the corresponding chapters of this PDEIS.

This impact would be the same as Impacts Trans-2 (CP3) and Trans-2 (CP4), but greater than Impacts Trans-2 (CP1) and Trans-2 (CP2) because the duration of project construction would be longer. This impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5. Potential indirect effects are evaluated in Chapter 5, "Air Quality and Climate;" Chapter 8, "Noise and Vibration;" and Chapter 18, "Recreation and Public Access."

Impact Trans-3 (CP5): Hazards in the Primary Study Area Caused by a Design Feature Relocated road segments and vehicular and railroad bridges would be designed to current engineering design standards. This impact would be beneficial.

This impact would be the same as Impacts Trans-3 (CP3) and Trans-3 (CP4) and similar to Impacts Trans-3 (CP1) and Trans-3 (CP2); however, like CP3 and CP4, CP5 would result in a greater beneficial effect than CP1 and CP2 because more obsolete bridges would be replaced under CP5 than under CP1 or CP2. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Trans-4 (CP5): Adverse Effects on Emergency Access in the Primary Study Area Road closures may result in increased response times for emergency vehicles. This direct impact would be potentially significant. Indirect impacts on air quality resulting from extended driving lengths, increased emergency vehicle response times, and potential noise impacts on sensitive receptors are discussed in the respective chapters of this PDEIS.

This impact would be the same as Impacts Trans-4 (CP3) and Trans-4 (CP4) and similar to Impacts Trans-4 (CP1) and Trans-4 (CP2). For the same reasons as described under Impact Trans-4 (CP3), the impact would be greater under CP5 than under CP1 or CP2 and would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

Impact Trans-5 (CP5): Accelerated Degradation of Surface Transportation Facilities in the Primary Study Area Trucks used to import fill material and export construction waste would accelerate degradation of surface transportation facilities used as haul routes. This impact would be potentially significant.

This impact would be similar to Impact Trans-5 (CP4) and greater than Impacts Trans-5 (CP1), Trans-5 (CP2), and Trans-5 (CP3) because gravel augmentation would affect more roadways for a longer duration. For the same reasons as described under Impact Trans-5 (CP3), this impact would be potentially significant. Mitigation for this impact is proposed in Section 20.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
No effects on traffic or transportation are expected to occur in the lower

Sacramento River and Delta or the CVP/SWP service areas; therefore, potential effects in those geographic regions are not discussed further in this PDEIS.

20.3.5 Mitigation Measures

Table 20-3 presents a summary of mitigation measures for transportation and traffic.

Table 20-3. Summary of Mitigation Measures for Transportation and Traffic

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Trans-1: Short-Term and Long-Term Increases in Traffic in the Primary Study Area in Relation to the Existing Traffic Load and Capacity of the Street System	LOS before Mitigation	LTS	LTS (short term), PS (long term)	LTS (short term), PS (long term)	LTS (short term), PS (long term)	LTS (short term), PS (long term)	LTS (short term), PS (long term)
	Mitigation Measure	None required.	Mitigation Measure Trans-1: Prepare and Implement a Traffic Control and Safety Assurance Plan				
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS

Key:
B = beneficial
LOS = level of significance
LTS = less than significant
N/A = not applicable
PS = potentially significant

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impact Trans-3 (CP1). Mitigation is provided below for the remaining impacts of CP1 on traffic and transportation.

Mitigation Measure Trans-1 (CP1): Prepare and Implement a Traffic Control and Safety Assurance Plan Before construction starts, Reclamation and its primary contractors for engineering and construction will develop a coordinated construction traffic control plan to minimize the simultaneous use of roadways by different construction contractors for worker commute trips, material hauling, and equipment delivery to the extent feasible. The plan will outline phasing of activities and the use of multiple routes to and from off-site locations to minimize the daily amount of traffic on individual roadways. Reclamation will require that the construction contractors implement and enforce the plans throughout the construction periods. In addition, the plan will include the following elements:

- To the extent feasible, limit the construction work zone to a width that, at a minimum, maintains alternate one-way traffic flow past the construction zone.

- Provide flagger control at construction zones to manage traffic control and flows as necessary.

- Install temporary steel-plate trench crossings, as needed, to maintain reasonable traffic, bicycle, and pedestrian access to homes, businesses, and streets.

- Maintain access for emergency vehicles at all times. Provide advance notification to local law enforcement, fire, and emergency service providers of the timing, location, and duration of construction activities that could affect the movement of emergency vehicles on local roadways.

- Post advance warning of construction activities (for any affected roadways that would be closed or major roadways where lane closures would occur) in the local newspaper(s) and/or coordinate with the local jurisdictions to post such warnings in highly visible locations near the affected roadways.

- Post advance warnings about the potential presence of slow-moving vehicles in construction zones, where needed to reduce potential traffic hazards.

- Place and maintain barriers and install traffic control devices necessary for safety, as specified in Caltrans *Manual of Traffic Controls for Construction and Maintenance Work Zones* and in accordance with the guidance provided by the affected local jurisdictions.

- Limit the accumulation of project-generated mud or dirt on roadways adjacent to construction areas. The construction contractor will sweep the affected paved roadways (water sweeper with reclaimed water recommended) at the end of each day if substantial volumes of soil material have been carried onto adjacent paved, public roads from construction sites.

- Train construction personnel in appropriate safety measures as described in the plan.

Reclamation will also inform the community at a public hearing about the potential traffic delays and the preparation of the traffic control plan.

Implementation of this mitigation measure would reduce Impact Trans-1 (CP1) to a less than significant level.

Mitigation Measure Trans-2 (CP1): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Local Access Reclamation will implement Mitigation Measure Trans-1 (CP1) as described above to reduce adverse effects of road closures and detours or partial road closures on access to local streets and adjacent uses.

Implementation of this mitigation measure would reduce Impact Trans-2 (CP1) to a less than significant level.

Mitigation Measure Trans-4 (CP1): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Emergency Access Reclamation will implement Mitigation Measure Trans-1 as described above to reduce adverse effects of road closures on access by emergency vehicles.

Implementation of this mitigation measure would reduce Impact Trans-4 (CP1) to a less than significant level.

Mitigation Measure Trans-5 (CP1): Identify and Repair Roadway Segments Damaged by the Project The following measures will be implemented to require that Reclamation provides compensation for the repair of roadways that are degraded as a result of hauling:

- The contractor(s) responsible to Reclamation for delivery of borrow material shall identify all proposed haul routes on a map. The map will identify the owner of the rights-of-way (ROW) that are proposed for use as haul routes.

- The contractor(s) shall notify the owner of the ROW in writing and request conditional approval to use the ROW as a haul route. The contractor(s) shall submit a copy of the written request to Reclamation for Reclamation's file.

- The contractor(s) shall implement the conditions of approval for use of the haul route ROW. Conditions may include constructing repairs to damaged lengths of roadway or the payment of fees to compensate for roadway wear resulting from truck trips. Before commencement of hauling activities, the contractor(s) shall submit a copy of the ROW owner's conditional approval to Reclamation for Reclamation's file.

- Within 90 days after hauling activities are completed (that is the haul route is no longer in use for the project term), the contractor(s) shall submit a project close-out report to Reclamation to document compliance with the conditions of approval. Reclamation will keep the project close-out report on file.

Implementation of this mitigation measure would reduce Impact Trans-5 (CP1) to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impact Trans-3 (CP2). Mitigation is provided below for the remaining impacts of CP2 on traffic and transportation.

Mitigation Measure Trans-1 (CP2): Implement Mitigation Measure Trans-1 (CP1): Prepare and Implement a Traffic Control and Safety Assurance Plan This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-1 (CP2) to a less than significant level.

Mitigation Measure Trans-2 (CP2): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Local Access This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-2 (CP2) to a less than significant level.

Mitigation Measure Trans-4 (CP2): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Emergency Access This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-4 (CP2) to a less than significant level.

Mitigation Measure Trans-5 (CP2): Identify and Repair Roadway Segments Damaged by the Project This mitigation measure is identical to

Mitigation Measure Trans-5 (CP1). Implementation of this mitigation measure would reduce Impact Trans-5 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impact Trans-3 (CP3). Mitigation is provided below for the remaining impacts of CP3 on traffic and transportation.

Mitigation Measure Trans-1 (CP3): Implement Mitigation Measure Trans-1 (CP1): Prepare and Implement a Traffic Control and Safety Assurance Plan This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-1 (CP3) to a less than significant level.

Mitigation Measure Trans-2 (CP3): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Local Access This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-2 (CP3) to a less than significant level.

Mitigation Measure Trans-4 (CP3): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Emergency Access This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-4 (CP3) to a less than significant level.

Mitigation Measure Trans-5 (CP3): Identify and Repair Roadway Segments Damaged by the Project This mitigation measure is identical to Mitigation Measure Trans-5 (CP1). Implementation of this mitigation measure would reduce Impact Trans-5 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus

No mitigation is needed for Impact Trans-3 (CP4). Mitigation is provided below for the remaining impacts of CP4 on traffic and transportation.

Mitigation Measure Trans-1 (CP4): Implement Mitigation Measure Trans-1 (CP1): Prepare and Implement a Traffic Control and Safety Assurance Plan This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-1 (CP4) to a less than significant level.

Mitigation Measure Trans-2 (CP4): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Local Access This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-2 (CP4) to a less than significant level.

Mitigation Measure Trans-4 (CP4): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Emergency Access This mitigation

measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-4 (CP4) to a less than significant level.

Mitigation Measure Trans-5 (CP4): Identify and Repair Roadway Segments Damaged by the Project This mitigation measure is identical to Mitigation Measure Trans-5 (CP1). Implementation of this mitigation measure would reduce Impact Trans-5 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impact Trans-3 (CP5). Mitigation is provided below for the remaining impacts of CP5 on traffic and transportation.

Mitigation Measure Trans-1 (CP5): Implement Mitigation Measure Trans-1 (CP1): Prepare and Implement a Traffic Control and Safety Assurance Plan This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-1 (CP5) to a less than significant level.

Mitigation Measure Trans-2 (CP5): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Local Access This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-2 (CP5) to a less than significant level.

Mitigation Measure Trans-4 (CP5): Implement Mitigation Measure Trans-1 (CP1) to Reduce Effects on Emergency Access This mitigation measure is identical to Mitigation Measure Trans-1 (CP1). Implementation of this mitigation measure would reduce Impact Trans-4 (CP5) to a less than significant level.

Mitigation Measure Trans-5 (CP5): Identify and Repair Roadway Segments Damaged by the Project This mitigation measure is identical to Mitigation Measure Trans-5 (CP1). Implementation of this mitigation measure would reduce Impact Trans-5 (CP5) to a less than significant level.

20.3.6 Cumulative Effects

The majority of the current and reasonably foreseeable projects are related to SLWRI through operations of Shasta Dam. The projects in the extended study area are not evaluated further because construction of the SLWRI would not affect transportation facilities. Projects that could influence the local transportation network where SLWRI could contribute include implementation of the *Shasta-Trinity National Forest Land and Resource Management Plan, Iron Mountain Mine Restoration Plan, and Mendocino National Forest Land and Resource Management Plan*; development of the *Turntable Bay Master Development Plan*, and construction of the Antlers Bridge Replacement. The geographic scope of the management plans is vast while the geographic scopes

of Turntable Bay and Antlers Bridge are relatively limited. Individually and combined, none of these projects would result in significant haul trips that would occur during the peak-hour period. The ITE threshold of 50 trips during the peak-hour period on any particular route is not expected because the actions would be distributed throughout a large study area. Another reason that the ITE threshold would not be exceeded is that the forest and mine management and restoration actions and *Turntable Bay Master Plan* would take place over a long period and the Antlers Road Bridge would be completed in 2014. Consequently, no significant cumulatively adverse effects on traffic and transportation would occur in the primary study area.

Potential impacts of the project alternatives (CP1–CP5) are related to construction activities and increased vehicle trips resulting from increased recreational opportunities at Shasta Lake and its tributaries. Construction impacts would be temporary and short term, and recreational vehicle trips would be permanent and long term.

For the following reasons, implementation of any of the project alternatives (CP1–CP5), when combined with construction traffic for present and reasonably foreseeable actions, would not result in a considerable contribution to a significant cumulatively adverse condition on localized traffic and circulation. Under CP5, the maximum-intensity option, approximately 12 truck trips would be added to the a.m. and p.m. peak hours. These truck trips would not occur simultaneously on the haul routes. They would be distributed throughout the shoreline region of the lake, gravel augmentation sites (the sites that would change annually), and at Reading Island. The truck trips for the gravel augmentation and Reading Island would occur during a 2-month period, while the eight peak-hour trips upstream from Shasta Dam would occur over a much longer portion of the construction year. To result in a cumulatively adverse effect on traffic and circulation, the present reasonably foreseeable future projects would need to generate 38 trips during the a.m. or p.m. peak hour. Because of the large geographic scope and length of time for implementing the present and reasonably foreseeable future projects, it is reasonable that they would not generate peak-hour truck trips that would be 68 percent more than the peak-hour truck trips that would be generated by CP5. Furthermore, the cumulative peak-hour truck trips would not be concentrated at any one road segment or intersection.

For the reasons set forth for adverse effects of construction traffic on localized traffic and circulation problems, construction traffic under any of the project alternatives (CP1–CP5) would not result in a considerable contribution to a significant cumulatively adverse effect on emergency access.

For potential accelerated degradation of roadways from construction traffic, none of the construction alternatives (CP1–CP5) would result in cumulatively adverse effects. The reason is that the mitigation measure for these alternatives requires physical repair of damaged roadways, thereby eliminating the adverse

effects of the alternatives. Implementation of Mitigation Measure Trans-5 (CP1) would ensure that the roadways would be in better condition than under preproject conditions. In addition, roads and bridges that would be relocated under any of the project alternatives would be better than existing facilities and could replace functionally or structurally obsolete facilities before they were scheduled to be replaced by the local transportation agencies.

In conclusion, with implementation of any of the project alternatives (CP1–CP5) no significant cumulatively adverse effects on traffic and circulation, emergency access, or transportation facilities would occur.

Chapter 21
Utilities and Service Systems

21.1 Affected Environment

This chapter describes the affected environment related to utilities and service systems for the dam and reservoir modifications proposed under SLWRI.

Because of the potential influence of the proposed modification of Shasta Dam, and subsequent water deliveries over a large geographic area, the SLWRI includes both a primary and an extended study area. The primary area has been further divided into Shasta Lake and vicinity and upper Sacramento River (Shasta Dam to Red Bluff). The extended study area has been further divided into the lower Sacramento River and Sacramento–San Joaquin River Delta Delta and the CVP/SWP service areas.

The utilities and service systems addressed are water supply in the Shasta Lake and vicinity portion of the primary study area, wastewater infrastructure, stormwater drainage and infrastructure, solid waste management, electrical service and infrastructure, natural gas service and infrastructure, and telecommunications infrastructure. Hydropower generation, public services (e.g., fire protection law enforcement, emergency services), roadways and bridges, and recreation are addressed in separate chapters.

The utilities and service systems setting for the Shasta Lake and vicinity portion of the primary study area consists of the portion of Shasta County above Shasta Dam and includes the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). Utilities and service systems are influenced by rugged, mountainous terrain, lakeside communities, and Shasta Lake. The utilities and service systems setting for the upper Sacramento River portion of the primary study area consists of Shasta County below Shasta Dam and Tehama County. Two incorporated cities, Redding and Red Bluff, necessitate urban utilities and service systems needs in the otherwise rural upper Sacramento Valley, which is characterized by rolling hills with mountains to the north, east, and west.

The utilities and service systems setting for the extended study area consists of 21 counties downstream from the Red Bluff Diversion Dam and encompasses all areas served by the CVP and the SWP. A discussion of project impacts on CVP/SWP water supply and overall CVP and SWP management and operations is provided in the PDEIS Chapter 6, “Hydrology, Hydraulics, and Water Management” and in the *Hydrology, Hydraulics, and Water Management Technical Report*.

21.1.1 Water Supply

Shasta Lake and Vicinity

Water supplies for the Shasta Lake and vicinity portion of the primary study area are provided in one of three ways: by a community service area (CSA) run by Shasta County, by a mutual water company, or by an individual or group well. CSA #2 provides water for the Sugarloaf community, and CSA #6 provides water for the Silverthorn community. Fifteen mutual water companies serve the Shasta Lake and vicinity portion of the primary study area. Mutual water companies are cooperative or mutual associations that furnish water to resorts and other developments (Reclamation 2007) (Figure 21-1).

Upper Sacramento River (Shasta Dam to Red Bluff)

Provided below are descriptions of each entity in Shasta County that currently relies on Reclamation to provide a portion of its water supply and the associated Shasta and Trinity River diversions and facilities. This information was taken from the Final Environmental Assessment for the Long-Term Contract Renewal Shasta and Trinity River Divisions (Reclamation 2005).

City of Redding (Sacramento River, Spring Creek, Toyon) Before 1941, water service for the City of Redding was provided by the California Water Service Company, which had water rights to the Sacramento River dating from 1886. The City of Redding acquired the local facilities and water rights of the company in 1941 and filed for an additional appropriative water right of 5 cubic feet per second in 1944. Subsequent annexations to the City of Redding's service area include the Buckeye County Water District, the Cascade Community Services District, and the Enterprise Public Utility District in 1967, 1976, and 1977, respectively.

The Buckeye zone service area includes two City of Redding pressure zones: Buckeye and Summit City. Approximately half of the Buckeye zone is located within the Redding city limits, and the other half is in an unincorporated area of Shasta County. Approximately one-quarter of the Summit City zone is in an unincorporated area of Shasta County, and three-quarters is in the City of Shasta Lake. The City of Redding currently receives water to its Buckeye zone under a long-term CVP contract with Reclamation (the water comes from Whiskeytown Lake via the Spring Creek tunnel). There are no known groundwater resources within the Buckeye zone service area. During peak demand periods, supplemental water is pumped from the Sacramento River, then treated and delivered into the Buckeye zone service area. The municipal and industrial (M&I) connections in the Summit City zone are supplied exclusively by water diverted from Shasta Lake via the Toyon pipeline. The water is treated by the City of Shasta Lake and delivered to the Summit City zone.

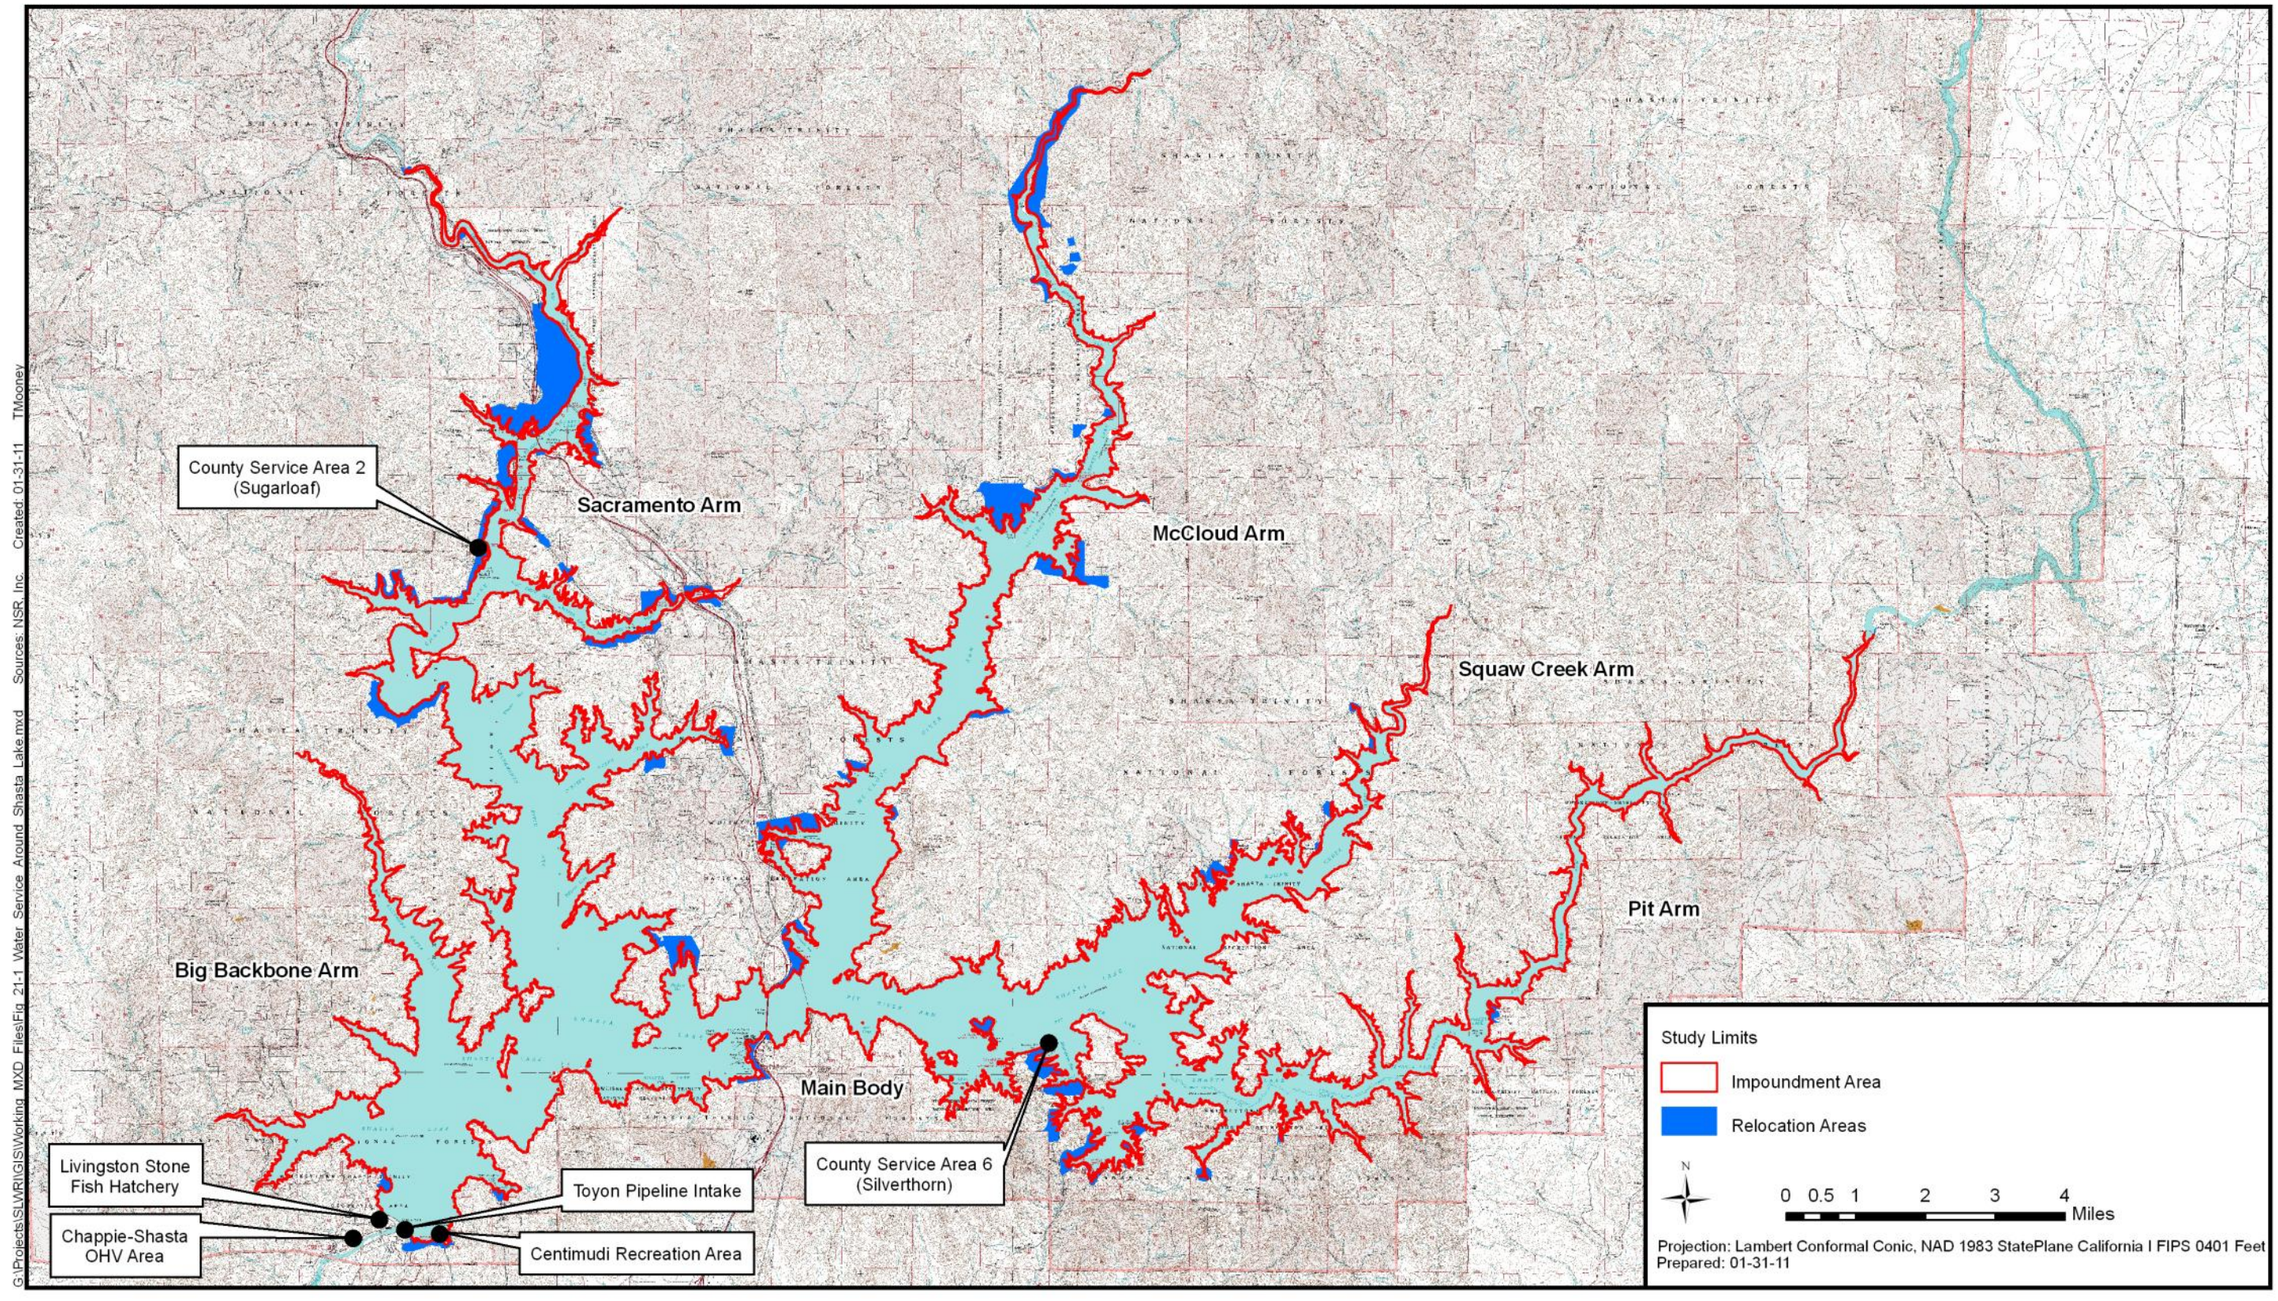

Figure 21-1. Water Service Around Shasta Lake

This page left blank intentionally.

The City of Redding has one additional water contract with Reclamation. Redding's 1966 Settlement Contract with Reclamation specifies a base supply and a project water supply. In 2003, the maximum base supply was set at 17,850 acre-feet per year, and the project water supply was set at 3,150 acre-feet per year; since 1995, project water supply entitlements have been increased by 45 acre-feet annually.

Redding's surface-water supply comes from the Sacramento River and Whiskeytown Lake. Sacramento River water is treated at the 24 million gallons per day (mgd) Foothill Water Treatment Plant, and Whiskeytown Lake water is treated at the 7 mgd Buckeye Water Treatment Plant. Redding supplements its surface-water supply with well production capacity from the Redding groundwater basin primarily during peak demand periods. Currently, 14 wells are operational, providing a total capacity of up to 12 mgd.

Redding provides CVP and non-CVP water service to about 24,709 connections. Connections provide water primarily for M&I uses and a small number of agricultural uses. The city administers 4,179 connections in the Buckeye zone and 58 M&I connections in the Summit City zone.

City of Shasta Lake Water for the City of Shasta Lake comes from Shasta Lake via a pump station at Shasta Dam that has a maximum diversion of 5.0 mgd. Water is pumped from an intake in the face of Shasta Dam to a storage/treatment facility immediately east of the Shasta Dam compound. From there it is delivered to the City of Shasta Lake. An interim contract with Reclamation (Contract No. 4-7-20-W1134-IR10) provides an allocation of 4,400 acre-feet per year from this source. Reclaimed water is also available for industrial and landscaping use. Groundwater use is limited because of low aquifer yields.

Prior to incorporation, the community water supply and utility services were provided by the Shasta Dam Area Public Utilities District (PUD), which was formed in 1945 to provide a reliable water supply for an area of 3.5 square miles. Originally, the PUD service area was a residential area established to house workers who were constructing Shasta Dam. Reclamation constructed a water transmission pipeline from Shasta Lake to the PUD in 1948, and the PUD concurrently constructed water storage and distribution systems. The Summit City PUD was annexed in 1978. Before annexation, water was supplied by a series of wells with low and unreliable yields.

The City of Shasta Lake provides water service to 3,800 connections for primarily urban and residential uses, although industrial use has increased over the past decade. The City of Shasta Lake also provides water service to Reclamation's Northern California Area Office.

Bella Vista Water District The Bella Vista Water District (BVWD) is a publicly owned water agency formed in 1957 to serve agricultural irrigation

demands (California Water Code Division 13, Sections 34000 through 38501). The BVWD service area is located generally east of Redding and south of Shasta Lake. The service area includes the rural communities of Bella Vista and Palo Cedro.

BVWD's primary water source is the Sacramento River. The BVWD supply system consists of the Wintu Pump Station on the Sacramento River and five wells. Water pumped from the river is treated at the district's treatment plant, which provides inline filtration. Distribution facilities include a network of transmission and distribution pipelines, three storage tanks, nine booster pump stations, and pressure-reducing facilities. The major distribution piping was initially constructed by Reclamation but has been expanded over time. The main supply system is still Federally owned, but it was constructed solely for use by BVWD. Both domestic and agricultural users are served through the same distribution system, so all water is treated to meet the higher water quality standards for domestic use. The CVP water that BVWD purchases from the Shasta County Water Agency (SCWA) is described below.

BVWD's original contract allows for up to 24,000 acre-feet per year, which is supplemented with 578 acre-feet per year of CVP water purchased through SCWA. Both of these allotments are subject to reduction during dry years. In the severe drought years of 1991 and 1992, water supplies for M&I were reduced by 25 percent and water for agricultural uses was reduced by 75 percent. Available surface water was supplemented with groundwater from wells located near the southern boundary of the district. These reductions in supply caused severe drought restrictions to be imposed, which have had a continuing impact on district water sales. The supplementary water provided by the wells constitutes about 10 percent of the supply normally available from the Sacramento River and about 15 percent to 20 percent of the reduced supply during a severe drought year. The aquifers in the district have limited yield, so it is not practical to greatly increase the production of wells in the district.

Agricultural and irrigation still represent 70 percent to 80 percent of the district's water demand. However, most of the service connections are now either domestic or rural residential. BVWD currently has 4,538 residential connections and 615 agricultural connections. Urban uses predominate in the southeast portion of the district where sewage disposal facilities are available. Residential uses, with lot sizes between 1 and 5 acres, are dispersed across the rest of the district. Agricultural uses are almost exclusively confined to the fertile soil along Stillwater Creek and Cow Creek. Pasture represents the bulk of agricultural use, although there is a broad range of other crops.

Centerville Community Services District The Centerville Community Services District (CCSD) was originally formed in September 1959 to supply water for domestic use, irrigation, sanitation, industrial use, fire protection, and recreation (California Government Code, Division 3, Community Services Districts, Section 61000, et seq.). The CCSD service boundary encompasses

11,278 acres in the unincorporated area of Shasta County immediately west of Redding.

The source of the district's water supply is Whiskeytown Lake, a key feature of the Trinity River Division of the CVP. This reservoir covers about 3,250 acres at maximum capacity and provides water storage of about 241 thousand acre-feet. The reservoir regulates the flows of the Clear Creek watershed and the imported flows from the Trinity River, which discharge through the Carr Powerhouse into the reservoir.

Designed and constructed by Reclamation, the district's water system dates back to 1967. Water is diverted to the district through two intakes in Whiskeytown Dam, one at an elevation of 1,110 feet and the other at an elevation of 965 feet. The ability to select the depth of the diverted water gives CCSD the capacity to draw less turbid water. The water is treated at a 30 mgd capacity plant located at the base of Whiskeytown Dam. CCSD shares the inline treatment facility with the Clear Creek Community Services District (CCCSD).

Treated water is distributed to the district through an aqueduct that begins at Whiskeytown Dam and terminates at a 250,000-gallon control tank about 8.5 miles south of the dam. This aqueduct, commonly called the Muletown Aqueduct (also Muletown Conduit), consists of about 27,500 feet of 45-inch pipe and 17,400 feet of 42-inch pipe buried along Muletown Road, paralleling Clear Creek. The steel pipe, lined and coated in coal tar, was installed in 1965.

CCSD has a contract with CCCSD that allocates CCSD a 25 percent share of the capacity. CCSD holds two contracts with Reclamation for a total allocation of 3,800 acre-feet per year. The first contract, entered into on April 11, 2001, is an assignment contract. This contract permanently assigned 2,900 acre-feet per year of CVP water from SCWA's 5,000 acre-feet per year contract with Reclamation. This contract carries with it those terms and conditions defined in SCWA's contract, which also includes a binding agreement for early renewal. The second contract, entered into on August 11, 2000, is an exchange contract. This contract with Reclamation for 900 acre-feet per year was intended to provide CCSD with substitute project water for its pre-1914 water rights on Clear Creek. The district does not have access to a groundwater supply source.

CCSD currently provides M&I water to 1,125 metered connections that serve a population of approximately 2,850.

Clear Creek Community Services District CCCSD was formed in 1961 and encompasses about 14,314 acres. The facilities were designed and constructed by Reclamation, and CCCSD began operating in 1967. CCCSD is located approximately 10 miles southwest of Redding and 6 miles west of Anderson in southern Shasta County. The district's service area includes the rural areas known as Olinda and Cloverdale. The general area served by the district is commonly known as Happy Valley.

The source and treatment of CCCSD water is the same as CCSD water; water from Whiskeytown Lake is treated and diverted to service connections via the Muletown Aqueduct. The distribution system within the district's boundaries consists of approximately 75 miles of pipe ranging in size from 2 inches to 45 inches. Title to the distribution line system was transferred to CCCSD on May 29, 2001.

CCCSD has one storage tank along the aqueduct with a capacity of 1 million gallons. A control tank with a 250,000-gallon capacity regulates pressure at the upper elevation of the district. A 32,000-gallon storage tank is located outside of the district boundary at the booster station facility.

The district has developed the first of three planned wells, and it has installed 13,800 feet of 18-inch pipeline to connect a groundwater supply to the distribution system. The first well attached to the distribution system (Well #1) became operational in October 1992. Well #1 and the two proposed wells are intended for use only when surface supplies are inadequate to meet emergency demands.

CCCSD currently provides service for approximately 5,817 acres of irrigated agricultural land and approximately 4,000 acres of rural residences receiving M&I water. Approximately 4,497 acres in the district are undeveloped. The majority of the developed agricultural property in the district is ditch or flood irrigated. The balance of irrigation is done by overhead and drip systems.

Shasta Community Services District The Shasta Community Services District (SCSD), located west of Redding, was formed in 1959 to supply water for domestic use and fire protection for the City of Shasta Lake and adjacent developed areas of the district (Community Services District Laws: California Governmental Code, Sections 61000 through 61934). Congress authorized a water system for the area as part of the Trinity River Division of the CVP. Bonds that were issued by SCSD to finance construction of the transmission and distribution systems have been repaid.

A long-term CVP water service contract provides up to 1,000 acre-feet annually. Water is supplied by gravity from Whiskeytown Lake via a turnout on the Spring Creek conduit. The Spring Creek conduit is the only source of supply, and there are only 0.30 million gallons of storage located near the source. Downstream from the turnout, a single transmission main serves as the backbone of the distribution system and most mains are not looped. Historically, SCSD has been vulnerable to disruptions in supply from its Reclamation contract. During the 1991 drought, Reclamation reduced SCSD's allotment by 25 percent to 750 acre-feet per year.

The district currently serves 630 connections. Virtually all of the active land use is residential or municipal, consisting primarily of ranchettes. Wells are not feasible because the district does not lie over an aquifer.

Shasta County Water Agency SCWA was formed in 1957 to develop water resources for Shasta County (Shasta County Water Agency Act (Legislative Act 7580)). SCWA evolved from the Shasta County Department of Water Resources, which organized Shasta County efforts in conjunction with the Trinity River Division of the CVP.

SCWA has assisted with the creation of BVWD, CCSD, CCCSD, and SCSD and helped create CSAs for water and sewer services in Shasta County. The agency also acts as staff to the Redding Area Water Council, a group that works to preserve the quality and quantity of water in the Redding groundwater basin. Funding for SCWA comes from Shasta County property taxes.

Other Shasta and Trinity River Divisions CVP Contractors Three smaller water districts (see below) are served by either the Shasta or Trinity River division of the CVP. The three districts constitute about 1 percent of the CVP long-term contract water supply to the divisions.

Keswick County Service Area The Keswick County Service Area (KCSA), located west of Redding, was formed in 1990 (California Government Code Sections 25210.1 through 25250). Previously, KCSA operated as the Keswick Community Services District, which was formed in the early 1960s to supply water for domestic use and fire protection for the town of Keswick and adjacent developed areas (California Government Code Sections, 61000 et seq.). The district boundary encompasses Keswick Dam and the Spring Creek Diversion Dam; however, these facilities are not served by the district.

Congress authorized a water system for the Keswick area as part of the Trinity Project Act (69 Stat. 719), and the facilities were constructed in 1965. A repayment schedule was established whereby the Federal government would be reimbursed by KCSA for delivery system construction costs. On completion of repayment, ownership of all project facilities were to remain with the Federal government.

The water source for KCSA is Whiskeytown Lake. Water is transported by gravity flow to a turnout on the Spring Creek conduit that is located upstream from the Spring Creek powerhouse. Two storage tanks provide 0.2 million gallons of storage.

A CVP water service contract provides for up to 500 acre-feet annually. KCSA serves about 195 connections, which are concentrated in the town of Keswick. Land served by KCSA is exclusively rural residential properties.

Mountain Gate Community Services District The Mountain Gate Community Services District (MGCSD) was initially formed in 1956 to provide water service for a 2-square-mile area north of the City of Shasta Lake (California Government Code, Sections 61000 et seq.). The water source for MGCSD is Shasta Lake. The distribution system consists of 29 miles of pipelines that serve

3,750 acres in MGCSD and Bridge Bay Resort (located between the Sacramento and McCloud arms of Shasta Lake on U.S. Forest Service land).

A CVP water service contract provides 350 acre-feet annually. District water supplies are supplemented by a contract with SCWA that provides 1,000 acre-feet annually. MGCSD also operates three wells that take water from a local aquifer. The wells supply nearly half of MGCSD's total needs. There is no water storage in the district.

MGCSD provides water service to 593 connections and fire protection services for its service area. Although the MGCSD primarily provides water for residential uses, it also serves municipal and industrial customers.

U.S. Forest Service The Toyon Pipeline, a Reclamation facility constructed by the USFS, originates from the left abutment of Shasta Dam and diverts water to a point near Government Camp at Toyon (west of the City of Shasta Lake). USFS operates and maintains the water diversion system, which includes pipelines, pumps, and meters (Figure 21-1).

USFS diverts water for the Centimudi Recreation Area located east/southeast of Shasta Dam. A memorandum of agreement between USFS and Reclamation provided USFS with up to 10 acre-feet of municipal, industrial, and domestic water diverted from the Toyon Pipeline before it reaches the City of Shasta Lake to supply the Centimudi Recreation Area. The Centimudi facilities continue to receive water under this memorandum of agreement.

Livingston Stone National Fish Hatchery The Livingston Stone National Fish Hatchery is located near the foot of Shasta Dam and is managed by the USFWS. The hatchery receives its water from the penstocks of Shasta Dam. Water flows through pipes fitted with pressure-reducing valves that pierce manhole covers near the bases of the penstocks. Then the water is routed via a buried pipeline to the hatchery, where it passes through a degassing device, flows through the hatchery, and then returns to the Sacramento River.

Other Users of Lake Water No other entities draw water directly from Shasta Lake for domestic or industrial uses. However, some marinas draw raw water from the lake for washing out boats. Return water drains back into the lake.

Shasta County Water supplies in Shasta County are provided by CVP, surface water diversions, and groundwater wells. The City of Redding uses groundwater wells for 40 percent of its water supply to supplement CVP water sources described in the preceding section. Maximum available groundwater production is approximately 19,000 acre-feet per year. Most city groundwater comes from 10 wells located near Redding Municipal Airport, within the Redding groundwater basin. These wells supply a maximum of 16.5 mgd. Four additional wells in the county supply a maximum of 0.7 mgd.

Tehama County Water supplies in Tehama County are provided by CVP, local surface water diversions, and groundwater wells. The recent trend in the county is a shift from reliance on CVP water supplies to groundwater supplies. There are more than 10,000 wells designated for domestic, irrigation, municipal, monitoring, and other uses in the county. CVP deliveries provide 21,300 acre-feet per year; local stream diversions provide 106,300 acre-feet in a normal water year; and groundwater provides approximately 382,000 acre-feet per year, which represents two-thirds of the county's irrigated water supply.

Red Bluff The City of Red Bluff obtains all of its water from 14 wells. It maintains a 3-million-gallon storage tank used for equalizing storage, fire flow, and emergency storage. The City of Red Bluff is in the process of seeking funding for an additional storage tank similar to the first. The wells produce between 500 and 2,500 gallons per minute, with the majority producing between 800 and 1,000 gallons per minute. Well depths range from 150 to 250 feet.

Other Nearby Uses The Chappie-Shasta Off-Highway Vehicle Area and residential and commercial uses in the community of Coram draw water from local groundwater wells.

Lower Sacramento River and Delta and CVP/SWP Service Areas The overall CVP/SWP water supply discussion describes the environmental setting for water supply for the extended study area. Other water supplies come from local surface water diversions and wells, which serve domestic, irrigation, municipal, and commercial uses. A detailed discussion of the overall CVP and SWP management and operations is provided in the PDEIS Chapter 6, "Hydrology, Hydraulics, and Water Management" and in the *Hydrology, Hydraulics, and Water Management Technical Report*.

21.1.2 Wastewater Infrastructure

Shasta Lake and Vicinity

Wastewater is treated and returned to the natural environment using one of several technical methods with either community or individual onsite disposal systems. Most residential, commercial, and recreational developments located in the Shasta Lake and vicinity portion of the primary study area use on-site septic tank/leachfield systems for wastewater treatment. Typically, individual homes, cabins, or businesses are routed to individual septic systems. Large resorts route septic from several buildings to a single tank/leachfield system. Campgrounds and public restrooms use either septic tank/leachfield systems or vault/pit toilets (Reclamation 2007). Marinas also use booster pumps to lift gray water to upslope leachfield areas. No large wastewater collection or treatment systems are located near Shasta Lake.

The highest concentrations of wastewater facilities near Shasta Lake are located in the Lakeshore and Sugarloaf areas, with a substantial number of facilities in

the Bridge Bay, Holiday Harbor, Salt Creek, Campbell Creek, Silverthorn, Jones Valley, Tsadi Resort, and Digger Bay Marina areas (Figure 21-2). The Utilities and Miscellaneous Minor Infrastructure Technical Memorandum shows detailed maps of the wastewater facilities in the ancillary areas near Shasta Lake (Reclamation 2007).

Upper Sacramento River (Shasta Dam to Red Bluff)

Many areas scattered throughout Shasta and Tehama counties are serviced by individual septic systems. The remaining wastewater treatment systems are a form of community collection, treatment, and disposal. The most common form of community system is the treatment plant, which discharges treated effluent to a storage and irrigation system (land disposal) or, diluted, to a surface watercourse.

Below Shasta Dam, a number of community wastewater systems are operated by the cities of Anderson, Redding, Red Bluff, and the City of Shasta Lake. Several unincorporated communities have community wastewater systems that are operated by CSAs.

Redding operates both the Clear Creek Wastewater Treatment Plant (WWTP) and Stillwater WWTP, both of which discharge treated effluent year around to the Sacramento River. The Clear Creek WWTP is currently permitted by the Central Valley Regional Water Quality Control Board to discharge up to 8.8 mgd of average dry-weather flow into the Sacramento River. The wastewater receives advanced secondary treatment. The Stillwater WWTP receives an average of 2.0 mgd of wastewater, approximately one-third of its design capacity of 6 mgd for average dry-weather flow. The Anderson WWTP discharges year around into the Sacramento River at a location approximately 0.25 mile from the Stillwater WWTP.

The City of Shasta Lake operates a large community wastewater system that is permitted to seasonally discharge treated effluent to surface water, namely Churn Creek; a major goal of the city's capital improvement plan has been to significantly reduce these discharges. Churn Creek eventually discharges to the Sacramento River about 0.5 mile upstream from the Stillwater WWTP.

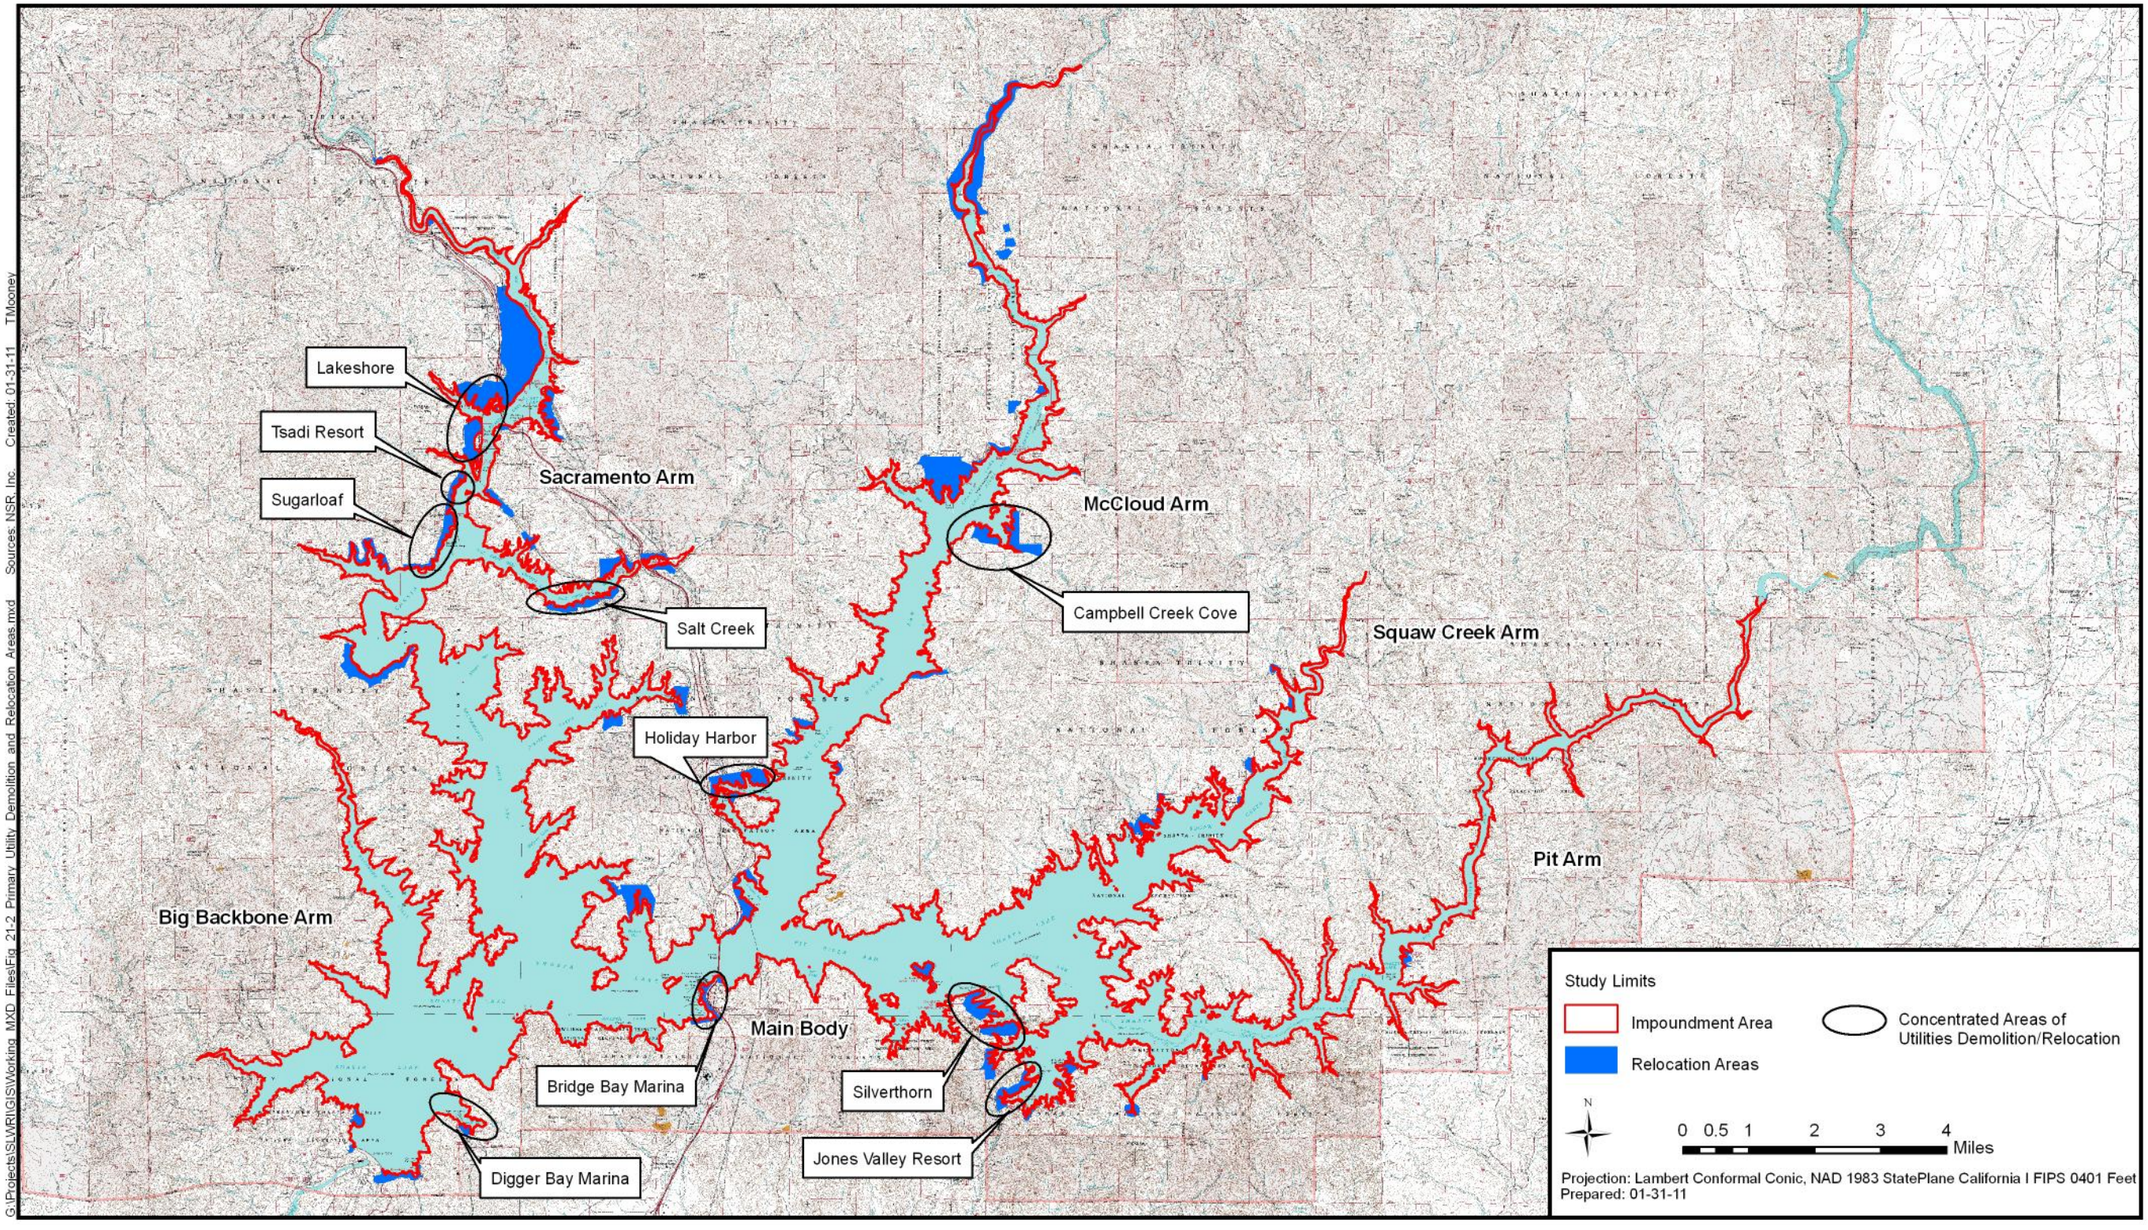

Figure 21-2. Primary Utility Demolition and Relocation Areas

This page left blank intentionally.

The Red Bluff WWTP has a treatment capacity of 4.8 mgd and discharges tertiary treated wastewater by gravity into the Sacramento River at approximately 1.4 mgd. The City of Red Bluff operates a wastewater treatment system at the south end of the city. The Rio Alto Water District provides wastewater treatment services for some portions of the community of Cottonwood. Septic/leachfield systems or seepage pits are used in areas not served by these systems.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Wastewater systems in the extended study area are similar to those discussed for the primary study area. Community wastewater service systems are provided through a collection network of gravity and force main sewer lines operated primarily by local utility agencies. Pump stations and lift stations augment sewer line networks. These conveyance systems terminate at wastewater treatment plants that discharge treated effluent to storage and irrigation systems (land disposal) or to surface watercourses where the treated effluent is diluted. Individual on-site wastewater treatment methods are also used where the land is able to accommodate a leachfield/septic tank system.

21.1.3 Stormwater Drainage and Infrastructure

Shasta Lake and Vicinity

Stormwater drainage is primarily a function of the precipitation and runoff characteristics of a watershed. About 6.5 percent (5.8 million acre-feet) of all surface runoff in the state of California originates in Shasta County, representing a substantial portion of the total surface runoff in the Sacramento River system. Runoff in the Shasta Lake and vicinity portion of the primary study area is discharged to the McCloud River, the Sacramento River, and the Pit River, which drain into Shasta Lake. Numerous creeks and small local tributaries also drain into Shasta Lake.

The California Department of Transportation maintains a stormwater drainage system along the Interstate 5 (I-5) corridor. Drainage facilities in developed communities include gutters, swales, ditches, culverts, storm drain inlets, catch basins, storm drainage pipes, and detention basins. Roads also channel stormwater drainage from residences, commercial, and industrial land uses to adjacent lands and stormwater drains.

Upper Sacramento River (Shasta Dam to Red Bluff)

Runoff in the upper Sacramento River portion of the primary study area is discharged to the Sacramento River directly and indirectly via numerous major creeks and small local tributaries in rural and urban areas. Stormwater drainage in undeveloped portions of Shasta and Tehama counties generally consists of natural swales and topographic features.

Stormwater collection systems are present in urban areas and developed communities. Drainage facilities in urban areas include gutters, swales, ditches,

culverts, storm drain inlets, catch basins, storm drainage pipes, canals, detention basins, and pump stations. Roads also channel stormwater drainage from residences and commercial and industrial land uses to adjacent lands and stormwater drains. The cities of Redding, Anderson, and Red Bluff and the City of Shasta Lake each operate municipal storm drainage systems in the city limits. The California Department of Transportation I-5 stormwater drainage system continues along I-5 in the upper Sacramento River area.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Stormwater systems in the extended study area are similar to those discussed for the primary study area. Various storm drainage facilities and collection/conveyance systems are located throughout the extended study area. Stormwater facilities and infrastructure are operated primarily by local districts and road departments, and include gutters, swales, ditches, culverts, storm drain inlets, catch basins, storm drainage pipes, canals, detention basins, and pump stations. Treated stormwater is often discharged to rivers, tributaries, and major creeks throughout the extended study area.

21.1.4 Solid Waste Management

Shasta Lake and Vicinity

Contractors, under the auspices of Shasta County, provide solid waste disposal services for the private sector. The Shasta-Trinity National Forest (STNF), Reclamation, and California Department of Transportation use contractors to provide disposal services for facilities on public lands. A number of sites are used to collect solid waste and recyclables, which are later transferred to landfills or recycling centers in the extended study area, primarily in Shasta County.

Upper Sacramento River (Shasta Dam to Red Bluff)

The Shasta County Department of Public Works is responsible for providing solid waste management in unincorporated areas of the county. Three landfills (West Central Landfill, Anderson Landfill, and Twin Bridges Landfill) and 11 collection/transfer stations are currently operating in Shasta County. Shasta County generated 187,909 tons of solid waste in 2006; however, 307,568 tons of solid waste were disposed of in the county during the same period (CIWMB 2008).

In 2006, the 1,200-acre West Central Landfill received approximately 417 tons per day (CIWMB 2008) of nonhazardous waste from residential, commercial, industrial, and agricultural sources. This Class III landfill has a permitted capacity of 7,078,000 cubic yards and a storage area of 107 acres. In 2001, the State of California estimated that the landfill had a remaining capacity of 6,606,000 cubic yards (CalRecyle 2010). Under existing State permits, the landfill has sufficient capacity to accommodate the disposal of solid waste at least until the year 2019. In 2006, the 246-acre Anderson Landfill, a Class III landfill and asbestos-containing waste disposal site, received approximately 426

tons of solid waste per day (CIWMB 2008). This landfill has a permitted capacity of 16,840,000 cubic yards, and in 2008 the State of California estimated that the landfill had a remaining capacity of 11,914,000 cubic yards (CalRecycle 2010). The estimated year of closure is 2055. The Twin Bridges Landfill is a Class II landfill that has ceased accepting solid waste and is undergoing closure (CIWMB 2008).

Tehama County operates the 102-acre Tehama County/Red Bluff Sanitary Landfill, located approximately 2.5 miles northwest of Red Bluff. This landfill, a Class III facility, has a maximum permitted daily capacity of 400 tons (CIWMB 2008). This landfill has a permitted capacity of 5,097,000 cubic yards, and in 2008 the State of California estimated that the landfill had a remaining capacity of 2,149,000 cubic yards (CalRecycle 2010). The estimated year of closure is 2040. The landfill is owned by the Tehama County Sanitary Landfill Association, a joint-powers authority composed of Tehama County and the cities of Red Bluff, Corning, and Tehama. The Tehama County/Red Bluff Landfill Management Agency oversees daily landfill operations at the Tehama County/Red Bluff Landfill and at the Material Recovery Facility. Tehama County/Red Bluff Landfill Management Agency is another joint-powers authority and is composed of Tehama County and the City of Red Bluff. This agency is also responsible for maintaining permits and monitoring environmental compliance at the landfill.

In addition to the landfill and material recovery facilities, Tehama County operates two household hazardous waste facilities, in Corning and Red Bluff, and four transfer stations in the outlying rural areas of Manton, Payne's Creek, Mineral, and Rancho Tehama. There are no facilities authorized to accept commercial hazardous waste within the primary study area.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Solid waste services and infrastructure in the extended study area are similar to those discussed for the primary service area. Urban centers in the extended study area may generate more solid waste than the population centers in the primary study area; however, the mechanisms used for transfer and disposal of the waste are similar. Solid waste facilities, including landfills and transfer stations, provide pickup and disposal services. There are three commercial hazardous waste disposal facilities authorized to accept various types of commercial hazardous waste in the extended study area. These facilities are located in Kings, Kern, and Imperial counties. Only the facility in Kings County is certified to accept materials that contain polychlorinated biphenyls.

21.1.5 Electrical Service and Infrastructure

Shasta Lake and Vicinity

Pacific Gas and Electric Company (PG&E) provides electrical service to Shasta Lake and vicinity. This service area is part of a larger PG&E territory, which encompasses 70,000 square miles in northern and central California, from

Eureka in the north to Bakersfield in the south. Power transmission facilities serving the Shasta Lake and vicinity portion of the primary study area have developed mostly parallel to I-5 and adjacent to developed communities.

Currently, PG&E is capable of providing three-phase power parallel to the I-5 corridor, north to Bridge Bay and south from Lakehead to Turntable Bay. Power lines around Shasta Lake are typically routed overhead on utility poles or towers, although a portion of the lines serving individual businesses, homes, and cabins are routed underground. Power lines serving the Shasta Lake and vicinity portion of the primary study area are frequently attached to bridges when routed over rivers and lake inlets. The voltage of local distribution lines is typically 12 kilovolts (kV), whereas the voltage of high-voltage power transmission lines is typically 60 kV to 230 kV. Service to individual homes and businesses is typically 120 volts to 480 volts.

The highest concentrations of electrical service facilities near Shasta Lake are in the Lakeshore and Sugarloaf areas, with a substantial number of facilities in the Bridge Bay, Holiday Harbor, Salt Creek, Campbell Creek, Silverthorn, Jones Valley, Tsadi Resort, and Digger Bay Marina areas (Figure 21-2). The Utilities and Miscellaneous Minor Infrastructure Technical Memorandum shows detailed maps of the electrical service facilities in the ancillary areas near Shasta Lake (Reclamation 2007).

Upper Sacramento River (Shasta Dam to Red Bluff)

Electrical service and related infrastructure in the upper Sacramento River portion of the primary study area are similar to those discussed for the Shasta Lake and vicinity portion. The City of Shasta Lake, city of Anderson, outlying rural areas of Shasta County, and Tehama County (Red Bluff and Corning) receive electrical service from PG&E.

The City of Redding owns and operates a looped 115 kV system, which delivers energy to 11 115/12 kV distribution substations that step the voltage down to 12 kV for delivery to the city's customers. The system is managed by the Redding Electric Utility. In total, Redding's distribution system has 67.3 miles of 115 kV local transmission lines and approximately 610 miles of overhead and underground 12 kV distribution lines. Delivery of all power from outside the city is made to the Redding Municipal Airport 230/115 kV transmission substation and to the Keswick Dam switch yard. Redding jointly owns the airport substation with the Western Area Power Administration. The Western Area Power Administration owns and operates the Keswick switching substation and an electrical transmission line that runs north and south along the western side of the City of Redding and the City of Shasta Lake.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Electrical services and infrastructure in the extended study area are similar to those discussed for the primary study area. Power generation and transmission facilities have developed parallel to population centers, power, natural gas,

nuclear, oil, hydroelectric, wind, solar, and other technologies used for power production.

Infrastructure in the Sacramento River basin downstream from the Red Bluff Diversion Dam, the American River basin, and the San Joaquin River basin consists primarily of natural gas–fired and hydroelectric generating facilities, transmission lines, substations, and distribution lines. In the Sacramento–San Joaquin River Delta, PG&E and the Western Area Power Administration have developed power transmission lines across Delta islands and waterways. Many of the corridors are within the periphery of the Delta upland areas, including several natural gas–fired plants. There are no power-generating facilities in the central Delta. In other portions of the CVP and SWP service areas, a complex system of electrical generating facilities, substations, and transmission infrastructure exists.

21.1.6 Natural Gas Service and Infrastructure

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

PG&E is responsible for providing natural gas service to the primary study area. Gas is delivered to customers below Shasta Dam, including residents of the cities of Redding, Anderson, and Red Bluff and the City of Shasta Lake. Although the study area is bisected by a large PG&E natural gas pipeline, service varies based on PG&E's distribution system. No natural gas facilities are present in the Shasta Lake and vicinity portion of the primary study area.

A number of rural residences and businesses in the primary study area rely on propane for various purposes. Propane is supplied by various local providers to individual on-site tanks. Propane tanks for homes and businesses are portable and are typically leased (Reclamation 2007).

Lower Sacramento River and Delta and CVP/SWP Service Areas

Natural gas services and infrastructure are located throughout the extended study area and are supplied by various energy providers. Pipelines, storage areas, and compressor stations are located in the Sacramento River and San Joaquin River valleys and in the CVP/SWP service areas. Natural gas discovered in the Delta region has been developed into a significant supply source and depot for underground storage. Gas fields, pipelines, and related infrastructure have been developed throughout the CVP/SWP service areas. Natural gas infrastructure is owned by oil and gas companies, public utilities, and various independent leaseholders.

21.1.7 Telecommunications

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Landline telephone service in the primary study area is provided by various commercial communications companies. The majority of the landline facilities

are located in county- or city-owned rights-of-way and on private easements. Telecommunications lines are either copper wire or fiber optic cable and are routed overhead on utility poles and underground. Telephone lines are frequently attached to bridges when routed over rivers and lake inlets. There are no transcontinental fiber optic lines in the Shasta Lake and vicinity portion of the primary study area.

In addition to landline service, a large number of communications towers have been constructed throughout the primary study area for cellular phone service. Cellular towers have been erected along major travel corridors to meet emergency service objectives. Cellular service is available, to varying degrees, throughout the service area.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Telecommunications systems in the extended study area are similar to those discussed for the primary study area and are supplied by various providers. Associated infrastructure is located throughout the extended study area and consists of underground fiber optic cable, telephone transmission lines (overhead and underground), and cellular towers owned or leased by telecommunications service providers.

21.2 Regulatory Framework

21.2.1 Federal

Reclamation Act

The 1902 Reclamation Act authorized the Federal government to finance and build water supply projects. The act set up the Reclamation Fund to finance single-purpose irrigation projects in the western United States. Since that time, water supply projects and the financing needed to construct and maintain infrastructure have grown substantially. The act has been amended several times, most recently in 1982 with the passage of the Reclamation Reform Act.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) was passed to protect public health by regulating the nation's drinking water supply. The law requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and groundwater wells. Originally, the SDWA focused on water treatment as the primary means to provide safe drinking water at the tap. In 1996, amendments to the SDWA expanded the act to include source water protections.

The U.S. Environmental Protection Agency (EPA) is responsible for administering the act. EPA establishes National Primary Drinking Water Regulations for contaminants that may cause adverse public health effects. These regulations set maximum contaminant levels and nonenforceable health

goals (called Maximum Contaminant Level Goals) for recognized contaminants.

The SDWA does not regulate private wells that serve fewer than 25 people. However, the act does apply to all public water systems. A public water system is one that provides water for public consumption that regularly serves at least 25 people or has at least 15 service connections. This includes facilities such as resorts and marinas.

Clean Water Act

The objective of the Clean Water Act is to restore and maintain the chemical, physical, and biological integrity of the nation's waters by preventing point and nonpoint pollution sources, providing assistance to publicly owned treatment works for the improvement of wastewater treatment, and maintaining the integrity of wetlands. The act regulates discharges of pollutants into the waters of the United States. EPA is responsible for administering waste discharge permits under the National Pollutant Discharge Elimination System. M&I wastewater facilities that discharge effluent into surface waters are required to obtain National Pollutant Discharge Elimination System permits. Large and medium storm sewer systems also require a National Pollutant Discharge Elimination System permit. The stormwater permits often require implementation of a pollution prevention plan to prevent contaminants from reaching surface waters.

Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (RCRA) is designed to provide "cradle to grave" control of hazardous waste by imposing management requirements on generators and transporters of hazardous wastes and on owners and operators of treatment, storage, and disposal facilities. The RCRA also applies to the management of nonhazardous solid waste through the municipal solid waste landfill. EPA is responsible for administering the RCRA.

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF Land and Resource Management Plan (LRMP) identifies goals, standards, and guidelines related to utilities and service systems in the Shasta-Trinity National Forest. The following public services goals, standards, and guidelines related to the project area were excerpted from the LRMP (USFS 1995).

Facilities Goals:

- Provide and maintain those administrative facilities that effectively and safely serve the public and Forest Service workforce.

Facilities Standards and Guidelines:

- Manage, construct, and maintain buildings and administrative sites to meet applicable codes and to provide the necessary facilities to support resource management.

Lands Goals:

- Provide for continued use and new development of hydroelectric facilities.

Lands, Special Uses Standards and Guidelines:

- Do not approve special use applications if such use can reasonably be accommodated on private land.
- Bury new telephone lines and new or reconstructed power distribution lines less than 35 kV, unless:
- Visual quality objectives (VQO) can be met without burying,
- Geologic conditions make burying infeasible, and
- Burying will produce greater long-term site disturbance.

Whiskeytown-Shasta-Trinity National Recreation Area Management Plan

- Road construction will be restricted to that which is compatible with the purpose of the NRA and to provide essential private land access.
- Road closures will be implemented as opportunities arise in order to decrease road density and associated wildlife disturbance.
- No additional roads will be constructed for timber harvest.
- Any timber harvest must be consistent with NRA goals and objectives.
- All developments and long-term activities in the NRA will be designed with the intent of meeting VQOs. Those objectives include areas designated as retention, partial retention, and modification.
- Management activities that can be seen from within developed recreation sites will meet a VQO of retention in the foreground and partial retention in the middle ground.
- Best management practices and soil quality standards apply to all management activities.
- Riparian reserve standards and guidelines apply to all management activities within riparian reserves.

21.2.2 State

California Water Plan

The California Water Plan provides a framework for water supply planning for the state. It identifies and evaluates existing and proposed statewide demand, water supply programs, and projects to address the state's water supply needs.

DWR is responsible for the preparation of the California Water Plan and the management of the state's surface water and groundwater resources. DWR also oversees California's SWP and the regulation and protection of dams, assists local agencies in preparing urban water management plans, and reviews the plans to ensure compliance with the Urban Water Management Act.

The State Water Resources Control Board (SWRCB) has broad authority over water rights and regulations for the state. SWRCB and its nine regional water quality control boards administer water rights and enforce pollution control standards throughout the state. SWRCB is responsible for granting water rights through an appropriation process following public hearings and requisite environmental review by applicants and responsible agencies. In granting water rights permits, SWRCB must consider all beneficial uses, including water for downstream human and environmental needs.

Water suppliers must obtain a permit from the Department of Public Health, Office of Drinking Water, for a community water system, defined as a "public water system that serves at least 15 service connections used by year-round residents or regularly serves at least 25 year-round residents of the area served by the system" (42 Code of Federal Regulations Section 300f).

Water Quality Control Plan for the Sacramento and San Joaquin River Basins

The Water Quality Control Plan for the Sacramento and San Joaquin River Basins (Basin Plan) provides guidance for wastewater and stormwater facilities and development that could affect water quality in the basins. Basin Plan objectives are incorporated into county and city general plans, zoning ordinances, building codes, and subdivision ordinances. Central Valley Regional Water Quality Control Board is responsible for issuing and enforcing waste discharge requirements, including discharge prohibitions and user reuse requirements for wastewater reclamation projects.

Nonhazardous Solid Waste Disposal Standards

Title 14, Chapter 3, of the California Code of Regulations provides minimum standards for solid waste handling and disposal in California and pertains to nonhazardous solid waste management. The California Department of Resources Recycling and Recovery is a new department in the California Natural Resources Agency that administers the programs formerly managed by the California Integrated Waste Management Board, including the regulation of nonhazardous solid waste facilities in the state.

Hazardous Waste Control Act

The California Hazardous Waste Control Act governs hazardous waste management and cleanup in California (Health and Safety Code, Ch. 6.5–6.98). The act mirrors the RCRA and imposes a "cradle to grave" regulatory system for handling hazardous waste in a manner that protects human health and the environment. County Environmental Health Departments and California

Environmental Protection Agency Certified Unified Program Agencies assume responsibility for enforcing local hazardous waste reporting requirements. Sites that store, handle, or transport specified quantities of hazardous materials are inspected annually. California Environmental Protection Agency, Department of Toxic Substances Control, regulates the generation, transportation, treatment, storage, and disposal of hazardous waste under the RCRA and the State Hazardous Waste Control Act.

California Public Utilities Code

The California Public Utilities Code has broad regulatory authority over public utilities in California, which include electrical utilities, mutual water companies, private energy producers, telephone corporations, and railroad corporations. The California Public Utilities Commission is the government body that administers the California Public Utilities Code. The California Public Utilities Commission issued Order-95 to provide safety standards for construction of power transmission facilities.

21.2.3 Regional and Local

City and County General Plans

The general plans for the counties and cities in the primary and extended study areas contain policies regarding utilities and services systems. Water supply, wastewater treatment, solid waste disposal, and utilities are subjects covered in the general plans and are considered essential public services required by all types and densities of development.

21.3 Environmental Consequences and Mitigation Measures

21.3.1 Methods and Assumptions

Evaluation of potential utility and services system impacts was based on a review of planning documents pertaining to the primary and extended study areas, including the STNF LRMP, Department of Toxic Substances Control databases, and the general plans for the cities of Redding and Red Bluff, the City of Shasta Lake, and Shasta and Tehama counties. The analysis also uses an inventory of utilities and service system infrastructure in the primary study area as it relates to the SLWRI.

Effects on water supply in the Shasta Lake and vicinity portion of the primary study area were evaluated based on construction and operational activities that would result from project implementation. It was generally assumed that construction activities associated with modifying Shasta Dam could result in short-term effects on the delivery of local water supplies if the surface elevation of the reservoir were lowered to accommodate construction. A long-term effect would result if project operation would create a substantial disruption or reduction in the distribution or quantity of water supply.

Impacts on utilities and service systems were evaluated based on the duration and extent to which such services would be affected, as well as the ability of the service provider to continue to provide a level of service that could meet the needs of the public. The evaluation compares the duration of the effect with the service provided, taking into account the ability of the provider to maintain necessary services through alternative means.

21.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by State CEQA Guidelines and consider the context and intensity of the environmental effects as required under NEPA. An alternative was determined to result in a significant effect related to utilities and service systems if it would result in any of the following:

- Not comply with published local, State, or Federal statutes, regulations, or standards relating to solid waste
- Exceed permitted landfill capacity with waste generated by the project
- Degrade the level of service of a public utility or services system
- Require relocating utility infrastructure
- Exceed wastewater treatment requirements of the applicable SWRCB
- Exceed water supplies available to service the project from existing entitlements and resources, such that new or expanded entitlements would be needed
- Disrupt utilities service to create a public health hazard or extended service disruption

- Require substantial improvements to the infrastructure or level of staffing of a utility or services system to maintain its existing level of service

- Require or result in the construction of new water treatment, wastewater treatment, or stormwater drainage facilities, or the expansion of such existing facilities, the construction of which could cause significant environmental effects

21.3.3 Topics Eliminated from Further Consideration

The action alternatives would increase availability of water supply for water users on the Sacramento River and Delta. Increased water supplies might increase demand for new or expanded wastewater plants that discharge to the Sacramento River or Delta. SWRCB has review, approval, and permitting authority over operation of new or expanded wastewater treatment plants, and the environmental effects of approving wastewater treatment plants must be evaluated under CEQA. If approved, wastewater treatment plants must operate within the limits established in the waste discharge requirements issued by SWRCB. Although increased water supplies might increase demand for new or expanded wastewater plants that discharge to the Sacramento River or Delta, it is speculative to assume that SWRCB would approve new or expanded wastewater treatment plants. Therefore, increased discharge of treated wastewater into the Sacramento River or Delta that is not currently authorized as a result of this project (and that has not already been evaluated under CEQA) is not reasonably foreseeable and is eliminated from further consideration.

21.3.4 Direct and Indirect Effects

Utilities and service system impacts in the Shasta Lake and vicinity and upper Sacramento River (Shasta Dam to Red Bluff) of the primary study area caused by project construction and operation are described below. Only minimal, if any, project-related impacts to utilities and service systems are expected to occur downstream from Red Bluff Diversion Dam or in the remainder of the extended study area.

No-Action Alternative

Shasta Lake and Vicinity, Upper Sacramento River (Shasta Dam to Red Bluff), Lower Sacramento and Delta, and CVP/SWP Service Areas The impact discussion for the No-Action Alternative addresses all three study areas together, because this alternative would not impact utilities in either of the three study areas.

Impact Util-1 (No-Action): Damage or Disruption of Public Utility and Service Systems Infrastructure Under the No-Action Alternative, no new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, no damage to public utilities infrastructure or temporary disruption of services in the vicinity of Shasta Lake would occur from

implementing the No-Action Alternative. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Util-2 (No-Action): Utility Infrastructure Relocation or Modification Under the No-Action Alternative, no new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, relocation or modification of existing utilities infrastructure in the vicinity of Shasta Lake would not occur from implementing the No-Action Alternative. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Util-3 (No-Action): Short-Term Increase in Solid Waste Generation Under the No-Action Alternative, no new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, no solid waste would be generated as a result of implementing the No-Action Alternative. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Util-4 (No-Action): Increases in Solid Waste Generation from Increased Recreational Opportunities Under the No-Action Alternative, no new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, no solid waste associated with increased recreational opportunities would be generated as a result of implementing the No-Action Alternative. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Util-5 (No-Action): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Under the No-Action Alternative, no new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, increased demand for water treatment and distribution facilities related to increases in water supply would not occur from implementing the No-Action Alternative. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Utilities and service systems impacts would occur primarily in the Shasta Lake and vicinity portion of the primary study area. The majority of impacts identified would be short-term impacts resulting from the abandonment and relocation of utilities and service systems. Individual utilities or service systems are discussed where project detail is available. However, stormwater, wastewater, solid waste management, and water supply systems are also referred to as service systems when a general reference to all of the systems would be appropriate; and electrical service and infrastructure, natural gas service and infrastructure, and telecommunications service and infrastructure are referred to as utilities when a general reference to all of the utilities would be appropriate.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP1 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact Util-1 (CP1): Damage or Disruption of Public Utility and Service Systems Infrastructure Project construction activities could damage public utility and service systems infrastructure, which could result in short-term disruptions of service. Construction activities would occur in areas proposed for utilities or service systems abandonment and relocation. Project implementation could require disruption of public utilities or service systems to accommodate construction activity. This impact would be potentially significant.

The quantity of utility and service systems infrastructure relocation varies for the developed areas in the general vicinity of Shasta Lake. The bulk of the work would be done along the shores of the Sacramento Arm, the most developed portion of Shasta Lake. Utility abandonment and relocation would take approximately 36 months. Some service systems construction would occur in the upper Sacramento River portion of the primary study area, primarily at the Shasta Dam compound. Disruptions of utilities service in the upper Sacramento River area could result from project implementation and are discussed below.

Project construction activities associated with abandonment and relocation of utilities and service systems infrastructure could damage existing public utility lines. Excavation activities, vegetation clearing, and heavy equipment operations could accidentally damage utility lines or service system pipes/ditches, which could result in a disruption of public utilities or service systems.

Reclamation inventoried utilities and service systems on lands surrounding Shasta Lake that could be inundated by an increased reservoir elevation. Based on Reclamation's inventory, a 6.5-foot raise in the level of Shasta Lake would require abandonment and relocation of approximately 31,000 feet (5.8 miles) of power lines and 35,000 feet (6 miles) of telecommunications lines. Power and telecommunications facilities that could be inundated and that would require relocation include transmission towers, power poles, underground power and telecommunications lines, above-ground power and telecommunications lines, and cable lines. Approximately 20 percent of the power transmission facilities that could be inundated would consist of high voltage power lines; the remaining 80 percent would consist of low voltage power lines. Numerous individual onsite wastewater systems and stormwater systems (primarily adjacent to roads) would be relocated to areas that would not be affected under CP1 (Figure 21-2). The Utilities and Miscellaneous Minor Infrastructure Technical Memorandum shows detailed maps of the utilities in the ancillary areas that would need to be demolished or relocated (Reclamation 2007).

Disruptions in services resulting from damage to utility lines would likely be localized because the majority of power and telecommunication lines that would require relocation serve the local population around Shasta Lake. Reclamation or project contractors would likely repair potential infrastructure damage immediately after discovery of the damage. Therefore, disruptions of public utilities in the Shasta Lake and vicinity portion of the primary study area would not continue for extended periods of time. However, periodic service disruptions could occur throughout the 36-month construction period, which could inconvenience the local population.

Project construction activities associated with raising Shasta Dam could damage existing public utilities infrastructure and result in disruptions of public utilities service in the primary study area. Activities that could damage public utilities at the dam and result in disruptions of service include drilling activities, heavy equipment operations, and other worksite accidents. As explained above, infrastructure damage would be repaired immediately. If hydropower generation is interrupted at Shasta Dam, repair time could be extended and there would be prolonged impacts to the upper Sacramento River portion of the primary study area.

Public utilities or service systems could be disrupted during construction activities that require a temporary shut-off for safety or mechanical purposes. This effect would be most likely to occur in the Shasta Lake and vicinity portion of the primary study area because of the amount of project construction in that area relating to local utilities and service systems relocation activities. Occasional disruptions of public utilities could also occur in the upper Sacramento River area because of construction activities at Shasta Dam that require temporary power outages. Construction activities in the immediate vicinity of the Shasta Dam compound could occasionally impact the treatment and delivery of water to the City of Shasta Lake. This impact would be short term and would continue intermittently until project construction activities were completed. Construction would take approximately 36 months.

To minimize potential disruption of service and damage to the utilities and service systems infrastructure, project contractors would follow local, State, and Federal regulations pertaining to utilities and service systems location and construction. However, the magnitude of the project and number of utilities and service systems requiring relocation make it likely that utilities or service systems could be damaged or services disrupted. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-2 (CP1): Utility Infrastructure Relocation or Modification Project implementation would require relocation or modification of utilities infrastructure, which could result in localized impacts on vegetation, land use, transportation, wildlife, noise, air quality, water quality, and utilities service. This impact would be potentially significant.

In general, short-term impacts that could result from relocation of utilities infrastructure would be localized (Shasta Lake and vicinity) and could include disruptions caused by noise, traffic, and dust associated with construction activities. Relocation of utilities infrastructure could result in localized long-term impacts related to visual quality, land use, vegetation, transportation, water quality, air quality, noise, and wildlife in the Shasta Lake and vicinity portion of the primary study area; these impacts are discussed in separate Environmental Impact Statement/Environmental Impact Report chapters. Some utilities infrastructure would also be modified in the upper Sacramento River portion of the primary study area, particularly in the general vicinity of the Shasta Dam compound.

As discussed in Impact Util-1 (CP1), project construction and operation would result in relocation and/or modification of utilities infrastructure at Shasta Dam and in communities in the Shasta Lake and vicinity portion of the primary study area (Figures 21-1 and 21-2). The infrastructure components include water and wastewater service and electrical infrastructure, telephone lines, and cable lines. Proposed infrastructure relocation was based on (1) whether utilities components would be inundated by an increased lake elevation and (2) whether the inundation would warrant relocation or permanent abandonment.

The largest potentially impacted residential developments near Shasta Lake are in the Lakeshore and Sugarloaf areas. Recreational facilities (e.g., campgrounds and marinas) would also change substantially. The quantity of services and utilities infrastructure reconstruction varies around Shasta Lake with an emphasis on the Sacramento, McCloud, and Pit arms as well as the Main Body. Abandonment and relocation of utilities infrastructure would take 36 months. The Utilities and Miscellaneous Minor Infrastructure Technical Memorandum shows detailed maps of the utilities in the ancillary areas that would need to be demolished or relocated (Reclamation 2007).

Consistent with Shasta County Development Standards, septic systems within 200 feet of the new full pool waterline or 100 feet downslope of the new full pool waterline would be demolished. Wastewater pipes, septic tanks, vaults/pits, and leachfields would be abandoned in place, and restroom buildings and contents would be removed and taken to an approved landfill. Relocation of septic systems in the project area would be done in one of two ways: (1) construct new septic systems on the property of the impacted home or facility, where feasible, or (2) define a possible localized wastewater treatment plant alternative for homes that do not meet Shasta County requirements for septic system separation from the lake. The general wastewater treatment plant would include a pressurized sewer collection system to transport wastewater flows to several centralized package wastewater treatment plants. Localized wastewater treatment plants would likely be constructed to serve the areas of Salt Creek, Sugarloaf/Tsadi Resort, Lakeshore (possibly several plants), Antlers Campground, Campbell Creek Cove, Bridge Bay Marina, Silverthorn Resort, and Jones Valley.

Wastewater treatment plant operation can result in undesirable environmental effects. For example, discharge of treated wastewater could impact the water quality of Shasta Lake, pump stations could generate unwanted noise, and the treatment process could generate undesirable odors. The environmental impacts of constructing and operating wastewater treatment facilities are evaluated in the pertinent technical chapters of the Environmental Impact Statement/Environmental Impact Report.

Power lines and telecommunications lines usually follow parallel alignment and typically use the same power pole. Some of the utility lines serving individual houses, businesses, government facilities, and cabins are routed underground. All transmission towers, power poles, underground power lines, and telecommunications lines that would be inundated under CP1 would need to be removed and relocated.

Low-voltage power lines, telecommunications lines, or power poles located within 50 feet of the CP1 maximum lake elevation would be considered threatened by inundation, and high voltage power lines and towers located within 100 feet would be considered inundated. Relocation of utilities infrastructure would be consistent with applicable local, State, and Federal requirements.

CP1 would inundate 31,060 feet (approximately 5.8 miles) of power lines and 35,000 feet (about 6 miles) of telecommunications lines near Shasta Lake. All associated transmission towers, power poles, underground power lines, telecommunications lines, and cable lines that would be inundated under CP1 would need to be removed and relocated.

Relocation of infrastructure would include vegetation removal, which would result in project impacts. Clearing of vegetation would be required to provide space for utilities structures and to create a safety buffer. Reclamation would clear the appropriate space for utilities infrastructure as provided by local, State, and Federal regulations. Additional space could be cleared to provide the highest level of safety for project operation and maintenance. In addition, Reclamation would apply the National Electric Safety Code, a voluntary safety code followed by the utilities industry, to ensure that relocated infrastructure would operate as safely or safer than existing utilities. Widths of vegetation clearance would range from 40 to 75 feet. Cleared areas could be wider, depending on site-specific conditions, such as on steep slopes or when tall trees are nearby.

Impacts resulting from vegetation clearing associated with relocation of utilities infrastructure would be minimized where possible. When possible, Reclamation would locate utilities corridors in sites that are not heavily forested to minimize vegetation clearing. Where heavily forested areas cannot be avoided for relocation of utilities infrastructure, Reclamation would coordinate vegetation removal with USFS and other landowners/managers to minimize impacts.

Relocation of utilities infrastructure would require additional roads for construction and maintenance of the new facilities. Roads would be constructed in the rights-of-way of the cleared utility lines and would be constructed according to the appropriate jurisdiction's standards (i.e., USFS or Shasta County). New roads serving relocated utilities infrastructure would be located and designed to prevent erosion and avoid geologic hazards.

As discussed in Chapter 20, "Transportation and Traffic," some work in the road relocation areas could require a road closure with detours, lane closures, or a combination of both. Road closures would temporarily impede access to local connector roads and recreational land uses, affecting residents, local recreational and nonrecreational businesses, and visitors to Shasta Lake.

To minimize potential impacts resulting from relocation of utilities infrastructure, Reclamation and project contractors would follow local, State, and Federal regulations pertaining to installation of utilities infrastructure, the STNF LRMP standards and guidelines, and the Shasta County General Plan and zoning guidance. Before vacating a street or public service easement, the Shasta County Board of Supervisors must consider applicable consistency with the general plan. Shasta County Streets and Highways Code Section 8313 and Public Utilities Code Section 12808.5 require cities and counties approving electrical transmission and distribution lines of municipal utilities districts to make a finding concerning the consistency of the lines with the general plan.

Reclamation is committed to funding the demolition and relocation of existing infrastructure and construction of replacement infrastructure, including localized wastewater treatment plants that might replace some individual septic systems. Reclamation is also committed to facilitating establishment of community services districts and transferring plant ownership to the districts, which would be responsible for long-term operation and management.

Project implementation would result in relocation or modification of utilities infrastructure. The extent of relocation of utilities infrastructure and/or modification that would be necessary could result in short-term impacts on noise, traffic, and utilities services; and project implementation could result in long-term impacts on land use, wildlife, water quality, and soils. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-3 (CP1): Short-Term Increase in Solid Waste Generation Project implementation would result in a short-term increase of solid waste generation during construction activities. The project would not generate construction waste materials that would exceed the capacity of local landfills. This impact would be less than significant.

Demolition and construction activities would generate waste materials, including concrete, metal, and other materials from the dam renovation;

structural metal, concrete, and wood from demolished bridges and buildings; concrete and asphalt from relocated boat launch facilities; unusable recreation equipment from relocated campgrounds and picnic areas; cables, pumps, wiring, and power towers from utility relocations; and scrap material generated as a byproduct of construction. Demolition and construction waste for CP1 would total about 176,627 cubic yards. Reclamation's contractors will take measures to recycle or reuse demolished materials, such as steel or copper wire, where practical. Therefore, some of the demolition and construction waste would be brought to nearby recycling facilities. Hazardous materials (e.g., asbestos, if found) would be brought to an approved hazardous waste landfill for disposal. Much of the underground utilities and service systems proposed for abandonment would be abandoned in place and would not be removed to a landfill or recycling facility.

Table 21-1 provides a summary of project-generated solid waste for the five action alternatives.

Table 21-1. Waste Generated by Project Construction

Feature	Estimated Volume (cubic yards)		
	CP1	CP2	CP3, CP4, CP5
Vehicle bridge replacements	10,700	10,700	10,700
Doney Creek UPRR bridge replacement	4,718	4,718	7,334
Sacramento River UPRR second crossing	15,558	15,558	15,558
Pit River Bridge piers 3 and 4 protection	0	0	0
Railroad realignment	2,420	2,420	2,420
Major road relocations	10,980	20,659	23,516
Reservoir area utilities (removals/relocations)	1,364	3,251	4,070
Reservoir area recreation (removals/relocations)	99,240	102,076	105,220
Main dam	2,263	1,553	1,553
Outlet works	388	388	388
Spillway	18,305	16,590	12,765
Temperature control device modification	20	20	20
Powerplant and penstocks	0	0	0
Right wing dam	531	511	511
Left wing dam	8,630	8,630	8,630
Visitor Center Replacement	1,510	1,510	1,510
Reservoir area dikes	0	0	0
Pit 7 modifications	0	0	0
Total	176,627	188,584	194,195

Key:
CP = Comprehensive Plan
UPRR = Union Pacific Railroad

Two landfills are currently operational in Shasta County: the West Central Landfill and the Anderson Landfill. The West Central Landfill, in the City of Redding, is the closest facility to Shasta Dam and would likely receive the majority of solid waste generated during construction. This landfill has sufficient permitted capacity to accommodate solid waste disposal needs during construction of the project. CP1 would generate roughly 176,627 cubic yards of solid waste; however, the West Central Landfill has a remaining capacity of approximately 5,000,000 cubic yards, and the Anderson Landfill has a remaining capacity of approximately 11,000,000 cubic yards. Recycling of demolition and construction waste materials would further reduce the volume of waste disposed at landfills.

Three commercial hazardous waste landfills operate in Southern California. Utilities poles, materials containing asbestos or lead-based paints, and transformers containing polychlorinated biphenyls would be sent to one of these landfills or to another EPA-permitted hazardous waste facility.

Solid waste generated by the project would be a short-term impact. Furthermore, accepting the project waste would not impair solid waste facilities that would serve the project. Therefore, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-4 (CP1): Increases in Solid Waste Generation from Increased Recreational Opportunities Project implementation could result in more recreationists in and around Shasta Lake, on streams near Shasta Lake, and along the upper Sacramento River, which could cause incremental increases in the amount of solid waste generated. However, multiple landfills are located throughout the region with adequate capacity for disposal of solid waste generated from implementation of the project. Therefore, this impact would be less than significant.

Implementation of the project could increase and enhance recreational opportunities in and around Shasta Lake, on streams near Shasta Lake, and along the upper Sacramento River. Additional recreationists could incrementally increase the amount of solid waste generated. Multiple landfills, including the West Central Landfill, the Anderson Landfill, and the Tehama County/Red Bluff Landfill, are located in the project region and have a substantial amount of available capacity. Private transfer stations are located throughout the region as well. These multiple facilities have adequate capacity for disposal of solid waste generated by implementation of the project (CIWMB 2008). Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-5 (CP1): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply It is reasonable to assume that the increased water supply expected under this alternative would increase demand for construction and operation of water treatment and distribution

facilities within the CVP service area. No information is currently available about future water facilities that might be built in response to the expected increase in water supply. Therefore, it is not possible to evaluate the environmental effects of building and operating such facilities. Such an evaluation would be remote and speculative and, therefore, is not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Util-6 (CP1): Damage or Disruption of Public Utility and Service Systems Infrastructure Construction would not occur outside of the primary study area; therefore, there would be no impact related to temporary disruption of utilities during construction in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-7 (CP1): Utility Infrastructure Relocation or Modification
Construction would not occur outside of the primary study area; therefore, there would be no impact related to relocation or modification of utilities infrastructure in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-8 (CP1): Short-Term Increase in Solid Waste Generation
Construction would not occur outside of the primary study area; therefore, there would be no impact related to increases in solid waste generation from construction activities in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-9 (CP1): Increases in Solid Waste Generation from Increased Recreational Opportunities Increased recreational opportunities resulting from project implementation would not occur outside of the primary study area; therefore, no impacts related to increases in solid waste generation from increased recreational opportunities would occur in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-10 (CP1): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply It is reasonable to assume that the increased water supply expected under this alternative would increase demand for construction and operation of water treatment and distribution facilities within the extended study area. No information is currently available about future water facilities that might be built in response to the expected increase in water supply. Therefore, it is not possible to evaluate the environmental effects of building and operating such facilities. Such an evaluation would be remote and speculative and, therefore, is not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP2 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact Util-1 (CP2): Damage or Disruption of Public Utility and Service Systems Infrastructure Project implementation could damage public utilities and service systems infrastructure, which could result in short-term disruptions of service. The potential exists for construction activities to damage or interfere with utilities and service systems infrastructure and, thus, service, during construction operations. Construction activities would occur in areas proposed for abandonment of utilities or service systems, and implementation of relocation projects could require disruption of public utilities or services to accommodate construction activity. This impact would be potentially significant.

This impact would be similar to Impact Util-1 (CP1). An increase in the height of the dam could result in a larger area of inundation and additional infrastructure and service systems construction activities. Construction activities for CP2 would take longer than for CP1 and would extend the duration of impacts resulting from CP2. CP2 would require the relocation of approximately 5,000 more feet of power lines, about 2,000 more feet of telecommunications lines, and take approximately 12 more months than CP1. Additional service systems would need to be demolished and/or relocated for CP2.

Project implementation could damage public utilities and service systems infrastructure, or result in short-term disruption of utilities and service systems service. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-2 (CP2): Utility Infrastructure Relocation or Modification Project implementation would require relocation or modification of utilities infrastructure, which could result in localized impacts on vegetation, land use, transportation, wildlife, noise, water quality, and utility service. This impact would be potentially significant.

This impact would be similar to Impact Util-2 (CP1). An increase in the height of the dam could result in a larger area of inundation, which would result in additional relocation or modification of utilities infrastructure compared to Util-1 (CP1). Construction activities for CP2 would take longer than for CP1 and would extend the duration of impacts resulting from CP2. CP2 would require the relocation of approximately 5,000 more feet of powers lines and associated transmission facilities, relocation of about 2,000 more feet of telecommunications lines and associated facilities, and take approximately 8

more months than CP1. Additional vegetation clearing would also be required to accommodate relocation of infrastructure.

Project implementation could result in localized impacts on vegetation, land use, transportation, wildlife, noise, water quality, and utilities service. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-3 (CP2): Short-Term Increase in Solid Waste Generation Project implementation would result in a short-term increase of solid waste generation during construction activities. The project would not generate construction waste materials that would exceed the capacity of local landfills. This impact would be less than significant.

This impact would be similar to Impact Util-3 (CP1). An increase in the height of the dam would result in a larger area of inundation, which could result in a greater potential for generation of construction waste materials compared to Impact Util-1 (CP1). CP2 would generate roughly 188,584 cubic yards of solid waste (see Table 21-1). Similar to CP1, the anticipated increase in the amount of solid waste generated during construction of this alternative would still be sufficiently handled by the three local landfills and permitted hazardous waste landfills. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-4 (CP2): Increases in Solid Waste Generation from Increased Recreational Opportunities Project implementation could result in more recreationists around Shasta Lake, on streams near Shasta Lake, and along the upper Sacramento River, in which could cause incremental increases in the amount of solid waste generated. However, multiple landfills are located throughout the region with adequate capacity for disposal of solid waste generated from implementation of the project. Therefore, this impact would be less than significant.

This impact would be similar to Impact Util-4 (CP1). An increase in the height of the dam could result in a larger area of inundation, which could result in more recreationists and greater potential for generation of solid waste materials than with Impact Util-1 (CP1). The anticipated increase in the amount of construction waste generated during long-term operation of this alternative is expected to be sufficiently handled by the three local landfills, which have a substantial amount of available capacity. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-5 (CP2): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Similar to CP1, it is reasonable to assume that the increased water supply expected under CP2 would increase demand for construction and operation of water treatment and distribution facilities. However, evaluation of the environmental effects of

building and operating such facilities would be remote and speculative and, therefore, is not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Util-6 (CP2): Damage or Disruption of Public Utility and Service Systems Infrastructure Construction would not occur outside of the primary study area; therefore, there would be no impact related to temporary disruption of utilities service during construction in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-7 (CP2): Utility Infrastructure Relocation or Modification Construction would not occur outside of the primary study area; therefore, there would be no impact related to relocation or modification of utilities infrastructure in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-8 (CP2): Short-Term Increase in Solid Waste Generation Construction would not occur outside of the primary study area; therefore, there would be no impact related to increases in solid waste generation from construction activities in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-9 (CP2): Increases in Solid Waste Generation from Increased Recreational Opportunities Increased recreational opportunities resulting from project implementation would occur only in the primary study area; therefore, no impacts related to increases in solid waste generation from increased recreational opportunities would occur in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-10 (CP2): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Similar to CP1, it is reasonable to assume that the increased water supply expected under CP2 would increase demand for construction and operation of water treatment and distribution facilities within the extended study area. However, evaluation of the environmental effects of building and operating such facilities would be remote and speculative and, therefore, is not provided in this document.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply
Shasta Lake and Vicinity/Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP3 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact Util-1 (CP3): Damage or Disruption of Public Utility and Service Systems Infrastructure Project implementation could damage public utilities and service systems infrastructure, which could result in short-term disruptions

of service. The potential exists for construction activities to damage or interfere with utilities and service systems infrastructure and, thus, service during construction operations. Construction activities would occur in areas proposed for abandonment and relocation of utilities or service systems. Project implementation could require disruption of public utilities or services to accommodate construction activity. This impact would be potentially significant.

This impact would be similar to Impact Util-1 (CP1). An increase in the height of the dam could result in a larger area of inundation and additional infrastructure and service systems construction activities. Construction activities for CP3 would take longer than for CP1 and would extend the duration of impacts resulting from CP3. CP3 would require the relocation of approximately 7,500 more feet of power lines and about 5,000 more feet of telecommunications lines and take approximately 24 more months than CP1. Additional service systems would need to be demolished and/or relocated for CP3 to prevent inundation.

Project implementation could damage public utility and service systems infrastructure, or result in short-term utility and service systems service. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-2 (CP3): Utility Infrastructure Relocation or Modification Project implementation would require relocation or modification of utility infrastructure, which could result in localized impacts on vegetation, land use, transportation, wildlife, noise, water quality, and utility service. This impact would be potentially significant.

This impact would be similar to Impact Util-2 (CP1). An increase in the height of the dam could result in a larger area of inundation, which would result in additional relocation or modification of utility infrastructure compared to Impact Util-1 (CP1). Construction activities for CP3 would take longer than for CP1 and would extend the duration of impacts resulting from CP3. CP3 would require the relocation of approximately 7,500 more feet of power lines and associated transmission facilities and about 5,000 more feet of telecommunications lines and associated facilities; CP3 would take approximately 24 more months than CP1 to implement. Additional vegetation clearing would also be required to accommodate infrastructure relocation.

Project implementation could result in localized impacts on vegetation, land use, transportation, wildlife, noise, water quality, and utility service. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-3 (CP3): Short-Term Increase in Solid Waste Generation Project implementation would result in a short-term increase of solid waste generation

during construction activities. The project would not generate construction waste materials that would exceed the capacity of local landfills. This impact would be less than significant.

This impact would be similar to Impact Util-3 (CP1). An increase in the height of the dam would result in a larger area of inundation, which could result in a greater potential for generation of construction waste materials compared to Impact Util-1 (CP1). CP3 would generate roughly 194,195 cubic yards of solid waste (see Table 21-1). Similar to CP1, the anticipated increase in the amount of solid waste generated during construction of this alternative would still be sufficiently handled by the three local landfills and permitted hazardous waste landfills. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-4 (CP3): Increases in Solid Waste Generation from Increased Recreational Opportunities Project implementation could result in more recreationists in and around Shasta Lake, on streams near Shasta Lake, and along the upper Sacramento River, creating incremental increases in the amount of solid waste generated. However, multiple landfills are located throughout the region with adequate capacity for disposal of solid waste generated from implementation of the project. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to Impact Util-4 (CP1). An increase in the height of the dam could result in a larger area of inundation, which could result in more recreationists and greater potential for generation of solid waste materials compared to Impact Util-1 (CP1). The anticipated increase in the amount of solid waste generated during long-term operation of this alternative would be handled by the three local landfills and permitted hazardous waste landfills. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-5 (CP3): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Similar to CP1, it is reasonable to assume that the increased water supply expected under CP3 would increase demand for construction and operation of water treatment and distribution facilities. However, evaluation of the environmental effects of building and operating such facilities would be remote and speculative and, therefore, is not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta/CVP/SWP Service Areas

Impact Util-6 (CP3): Damage or Disruption of Public Utility and Service Systems Infrastructure Construction would not occur outside of the primary study area; therefore, there would be no impact related to temporary disruption of utilities service during construction in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-7 (CP3): Utility Infrastructure Relocation or Modification Construction would not occur outside of the primary study area; therefore, there would be no impact related to relocation or modification of utilities infrastructure in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-8 (CP3): Short-Term Increase in Solid Waste Generation Construction would not occur outside of the primary study area; therefore, there would be no impact related to increases in solid waste generation from construction activities in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-9 (CP3): Increases in Solid Waste Generation from Increased Recreational Opportunities Increased recreational opportunities resulting from project implementation would occur only in the primary study area; therefore, no impacts related to increases in solid waste generation from increased recreational opportunities would occur in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-10 (CP3): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Similar to CP1, it is reasonable to assume that the increased water supply expected under CP3 would increase demand for construction and operation of water treatment and distribution facilities within the extended study area. However, evaluation of the environmental effects of building and operating such facilities would be remote and speculative and, therefore, is not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP2 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact Util-1 (CP4): Damage or Disruption of Public Utility and Service Systems Infrastructure Project implementation could damage public utilities and service systems infrastructure, which could result in short-term disruptions of service. The potential exists for construction activities to damage or interfere with utilities and service systems infrastructure and, thus, service during construction operations. Construction activities would occur in areas proposed for utilities or service systems abandonment and relocation. Project implementation could require disruption of public utilities or services to accommodate construction activity. This impact would be potentially significant.

This impact would be similar to Impact Util-1 (CP1) and identical to Impact Util-1 (CP3). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-2 (CP4): Utility Infrastructure Relocation or Modification Project implementation would require relocation or modification of utilities infrastructure, which could result in localized impacts on vegetation, land use, transportation, wildlife, noise, water quality, and utility service. This impact would be potentially significant.

This impact would be similar to Impact Util-2 (CP1) and identical to Impact Util-2 (CP3). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-3 (CP4): Short-Term Increase in Solid Waste Generation Project implementation would result in a short-term increase of solid waste generation during construction activities. The project would not generate construction waste materials that would exceed the capacity of local landfills. This impact would be less than significant.

This impact would be similar to Impact Util-3 (CP3), with a very slight increase in solid waste generation related to downstream restoration construction activities. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-4 (CP4): Increases in Solid Waste Generation from Increased Recreational Opportunities Project implementation could result in more recreationists in and around Shasta Lake, on streams near Shasta Lake, and along the upper Sacramento River, which could cause incremental increases in the amount of solid waste generated. However, multiple landfills are located throughout the region with adequate capacity for disposal of solid waste generated from project implementation. Therefore, this impact would be less than significant.

This impact would be similar to Impact Util-4 (CP1) and identical to Impact Util-4 (CP3). Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-5 (CP4): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Similar to CP1, it is reasonable to assume that the increased water supply expected under CP4 would increase demand for construction and operation of water treatment and distribution facilities. However, evaluation of the environmental effects of building and operating such facilities would be remote and speculative and, therefore, is not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Util-6 (CP4): Damage or Disruption of Public Utility and Service Systems Infrastructure Construction would not occur outside of the primary study area. Gravel augmentation and the Reading Island habitat restoration along the upper Sacramento River would slightly, but not substantially, increase the potential for temporary disruption of utilities service. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-7 (CP4): Utility Infrastructure Relocation or Modification No utility infrastructure relocation or modification would occur outside of the primary study area; therefore, there would be no impact related to relocation or modification of utilities infrastructure in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-8 (CP4): Short-Term Increase in Solid Waste Generation Construction would not occur outside of the primary study area. Gravel augmentation and the Reading Island habitat restoration along the upper Sacramento River would generate a nominal amount of solid waste. However, substantial landfill capacity is available to accommodate solid waste generated by these activities. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-9 (CP4): Increases in Solid Waste Generation from Increased Recreational Opportunities Increased recreational opportunities resulting from project implementation would occur only in the primary study area; therefore, no impacts related to increases in solid waste generation from increased recreational opportunities would occur in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-10 (CP4): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Similar to CP1, it is reasonable to assume that the increased water supply expected under CP4 would increase demand for construction and operation of water treatment and distribution facilities within the extended study area. However, evaluation of the environmental effects of building and operating such facilities would be remote and speculative and is, therefore, not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan
Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP2 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together, because impacts from construction activities would affect both study areas.

Impact Util-1 (CP5): Damage or Disruption of Public Utility and Service Systems Infrastructure Project implementation could damage public utilities

and service systems infrastructure, which could result in short-term disruptions of service. The potential exists for construction activities to damage or interfere with utilities and service systems infrastructure and, thus, service during construction operations. Construction activities would occur in areas proposed for abandonment and relocation of utilities or service systems. Project implementation could require disruption of public utilities or services to accommodate construction activity. This impact would be potentially significant.

This impact would be similar to Impact Util-1 (CP1) and identical to Impact Util-1 (CP3). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-2 (CP5): Utility Infrastructure Relocation or Modification Project implementation would require relocation or modification of utilities infrastructure, which could result in localized impacts on vegetation, land use, transportation, wildlife, noise, water quality, and utility service. This impact would be potentially significant.

This impact would be similar to Impact Util-2 (CP1) and identical to Impact Util-2 (CP3). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 21.3.5.

Impact Util-3 (CP5): Short-Term Increase in Solid Waste Generation Project implementation would result in a short-term increase of solid waste generation during construction activities. The project would not generate construction waste materials that would exceed the capacity of local landfills. This impact would be less than significant.

This impact would be similar to Impact Util-3 (CP4) , with a very slight increase in solid waste generation related to enhancement of tributary and warm-water habitat and recreational trails. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-4 (CP5): Increases in Solid Waste Generation from Increased Recreational Opportunities Project implementation could result in more recreationists in and around Shasta Lake, on streams near Shasta Lake, and along the upper Sacramento River, which could cause incremental increases in the amount of solid waste generated. However, multiple landfills are located throughout the region with adequate capacity for disposal of solid waste generated from implementation of the project. Therefore, this impact would be less than significant.

This impact would be similar to Impact Util-4 (CP1) and identical to Impact Util-4 (CP3). Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-5 (CP5): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Similar to CP1, it is reasonable to assume that the increased water supply expected under CP5 would increase demand for construction and operation of water treatment and distribution facilities. However, evaluation of the environmental effects of building and operating such facilities would be remote and speculative and, therefore, is not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Util-6 (CP5): Damage or Disruption of Public Utility and Service Systems Infrastructure Construction would not occur outside of the primary study area. Gravel augmentation and the Reading Island habitat restoration along the upper Sacramento River would slightly, but not substantially, increase the potential for temporary disruption of utilities service. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-7 (CP5): Utility Infrastructure Relocation or Modification No utility infrastructure relocation or modification would occur outside of the primary study area; therefore, there would be no impact related to relocation or modification of utilities infrastructure in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-8 (CP5): Short-Term Increase in Solid Waste Generation Construction would not occur outside of the primary study area. Gravel augmentation and the Reading Island habitat restoration along the upper Sacramento River would generate a nominal amount of solid waste. However, substantial landfill capacity is available to accommodate solid waste generated by these activities. This impact is considered less than significant. Mitigation for this impact is not needed, and thus not proposed.

*Impact Util-9 (CP5): Increases in Solid Waste Generation from Increased Recreational Opportunitie*s Increased recreational opportunities caused by project implementation would occur only in the primary study area; therefore, no impacts related to increases in solid waste generation from increased recreational opportunities would occur in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact Util-10 (CP5): Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply Similar to CP1, it is reasonable to assume that the increased water supply expected under CP5 would increase demand for construction and operation of water treatment and distribution facilities within the extended study area. However, evaluation of the environmental effects of building and operating such facilities would be remote and speculative and, therefore, is not provided in this document. Mitigation for this impact is not needed, and thus not proposed.

21.3.5 Mitigation Measures

Table 21-2 presents a summary of mitigation measures for utilities and service systems.

Table 21-2. Summary of Mitigation Measures for Utilities and Service Systems

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Util-1: Damage or Disruption of Public Utility and Service Systems Infrastructure (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	Util-1: Implement Procedures to Avoid Damage to or Temporary Disruption of Service.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Util-2: Utility Infrastructure Relocation or Modification (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	Util-2: Adopt Measures to Minimize Infrastructure Relocation Impacts.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Util-3: Short-Term Increase in Solid Waste Generation (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Util-4: Increases in Solid Waste Generation from Increased Recreational Opportunities (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS

	Mitigation Measure	None required.	None needed; thus none proposed.				
	LOS after Mitigation	N/A	NI	NI	NI	NI	NI
Impact Util-10: Increased Demand for Water Treatment and Distribution Facilities Resulting from Increases in Water Supply (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	N/A	N/A (RS)	N/A (RS)	N/A (RS)	N/A (RS)	N/A (RS)
	Mitigation Measure	None required.	None needed; thus none proposed.				
	LOS after Mitigation	N/A	N/A (RS)	N/A (RS)	N/A (RS)	N/A (RS)	N/A (RS)

Key:
B = beneficial
LOS = level of significance
LTS = less than significant
N/A = not applicable
RS = remote and speculative
NI = no impact
PS = potentially significant
S = significant

No-Action Alternative

No mitigation is required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impact Util-3 and Impact Util-4. Mitigation is provided below for other impacts of CP1 on utilities and service systems.

Mitigation Measure Util-1 (CP1): Implement Procedures to Avoid Damage to or Temporary Disruption of Service To avoid temporary disruption of service, the following measures will be implemented during project construction to ensure that existing utilities infrastructure is not damaged:

- **Permits** – Reclamation will obtain utilities excavation or encroachment permits as necessary before initiating any work with potential to affect utility lines and will include all necessary permit terms in construction contract specifications.

- **Locating Line** – Utility locations will be identified through field surveys and the use of the Underground Service Alert services. Any buried utility lines will be clearly marked before initiation of any ground-disturbing construction activity.

- **Clearing Right-of-Way and Road Access** – If necessary, infrastructure will be removed or reinforced in coordination with all potential service providers known to have, or potentially having, utilities infrastructure in the project area.

- **Response Plan** – The construction contractor will prepare a response plan to address potential accidental damage to utility lines prior to the start of construction. The plan will identify chain of command rules for notification of authorities and appropriate actions and responsibilities to ensure the safety of the public and workers. The response plan will be circulated to the potentially affected service system providers for review and approval prior to the start of construction activities. Worker education training in response to such situations will be conducted by the contractor.

Implementation of this mitigation measure would reduce Impact Util-1 (CP1) to a less than significant level.

Mitigation Measure Util-2 (CP1): Adopt Measures to Minimize Infrastructure Relocation Impacts For each segment of a utility line that would need to be relocated or modified as a result of project construction and operations, the following measures will be implemented:

- **Permits** – Reclamation will obtain utilities excavation or encroachment permits as necessary before initiating any work associated with modification or relocation of an existing utility line and will include all necessary permit terms in construction contract specifications.

- **Locating and Staking Line** – Locations for relocated utility lines will be identified in coordination with affected service providers. As part of this effort, field surveys will be conducted and the Underground Service Alert services will be used to ensure that there are no conflicts with other existing utility lines. After the alignment of the line has been finalized, a survey will be made to map the route of the line. The results of the survey will be plan and profile drawings, which will be used to spot the poles. After exact positions have been fixed, a stake will be driven to indicate the center of the structure or pole.

- **Clearing Right-of-Way and Road Access** – The right-of-way must be cleared of all obstructions that will interfere with the operation of the power line. A strip of land must be cleared on each side of the centerline of the transmission line by cutting or trimming the trees and brush. All trees and brush should be cut 3 inches or less from the ground line so that the passage of trucks and tractors will not be hindered. The cut trees and brush must be disposed of by chipping or spreading, burning, or hauling away. Disposal of the debris by burning, or otherwise, must be accomplished in accordance with State and local laws and regulations without creating a hazard or nuisance. The right-of-way should be treated with chemical spray to retard the growth of brush or trees that could endanger the operation of the transmission line.

- **Installing Pole Footings and Foundations** – Pole sites must be properly graded in accordance with the specifications. Usually the slope of the grade must not be more than 3:1. All topsoil should be removed prior to grading the pole location.

- **Utilities Modification Plan** – The construction contractor will prepare a utilities modification and relocation plan prior to the start of construction. The plan will identify chain of command rules for notification of authorities and appropriate actions and responsibilities to ensure the safety of the public and workers and include a description of how utilities infrastructure will be modified or relocated and identification of precise alignment where utility lines will be relocated. The plan will be circulated to the potentially affected service system providers for review and approval prior to the start of construction activities. Worker education training in response to such situations will be conducted by the contractor.

- The contractor will stage utility line modifications and relocations in a manner that minimizes interruption of service.

- In accordance with the STNF LRMP, relocated power lines less than 35 kV and telephone lines on Forest Service land within the STNF will be buried unless the STNF VQO can be met without burying, geologic conditions make burying infeasible, or burying will produce greater long-term site disturbance.

- **Traffic Control and Safety Assurance Plan** – Reclamation will implement Mitigation Measure Trans-1 as described in PDEIS Chapter 20, "Transportation and Traffic" to reduce adverse effects of road closures and detours or partial road closures on access to local streets and adjacent uses.

Implementation of this mitigation measure would reduce Impact Util-2 (CP1) to a less than significant level.

CP2 - 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impact Util-3 and Impact Util-4. Mitigation is provided below for other impacts of CP2 on utilities and service systems.

Mitigation Measure Util-1 (CP2): Implement Procedures to Avoid Damage to or Temporary Disruption of Service This mitigation measure is identical to Mitigation Measure Util-1 (CP1). Implementation of this mitigation measure would reduce Impact Util-1 (CP2) to a less than significant level.

Mitigation Measure Util-2 (CP2): Adopt Measures to Minimize Infrastructure Relocation Impacts This mitigation measure is identical to Mitigation Measure Util-2 (CP1). Implementation of this mitigation measure would reduce Impact Util-2 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is required for Impact Util-3 and Impact Util-4. Mitigation is provided below for other impacts of CP3 on utilities and service systems.

Mitigation Measure Util-1 (CP3): Implement Procedures to Avoid Damage to or Temporary Disruption of Service This mitigation measure is identical to Mitigation Measure Util-1 (CP1). Implementation of this mitigation measure would reduce Impact Util-1 (CP3) to a less than significant level.

Mitigation Measure Util-2 (CP3): Adopt Measures to Minimize Infrastructure Relocation Impacts This mitigation measure is identical to Mitigation Measure Util-2 (CP1). Implementation of this mitigation measure would reduce Impact Util-2 (CP3) to a less than significant level.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is required for Impact Util-3 and Impact Util-4. Mitigation is provided below for other impacts of CP4 on utilities and service systems.

Mitigation Measure Util-1 (CP4): Implement Procedures to Avoid Damage to or Temporary Disruption of Service This mitigation measure is identical to Mitigation Measure Util-1 (CP1). Implementation of this mitigation measure would reduce Impact Util-1 (CP4) to a less than significant level.

Mitigation Measure Util-2 (CP4): Adopt Measures to Minimize Infrastructure Relocation Impacts This mitigation measure is identical to Mitigation Measure Util-2 (CP1). Implementation of this mitigation measure would reduce Impact Util-2 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impact Util-3 and Impact Util-4. Mitigation is provided below for other impacts of CP5 on utilities and service systems.

Mitigation Measure Util-1 (CP5): Implement Procedures to Avoid Damage to or Temporary Disruption of Service This mitigation measure is identical to Mitigation Measure Util-1 (CP1). Implementation of this mitigation measure would reduce Impact Util-1 (CP5) to a less than significant level.

Mitigation Measure Util-2 (CP5): Adopt Measures to Minimize Infrastructure Relocation Impacts This mitigation measure is identical to Mitigation Measure Util-2 (CP1). Implementation of this mitigation measure would reduce Impact Util-2 (CP5) to a less than significant level.

21.3.6 Cumulative Effects

Cumulative Effects

Past, present, and reasonably foreseeable future projects would generate construction-related solid waste. As discussed in Impacts Util-3, affected landfills have sufficient capacity to accommodate project-generated solid waste, and are also expected to have sufficient capacity to accommodate reasonably foreseeable development in addition to project waste. Therefore, none of the action alternatives would contribute to cumulative effects related to solid waste disposal.

Implementing the proposed SLWRI alternatives would have a significant cumulative effect on utilities and service systems in the primary study area. As discussed above, construction activities associated with CP1 through CP5 could inadvertently damage utilities and public service systems infrastructure. In addition, utilities and service systems could be temporarily disrupted to accommodate construction activities. These effects would be of greater and longer in duration with the larger dam raises. Thus, effects of CP2 would be similar to but greater than those of CP1, and similar to but less than those of

CP3 through CP5. Although Mitigation Measure Util-1 would reduce these effects, the effects would not be eliminated. Given the reasonably foreseeable development actions described previously, utilities and service systems provided by local, State, and Federal agencies within the primary study area could be subject to cumulatively considerable incremental effects resulting from CP1 through CP5. However, these effects would diminish with distance from the project construction sites, and CP1 through CP5 would not have cumulatively considerable effects on utilities and public service systems downstream from Red Bluff (i.e., in the extended study area).

Chapter 22
Public Services

22.1 Affected Environment

This chapter describes the affected environment related to public services for the dam and reservoir modifications proposed under the SLWRI. The public services addressed are fire protection, emergency services, law enforcement, and schools. Utilities, sewer services, and water supply are analyzed in Chapter 21, "Utilities and Service Systems," of this PDEIS.

Because of the potential influence of the proposed modification of Shasta Dam and water deliveries over a large geographic area, the SLWRI includes both a primary study area and an extended study area. The primary study area has been further divided into Shasta Lake and vicinity and upper Sacramento River (Shasta Dam to Red Bluff). The extended study area has been further divided into the lower Sacramento River and Delta and the CVP/SWP service areas.

The public services setting for Shasta Lake and vicinity consists of the portion of Shasta County above Shasta Dam. Public services needs in this region are influenced by rugged, mountainous terrain, rural lakeside communities, and Shasta Lake. The public services setting for the upper Sacramento River study area consists of Shasta County below Shasta Dam and Tehama County. Public services needs in this area are influenced by topography and population densities. Four incorporated cities, City of Shasta Lake, Redding, Anderson, and Red Bluff, create an urban setting in the otherwise rural upper Sacramento Valley, which is characterized by rolling hills with mountains to the north, east, and west.

The public services setting for the extended study area consists of 24 counties downstream from Red Bluff and encompasses all areas served by the CVP and the SWP.

Table 22-1 lists the public service providers considered in this PDEIS.

Table 22-1. Key Public Service Providers

Fire Protection Services
U.S. Forest Service
California Department of Forestry and Fire Protection
Shasta County Fire Department
Tehama County Fire Department
Redding Fire Department
Shasta Lake Fire Protection District
Anderson Fire Protection District
Red Bluff Fire Department
Corning Volunteer Fire Department
Emergency Services
California Highway Patrol
California Office of Emergency Services

Tehama County Sheriff's Department
Shasta Area Safety Communications Agency
Law Enforcement
U.S. Forest Service
California Highway Patrol
California Department of Fish and Game
Shasta County Sheriff's Office
Tehama County Sheriff's Department
Red Bluff Police Department
Corning Police Department
Schools
Gateway Unified School District

22.1.1 Fire Protection Services

Fire protection services consist of fire suppression, emergency dispatching, specialized training, fire prevention, fire safety education, and emergency medical response.

Shasta Lake and Vicinity

The Shasta County Fire Department (SCFD) and the California Department of Forestry and Fire Protection (CDF) respond to nonwildland fires in the Shasta Lake and vicinity portion of the primary study area. Nonwildland fires consist of structural, chemical, petroleum, electrical, vehicle, and other fires that involve human-made materials. CDF and the USFS are responsible primarily for wildland fires, which consist of fires in vegetated areas such as forests, chaparral, and grassland.

CDF and USFS generally respond according to established jurisdictional boundaries. However, a fire protection agreement between CDF and USFS provides for the sharing of fire protection resources to augment the capabilities of each agency (USFS 1995). In practice, SCFD, CDF, and USFS provide mutual assistance when needed.

The National Interagency Fire Center, located in Boise, Idaho, assists with wildland fire suppression nationwide. The center is a collaboration among seven Federal agencies: the Bureau of Indian Affairs, the Bureau of Land Management, USFS, USFWS, the National Park Service, the National Weather Service, and the Office of Aircraft Services. These agencies work together to coordinate and support wildland fire and disaster operations. CDF and the California Office of Emergency Services (OES) work closely with these agencies to manage wildland fire operations.

Upper Sacramento River (Shasta Dam to Red Bluff)

Fire protection services in the upper Sacramento River study area are similar to those in the Shasta Lake and vicinity portion of the primary study area. SCFD and the Tehama County Fire Department (TCFD) are responsible primarily for nonwildland fires, and CDF and USFS respond primarily to wildland fires.

In Shasta County, the Redding Fire Department, SCFD, and CDF have mutual automatic aid agreements to ensure adequate fire protection services and to share resources. Under these agreements, the agencies respond automatically to emergencies in Shasta County that are in adjacent jurisdictions.

Fire departments serving the unincorporated areas of Shasta County include one SCFD station that is housed in Redding, 12 community fire districts, and 19 volunteer fire companies. CDF operates several fire stations during the off-season winter months through an agreement with local fire departments. The community fire districts operate autonomously; the remaining fire departments, fire stations, and the Shasta County Fire District fall under the jurisdiction of SCFD.

The City of Shasta Lake, Redding, and Anderson are incorporated cities in Shasta County. Fire protection in Redding is provided by the Redding Fire Department, which has eight fully equipped stations and 72 full-time employees. The City of Shasta Lake provides fire protection supported by three fire stations with 27 employees. The Anderson Fire Protection District provides service to Anderson and operates two fire stations with 15 employees.

Shasta and Tehama counties share fire protection resources along their shared county line through a mutual automatic aid agreement. Like

SCFD, TCFD has mutual automatic aid agreements with local fire protection agencies that operate in the county. One difference between Shasta and Tehama counties is the level of integration with CDF: TCFD is fully integrated with CDF, which administers fire protection services in all unincorporated areas of the county except for the areas covered by the Gerber and Capay Fire Protection Districts.

TCFD provides fire protection services for the citizens of Tehama County through a network of 16 fire stations and 15 volunteer fire companies. Five of the stations, Los Molinos, Corning, Bowman, El Camino, and Antelope, are staffed 24 hours a day year around. The distribution of stations places most residents of Tehama County within 5 road miles of a responding fire station.

Red Bluff and Corning are incorporated cities in Tehama County; both cities provide fire protection services for their residents. Fire protection in Red Bluff is provided by the Red Bluff Fire Department. The Corning Volunteer Fire Department, which employs full-time staff assisted by volunteers, provides fire protection for the incorporated area of Corning.

Other fire protection services in Tehama County include the Gerber Fire Protection District, Lassen Volcanic National Park, Capay Fire Protection District, and Cottonwood Fire Protection District.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Fire protection services in the extended study area are similar to those discussed for the primary study area. However, urban population densities are higher in parts of the extended study area, which influences the types and extent of fire protection services provided. Cities and counties in the extended study area provide fire protection services primarily for nonwildland fires, and CDF and USFS provide fire protection services primarily for wildland fires.

22.1.2 Emergency Services

Emergency services consist of emergency preparation, response, and recovery efforts. Emergencies range from calls for medical assistance to individuals to large-scale disasters, such as evacuations resulting from wildland fires and floods.

Shasta Lake and Vicinity

The Shasta County Sheriff's Office (SCSO) is responsible for coordinating emergency services on Shasta Lake and in the unincorporated areas of Shasta County upstream from Shasta Dam. Large scale emergency services are handled by SCSO in cooperation with the State emergency response network run by OES. As of 1996, OES has designated emergency service "Operational Areas" for all California counties, cities, and special districts (e.g., school, water, and

waste reclamation districts). Shasta Lake and vicinity is located in the Region 3 Operational Area, which consists of 12 Northern California counties. Emergency services providers could be called on to assist with emergencies that occur in their designated region and to assist the Central and South emergency services regions. CDF, USFS, the Federal Emergency Management Agency, and the American Red Cross also provide assistance in large-scale emergencies.

SCSO provides emergency services, including patrol boats and deputies, at Shasta Lake from a substation at Bridge Bay Marina. Medical aid is provided by Shasta County fire departments and private ambulance companies, including land and air ambulance services, based in the Redding area.

Upper Sacramento River (Shasta Dam to Red Bluff)

Emergency services in the upper Sacramento River area are similar to those described in the previous section. SCSO is responsible for coordinating emergency services in the Shasta County portion of the upper Sacramento River study area, and Tehama County Sheriff's Department is responsible for coordinating emergency services in the Tehama County portion. Both county agencies coordinate emergency services with OES and serve as the emergency services headquarters during declared public emergencies.

A number of emergency services agencies in Shasta County have formed a joint-powers agency, called the Shasta Area Safety Communications Agency, to consolidate emergency services related to fire, medical services, and law enforcement. Current participants include the Redding Fire Department, the Redding Police Department, and SCSO. American Medical Response, Redding Medical Center, and Mercy Medical Center in Redding participate in the Shasta Area Safety Communications Agency under a contractual agreement for ambulance services. Emergency medical response is also provided by St. Elizabeth Community Hospital in Red Bluff.

The Tehama County Sheriff's Department is responsible for emergency services coordination in Tehama County. In addition, TCFD responds to some medical emergencies in Tehama County.

The California Highway Patrol (CHP), Northern Division, provides ground and air support for emergencies along the Interstate 5 (I-5) corridor and State highways throughout the primary study area. CHP maintains two A-star helicopters and two Cessna airplanes that are used to assist other agencies with search and rescue and fire response. In addition, CHP assists with traffic control during emergencies.

Emergency services in the upper Sacramento River area are also supplemented by CDF, USFS, the Federal Emergency Management Agency, and the American Red Cross.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Emergency services in the extended study area are similar to those discussed for the primary study area. Cities and counties in the extended study area are primarily responsible for providing emergency services, and receive assistance from regional, State, and Federal agencies for emergencies that require resources beyond the capability of the local jurisdiction.

22.1.3 Law Enforcement

Law enforcement services consist of crime prevention, investigation, and apprehension of lawbreakers and include duties to keep the peace and protect life and property. Law enforcement agencies often enter into cooperative aid agreements with neighboring or overlapping law enforcement jurisdictions to consolidate resources and facilitate communication.

Shasta Lake and Vicinity

Law enforcement services in the Shasta Lake and vicinity portion of the primary study area are provided by SCSO, CHP, DFG, and USFS. In general, the nature of an offense or law enforcement duty establishes jurisdiction. SCSO has primary responsibility for conflicts between people and most violations of State law, CHP handles most traffic violations, DFG enforces State fish and game laws, and USFS handles violations of Federal law.

Agencies responsible for law enforcement on Shasta Lake and the surrounding area carry out their duties from several locations. SCSO operates a substation in the City of Shasta Lake with nine assigned deputies and another substation in Lakehead with two resident deputies. Because of the nature and volume of human activity around Shasta Lake, SCSO also maintains a substation at Bridge Bay Marina, located on the main dock above the store. SCSO boat dock is located on the main dock near the substation. Services provided by SCSO include search and rescue, safety patrol boats, boating safety education, emergency services, and animal control.

USFS uses Federal law enforcement officers with jurisdiction on Federal lands. USFS does not assume the Sheriff's responsibilities; instead, it enforces the Federal codes that govern public behavior on lands managed by USFS. The DFG Northern District enforcement unit is based in Redding and provides law enforcement related to State fish and game laws in Shasta, Trinity, and Tehama counties.

Traffic law enforcement along I-5, State routes, and State highways is provided primarily by the Northern Division of the CHP. The CHP operates several offices in the primary study area, including offices in Redding and Red Bluff.

Upper Sacramento River (Shasta Dam to Red Bluff)

SCSO provides law enforcement services for the unincorporated areas of Shasta County. County law enforcement operations are based in Redding. Sheriff substations are located in Burney, the City of Shasta Lake, and Shingletown. The incorporated cities of Redding and Anderson provide law enforcement services for their residents.

The Tehama County Sheriff's Department office is located in Red Bluff. The sheriff is the chief law enforcement officer of Tehama County, with jurisdiction throughout the unincorporated county, the incorporated cities, and State-owned property. The incorporated cities of Red Bluff and Corning provide law enforcement services for their residents.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Law enforcement services in the extended study area are similar to those discussed for the primary study area. Counties maintain sheriff's departments that have jurisdiction within the county boundaries, and incorporated cities maintain police departments that have jurisdiction within the city limits. However, urban population densities are higher in parts of the extended study area, which influences the types and extent of law enforcement services provided.

22.1.4 Schools

School districts are autonomous entities responsible for providing educational services for elementary, middle school, and high school students. Districts elect their own governing boards and appoint their own superintendents. County offices of education assist the school districts with administrative and curricular support.

Shasta Lake and Vicinity

There are no schools located in the Shasta Lake and vicinity portion of the primary study area. The Gateway Unified School District serves residents in this area and previously operated Canyon Elementary in Lakehead. This school, however, is currently closed.

Upper Sacramento River (Shasta Dam to Red Bluff)

School districts in the upper Sacramento River area serve students in levels kindergarten through grade 12. Shasta County is served by 25 school districts, and Tehama County is served by 21 school districts. The California Community College system provides continuing education services at locations in Shasta County and Tehama County.

Simpson University, located in Redding, also provides college-level educational services.

The Gateway Unified School District operates several schools in Shasta Lake and Redding. Mountain Lakes High School (grades 10 through 12) and Shasta Lake Alternative School (kindergarten through grade 12) are located at the northeast corner of the intersection of Lake Boulevard and Shasta Dam Boulevard.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Educational services in the extended study area are similar to those discussed for the primary study area. Cities and counties form school districts to provide educational services for children between 6 and 18 years of age. Numerous community colleges and 4-year colleges and universities are also located in the extended study area. Urban population densities are higher in parts of the extended study area, which may influence the variety of educational services provided.

22.2 Regulatory Framework

22.2.1 Federal

Shasta-Trinity National Forest Land and Resource Management Plan

USFS personnel conduct their responsibilities for regulating the use of and protecting National Forest lands under Title 36 and sections of Title 16, 18, and 21 of the Code of Federal Regulations. Public services directives from the code are integrated into the Shasta-Trinity National Forest Land and Resource Management Plan (LRMP), which includes the following topics: fire and fuels management, facilities management, law enforcement, and land management.

The LRMP identifies goals, standards, and guidelines related to public services in Shasta-Trinity National Forest. The following goals, standards, and guidelines related to public services in Shasta-Trinity National Forest were excerpted from the LRMP (USFS 1995).

Fire and Fuels Goals (LRMP, p. 4-4):

- Achieve a balance of fire suppression capability and fuels management investments that are cost effective and able to meet ecosystem objectives and protection responsibilities.

Fire and Fuels Standards and Guidelines (LRMP, p 4-17):

- Wildland fires will receive an appropriate suppression response that may range from confinement to control. Unless a different suppression response is authorized in this plan, or subsequent

approved plans, all suppression responses will have an objective of "control."

- All wildland fires, on or threatening private land protected by agreement with the State of California, will receive a "control" suppression response.

- Fire prevention efforts will be designed to minimize human-caused wildfires commensurate with the resource values at risk.

Facilities Goals (LRMP, p. 4-4):

- Provide and maintain those administrative facilities that effectively and safely serve the public and USFS workforce.

Facilities Standards and Guidelines (LRMP, p 4-17):

- Manage, construct, and maintain buildings and administrative sites to meet applicable codes and to provide the necessary facilities to support resource management.

- Closure of roads and/or selected areas to assist in management of Forest resources may be made by regulatory and/or physical devices on the road for the following purpose[s]: safety, fire, and general administrative purposes.

Law Enforcement Goals (LRMP, p. 4-5):

- Establish priority in law enforcement activities as follows: (a) provide for employee and public safety, (b) protect resources and property, (c) provide for the accomplishment of management objectives, and (d) prevent violation of laws and associated loss and damage.

Law Enforcement Standards and Guidelines (LRMP, p 4-21):

- Protect the public interest by a thorough and aggressive program of violation prevention, violation detection, investigation and apprehension of violators, and prosecution.

22.2.2 State

Standardized Emergency Management Systems

The Standardized Emergency Management Systems law (Govt. Code 8607) directs OES to establish, implement, and maintain a coordinated emergency response system. The California Mutual Aid Agreement defines responsibilities and resource sharing between agencies to ensure that adequate resources, facilities, and other support are provided to jurisdictions when their own resources are insufficient to cope with the needs of a given emergency.

California Education Code

The California Education Code provides educational goals and requirements for the educational providers in the State (California Code of Regulations Title 5). It governs school district formation and operation, county board of education authorities and responsibilities, and educational criteria for children between 6 and 18 years of age.

California Fire Plan

The California Fire Plan provides guidance for reducing the risk of wildfire. The basic principles of the fire plan are:

- Community involvement
- Community risk assessment
- Development of solutions and implementation of projects

22.2.3 Regional and Local

Shasta County

The Shasta County General Plan (Shasta County 2004) identifies goals, objectives, and policies related to public services in Shasta County. Fire protection and law enforcement services are discussed in the section titled "Fire Safety and Sheriff Protection." Schools are discussed in the section titled "Public Facilities."

Tehama County

The Tehama County General Plan Update (Tehama County 2009) identifies goals, objectives, and policies for public services in Tehama County. The public services element of the general plan addresses concerns associated with growth and development as they relate to public services including schools. The safety element addresses potential dangers and damages associated with fire, floods, earthquakes, landslides, and other hazards.

22.3 Environmental Consequences and Mitigation Measures

22.3.1 Methods and Assumptions

This chapter addresses potential impacts associated with implementation of the project on the following public services: law enforcement, fire protection, emergency services, and schools. The analysis is based on a review of planning documents applicable to the project area, consultation with various agencies, and field reconnaissance.

22.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with the NEPA must consider the context and intensity of the environmental effects that

would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with the CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines and consider the context and intensity of the environmental effects as required under NEPA. An alternative was determined to result in a significant impact related to public services if it would do any of the following:

- Interfere with emergency services
- Degrade the level of service of a public service
- Require relocating public service facilities
- Require substantial improvements to the facilities or level of staffing of a public service to maintain its existing level of service

22.3.3 Topics Eliminated from Further Consideration

No topics were eliminated from consideration.

22.3.4 Direct and Indirect Effects

No-Action Alternative

The impact discussion for the No-Action Alternative addresses all of the study areas together because this alternative would not affect land use in any of the study areas. It also addresses the Lower Sacramento River and Delta study area and the CVP/SWP Service Areas together because their distance from the project area results in similar impacts.

Shasta Lake and Vicinity, Upper Sacramento River (Shasta Dam to Red Bluff), Lower Sacramento River and Delta, and CVP/SWP Service Areas

Impact PS-1 (No-Action): Disruption of Public Services Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas, and no changes in Reclamation's existing facilities or operations would occur that would directly or

indirectly result in the disruption of public services in the project area. Therefore, there would be no impact related to the disruption of public services associated with the No-Action Alternative. Mitigation is not required for the No-Action Alternative..

Impact PS-2 (No-Action): Degraded Level of Public Services Under the No-Action Alternative, no new facilities or infrastructure would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in degraded levels of public services in the project area. Therefore, there would be no impact related to degraded levels of public services associated with the No-Action Alternative. Mitigation is not required for the No-Action Alternative.

Impact PS-3 (No-Action): Relocation of Public Service Facilities
Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in the relocation of public service facilities in the project area. Therefore, there would be no impact on public services related to the relocation of infrastructure for public service facilities associated with the No-Action Alternative. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The impact discussion for CP1 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together because impacts from construction activities would affect both study areas. It also addresses the Lower Sacramento River and Delta study area and the CVP/SWP Service Areas together because their distance from the project area results in similar impacts.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact PS-1 (CP1): Short-Term Disruption of Public Services
Construction activities associated with enlarging Shasta Dam and related infrastructure (e.g., road relocations, bridge replacements) near the dam and near relocation sites for utilities, roads, and structures could temporarily disrupt transportation and circulation patterns in the vicinity, which could affect emergency services response and school bus service. Emergency preparedness, emergency communications, and emergency supplies, including food and shelter for emergency crews and public services staff, could also be affected by project implementation because of temporary increases in the work force.

Direct impacts could include disruption of traffic flows and street operations through temporary lane closures, detours, blockages, and restrictions on curbside parking; these impacts could result in delays for emergency services vehicles and school buses traveling through or around construction zones. In addition, project construction could cause short-term interruptions in power and telecommunications services, which could affect emergency response capabilities in the primary study area.

Construction activities that could disrupt emergency services and school bus service in the primary study area include road and bridge replacement, telecommunications facility replacement, power facility replacement, vegetation clearing for utility relocation, structure removal, and emergency services facility relocation. Reclamation estimates that construction activities for CP1 would take 36 months.

Routes proposed for transporting construction materials to the dam consist of I-5 and local roads, particularly Shasta Dam Boulevard and Lake Boulevard. These routes are used primarily by Reclamation personnel to access the Shasta Dam facilities, by visitors and tourists, and by residents of the City of Shasta Lake. At this time, there are no detours or lane closures proposed for the portions of Shasta Dam Boulevard and Lake Boulevard that serve the City of Shasta Lake. Road closures would likely be required adjacent to the facilities in the immediate vicinity of Shasta Dam and Reclamation's Northern California Area Office.

The Gateway Unified School District covers Shasta Lake and vicinity and portions of the upper Sacramento River area. Project construction could result in traffic delays and the need to reroute local traffic to ensure public health and safety. School bus routes could be temporarily affected by road closures and detours during project construction in communities around Shasta Lake.

Several roads around Shasta Lake would be affected by infrastructure and utility relocation activities. These activities could require road closures, detours, or traffic restrictions on Lakeshore Drive.

Emergency supplies and resources that could be affected by project implementation include food, shelter for emergency crews and local residents, and public services staff and equipment. Project construction activities are located within commuting distance of Redding, where ample food and shelter are available in emergencies. The OES network could supplement local emergency services staffing and equipment levels. However, OES may not be able to provide assistance when wildfires in the state require OES resources.

Construction activities at Shasta Dam and various locations surrounding Shasta Lake could affect emergency response capabilities throughout Shasta County (i.e., in a portion of the upper Sacramento River area) because the areas share emergency services resources and responsibilities.

In summary, project construction could result in short-term disruptions of school bus services throughout the Gateway Unified School District. Short-term traffic delays and access restrictions would require traffic controls and coordination with public services agencies. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-2 (CP1): Degraded Level of Public Services Project implementation could result in short-term degradation of levels of public services, including law enforcement, fire protection, and emergency services. This conclusion is based on the size of the project and proposed locations for construction activity associated with infrastructure alterations. The relocation of infrastructure combined with possible consolidation of recreational facilities (e.g., campgrounds, boat ramps, marinas) could result in changing demands for public services. Project construction activities proposed around Shasta Lake could require local, State, and Federal agencies to change the locations of some public services, which could affect the areas where the public services are currently located.

Project implementation could also result in degraded levels of public services in the upper Sacramento River study area because the Shasta Lake area and portions of the upper Sacramento River area share public services. Project construction activities at Shasta Lake could require the use of public services resources that could be needed simultaneously for public services assistance in the upper Sacramento River area.

Reclamation estimates that CP1 would take 36 months to complete. Public services levels that are increased as a result of the project would return to pre-project levels once construction activities have been completed. However, project implementation could temporarily degrade local public resources. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-3 (CP1): Relocation of Public Services The project would require relocation of some public service facilities in the Shasta Lake and vicinity portion of the study area. No public services facilities in the upper Sacramento River portion of the primary study area would need to be relocated.

The NRA is managed by USFS, which has several facilities throughout the reservoir area. Two USFS facilities would be inundated and thus require relocation or replacement. The station located in the Lakeshore area would be inundated by raising Shasta Dam and would have to be relocated to an area above the new full pool. The new facility would contain all of the features that exist at the current facility. The inundated facility would be demolished and hauled to waste. At Turntable Bay, another USFS facility would be inundated by the raising of Shasta Dam. Additional space at Turntable Bay would allow for the facility to be relocated on fill in the current location. Also, the SCSO substation and dock at the Bridge Bay Marina could need to be relocated within the marina complex. Reclamation would construct the replacement facilities before abandonment and demolition of the existing facilities, thereby ensuring that levels of public services provided by these facilities would not be adversely affected by the relocation process. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact PS-4 (CP1): Short-Term Disruption of Public Services Project implementation would not disrupt public services in the extended study area because of the distance of the extended study area from project elements that could affect public services.

The northern end of the extended study area is more than 30 miles from the nearest project construction activities. Emergency services providers with mutual aid agreements that could be called on to assist with emergencies resulting from project activities are located in the primary study area. Project construction activities in the primary study area that could disrupt public services are too far removed from the extended study area to disrupt emergency services or law enforcement serving areas south of Red Bluff. Project implementation would not disrupt school bus service in the extended study area because school districts located in the extended study area do not operate school bus routes in or near project construction activities. Therefore, there would be no impact related to disruption of public services in the extended study area. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-5 (CP1): Degraded Levels of Public Services Construction activities are not expected to affect public service levels in the extended study area. Existing facilities, personnel, and equipment in the extended study area could provide short-term assistance for project-related public services needs without degrading public services levels in the extended study area.

The northern end of the extended study area is more than 30 miles from the nearest project construction activities. Public services providers with

mutual aid agreements that could be called on to assist with law enforcement, fire suppression, or other emergencies resulting from project activities are located in the primary study area. Project construction activities around Shasta Lake are too far removed from the extended study area to disrupt public services below Red Bluff. Public services providers located in the extended study area could be called on by OES to assist with large-scale emergencies in the primary study area that result from project implementation. However, existing facilities, personnel, and equipment in the extended study area are adequate to maintain current levels of service while providing assistance to the primary study area.

Indirect impacts to public services in the extended study area could result from traffic accidents associated with the transport of project materials and workers. Some project materials and workers could originate in the extended study area, requiring northbound travel to the primary study area. At this time, Reclamation estimates that the project would employ 350 workers. Project-related travel that would likely occur on I-5, the railway, or via air transport is not anticipated to result in accidents in the extended study area that would require significant response from law enforcement, fire protection, or emergency services providers; however, the fact that traffic accidents resulting from project-related travel could occur in the extended study area means that the possibility of travel-related accidents exists. It is expected that existing facilities, personnel, and equipment in the extended study area would be adequate to maintain current levels of service while providing assistance for any such accidents.

Existing facilities, staff, and equipment in the extended study area would be capable of providing short-term assistance for project-related public services needs without degrading levels of public services in the extended study area. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-6 (CP1): Relocation of Public Services Facilities Project implementation would not result in the relocation of public services facilities in the extended study area. Therefore, public services in the extended study area would not be affected by relocation of public services facilities. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The impact discussion for CP2 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together because impacts from construction activities would affect both study areas. It also addresses

the Lower Sacramento River and Delta study area and the CVP/SWP Service Areas together because their distance from the project area results in similar impacts.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact PS-1 (CP2): Short-Term Disruption of Public Services
Construction activities associated with enlarging Shasta Dam and related infrastructure (e.g., road relocations, bridge replacements) near the dam and near the relocation sites for utilities, roads, and structures could temporarily disrupt transportation and circulation patterns in the vicinity of Shasta Lake, which could affect emergency services response and school bus service. Emergency preparedness, emergency communications, and emergency supplies (e.g., food, shelter for emergency crews, public services staff) could also be affected by project implementation.

Impacts related to short-term disruption of emergency services that would result from implementing the 12.5-foot dam raise (CP2) are similar to those identified for the 6.5-foot dam raise (Impact PS-1 (CP1)). However, the duration of the impacts would be longer for CP2 because construction activities associated with the 12.5-foot dam raise would take more time than under the 6.5-foot dam raise. The 12.5-foot dam raise would require significantly more concrete and is anticipated to take 12 more months to construct than the 6.5-foot dam raise (CP1).

The increased amount of infrastructure demolition and relocation activity associated with CP2 would also require more time than under CP1. More structures would need to be demolished and relocated, and additional power and telecommunication lines would need to be relocated. Additional septic systems and wells would also require demolition and relocation, and 20 additional road segments would need to be realigned for CP2. The increased construction activity in the Shasta Lake and vicinity portion of the primary study area under CP2 would extend the duration of potential disruptions to emergency services and school bus service in the Shasta Lake and vicinity portion of the study area. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-2 (CP2): Degraded Levels of Public Services Project implementation could result in short-term degradation of levels of public services, including law enforcement, fire protection, and emergency services. This conclusion is based on the size of the project and proposed locations for construction activity associated with infrastructure alterations. The relocation of infrastructure combined with possible consolidation of recreational facilities (e.g., campgrounds, boat ramps, marinas) could result in changing demands for public services.

Project construction activities proposed around Shasta Lake could require local, State, and Federal agencies to change the locations of some public services, which could affect the areas where the resources are currently located.

This impact would be similar to Impact PS-2 (CP1). However, the impacts would last longer for CP2 than CP1 because more time would be needed to complete project construction under the 12.5-foot dam raise. Reclamation estimates that CP2 would take 48 months to complete. Project implementation could temporarily degrade local public services. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-3 (CP2): Relocation of Public Services Facilities This impact would be similar to Impact PS-3 (CP1). Facility relocation would not degrade levels of public services while the public service agencies are relocating to their new facilities. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact PS-4 (CP2): Short-Term Disruption of Public Services This impact would be similar to Impact PS-4 (CP1) for the extended study area. Project implementation would not disrupt public services in the extended study area because of the distance of the extended study area from project elements that could affect public services. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-5 (CP2): Degraded Levels of Public Services This impact would be similar to Impact PS-5 (CP1) for the extended study area. Project construction activities are not expected to affect public services levels in the extended study area. Existing facilities, staff, and equipment in the extended study area would be capable of providing short-term assistance for project-related public services needs without degrading levels of public services in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-6 (CP2): Relocation of Public Services Facilities This impact would be identical to Impact PS-6 (CP1) for the extended study area. Project implementation would not result in the relocation of public service facilities in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The impact discussion for CP3 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together because impacts from construction activities would affect both study areas. It also addresses the Lower Sacramento River and Delta study area and the CVP/SWP Service Areas together because their distance from the project area results in similar impacts.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact PS-1 (CP3): Short-Term Disruption of Public Services
Construction activities associated with enlarging Shasta Dam and the related infrastructure (e.g., road relocations, bridge replacements) near the dam and near the relocation sites for utilities, roads, and structures could temporarily disrupt transportation and circulation patterns in the vicinity, which could affect emergency services response and school bus service. Emergency preparedness, emergency communications, and emergency supplies (food, shelter for emergency crews, public services staff) could also be affected by project implementation.

This impact would be similar to Impact PS-1 (CP1). However, the impact would last longer for CP3 because construction activities associated with the 18.5-foot dam raise would take more time than for the 6.5-foot dam raise. Reclamation estimates that the 18.5-foot dam raise would take 60 months. The 18.5-foot dam raise would require significantly more concrete and is anticipated to take 24 more months to construct than the 6.5-foot dam raise (CP1). The increased amount of infrastructure demolition and relocation activity associated with CP3 would also require more time than for CP1. Almost twice as many structures would need to be demolished and relocated, and additional power and telecommunication lines would require removal and relocation. Additional septic systems and wells would be abandoned and relocated, and 25 more road segments would be realigned. The increased construction activity at Shasta Dam and in the surrounding area would extend the time of potential disruptions to emergency services. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-2 (CP3): Degraded Levels of Public Services Project implementation could result in short-term degradation of levels of public services, including law enforcement, fire protection, and emergency services. This conclusion is based on the size of the project and proposed locations for construction activity associated with infrastructure alterations. The relocation of infrastructure, combined with possible consolidation of recreational facilities (e.g., campgrounds, boat ramps, marinas), could result in changing demands for public

services. Project construction activities proposed around Shasta Lake could require local, State, and Federal agencies to change the locations of some public services, which could affect the areas where the public services are currently located.

This impact would be similar to Impact PS-2 (CP1). However, the impact would last longer for CP3 than for CP1 because more time would be needed to complete project construction for the 18.5-foot dam raise. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-3 (CP3): Relocation of Public Services Facilities This impact would be similar to Impact PS-3 (CP1). Facilities relocation would not degrade levels of public services while the public services agencies are relocating to new facilities. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact PS-4 (CP3): Short-Term Disruption of Public Services This impact would be similar to Impact PS-4 (CP1) for the extended study area. Project implementation would not disrupt public services in the extended study area because of the distance of the extended study area from project elements that could affect public services. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-5 (CP3): Degraded Levels of Public Services This impact would be similar to Impact PS-5 (CP1) for the extended study area. Project construction activities are not expected to affect public services levels in the extended study area. Existing facilities, staff, and equipment in the extended study area would be capable of providing short-term assistance for project-related public services needs without degrading levels of public services in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-6 (CP3): Relocation of Public Services Facilities This impact would be identical to Impact PS-6 (CP1) for the extended study area. Project implementation would not result in the relocation of public services facilities in extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

The impact discussion for CP4 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together because impacts from

construction activities would affect both study areas. It also addresses the Lower Sacramento River and Delta study area and the CVP/SWP Service Areas together because their distance from the project area results in similar impacts.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact PS-1 (CP4): Short-Term Disruption of Public Services This impact would be similar to Impact PS-1 (CP3). Construction activities associated with enlarging Shasta Dam and related infrastructure (e.g., road relocations, bridge replacements) near the dam and near the relocation sites for utilities, roads, and structures could temporarily disrupt transportation and circulation patterns in the vicinity of Shasta Lake, which could affect emergency services response and school bus service. Emergency preparedness, emergency communications, and emergency supplies (e.g., food, shelter for emergency crews, public services staff) could also be affected by project implementation. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-2 (CP4): Degraded Levels of Public Services This impact would be similar to Impact PS-2 (CP3). Project implementation could result in short-term degradation of levels of public services, including law enforcement, fire protection, and emergency services. This conclusion is based on the size of the project and proposed locations for construction activity associated with infrastructure alterations. The relocation of infrastructure, combined with possible consolidation of recreational facilities (e.g., campgrounds, boat ramps, marinas), could result in changing demands for public services. Project construction proposed around Shasta Lake could require local, State, and Federal agencies to change the location of some public services, which could affect the areas where the public services are currently located. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-3 (CP4): Relocation of Public Services Facilities This impact would be similar to Impact PS-3 (CP1). Facilities relocation would not degrade levels of public services while the public services agencies are relocating to new facilities. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact PS-4 (CP4): Short-Term Disruption of Public Services This impact would be similar to Impact PS-4 (CP1), except that gravel augmentation and Reading Island habitat restoration along the upper Sacramento River would slightly, but not substantially, increase the

potential for short-term disruption of public services in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-5 (CP4): Degraded Levels of Public Services This impact would be similar to Impact PS-5 (CP1), except that gravel augmentation and Reading Island habitat restoration along the upper Sacramento River would slightly, but not substantially, increase the potential for degradation of public services.

Existing facilities, personnel, and equipment in the extended study area could provide short-term assistance for project-related public services needs without degrading levels of public services in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-6 (CP4): Relocation of Public Services Facilities This impact would be identical to Impact PS-6 (CP1) for the extended study area. Project implementation would not result in the relocation of public services facilities in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

The impact discussion for CP5 addresses the Shasta Lake and Vicinity and Upper Sacramento River study areas together because impacts from construction activities would affect both study areas. It also addresses the Lower Sacramento River and Delta study area and the CVP/SWP Service Areas together because their distance from the project area results in similar impacts.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact PS-1 (CP5): Short-Term Disruption of Public Services This impact would be similar to Impact PS-1 (CP3). Construction activities associated with enlarging Shasta Dam and related infrastructure (e.g., road relocations, bridge replacement) near the dam and near relocation sites for utilities, roads, and structures could temporarily disrupt transportation and circulation patterns in the vicinity, which could affect emergency services response and school bus service. Emergency preparedness, emergency communications, and emergency supplies (e.g., food, shelter for emergency crews, public service staff) could also be affected by project implementation. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-2 (CP5): Degraded Levels of Public Services This impact would be similar to Impact PS-2 (CP3). Project implementation could

result in short-term degradation of levels of public services, including impacts on law enforcement, fire protection, and emergency services. This conclusion is based on the size of the project and proposed locations for construction activity associated with infrastructure alterations. Project construction activities proposed around Shasta Lake could require local, State, and Federal agencies to change the location of some public services, which could affect the areas where the public services are currently located. This impact would be potentially significant. Mitigation for this impact is proposed in Section 22.3.5.

Impact PS-3 (CP5): Relocation of Public Services Facilities This impact is similar to Impact PS-3 (CP1). Facilities relocation would not degrade levels of public service while the public service agencies are relocating to new facilities. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact PS-4 (CP5): Short-Term Disruption of Public Services This impact would be similar to Impact PS-4 (CP1), except that gravel augmentation and Reading Island habitat restoration along the upper Sacramento River would slightly, but not substantially, increase the potential for short-term disruption of public services in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-5 (CP5): Degraded Levels of Public Services This impact would be similar to Impact PS-5 (CP1), except that gravel augmentation and Reading Island habitat restoration along the upper Sacramento River would slightly, but not substantially, increase the potential for degradation of public services.

Existing facilities, personnel, and equipment in the extended study area could provide short-term assistance for project-related public services needs without degrading levels of public services in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact PS-6 (CP5): Relocation of Public Services Facilities This impact would be identical to Impact PS-6 (CP1) for the extended study area. Project implementation would not result in the relocation of public services facilities in the extended study area. There would be no impact. Mitigation for this impact is not needed, and thus not proposed.

22.3.5 Mitigation Measures

Table 22-2 presents a summary of mitigation measures for public services.

Table 22-2. Summary of Mitigation Measures for Public Services

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact PS-1: Disruption of Public Services (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	PS-1: Coordinate and Assist Public Services Agencies.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact PS-2: Degraded Level of Public Services (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	PS-2: Provide Support to Public Services Agencies.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact PS-3: Relocation of Public Service Facilities (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact PS-4: Short-Term Disruption of Public Services (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	NI	NI	NI	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	NI	NI	NI	LTS	LTS
Impact PS-5: Degraded Levels of Public Services (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact PS-6: Relocation of Public Services Facilities (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	NI	NI	NI	NI	NI
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	NI	NI	NI	NI	NI

Notes:
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant

No-Action Alternative

No mitigation measures are required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts PS-3 through PS-6. Mitigation is provided below for impacts of CP1 related to short-term disruptions of public services (PS-1) and degraded levels of public services in the primary study area (PS-2).

Mitigation Measure PS-1 (CP1): Coordinate and Assist Public Services Agencies Reclamation will coordinate all proposed road closures, detours, and traffic control measures with the Shasta County Sheriff's Office and Tehama County Sheriff's Office, which are the designated OES headquarters for the primary study area.

Reclamation will appoint a public liaison to communicate construction schedules, road closures, and project activities to the public. The liaison will organize and conduct public meetings for the purpose of communicating project information. The liaison will meet with all affected public services agencies to coordinate public meetings and information exchanges.

Reclamation will obtain all necessary permits and/or authorizations from public services agencies for matters requiring agency approval and/or cooperation.

Reclamation will meet with public services agencies to determine traffic controls for infrastructure, utility, and structure relocation.

Reclamation will develop and implement a monitoring plan to track the effectiveness of this mitigation measure, and will make adjustments, if necessary.

Traffic Control and Safety Assurance Plan Reclamation will implement Mitigation Measure Trans-1 as described in Chapter 20, "Transportation and Traffic" to reduce adverse effects of road closures and detours or partial road closures on access to local streets and adjacent uses.

Implementation of this mitigation measure would reduce Impact PS-1 (CP1) to a less than significant level.

Mitigation Measure PS-2 (CP1): Provide Support to Public Services Agencies Reclamation will provide affected public services providers (e.g., law enforcement, fire protection, emergency services) with sufficient funding and support to ensure that levels of public services are not substantially degraded by construction activities. Reclamation will coordinate with affected providers to develop a mutual understanding of the amount and schedule of financial and administrative support required to reduce this impact to a less than significant level.

Reclamation will develop and implement a monitoring plan to track the effectiveness of this mitigation measure, and will make adjustments, if necessary.

Implementation of this mitigation measure would reduce Impact PS-2 (CP1) to a less than significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts PS-3 through PS-6. Mitigation is provided below for the impacts of CP1 related to short-term disruptions of public services (PS-1) and CP2 related to degraded levels of public services (PS-2) in the primary study area.

Mitigation Measure PS-1 (CP2): Coordinate and Assist Public Services Agencies This mitigation measure is identical to Mitigation Measure PS-1 (CP1). Implementation of this mitigation measure would reduce Impact PS-1 (CP2) to a less than significant level.

Mitigation Measure PS-2 (CP2): Provide Support to Public Services Agencies This mitigation measure is identical to Mitigation Measure PS-2 (CP1). Implementation of this mitigation measure would reduce Impact PS-2 (CP2) to a less than significant level.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts PS-3 through PS-6. Mitigation is provided below for the impacts of CP1 related to short-term disruptions of public services (PS-1) and degraded levels of public services (PS-2) in the primary study area.

Mitigation Measure PS-1 (CP3): Coordinate and Assist Public Services Agencies This mitigation measure is identical to Mitigation Measure PS-1 (CP1). Implementation of this mitigation measure would reduce Impact PS-1 (CP3) to a less than significant level.

Mitigation Measure PS-2 (CP3): Provide Support to Public Services Agencies This mitigation measure is identical to Mitigation Measure PS-2 (CP1). Implementation of this mitigation measure would reduce Impact PS-2 (CP3) to a less than significant level.

CP4-18.5 Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is required for Impacts PS-3 through PS-6. Mitigation is provided below for the impacts of CP1 related to short-term disruptions of public services (PS-1) and degraded levels of public services (PS-2) in the primary study area.

Mitigation Measure PS-1 (CP4): Coordinate and Assist Public Services Agencies This mitigation measure identical to Mitigation Measure PS-1 (CP1). Implementation of this mitigation measure would reduce Impact PS-1 (CP4) to a less than significant level.

Mitigation Measure PS-2 (CP4): Provide Support to Public Services Agencies This mitigation measure is identical to Mitigation Measure

PS-2 (CP1). Implementation of this mitigation measure would reduce Impact PS-2 (CP4) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impacts PS-3 through PS-6. Mitigation is provided below for the impacts of CP5 related to short-term disruptions of public services (PS-1) and degraded levels of public services (PS-2) in the primary study area.

Mitigation Measure PS-1(CP5): Coordinate and Assist Public Services Agencies This mitigation measure is identical to Mitigation Measure PS-1 (CP1). Implementation of this mitigation measure would reduce Impact PS-1 (CP5) to a less than significant level.

Mitigation Measure PS-2 (CP5): Provide Support to Public Services Agencies This mitigation measure is identical to Mitigation Measure PS-2 (CP1). Implementation of this mitigation measure would reduce Impact PS-2 (CP5) to a less than significant level.

22.3.6 Cumulative Effects

As described above, CP1 through CP5 would result in short-term disruption of public services, degrade the levels of public services provided, and require the relocation of public services facilities in the primary study area. These effects would be of greater magnitude and duration with the larger dam raises. Thus, effects of CP2 would be similar to but greater than those of CP1, and similar to but less than those of CP3 through CP5. Although Mitigation Measures PS-1 and PS-2 would enhance the coordination of public services during project implementation, the adverse effects of CP1 through CP5 would not be eliminated, particularly regarding short-term disruption of public services. Given the reasonably foreseeable development actions, public services provided by Federal, State, and local agencies within the primary study area could be subject to cumulatively incremental effects resulting from CP1 through CP5. These effects would diminish with distance from the project construction sites. CP1 through CP5 would not have cumulative effects on public services downstream from Red Bluff (i.e., in the extended study area).

This page left blank intentionally.

Chapter 23
Power and Energy

23.1 Affected Environment

This chapter describes the affected environment related to hydropower generation and consumption for the dam and reservoir modifications proposed under the SLWRI. The affected environment includes the existing CVP and SWP generating and pumping plants. For a more in-depth description of the affected environment, see the *Power and Energy Technical Report.*

The CVP is a multipurpose project with 20 dams and reservoirs, 11 powerplants, and 500 miles of major canals, as well as conduits, tunnels, and related facilities. The power generated from these plants helps to meet California's energy needs. The Western Area Power Administration (Western), created in 1977 under the Department of Energy Organization Act, markets and transmits electric power throughout 15 western states. Western's Sierra Nevada Customer Service Region (Sierra Nevada Region) markets and transmits power generated from the CVP and the Washoe Project in excess of CVP use. Western follows a formal procedure for allocating CVP energy to "preference" customers. These customers have 20-year contracts for their share of CVP energy in excess of Reclamation's water pumping needs.

Major SWP facilities include 17 pumping plants, 8 hydroelectric powerplants, 32 storage facilities, and 660-plus miles of aqueducts and pipelines. The SWP is also a multipurpose project. The primary purpose of SWP power generation facilities is to meet energy requirements of the SWP pumping plants. To the extent possible, SWP pumping is scheduled during off-peak periods, and energy generation is scheduled during peak periods. Although the SWP uses more energy than it generates from its hydroelectric facilities, DWR has exchange agreements with other utility companies, and has developed other power resources. DWR sells surplus power, when it is available, to minimize the net cost of pumping energy.

23.1.1 Shasta Lake and Vicinity

The Shasta Division of the CVP contains Shasta Dam, Lake, and Powerplant, and Keswick Dam, Reservoir, and Powerplant; it captures water from the Sacramento River basin. Shasta Powerplant is located just below Shasta Dam as part of the Shasta Division. Water from the dam is released through five 15-foot penstocks leading to the five main generating units and two station service units with a maximum generation capacity of 715 megawatts (MW). Shasta Powerplant is a peaking plant and generally runs when demand for electricity is

high. Its power is dedicated first to meeting the requirements of CVP facilities. The remaining energy is marketed to various preference customers in Northern California. The 2007 net annual generation of Shasta Powerplant was 1,914,175 megawatt-hours (MWh).

23.1.2 Upper Sacramento River (Shasta Dam to Red Bluff)

CVP powerplants located downstream from Shasta Reservoir, but upstream from the Red Bluff Diversion Dam are the Trinity, Lewiston, Judge Francis Carr, and Spring Creek powerplants of the Trinity River Division and the Keswick Powerplant of the Shasta Division. The Trinity River Division captures headwaters from the Trinity River basin and diverts surplus water to the Sacramento River.

Trinity Dam stores water from the Trinity River in Trinity Reservoir and makes releases to the Trinity River through the Trinity Powerplant. Downstream, Lewiston Dam diverts water from the Trinity River through the Lewiston Powerplant into the Clear Creek Tunnel and through Judge Francis Carr Powerplant to Whiskeytown Reservoir. Some Whiskeytown Reservoir releases are made through the Spring Creek Power Conduit and Powerplant into Keswick Reservoir in the Shasta Division. The remainder of the releases from Whiskeytown Reservoir are made to Clear Creek. Releases from Keswick Reservoir are made through the Keswick Powerplant to the Sacramento River.

Keswick Powerplant belongs to the Shasta Diversion, is located at Keswick Dam, and has three generating units with a total capacity of 105 MW. Keswick Powerplant is a run-of-the-river plant, creating Shasta Powerplant's afterbay, and providing uniform flows to the Sacramento River.

23.1.3 Lower Sacramento River and Delta

Two CVP powerplants located between the Red Bluff Diversion Dam and Sacramento–San Joaquin River Delta (Delta) are the Folsom and Nimbus powerplants. Both powerplants belong to the Folsom Unit on the American River.

Folsom Powerplant is a peaking powerplant located at the foot of Folsom Dam on the north side of the American River. Water from the dam is released through three 15-foot-diameter penstocks to three generating units with a maximum capacity of 199 MW. Folsom Dam was constructed by the USACE and, on completion, was transferred to Reclamation for coordinated operation as an integral part of the CVP.

Nimbus Dam forms Lake Natoma to act as an afterbay for Folsom Powerplant. It allows dam operators to coordinate power generation and flows in the lower American River channel during normal reservoir operations. Nimbus Powerplant, with two units and a maximum capacity of 13.5 MW, is a run-of-the-river plant and provides station service backup for Folsom Powerplant.

23.1.4 CVP/SWP Service Areas

There are a number of generation facilities and pumping facilities in the greater CVP/SWP service areas, beyond the specific geographies discussed above. These facilities are discussed below.

Generation Facilities

The CVP powerplants located in the CVP south-of-Delta service area include New Melones Powerplant in the New Melones Unit of the CVP East Side Division, and the William R. Gianelli and O'Neill Pumping-Generating Plants in the San Luis Unit of the CVP West San Joaquin Division. The latter two, with dual functions of generating electricity and pumping water, are jointly owned by Reclamation and DWR.

New Melones Dam was completed in 1979, and inundated the original Melones Dam and created New Melones Reservoir on the Stanislaus River. New Melones Powerplant, located on the north bank immediately downstream from the dam, is a peaking plant. The powerplant contains two units and a maximum capacity of 300 MW.

The San Luis Unit, part of both the CVP and SWP, was authorized in 1960. Reclamation and the State of California constructed and operate this unit jointly; 45 percent of the total cost was contributed by the Federal Government and the remaining 55 percent by the State of California. The joint-use facilities are O'Neill Dam and Forebay, B.F. Sisk San Luis Dam, San Luis Reservoir, William R. Gianelli Pumping-Generating Plant, Dos Amigos Pumping Plant, Los Banos and Little Panoche Reservoirs, and San Luis Canal from O'Neill Forebay to Kettleman City, together with the necessary switchyard facilities. The Federal-only portion of the San Luis Unit includes the O'Neill Pumping-Generating Plant and Intake Canal, Coalinga Canal, Pleasant Valley Pumping Plant, and San Luis Drain.

San Luis Reservoir serves as the major storage reservoir, and O'Neill Forebay acts as an equalizing basin, for the upper stage dual-purpose pumping-generating plant. O'Neill Pumping-Generating Plant takes water from the Delta-Mendota Canal and discharges it into the O'Neill Forebay, where the California Aqueduct (SWP feature) flows directly. The William R. Gianelli Pumping-Generating Plant lifts water from O'Neill Forebay and discharges it into San Luis Reservoir. During releases from the reservoir, these plants generate electric power by reversing flow through the turbines. Water for irrigation is released into the San Luis Canal and flows by gravity to Dos Amigos Pumping Plant, where the water is lifted more than 100 feet to permit gravity flow to the canal terminus at Kettleman City. The SWP canal system continues to southern coastal areas.

The O'Neill Pumping-Generating Plant consists of an intake channel, leading off the Delta-Mendota Canal, and six pumping-generating units. Normally, these units operate as pumps to lift water from 45 to 53 feet into O'Neill

Forebay; each unit can discharge 700 cubic feet per second (cfs) and has a rating of 6,000 horsepower (hp). Water is occasionally released from the forebay to the Delta-Mendota Canal, and these units then operate as generators; each unit has a generating capacity of about 4.2 MW.

William R. Gianelli Pumping-Generating Plant, the joint Federal-State facility located at San Luis Dam, lifts water by pump-turbines from O'Neill Forebay into San Luis Reservoir. During the irrigation season, water is released from San Luis Reservoir back through the pump-turbines to the forebay and energy is reclaimed. Each of the eight pumping-generating units has a capacity of 63,000 hp as a motor and 53 MW as a generator. As a pumping plant to fill San Luis Reservoir, each unit lifts 1,375 cfs at a design dynamic head of 290 feet. As a generating plant, each unit passes 2,120 cfs at a design dynamic head of 197 feet.

Among the eight SWP hydroelectric powerplants, three powerplants are located in the Lake Oroville vicinity and the remaining in the south-of-Delta area.

Lake Oroville, the SWP's largest reservoir, stores winter and spring runoff from the Feather River watershed, and releases water for SWP needs. These releases generate power at three powerplants: the Edward Hyatt Pumping-Generating Plant, Thermalito Diversion Dam Powerplant, and Thermalito Pumping-Generating Plants (Oroville Facilities). DWR schedules hourly releases through the Oroville Facilities to maximize the amount of energy produced when power values are highest. Because the downstream water supply does not depend on hourly releases, water released for power in excess of local and downstream requirements is conserved by pumpback operation during off-peak times into Lake Oroville. Energy prices primarily dictate hourly operations for the power generation facilities.

The remaining five SWP powerplants are the jointly owned William R. Gianelli Pumping-Generating Plant, Alamo Powerplant, Mojave Siphon Powerplant, Devil Canyon Powerplant, and Warne Powerplant. They generate about one sixth of the total energy used by the SWP. The Alamo Powerplant uses the 133 foot head between Tehachapi Afterbay and Pool 43 of the California Aqueduct to generate electricity. The Mojave Siphon Powerplant generates electricity from water flowing downhill after its 540-foot lift by the Pearblossom Pumping Plant. The Devil Canyon Powerplant generates electricity with water from Silverwood Lake with more than 1,300 feet of head, the highest water head[1] in a powerplant in the SWP system. The Warne Powerplant uses the 725-foot drop

[1] [1] Potential hydropower generation is a function of the hydraulic net head and rate of fluid flow. The net head is the actual head available for power generation and is used for computing the energy generated. The net head is the gross head minus the head losses due to intake structures, penstocks, and outlet works. The gross or static head is the vertical distance between the tailwater elevation and the forebay water surface elevation (i.e., the height of water in the reservoir relative to its height after discharge). The head losses are generally assumed 2 to 10 percent of the gross head, depending on the configuration of the powerhouse structure.

from the Peace Valley Pipeline to generate electricity with its Pelton wheel turbines.

Pumping Facilities

CVP pumping plants to move water from the Delta to CVP service areas in the Central Valley include C.W. "Bill" Jones Pumping Plant, O'Neill and William R. Gianelli Pumping-Generating Plants, Dos Amigo Pumping Plant, and SWP Banks Pumping Plant. Reclamation constructed and operates the C.W. "Bill" Jones Pumping Plant. Harvey O. Banks Pumping Plant is an SWP facility; however, Reclamation has access to its pumping capacity through use of the Joint Point of Diversion, described in State Water Resource Control Board Water Right Decision 1641. The remaining plants, described previously, are joint-use facilities between the two agencies under the San Luis Unit.

C.W. "Bill" Jones Pumping Plant, formerly Tracy Pumping Plant, is a component of the CVP Delta Division. Construction of the plant started in 1947 and was completed in 1951, with an inlet channel, pumping plant, and discharge pipes. Delta water is lifted 197 feet up and carried about 1 mile into the Delta-Mendota Canal. Each of the six pumps at C.W. "Bill" Jones Pumping Plant is powered by a 22,500 hp motor and is capable of pumping 767 cfs. The intake canal includes the C.W. "Bill" Jones Fish Screen, which was built to intercept downstream migrant fish to be returned to the main channel to resume their journey to the ocean.

Dos Amigo Pumping Plant is a joint CVP/SWP facility, located 17 miles south of O'Neill Forebay on the San Luis Canal. It lifts water 113 feet to permit gravity flow to the terminus of San Luis Canal at Kettleman City. The plant contains six pumping units, each capable of delivering 2,200 cfs at 125 feet of head.

Among the SWP pumping plants, plants that historically consumed most of the energy are William R. Gianelli Pumping-Generating Plant (SWP share), Harvey O. Banks Pumping Plant, Dos Amigos Pumping Plant (SWP share), Ira J. Chrisman Pumping Plant, and A.D. Edmonston Pumping Plant.

The Harvey O. Banks Pumping Plant is located 2.5 miles (4 kilometers) southwest of the Clifton Court Forebay on the California Aqueduct. The plant is the first pumping plant for the California Aqueduct and the South Bay Aqueduct. It provides the necessary head[2] for water in the California Aqueduct to flow for approximately 80 miles south past O'Neill Forebay and San Luis Reservoir to the Dos Amigos Pumping Plant (another jointly owned facility, as previously described). The Harvey O. Banks Pumping Plant initially flows into Bethany Reservoir, where the South Bay Aqueduct truly begins. The design head is 236 to 252 feet and installed capacity is 10,670 cfs with 333,000 hp.

[2] In pumping plants, the design head is the gross head plus the head losses due to intake structures.

Along the California Aqueduct, the Pearblossom, Chrisman, and Edmonston Pumping Plants historically consumed the highest amount of energy. The Pearblossom Pumping Plant lifts water about 540 feet and discharges the water 3,479 feet above mean sea level (msl), the highest point along the entire California Aqueduct. The Chrisman and Edmonston Pumping Plants provide 524 and 1,970 feet of lift, respectively, to convey California Aqueduct water across the Tehachapi Mountains.

23.2 Regulatory Framework

There are two categories of regulatory framework for hydropower: Federal regulations for CVP hydroelectric operations and State regulations for the SWP.

23.2.1 Federal

Reclamation operates the CVP hydroelectric generation facilities to manage and release water in accordance with various acts authorizing specific projects, and with other laws, permits, and enabling legislation (see the *Hydrology, Hydraulics, and Water Management Technical Report* in the Physical Resources Appendix for details). Western's capacity and energy sales must conform with the laws that govern its sale of electrical power. Hydropower operations at each facility comply with water flows and other constraints set by Reclamation, the USWFS, or other regulatory agencies, acting in accordance with laws, regulations, and policies.

Western announced its 2004 Power Marketing Plan (Marketing Plan) for the Sierra Nevada Region because all of the Sierra Nevada Region’s long-term firm CVP power sales contracts expired on December 31, 2004. The Marketing Plan specifies the terms and conditions under which Western markets power from the CVP and the Washoe Project, beginning January 1, 2005. This Marketing Plan supersedes all previous marketing plans for these projects.

23.2.2 State

DWR is currently seeking a new 50-year hydroelectric license from the Federal Energy Regulatory Commission to operate the existing Oroville Facilities. The DEIS is available for public review and comment. The initial Federal Energy Regulatory Commission license for the Oroville Facilities, issued on February 11, 1957, expired on January 31, 2007. The Oroville Facilities are currently operating under an annual license issued by Federal Energy Regulatory Commission effective February 1, 2007.

23.2.3 Regional and Local

There are no known regional or local regulations that would govern power and energy resources.

23.3 Environmental Consequences and Mitigation Measures

The purpose of this section is to provide information about hydropower generation, energy use, and impacts on existing hydropower facilities from the SLWRI study alternatives described in the PDEIS. Hydropower modeling for the PDEIS was conducted to identify potential impacts from the SLWRI on hydropower generation and consumption at CVP and SWP facilities, which are operated by Reclamation, and DWR, respectively. This section describes the analytical methodology used to calculate, for all alternatives, the hydropower generation and pumping energy required in CVP and SWP existing hydropower facilities. This chapter also describes criteria for determining significant impacts and mitigation measures associated with the SLWRI alternatives, and then lists the impacts and mitigation measures.

23.3.1 Methods and Assumptions

Several modeling tools were used for the SLWRI hydropower analysis. CalSim-II was used to determine project operations, and the Common Assumptions power tools were used to quantify the hydropower generation and pumping energy associated with each alternative. A spreadsheet postprocessor was used to evaluate impacts to the Pit 7 Powerplant.

Common Assumptions Power Tools

Energy estimates were made using the Common Assumptions power tools, LongTermGen (LTG) and SWP Power CA (SWP Power), for CVP and SWP facilities, respectively. LTG and SWP Power use operations data from CalSim-II simulations to predict energy generation and consumption throughout the CVP and SWP.

Methods applied to evaluate power generation are discussed below.

For each SLWRI alternative, outputs from CalSim-II simulation were inputs to LTG and SWP Power to simulate power generation and consumption throughout the CVP and SWP systems, respectively. These CalSim-II outputs include reservoir releases, conveyance flow rates, and end-of-month reservoir storages. Both LTG and SWP Power are monthly models. Their simulation periods are from October 31, 1921, to September 30, 2003.

In LTG and SWP Power, energy generation is a function of turbine configuration, reservoir release, net head, and duration of generation. Net head is the actual head available for power generation; it is reservoir water surface elevation (a function of storage) minus tailrace elevation (a function of release).

Similarly, the calculation of energy required for pumping in both models is a function of pump configuration, pumping rate, pumping head (i.e., net head with hydraulic losses), and duration of pumping. Detailed descriptions of LTG and SWP Power are included in Chapter 9 of the Modeling Appendix.

CalSim-II

CalSim-II is the application of the Water Resources Integrated Modeling System software to the CVP/SWP. This application was jointly developed by Reclamation and DWR for planning studies relating to CVP/SWP operations. The primary purpose of CalSim-II is to evaluate the water supply reliability of the CVP and SWP at current and/or future levels of development (e.g., 2005, 2030), with and without various assumed future facilities, and with different modes of facility operations. Geographically, the model covers the drainage basin of the Delta, and CVP/SWP exports to the San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California.

CalSim-II typically simulates system operations for an 83-year period using a monthly time step. The model assumes that facilities, land use, water supply contracts, and regulatory requirements are constant over this period, representing a fixed level of development (e.g., 2005 or 2030). The historical flow record of October 1921 to September 2003, adjusted for the influences of land use changes and upstream flow regulation, is used to represent the possible range of water supply conditions. Major Central Valley rivers, reservoirs, and CVP/SWP facilities are represented by a network of arcs and nodes. CalSim-II uses a mass balance approach to route water through this network. Simulated flows are mean flows for the month; reservoir storage volumes correspond to end-of-month storage.

Monthly CalSim-II model results are intended to be used for comparative purposes. It is important to differentiate between "absolute" or "predictive" modeling applications and "comparative" applications. In "absolute" applications, the model is run once to predict a future outcome; errors or assumptions in formulation, system representation, data, operational criteria, etc., all contribute to total error or uncertainty in model results. In "comparative" applications, the model is run twice, once to represent a base condition (no project) and a second time with a specific change (project) to assess the change in the outcome due to the input change. In this comparative mode (the mode used for this PDEIS), the difference between the two simulations is of principal importance. Potential errors or uncertainties that exist in the "no project" simulation are also present in the "project" simulation such that their impacts are reduced when assessing the change in outcomes.

Spreadsheet Postprocessors For analysis of impacts from each alternative on generation from the Pit 7 Powerplant, a spreadsheet postprocessor was used in lieu of a model. Since no model was available for Pit 7 Powerplant operations, an evaluation of potential impacts of the SLWRI alternatives, as simulated using CalSim-II, on recent historical data was used instead.

The spreadsheet post-processor interpolated CalSim-II output for Shasta Reservoir storage to determine the reservoir water surface elevation. The Shasta Reservoir water surface elevations for each alternative were compared to historical Pit 7 Powerplant tailwater elevations to calculate the change in net

head at the Pit 7 Powerplant. Changes in net head at the Pit 7 Powerplant were assumed to be small enough that turbine/generator efficiencies would be unaffected. For each alternative, the monthly generation was determined by multiplying historical average monthly generation by the ratio of the alternative-reduced net head compared to the historical net head (assumed to be 200 feet based on historical average) raised to the 1.5 power.

23.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under the NEPA, the significance of an effect is used solely to determine whether an Environmental Impact Statement must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environment document propose feasible measures to avoid or substantially reduce significant environmental effects (State and CEQA Guidelines, Section 15126.4(a).

The significance criteria presented in Table 23-1 were developed based on guidance provided by the State CEQA Guidelines and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on power and energy would be significant if project implementation would have any of the results listed in the second column of the table.

Table 23-1. Impact Indicators and Significance Criteria for Energy Generation and Usage

Impact Indicator	Significance Criterion
Shasta Powerplant Energy Generation	Decrease in long-term average monthly hydropower generation of more than 5 percent, due to reduction in net head available for energy generation at Shasta Dam.
CVP and SWP Powerplants Energy Generation	Decrease in long-term average monthly hydropower generation of more than 5 percent, due to decrease in net head available for energy generation at various CVP and SWP powerplants.
CVP and SWP Pumping Plants Energy Consumption	Increase in long-term average monthly power requirement of more than 5 percent, due to increased pumping at various CVP and SWP pumping plants.
CVP and SWP Net Energy Generation	Decrease in long-term average monthly net energy generation, which is the difference between energy generation and energy consumption, of more than 5 percent at various CVP and SWP powerplants.
Pit 7 Powerplant Energy Generation	Decrease in long-term average annual hydropower generation of more than 5 percent, due to increase in Pit 7 tailwater elevation, resulting in reduced net head available for energy generation at Pit 7 Powerplant.

Key:
CVP = Central Valley Project
SWP = State Water Project

An alternative would be considered to have a potentially significant impact on hydropower production if the change in the average monthly energy generation or consumption over the 82-year period of simulation is greater than 5 percent.

A threshold of 5 percent was selected as the threshold of significance for hydroelectric generation for several reasons, including seasonal and annual hydrologic variability, short-term operations decisions that might affect water level in storage, and regional power market demands and prices that might dictate hydropower facilities operations. All these factors could contribute to potentially substantial variations in hydropower generation on a monthly or annual basis. As a result, generation variations of less than 5 percent are not considered significant.

Significance statements are relative to both existing conditions (2005) and future conditions (2030), unless stated, otherwise.

Shasta Powerplant Energy Generation

Shasta Powerplant energy generation would be directly affected by any potential enlargement. While long-term net releases are not likely to change under any enlargement scenario, the monthly pattern of releases could potentially be affected. Assuming there would be no corresponding reduction in power demand, a significant reduction in power production would require an increase in generation from another powerplant to meet any unmet demand.

An alternative would be considered to have a significant impact on Shasta Powerplant energy generation if its monthly average generation was reduced by more than 5 percent at a level of recurrence substantially affecting the power market.

CVP and SWP Powerplants Energy Generation

Changes in CVP operations due to any of the SLWRI alternatives could result in some reoperation of other CVP and SWP facilities, and could result in a decrease in generation at the various CVP and SWP powerplants. A decrease in generation from CVP and SWP powerplants could require an increase in generation in other parts of the generation market, even if the annual amount of generation did not change.

An alternative would be considered to have a significant impact on CVP/SWP powerplant energy generation if its monthly average generation was reduced by more than 5 percent at a level of recurrence substantially affecting the power market.

CVP and SWP Pumping Plants Energy Consumption

Changes in CVP operations due to any of the SLWRI alternatives could result in changes in operations of the CVP and SWP pumping plants. Changes in timing or volume of pumping could cause changes in energy consumption.

An alternative would be considered to have a significant impact on hydropower production if its monthly average pumping plant energy consumption would increase by more than 5 percent at a level of recurrence substantially affecting the power market.

CVP and SWP Net Energy Generation

While changes in CVP operations due to the SLWRI alternatives may increase generation at CVP and SWP powerplants, a similar increase in pumping could result in a net decrease in generation.

A decrease greater than 5 percent in net energy generation at hydropower facilities at a level of recurrence substantially affecting the power market would indicate a significant impact on hydropower production.

Pit 7 Powerplant Energy Generation

The Pit 7 Powerplant is owned and operated by the Pacific Gas and Electric Company. Increases in Shasta Lake water surface elevations could increase the tailwater elevation below the Pit 7 Powerplant, reducing the net head and decreasing generation. An alternative would be considered to have a significant impact on Pit 7 Powerplant energy generation if its monthly average generation was reduced by more than 5 percent at a level of recurrence substantially affecting the power market.

23.3.3 Direct and Indirect Effects

This section describes the environmental consequences of the SLWRI Comprehensive Plans, and proposed mitigation measures for any impacts determined to be significant or potentially significant. All Comprehensive Plans are compared to a basis of comparison; for the existing condition (2005 level of development), a CalSim-II simulation for the existing condition is used. Similarly, the future condition (2030 level of development) uses a CalSim-II simulation of the No-Action Alternative as a basis of comparison. Each of the Comprehensive Plans are simulated using the same level of development so that any changes from the basis of comparison hydropower generation or consumption can be attributed the alternative. Detailed tables of the monthly energy generation and energy consumption associated with each comprehensive plan are included in Attachment 1 of the *Power and Energy Technical Report*.

Modeling results for CP1, CP2, CP3, and CP4 are included below. The operation modeling results for CP5 are not included because they are identical to those of CP3.

The No-Action Alternative and five SLWRI Comprehensive Plans are described in the following subsections. Potential effects of the existing condition, No-Action Alternative, and various SLWRI Comprehensive Plans on energy generation and usage are also described.

No-Action Alternative

Under the No-Action Alternative, the Federal Government would take reasonably foreseeable actions, as defined above, but would take no additional action toward implementing a specific plan to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water reliability issues in California. Shasta Dam would not be modified, and the CVP would continue operating similar to the existing condition. Changes in regulatory conditions and water supply demands would result in differences in flows on the Sacramento River and at the Delta. Possible changes include the following:

- Firm Level 2 Federal refuge needs
- Implementation of the Sacramento Area Water Forum Agreement on the American River
- Increased Contra Costa Water District contract supply and water rights
- SWP deliveries based on full Table A[3] amounts
- Use of the Delta-Mendota Canal–California Aqueduct Intertie
- Implementation of the San Joaquin River Salinity Management Program
- CVP use of Banks Pumping Plant to move 50,000 acre-feet/year of Level 2 refuge water

This alternative is used as a basis of comparison for future condition comparisons.

In the impact analysis below, hydropower generation and consumption, and net energy generation at CVP and SWP facilities under the No-Action Alternative are compared with the existing condition.

Shasta Lake and Vicinity

Impact Hydro-1 (No-Action): Decrease in Shasta Powerplant Energy Generation Increasing the hydropower capabilities of Shasta Powerplant is a secondary planning objective of the SLWRI. An increase in Shasta Powerplant energy generation is one indicator of the project's beneficial impacts. Simulated monthly average Shasta Powerplant energy generation for the No-Action Alternative is shown in Table 23-2. The greatest decrease in long-term monthly average hydropower generation is more than 5 percent compared to the existing condition. In addition, monthly decreases in hydropower generation of greater

[3] The Monterey Agreement (DWR 2003) signed by 27 of the 29 SWP water contractors in 1995, restructured the SWP contracts to allocate water based on contractual Table A amounts instead of the amount of water requested for a given year.

than 5 percent were observed at a level of recurrence that would substantially affect the power market.

Consequently, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Table 23-2. Simulated Monthly Average Shasta Powerplant Energy Generation for No-Action Alternative

Month	Existing Condition (GWh)	No-Action Alternative Change (GWh (%))	
October	132	-9	-7%
November	120	-6	-5%

Upper Sacramento River Negligible effects on Power and Energy are expected to occur in the Upper Sacramento River geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Lower Sacramento River and Delta Negligible effects on Power and Energy are expected to occur in the Lower Sacramento River and Delta geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

CVP/SWP Service Areas

Impact Hydro-2 (No-Action): Decrease in CVP and SWP Powerplant Energy Generation Simulated monthly average CVP and SWP energy generation for the No-Action Alternative shown in Table 23-3 and Table 23-4, respectively. Hydropower generation at CVP powerplants under the No-Action Alternative is similar to that in the existing condition. However, the No-Action Alternative shows an overall beneficial impact from increases on hydropower generation at SWP powerplants compared to the existing condition. Monthly decreases

greater than 5 percent were observed at both CVP and SWP powerplants at a level of recurrence that would substantially affect the power market.

Therefore, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Hydro-3 (No-Action): Increase in CVP and SWP Pumping Plant Energy Consumption Simulated monthly average CVP and SWP energy consumption for the No-Action Alternative is shown in Table 23-5 and Table 23-6, respectively. The greatest increase in long-term monthly average energy consumption at CVP and SWP pumping plants for the No-Action Alternative is more than 5 percent compared to the existing condition, and would cause a potentially significant effect. In addition, monthly increases greater than 5 percent were observed at a level of recurrence that would substantially affect the power market.

Therefore, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Hydro-4 (No-Action): Decrease in CVP and SWP Net Energy Generation Net energy generation is the difference between long-term monthly average energy generation and monthly average energy consumption. Simulated monthly average CVP and SWP net energy generation for the No-Action Alternative is depicted in Table 23-7 and Table 23-8, respectively. The greatest decrease in long-term monthly average net energy generation is more than 5 percent and would cause a potentially significant impact. In addition, monthly decreases greater than 5 percent were observed at a level of recurrence that would substantially affect the power market.

Therefore, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Hydro-5 (No-Action): Decrease in Pit 7 Powerplant Net Energy Generation Simulated monthly average Pit 7 Powerplant energy generation for the No-Action Alternative is depicted in Table 23-9. Total Pit 7 Powerplant energy production for the No-Action Alternative would be similar to that of the existing condition.

Therefore, there would be no impacts. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability while contributing to increased anadromous fish survival, actions that are consistent with the 2000 CALFED Bay-Delta Program (CALFED) Record of Decision (ROD). In addition to the common features above, CP1 primarily consists of raising Shasta Dam 6.5 feet, an elevation change that increases the reservoir's full pool by 8.5 feet, and enlarges the total storage space in the reservoir by 256,000 acre-feet. Under this plan, Shasta Dam normal operational guidelines would continue essentially unchanged, with the additional storage retained for water supply reliability. This scenario helps to reduce future water shortages through increasing drought and average-year water supply reliability. This plan would also include the potential to revise the operational rules for flood control for Shasta Dam and Reservoir, which could benefit flood damage reduction and recreation. Reservoir reoperation would likely include increasing the bottom of the flood control pool elevation based on increased dam height and reservoir capacity. The increased Shasta Reservoir pool depth and volume would also contribute to maintaining lower seasonal water temperatures for anadromous fish on the upper Sacramento River.

This section describes the environmental consequences of CP1. Impacts discussed include the following:

- Decrease in Shasta Powerplant energy generation
- Decrease in CVP and SWP powerplant energy generation
- Increase in CVP and SWP pumping plant energy consumption
- Decrease in CVP and SWP net energy generation
- Decrease in Pit 7 Powerplant energy generation

Shasta Lake and Vicinity

Impact Hydro-1 (CP1): Decrease in Shasta Powerplant Energy Generation

Increasing the hydropower capabilities of Shasta Powerplant is one of the secondary objectives of the study. An increase in Shasta Powerplant energy generation is one indicator of the project's beneficial impacts. This impact would be potentially significant.

Table 23-10 shows an overall increase in monthly generation of 1 to 4 percent at Shasta Powerplant for CP1 compared to the existing condition. Similarly, CP1 shows an overall beneficial impact on hydropower generation from increases of 1 to 5 percent compared to the future condition. Although CP1 indicates an overall beneficial impact, monthly decreases in hydropower generation greater than 5 percent were observed 63 times in the existing condition level of

development and 95 times in the future condition level of development out of 984 occurrences.

Consequently, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation from Shasta Powerplant would be offset by increased generation from other sources.

Table 23-10. Simulated Monthly Average Shasta Powerplant Energy Generation for CP1

Month	Existing Condition (2005)			Future Condition (2030)

CVP/SWP Service Areas

Impact Hydro-2 (CP1): Decrease in CVP and SWP Powerplant Energy Generation Table 23-11 shows a beneficial impact from an overall increase in monthly generation at CVP powerplants of 1 to 2 percent for CP1 compared to the existing condition. A decrease in long-term monthly generation of 1 percent, observed for January and September, would be a less than significant impact. Similarly, CP1 shows an overall beneficial impact on hydropower generation from increases of 1 to 2 percent compared to the future condition. A decrease in long-term monthly average generation of 1 percent, in January, April, and September, would be a less than significant impact. However, when considering the maximum monthly for CP1 on hydropower generation, decreases greater than 5 percent were observed 75 times in the existing condition level of development and 93 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on CVP energy generation.

Table 23-11. Simulated Monthly Average CVP Energy Generation for CP1

Therefore, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Impact Hydro-3 (CP1): Increase in CVP and SWP Pumping Plant Energy Consumption Table 23-13 shows the change in monthly energy consumption at CVP pumping plants for CP1, compared to the existing condition that would result from additional pumping to accommodate the primary planning objectives of the study, increasing water supply reliability and anadromous fish survival. The greatest increase in long-term monthly average energy consumption, 3 percent, observed for March and July, would be a less than significant impact. Similar operations criteria governing CP1, compared to the future condition, resulted in a maximum increase of 2 percent in long-term average March energy consumption, which would also be a less than significant impact. However, when considering the maximum monthly impact for CP1 on energy consumption, increases greater than 5 percent were observed 97 times in the existing condition level of development and 104 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on CVP energy consumption.

Table 23-13. Simulated Monthly Average CVP Energy Consumption for CP1

Table 23-14 shows the change in monthly energy consumption at SWP pumping plants for CP1, compared to the existing condition, resulting from additional pumping. The greatest increase in long-term monthly average energy consumption, 2 percent, observed for February, would be a less than significant impact. Similar operations criteria governing CP1, compared to the future condition, resulted in a maximum increase of 3 percent in long-term average January energy consumption, which would also be a less than significant impact. However, when considering the maximum monthly impact for CP1 on energy consumption, increases greater than 5 percent were observed 125 times in the existing condition level of development and 102 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP energy consumption.

Therefore, this impact would be potentially significant. Mitigation for this impact is not proposed because increases in energy consumption would be offset by increased generation from other sources.

Impact Hydro-4 (CP1): Decrease in CVP and SWP Net Energy Generation
Table 23-15 shows the change in net energy generation, which is the difference between the long-term monthly average energy generation and monthly average energy consumption, at all CVP plants for CP1, compared to the existing condition. Overall, CP1 shows a beneficial impact in the form of increased long-term monthly net energy generation. The greatest decrease in long-term monthly average net energy generation, 2 percent, observed for January, would be a less than significant impact. Similarly, an overall beneficial impact from increase in net energy generation was observed for CP1, compared to the future condition. A maximum decrease in net energy generation of 2 percent, observed for September, would also be a less than significant impact. However, when considering the maximum monthly impact for CP1 on net energy generation, decreases greater than 5 percent were observed 128 times in the existing condition level of development and 158 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on CVP net energy generation.

Table 23-15. Simulated Monthly Average CVP Net Energy Generation for CP1

Table 23-16 shows the change in net energy generation, which is the difference between the long-term monthly average energy generation and monthly average energy consumption, at all SWP plants for CP1 compared to the existing condition. CP1 shows an overall decrease in long-term monthly net energy generation; the greatest decrease, 4 percent, occurring in February, would be a less than significant impact. Similarly, an overall decrease in net energy generation was observed for CP1 compared to the future condition; the greatest decrease, 5 percent, observed for January, would also be a less than significant impact. However, when considering the maximum monthly impact for CP1 on net energy generation, decreases greater than 5 percent were observed 54 times in the existing condition level of development and 84 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP net energy generation.

Therefore, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Impact Hydro-5 (CP1): Decrease in Pit 7 Powerplant Net Energy Generation
Table 23-17 shows the estimate of decreased energy production on Pit 7 Details

are included in Attachment 1 of the Power and Energy Technical Report, on energy generation, consumption, and change for CP1 compared to the existing condition and No-Action Alternative for all CVP and SWP powerplants and pumping plants.

Powerplant under CP1. Pit 7 Powerplant energy production would generally decrease only when the raised Shasta pool is higher than the normal Pit 7 tailwater elevation of 1,067 feet above msl based on National Geodetic Vertical Datum of 1929 (NGVD29). Assuming that the historic annual pattern of Shasta pool levels would be maintained with the higher maximum pool, in an average year, Pit 7 Powerplant energy production would decrease from March through July. These 5 months typically provide roughly 47 percent of the total average annual energy production. Taking these factors into account, total Pit 7 Powerplant average annual energy production for CP1 could decrease by roughly 4 gigawatt-hours (GWh) (1 percent) from the existing condition and future condition. Looking at maximum monthly impact for CP1, the decrease in net energy generation is less than 5 percent, which is a less than significant impact.

Table 23-17. Simulated Monthly Average Pit 7 Powerplant Energy Generation for CP1

Month	Existing Condition (2005)			Future Condition (2030)

Source: Spreadsheet model, Pit 7 Dam MONTHLY AVG.xls,2007

Note:
Simulation period: 1922 – 2003
Key:
CP = Comprehensive Plan
GWh = gigawatt-hour

Under the existing condition, the turbines operate over a net head range of approximately 173 to 204 feet. Under the 6.5-foot Shasta Dam raise option, the operating range of net head would decrease to about 168 to 193 feet, an approximately 4 percent decrease in net head. Assuming peak turbine efficiency is approximately 204 feet net head, the potential future minimum net head of 168 feet would be about 82 percent of the peak efficiency net head, which would still be an acceptable range for continuous operation. A decrease in maximum net head from 204 feet to 193 feet would reduce each unit's generating capacity by approximately 5 percent, from the current 56 MWh to approximately 53 MWh.

For these reasons, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As with CP1, this Comprehensive Plan focuses on enlargement of Shasta Dam and Reservoir consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increased water supply reliability and increased anadromous fish survival. In addition to the common features above, CP2 consists of raising Shasta Dam 12.5 feet, an elevation change that increases the full pool by 14.5 feet, and enlarges the total storage space in the reservoir by 443,000 acre-feet. This alternative would help reduce future shortages by increasing drought and average year water supply reliability. The increased cold-water pool also would contribute to improved seasonal water temperatures for anadromous fish on the upper Sacramento River.

Simulations of CP2 did not involve any changes to the modeling logic for deliveries or flow requirements; all benchmark rules were updated to include the new storage, but were not otherwise changed.

Shasta Lake and Vicinity

Impact Hydro-1 (CP2): Decrease in Shasta Powerplant Energy Generation A decrease in Shasta Dam energy generation is one indicator of project impacts because increasing the hydropower capabilities of Shasta Powerplant is one of the secondary planning objectives of the study. This impact would be potentially significant.

Table 23-18 shows an overall beneficial impact from increase in monthly generation at Shasta Powerplant for CP2 of 38 percent in December to 157 percent in April, compared to the existing condition. Similarly, CP2 shows an overall beneficial impact from increase in hydropower generation of 2 to 5 percent compared to the future condition. A decrease of 2 percent in long-term average energy generation, observed for December, would be a less than significant impact. The increase in power generation is due to raising Shasta Dam by 14.5 feet, which would increase the available head for power generation. However, when considering the maximum monthly impact for CP2

in hydropower generation, decreases greater than 5 percent were observed 9 times in the existing condition level of development and 88 times in the future condition level of development out of 984 occurrences.

Therefore, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Upper Sacramento River Negligible effects on Power and Energy are expected to occur in the Upper Sacramento River geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Lower Sacramento River and Delta Negligible effects on Power and Energy are expected to occur in the Lower Sacramento River and Delta geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

CVP/SWP Service Areas

Impact Hydro-2 (CP2): Decrease in CVP and SWP Powerplant Energy Generation Table 23-19 shows an overall beneficial impact from an increase in monthly generation of 21 to 67 percent at CVP powerplants for CP2, compared to the existing condition. Similarly, CP2 shows an overall beneficial impact from increases on hydropower generation of 1 to 3 percent compared to the future condition. A decrease in long-term monthly average energy generation of 1 percent, observed for January, would be a less than significant impact. However, when considering the maximum monthly impact for CP2 on hydropower generation, decreases greater than 5 percent were observed 79 times in the existing condition level of development and 93 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on CVP energy generation.

Table 23-20 shows an overall beneficial impact from an increase in monthly generation at SWP powerplants of 1 to 2 percent for CP2, compared to the existing condition. A decrease in long-term monthly generation of 1 percent, observed for November, January, February, and March, would be a less than significant impact. Similarly, CP2 shows an overall beneficial impact from increases of approximately 1 percent in hydropower generation compared to the future condition. A decrease of long-term monthly average energy generation of less than 1 percent, observed for June, would be a less than significant impact. However, when considering the maximum monthly impact for CP2 on hydropower generation, decreases greater than 5 percent were observed 61 times in the existing condition level of development and 100 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP energy generation.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Table 23-20. Simulated Monthly Average SWP Energy Generation for CP2

Month	Existing Condition (2005)			Future Condition (2030)		
	Existing Condition (GWh)	CP2 Change (GWh (%))		No-Action Alternative (GWh)	CP2 Change (GWh (%))

Impact Hydro-3 (CP2): Increase in CVP and SWP Pumping Plant Energy Consumption Table 23-21 shows the change in monthly energy consumption at CVP pumping plants for CP2, compared to the existing condition, resulting from additional pumping to accommodate the primary planning objectives of the study, increasing water supply reliability and anadromous fish survival. The greatest increase in long-term monthly average energy consumption, 3 percent, observed for July, would be a less than significant impact. Similar operations criteria governing CP2 compared to the future condition resulted in a maximum increase of 3 percent in long-term February average energy consumption, which also would be a less than significant impact. However, when considering the maximum monthly impact for CP2 on energy consumption, increases greater than 5 percent were observed 99 times in the existing condition level of development and 124 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact

Table 23-22 shows the change in monthly energy consumption at SWP pumping plants for CP2, compared to the existing condition, resulting from additional pumping. The greatest increase in long-term monthly average energy consumption, 2 percent, observed for November, would be a less than significant impact. Similar operations criteria governing CP2 compared to the future condition resulted in a maximum increase of 3 percent in long-term January average energy consumption, which would also be a less than significant impact. However, when considering the maximum monthly impact for CP2 in energy consumption, increases greater than 5 percent were observed 134 times in the existing condition level of development and 95 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP energy consumption.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because increases in energy consumption would be offset by increased generation from other sources.

Impact Hydro-4 (CP2): Decrease in CVP and SWP Net Energy Generation
Table 23-23 shows the change in net energy generation, which is the difference between long-term monthly average energy generation and monthly average energy consumption, at all CVP plants for CP2 compared to the existing condition. Overall, CP2 shows a beneficial impact in the form of increased long-term monthly net energy generation, ranging from 29 percent in September to 78 percent in April. No decrease in long-term monthly average net energy generation was observed. Similarly, an overall beneficial impact from increase in net energy generation was observed for CP2 compared to the future condition. A maximum decrease in net energy generation of 1 percent, observed for January and September, would be a less than significant impact. However, when considering the maximum monthly impact for CP2 on net energy generation, decreases greater than 5 percent were observed 127 times in the existing condition level of development and 150 times in future condition out of 984 occurrences. Consequently, there would be a potentially significant impact on CVP net energy generation.

Table 23-23. Simulated Monthly Average CVP Net Energy Generation for CP2

Month	Existing Condition (2005)			Future Condition (2030)

Table 23-24 shows the change in net energy generation, which is the difference between long-term monthly average energy generation and monthly average energy consumption, all SWP plants for CP2 compared to the existing condition. Table 23-16 also shows a decrease in net energy generation in all months. The decrease of 1 to 4 percent, with an annual decrease of 2 percent, would be a less than significant impact. Similarly, an overall decrease in net energy generation was observed for CP2 compared to the future condition. The decrease, ranging from 1 percent to 5 percent, would be a less than significant impact. The only beneficial impact from increase in net generation of 1 percent was observed for September. However, when considering the maximum monthly impact for CP2 on net energy generation, decreases greater than 5 percent were observed 58 times in the existing condition level of development and 99 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP net energy generation.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Details are included in Attachment 1 of the Power and Energy Technical Report, for energy generation, consumption, and change for CP2 compared to the existing condition and No-Action Alternative for all CVP and SWP powerplants and pumping plants.

Impact Hydro-5 (CP2): Decrease in Pit 7 Powerplant Net Energy Generation
Table 23-25 shows an estimate of reduced energy production for the Pit 7 Powerplant under CP2. Energy production for the Pit 7 Powerplant would generally decrease only when the raised Shasta pool is higher than the normal Pit 7 tailwater elevation of 1,067 feet above msl (NGVD29). Assuming that the historic annual pattern of Shasta pool level is maintained with the higher maximum pool, in an average year, Pit 7 Powerplant energy production would decrease from February through July. These 6 months typically provide roughly 56 percent of the total average annual energy production. Therefore, total average annual energy production for the Pit 7 Powerplant for CP2 could decrease by roughly 8.3 GWh (2 percent) from the existing condition and 8.2 GWh (2 percent) from the future condition. Considering the maximum monthly impact for CP2, decreases in net energy generation greater than 5 percent were observed in several instances, particularly in March through June, which could be a potentially significant impact on Pit 7 Powerplant net energy generation.

Table 23-25. Simulated Monthly Average Pit 7 Powerplant Energy Generation for CP2

Month	Existing Condition (2005)			Future Condition (2030)

CP = Comprehensive Plan
GWh = gigawatt-hour

Under the existing condition, the turbines operate over a net head range of approximately 173 to 204 feet. Under the 12.5-foot Shasta Dam raise option, the operating range of net head would decrease to about 162 to 187 feet, an approximate 7 percent reduction in net head. Assuming peak turbine efficiency is approximately 204 feet of net head, the potential future minimum net head of 162 feet would be about 79 percent of the peak efficiency net head, which should be an acceptable range for continuous operation. A reduction in maximum net head from 204 feet to 187 feet would reduce each unit's generating capacity by approximately 8 percent, from the current 56 MW to approximately 51 MW.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP3 is similar to CP1 and CP2. It focuses on the greatest practical enlargement of Shasta Dam and Reservoir consistent with the goals of the 2000 CALFED ROD, and was formulated for the primary purposes of increased water supply reliability and increased anadromous fish survival. In addition to the common features above, CP3 consists of raising Shasta Dam 18.5 feet, an elevation change that increases the full pool by 20.5 feet, and enlarges the total storage space in the reservoir by 634,000 acre-feet to 5.19 million acre-feet. This Comprehensive Plan would help reduce future shortages by increasing drought and average year water supply reliability. The increased pool depth and volume would also contribute to improving seasonal water temperatures for anadromous fish on the upper Sacramento River.

Simulations of CP3 did not involve any changes to the modeling logic for deliveries or flow requirements; all benchmark rules were updated to include the new storage, but were not otherwise changed.

Shasta Lake and Vicinity

Impact Hydro-1 (CP3): Decrease in Shasta Powerplant Energy Generation A decrease in Shasta Dam energy generation is one indicator of project impacts because increasing the hydropower capabilities of the Shasta Powerplant is a secondary planning objective of the study. This impact would be potentially significant.

Table 23-26 shows a large beneficial impact from increase in monthly generation at the Shasta Powerplant, ranging from 37 percent in December to 159 percent in April, for CP3 compared to the existing condition. No decrease in long-term monthly generation was observed. Similarly, CP3 shows an overall beneficial impact from increases on hydropower generation, ranging from 2 percent in January to 7 percent in August, compared to the future condition. A decrease in long-term average energy generation of 2 percent, observed for

December, would be a less than significant impact. However, when considering the maximum monthly impact for CP3 on hydropower generation, decreases greater than 5 percent were observed 11 times in the existing condition level of development and 84 times in the future condition level of development out of 984 occurrences.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Upper Sacramento River Negligible effects on Power and Energy are expected to occur in the Upper Sacramento River geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Lower Sacramento River and Delta Negligible effects on Power and Energy are expected to occur in the Lower Sacramento River and Delta geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Table 23-30 shows the change in monthly energy consumption at SWP pumping plants resulting from additional pumping for CP3 compared to the existing condition. The greatest increase in long-term monthly average energy consumption, 2 percent, observed for February, would be a less than significant impact. Similar operations criteria governing CP3 compared to the future condition resulted in a maximum increase of 3 percent for long-term average energy consumption in January, which would also be a less than significant impact. However, when considering the maximum monthly impact for CP3 on energy consumption, increases greater than 5 percent were observed 129 times in the existing condition level of development and 108 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP energy consumption.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because increases in energy consumption would be offset by increased generation from other sources.

Table 23-30. Simulated Monthly Average SWP Energy Consumption for CP3 and CP5

Month	Existing Condition (2005)			Future Condition (2030)

Impact Hydro-4 (CP3): Decrease in CVP and SWP Net Energy Generation
Table 23-31 shows the change in net energy generation, which is the difference between the long-term monthly average energy generation and monthly average energy consumption, at all CVP plants for CP3 compared to the existing condition. Overall, CP3 shows a beneficial impact in the form of increased long-term monthly net energy generation. No decrease in long-term monthly average net generation was observed. Similarly, an overall beneficial impact from increases on net energy generations was observed for CP3 compared to the future condition. A maximum decrease in net energy generation of 1 percent, observed for September, would also be a less than significant impact. However, when considering the maximum monthly impact for CP3 on net energy generation, decreases greater than 5 percent were observed 143 times in the existing condition level of development and 163 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on CVP net energy generation.

Table 23-31. Simulated Monthly Average CVP Net Energy Generation for CP3 and CP5

Month	Existing Condition (2005)			Future Condition (2030)

Table 23-32 shows the change in net energy generation, which is the difference between long-term monthly average energy generation and monthly average energy consumption, at all SWP plants for CP3 compared to the existing condition. CP3 shows an overall decrease in long-term monthly net energy generation; the greatest decrease, 4 percent, observed for February, would be a less than significant impact. Similarly, an overall decrease in net energy generation was observed for CP3 compared to the future condition; the greatest decrease in net generation, 5 percent, observed for January, would also be considered a less than significant impact. However, when considering the maximum monthly impact for CP3 on net energy generation, decreases greater than 5 percent were observed 48 times in the existing condition level of development and 99 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP net energy generation.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Details are included in Attachment 1 of the *Power and Energy Technical Report*, for energy generation, consumption, and change for CP3 compared to the existing condition and No-Action Alternative for all CVP and SWP powerplants and pumping plants.

Impact Hydro-5 (CP3): Decrease in Pit 7 Powerplant Net Energy Generation
Table 23-33 shows an estimate of decreased energy production for the Pit 7 Powerplant under CP3. Energy production for the Pit 7 Powerplant would generally decrease only when the raised Shasta pool is higher than the normal Pit 7 tailwater elevation of 1,067 feet above msl (NGVD29). Assuming that the historic annual pattern of Shasta pool levels is maintained with the higher maximum pool, in an average year, Pit 7 Powerplant energy production would decrease from February through July. These 6 months typically provide roughly 56 percent of the total average annual energy production. Therefore, total average annual energy production for the Pit 7 Powerplant for CP3 could decrease by roughly 14 GWh (3 percent) for the existing condition and 13.9 GWh (3 percent) for the future condition. Considering the maximum monthly impacts for CP3, decreases in net energy generation greater than 5 percent were observed in several instances, particularly in March through July, which could potentially be a significant impact on Pit 7 Powerplant net energy generation.

Table 23-33. Simulated Monthly Average Pit 7 Powerplant Energy Generation for CP3 and CP5

Month	Existing Condition (2005)			Future Condition (2030)		
	Existing Condition (GWh)	CP3 Change (GWh (%))		No-Action Alternative (GWh)	CP3 Change (GWh (%))

CP = Comprehensive Plan
GWh = gigawatt-hour

Under the existing condition, the turbines operate with a net head range of approximately 173 to 204 feet. Under the 18.5-foot Shasta Dam raise option, the operating range of net head would decrease to about 156 to 181 feet, an approximate 10 percent reduction in net head. Assuming peak turbine efficiency is approximately 204 feet net head, the potential future minimum net head of 156 feet would be about 75 percent of the peak efficiency net head, which should an acceptable range for continuous operation. A decrease in maximum net head from 204 feet to 181 feet would reduce each unit's generating capacity by approximately 17 percent, from the current 56 MW to approximately 47 MW.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

The primary function of CP4 is to address anadromous fish survival, while still improving water supply reliability. It focuses on increasing the volume of cold water available to the temperature control device through reservoir reoperations, and on raising Shasta Dam by 18.5 feet. As with CP3, and in addition to the common features above, this raise would increase the full pool by 20.5 feet and enlarge total reservoir storage space by 634,000 acre-feet. This additional storage space would expand Shasta Reservoirs' cold-water supply available to the temperature control device by 378,000 acre-feet, a feature that would help improve cooler water temperatures in the upper Sacramento River.

CP4 differs from CP3 by focusing on increased storage to maintaining cold-water volume, resulting in a higher seasonal carryover storage. The operations of CP4 are identical to those of CP1. With that constraint, simulation of CP4 did not involve any changes to the modeling logic for deliveries or flow requirements; all of the benchmark rules were updated to include the new storage, but were not otherwise changed.

Shasta Lake and Vicinity

Impact Hydro-1 (CP4): Decrease in Shasta Powerplant Energy Generation A decrease in Shasta Dam energy generation is one indicator of project impacts because increasing the hydropower capabilities of Shasta Powerplant is a secondary planning objective of the study. This impact would be potentially significant.

Table 23-34 shows an overall beneficial impact from increases on monthly generation at Shasta Powerplant of 5 to 8 percent for CP4 compared to the existing condition. No decrease in long-term monthly generation was observed. Similarly, CP4 shows an overall beneficial impact from increases on hydropower generation of 5 to 11 percent compared to the future condition. No decrease in long-term average monthly generation was observed. Although CP4 indicates an overall beneficial impact, maximum monthly decreases in hydropower generation greater than 5 percent were observed 43 times in the existing condition and 58 times in the future condition out of 984 occurrences.

For this reason, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Upper Sacramento River Negligible effects on Power and Energy are expected to occur in the Upper Sacramento River geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Table 23-34. Simulated Monthly Average Shasta Powerplant Energy Generation for CP4

Month	Existing Condition (2005)			Future Condition (2030)

Lower Sacramento River and Delta Negligible effects on Power and Energy are expected to occur in the Lower Sacramento River and Delta geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

CVP/SWP Service Areas

Impact Hydro-2 (CP4): Decrease in CVP and SWP Powerplant Energy Generation Table 23-35 shows an overall beneficial impact from increases on monthly generation at CVP powerplants of 1 percent in April and September to 5 percent in November for CP4 compared to the existing condition. No decrease in long-term monthly generation was observed. Similarly, CP4 shows an overall beneficial impact from increases on hydropower generation of 2 to 6 percent compared to the future condition. No decrease in long-term average monthly generation was observed. However, when considering the maximum monthly impact for CP4 on hydropower generation, decreases greater than 5 percent were observed 62 times in the existing condition level of development and 27 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on CVP energy generation.

Table 23-35. Simulated Monthly Average CVP Energy Generation for CP4

Month	Existing Condition (2005)			Future Condition (2030)

Table 23-36 shows an overall increase of 1 percent in monthly generation at SWP powerplants for CP4 compared to the existing condition. A decrease in long-term monthly generation of 1 percent, observed for January, March, and November, would be a less than significant impact. CP4 shows no change in hydropower generation compared to the future condition. A decrease in long-term monthly average generation of 1 percent, observed for February, would be a less than significant impact. However, when considering the maximum monthly impact for CP4 on hydropower generation, decreases greater than 5 percent were observed 60 times in the existing condition level of development and 33 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP energy generation.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Table 23-36. Simulated Monthly Average SWP Energy Generation for CP4

Table 23-40 shows the change in net energy generation, which is the difference between long-term monthly average energy generation and monthly average energy consumption, at all SWP plants for CP4 compared to the existing condition. CP4 shows an overall decrease in long-term monthly net energy generation. The greatest decrease in net generation, 4 percent, observed for February, would be a less than significant impact. No significant change in net energy generations was observed for CP4 compared to the future condition. The greatest decrease in net generation, 1 percent, observed for January, February, and June, would also be a less than significant impact. However, when considering the maximum monthly impact for CP4 on net energy generation, decreases greater than 5 percent were observed 54 times in the existing condition level of development and 32 times in the future condition level of development out of 984 occurrences. Consequently, there would be a potentially significant impact on SWP net energy generation.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

Source: Common Assumptions Common Modeling Package Version 9, SWP Power CA
Note:
Simulation period: 1922 – 2003
Key:
CP = Comprehensive Plan
GWh = gigawatt-hour
SWP = State Water Project

Details are included in Attachment 1 of the *Power and Energy Technical Report*, for energy generation, consumption, and change for CP4 compared to the existing condition and No-Action Alternative for all CVP and SWP powerplants and pumping plants.

Impact Hydro-5 (CP4): Decrease in Pit 7 Powerplant Net Energy Generation
Table 23-41 shows an estimate of decreased energy production for the Pit 7 Powerplant under CP4. Energy production for the Pit 7 Powerplant would generally decrease only when the raised Shasta pool is higher than the normal Pit 7 tailwater elevation of 1,067 feet above msl (NGVD29). Assuming that the historic annual pattern of Shasta full pool levels is maintained with the higher maximum pool, in an average year, Pit 7 Powerplant energy production would decrease from February through July. These 6 months typically provide roughly 56 percent of the total average annual energy production. Therefore, total average annual energy production for the Pit 7 Powerplant could decrease by roughly 12.2 GWh (2 percent). Considering maximum monthly impact for CP4, decreases in net energy generation greater than 5 percent were observed in several instances, particularly in March through June, which could potentially be a significant impact on Pit 7 Powerplant net energy generation.

Table 23-41. Simulated Monthly Average Pit 7 Powerplant Energy Generation for CP4

Month	Existing Condition (2005)			Future Condition (2030)		
	Existing Condition (GWh)	CP4 Change (GWh (%))		No-Action Alternative (GWh)	CP4 Change (GWh (%))	
January	52.6	0.0	(0%)	52.6	0.0	(0%)
February	52.6	-0.1	(0%)	52.6	-0.2	(0%)

Note:
Simulation period: 1922 – 2003
Key:
CP = Comprehensive Plan
GWh = gigawatt-hour

Under the existing condition, the turbines operate with a net head range of approximately 173 to 204 feet. Under the 18.5-foot Shasta Dam raise option, the operating range of net head would decrease to about 156 to 181 feet, an approximate 10 percent reduction in net head. Assuming peak turbine efficiency is approximately 204 feet net head, the potential future minimum net head of 156 feet would be about 75 percent of the peak efficiency net head, which should an acceptable range for continuous operation. A decrease in maximum net head from 204 feet to 181 feet would reduce each unit's generating capacity by approximately 17 percent, from the current 56 MW to approximately 47 MW.

For these reasons, this impact would be potentially significant. Mitigation for this impact is not proposed because reductions in power generation would be offset by increased generation from other sources.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 would address both the primary and secondary planning objectives. CP5 includes enlarging Shasta Dam by 18.5 feet, which is consistent with the objectives of the 2000 CALFED ROD, and also includes the common features above. In addition, CP5 includes (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing either additional or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. Formulation of specific environmental restoration features and increased recreation components is not yet complete but will be included in the Draft Feasibility Report.

Operations under CP5 would be identical to CP3. The differences between the two alternatives would be limited to nonperational features.

Shasta Lake and Vicinity

Impact Hydro-1 (CP5): Decrease in Shasta Powerplant Energy Generation

This impact would be the same as Impact Hydro-1 (CP3) and would be potentially significant.

Upper Sacramento River Negligible effects on Power and Energy are expected to occur in the Upper Sacramento River geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

Lower Sacramento River and Delta Negligible effects on Power and Energy are expected to occur in the Lower Sacramento River and Delta geographic region; therefore, potential effects in that geographic region are not discussed further in this PDEIS.

CVP/SWP Service Areas

Impact Hydro-2 (CP5): Decrease in CVP and SWP Powerplants Energy Generation This impact would be the same as Impact Hydro-2 (CP3) and would be potentially significant.

Impact Hydro-3 (CP5): Increase in CVP and SWP Pumping Plant Energy Consumption This impact would be the same as Impact Hydro-3 (CP3) and would be potentially significant.

Impact Hydro-4 (CP5): Decrease in CVP and SWP Net Energy Generation This impact would be the same as Impact Hydro-4 (CP3) and would be potentially significant.

Impact Hydro-5 (CP5): Decrease in Pit 7 Powerplant Net Energy Generation This impact would be the same as Impact Hydro-5 (CP3) and would be potentially significant.

23.3.4 Mitigation Measures

Table 23-42 presents a summary of mitigation measures for power and energy.

No-Action Alternative and CP1 – CP5

No specific mitigation measures are proposed for the decrease in hydropower generation, and the increase in consumption of electrical energy.

There are several potential significant unavoidable impact to energy generation and energy consumption associated with the implementation of No-Action Alternative and CP1 – CP5, as shown in Table 23-42.

Each of these potential significant unavoidable impacts is the result of decrease in energy production (decrease in hydropower generation) or increase in energy usage (increase in power consumption for pumping). These unavoidable impacts are potentially significant because they would likely require the generation of electrical energy from another source (to replace lost hydroelectric generation or to provide additional power for pumping). Replacement of additional generation would likely come from a thermal generation source, such as combined cycle natural gas fired turbine, or a coal fired powerplant. Generation from a source that meets the California Public Utilities Commission's Emissions Performance Standards would contribute up to 1,200 pounds/MWh of greenhouse, plus other pollutants such as particulates and oxides of nitrogen. Thus, additional pumping electoral load of 5,000 MWh per year would likely contribute 3,000 tons of more greenhouse gasses to the atmosphere.

Table 23-42. Summary of Mitigation Measures for Power and Energy

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact Hydro-1: Decrease in Shasta Powerplant Energy Generation	LOS before Mitigation	PS	PS	PS	PS	PS	PS

PS = potentially significant

23.3.5 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences" discusses the overall cumulative impacts of the project alternatives, including the relationship to CALFED Programmatic Cumulative Impacts Analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria.

This section provides an analysis of overall cumulative impacts of the project alternatives with other past, present, and reasonably foreseeable future projects producing related impacts.

The projects listed in the quantitative analysis section of Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences" are included in the 2030 level-of-development alternatives. Accordingly, quantitative effects of the projects combined with the SLWRI alternatives are described in the Section 23.2. Project alternatives would cause

potentially significant impacts on CVP and SWP facility hydropower generation and consumption. The discussion below focuses on the qualitative effect of the SLWRI alternatives and other past, present, and reasonably foreseeable future projects.

The effects of climate change on operations at Shasta Lake could potentially result in changes to power and energy. As described in the Climate Change Projection Appendix, climate change could result in higher reservoir releases in the winter and early spring due to an increase in runoff during these times. Similarly, climate change could result in lower reservoir inflows and Sacramento tributary flows during the late spring and summer due to a decreased snow pack. This reduction in inflow and tributary flow could result in Shasta Lake storage being reduced due to both a reduced ability to capture flows, and an increased need to make releases to meet downstream requirements.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

When combined with other past, present, and reasonably foreseeable future projects, it is likely there would be a change in river flows and reservoir elevations. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, any new project or program along the Sacramento River and in the Delta could potentially impact the CVP and SWP facility hydropower generation and consumption of CP1. With the implementation of many of the projects, Shasta Reservoir could be reoperated, which would result in changes to the Sacramento River flow regime and reservoir elevations, and could cause a potentially significant impact on CVP/SWP facility hydropower generation and consumption.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows and storage at other times. The additional storage associated with CP1 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Additionally, the increased storage volume would allow Shasta Lake to maintain greater storage and potentially greater hydropower generation. Therefore, the addition of anticipated effects of climate change, would not result in CP1 having a significant cumulative effect.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

When combined with other past, present, and reasonably foreseeable future projects, it is likely there would be a change in river flows and reservoir elevations. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, any new project or program along the Sacramento River and in the Delta could potentially impact the CVP and SWP facility hydropower generation and consumption of CP2. With the

implementation of many of the projects, Shasta Reservoir could be reoperated, which would result in changes to the Sacramento River flow regime and reservoir elevations, and could cause a potentially significant impact on CVP/SWP facility hydropower generation and consumption.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows and storage at other times. The additional storage associated with CP2 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Additionally, the increased storage volume would allow Shasta Lake to maintain greater storage and potentially greater hydropower generation. Therefore, the addition of anticipated effects of climate change, would not result in CP2 having a significant cumulative effect.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

When combined with other past, present, and reasonably foreseeable future projects, it is likely there would be a change in river flows and reservoir elevations. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, any new project or program along the Sacramento River and in the Delta could potentially impact the CVP and SWP facility hydropower generation and consumption of CP3. With the implementation of many of the projects, Shasta Reservoir could be reoperated, which would result in changes to the Sacramento River flow regime and reservoir elevations, and could cause a potentially significant impact on CVP/SWP facility hydropower generation and consumption.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows and storage at other times. The additional storage associated with CP3 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Additionally, the increased storage volume would allow Shasta Lake to maintain greater storage and potentially greater hydropower generation. Therefore, the addition of anticipated effects of climate change, would not result in CP3 having a significant cumulative effect.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

When combined with other past, present, and reasonably foreseeable future projects, it is likely there would be a change in river flows and reservoir elevations. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, any new project or program along the Sacramento River and in the Delta could potentially impact the CVP and SWP facility hydropower generation and consumption of CP4. With the implementation of many of the projects, Shasta Reservoir could be reoperated,

which would result in changes to the Sacramento River flow regime and reservoir elevations, and could cause a potentially significant impact on CVP/SWP facility hydropower generation and consumption.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows and storage at other times. The additional storage associated with CP4 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Additionally, the increased storage volume would allow Shasta Lake to maintain greater storage and potentially greater hydropower generation. Therefore, the addition of anticipated effects of climate change, would not result in CP4 having a significant cumulative effect.

CP5 – 18.5-Foot Dam Raise, Combination Plan

When combined with other past, present, and reasonably foreseeable future projects, it is likely there would be a change in river flows and reservoir elevations. Since Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and Delta, any new project or program along the Sacramento River and in the Delta could potentially impact the CVP and SWP facility hydropower generation and consumption of CP5. With the implementation of many of the projects, Shasta Reservoir could be reoperated, which would result in changes to the Sacramento River flow regime and reservoir elevations, and could cause a potentially significant impact on CVP/SWP facility hydropower generation and consumption.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows and storage at other times. The additional storage associated with CP5 would potentially diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Additionally, the increased storage volume would allow Shasta Lake to maintain greater storage and potentially greater hydropower generation. Therefore, the addition of anticipated effects of climate change, would not result in CP5 having a significant cumulative effect.

Chapter 24
Environmental Justice

24.1 Affected Environment

24.1.1 Minority and Low-Income Populations

The environmental setting of a project area can be viewed from both a geographic perspective and a human perspective. The physical environment provides a geographical context for the populations to be evaluated in this Environmental Impact Statement. The human perspective encompasses race, ethnic origin, and economic status of affected groups.

The intent of an environmental justice evaluation under Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority and Low Income Populations* (1994), is to identify communities and groups that meet environmental justice criteria, and suggest strategies to reduce potential adverse impacts of projects on affected groups.

In its guide to environmental justice under NEPA, the Council on Environmental Quality (CEQ) (1997) encourages agencies to consider all of the following groups in the scoping process:

- Religious organizations
- Newspapers, radio, and other media
- Civic associations
- Minority business associations
- Environmental and environmental justice organizations
- Legal aid providers
- Homeowners', tenants', and neighborhood watch groups
- Federal, State, local, and tribal governments
- Rural cooperatives
- Business and trade organizations
- Community and social service organizations
- Universities, colleges, vocational, and other schools
- Labor organizations

- Civil rights organizations
- Local schools and libraries
- Senior citizens' groups
- Public health agencies and clinics

Shasta Lake and Vicinity

This evaluation reviews minority and low-income communities situated near the reservoir, and those that directly depend on it for social, economic, cultural, historic, occupational, recreational, or other needs deemed significant by these communities.

Table 24-1 depicts a historically white population that is slowly diversifying and income levels consistently below the statewide average, resulting in relatively higher poverty rates among all ethnic groups. In 2005, the population of Shasta County was approximately 14.3 percent minority (nonwhite) and approximately 19.6 percent low-income, compared to statewide populations of 55.6 percent minority and 18.6 percent low-income. The slightly higher local poverty rate is not meaningfully greater than the statewide rate.

Lakehead-Lakeshore Community The Lakehead-Lakeshore community is located along Shasta Lake's northernmost reach, the Sacramento River Arm. Lakehead, an unincorporated seasonal community of approximately 1,200 residents (U.S. Census Bureau 2002a), is adjacent to Interstate 5 and includes typical services found near a major interstate highway. Lakehead provides a variety of campgrounds, boat ramps, and marinas. The Lakehead community includes low-income and minority residents and workers who could be affected by project construction and changes in outdoor recreation patterns resulting from the project.

Tourism and Outdoor Recreation Industry Shasta Lake and its vicinity are recreation destinations that draw visitors from throughout California. Most facilities in the area depend on Shasta Lake to draw visitors and customers. The tourism and outdoor recreation service industries are included in this discussion because this group includes a community of lower-paid service workers that could be affected by project actions related to Shasta Dam. A change in recreation opportunities could affect employment and revenue patterns, as well as social and recreational opportunities for minority or low-income residents. With the exception of Lakehead, the settlement and recreation-related development along Shasta Lake falls within unincorporated Shasta County. Residents and workers are dispersed throughout Shasta County, and affected minority and low-income communities are reflected in demographic data for Shasta County as shown in Table 24-1.

Table 24-1. Ethnicity, Income, and Poverty Trends in Shasta and Tehama Counties and California

Topic		Shasta County	Tehama County	State of California
Race/Ethnicity	White, 2005	153,771	46,375	16,408,477
	White, 2000–2005 (% change)	7.0	4.6	1.7

Note:
[a] Because of limited data availability, income/poverty data for Tehama County are for 2004.

Areas of Native American Concern As described in Chapter 14, "Cultural Resources," the Sacramento River and its major tributaries, particularly the Pit and McCloud rivers, were the focus of intensive Native American occupation during historic times, with a variety of religious, economic, historic, and other values identified here for Native American groups. Ten groups, including those listed by the Native American Heritage Commission, represent Native American interests in the study area. They include Grindstone Indian Rancheria, Paskenta Band of Nomlaki Indians, Pit River Environmental Council, Pit River Tribe of California, Redding Rancheria, Shasta Nation, United Tribe of Northern California, Inc., Winnemem Wintu Tribe, Wintu Educational and Cultural Council, and the Wintu Tribe of Northern California.

The Winnemem Wintu have identified important localities within the study area, many of which are locations where ceremonies are regularly conducted. Along the McCloud River, these include Children's Rock, Coyote Rock, Dekkas Rock, doctoring pools near Nawtawaket Creek, Eagle Rock and Samwel Cave, Hirz Bay, *Kaibai* village, North Gray Rocks, Puberty Rock, Saddle Rock, and *Watawacket* village and spiritual area. Along the Sacramento River, important localities include the Antlers area, Delta area, Doney Creek, Gregory Creek, LaMoine area, Packers Bay, Pollard's area, middle Salt Creek, and Sims area. The Winnemem Wintu have strong traditional and contemporary connections with the land, and their ongoing use of many archaeological and religious sites is fundamental to the well-being of their culture, particularly the education of their youth.

The Winnemem Wintu have also documented the location of some 155 ancestral villages within the Shasta Lake area. At least 81 village locations are known along the lower McCloud River and lower Pit River. An additional 73 villages are known to have existed on the east side of the Sacramento River. These village locations once contained between one and 30 houses each, some had associated cemeteries and each had a power place. Some of these villages are already under the waters of Shasta Lake, while others are just above the current Shasta Lake water level. The Winnemem Wintu have estimated that 120 of the known villages are still accessible (above the current high-water line).

Members of the Pit River Madesi Band stated that 22 ethnographic villages and associated burial grounds are located within the existing reservoir and proposed reservoir areas. One Tribal Member also noted that several Traditional Cultural Properties (TCP) exist within the Pit 6 and Pit 7 Dam areas.

Upper Sacramento River (Shasta Dam to Red Bluff)

Many social and public services are provided and a range of resource-dependent cultural activities take place in the cities of Shasta Lake, Redding, Anderson, Cottonwood, and Red Bluff. Each of these communities could be affected during project operation as a result of improved flood protection, enhanced water supply reliability, and increased recreational opportunities and spending related to improved salmonid habitat. Redding and Shasta County may be most

affected because local residents, businesses, public services, and fiscal resources likely would also be affected by construction-related spending and activities.

Groups affected by the project could include minority and low-income populations such as transient and seasonal workers, Native American and Hispanic/Latino populations, and low-income water and electric utility customers. In 2005, the population of Tehama County was approximately 23.9 percent minority (nonwhite) and 21.7 percent (2004) low-income, compared to statewide populations of 55.6 percent minority and 18.6 percent low-income (Table 24-1). Poverty levels are declining in Shasta County and are expected to soon reach statewide levels.

These groups often share the need for a reliable income and low costs of living, access to steady jobs, the need to protect the profitability of businesses that affect their personal income, access to high-quality public services, access to affordable and diverse housing, and a desire to enjoy a high quality of life.

Minority and low-income populations in the upper Sacramento River portion of the primary study area, many of which are employed by local agricultural operations, are especially susceptible to changes in employment opportunities. Changes in water and power supply reliability or delivery costs can have a major effect on the cost of living and on the operating costs and financial health of local businesses and employers. Changes in the frequency and duration of flooding along the Sacramento River and in the Delta also could affect agricultural operations and business owners and employees.

Lower Sacramento River and Delta

As discussed in Chapter 16, "Socioeconomics, Population, and Housing," this portion of the extended study area includes Red Bluff, the largest city in Tehama County with a population of 13,535 in 2006 (DOF 2007), and nine counties to the south. In 2006, the population of those nine counties totaled 4,056,430. The minority population was 47 percent overall and exceeded 50 percent in Colusa, San Joaquin, and Solano counties. In 2006, poverty levels in the region ranged from 7 percent to 18 percent, with low-income populations exceeding the 13.3 percent state poverty level in Butte, Glenn, San Joaquin, and Yolo counties (U.S. Census Bureau 2006b, 2006c, 2007a, 2007b, 2007c).

Regional employment and labor trends are generally consistent with statewide trends. In 2005, approximately 5.3 percent of the labor force was unemployed, compared to 5.4 percent statewide. Butte, San Joaquin, Glenn, Sutter and Colusa counties registered higher unemployment rates than California as a whole. The counties with the highest unemployment rates in 2005 were characterized by greater dependence on the agricultural industry and less industrial diversity. Four of the five counties with unemployment rates above the statewide average maintained more than 60 percent of their land mass in agricultural production. Unemployment rates tend to be higher in rural areas than in urban areas because farm work is typically seasonal or temporary.

The lower Sacramento River region becomes increasingly urbanized as the river flows past the city of Sacramento and toward the Delta. Along its course, the river passes through low-density agricultural and suburban metropolitan areas and near high-density centers of commerce and culture such as Sacramento. In the Delta, a complex network of highways and urban infrastructure is integrated with canals, dikes, and levees. Heavily engineered water control and conveyance systems have promoted and sustained a successful agriculture industry and protected the region against damaging floods.

CVP/SWP Service Areas

The CVP and SWP service areas include 36 of California's 58 counties, accounting for 91 percent (37,444,385 residents) of California's population in 2006 (U.S. Census Bureau 2006b). Minority groups have been steadily increasing and such ethnic diversification is expected to continue. Almost all of the minority groups (except African American) experienced double-digit population growth between 2000 and 2005 (U.S. Census Bureau 2002a, 2006b). Hispanics are the most numerous minority group in California, and many members of this ethnic group work on farms that receive some or all of their water from the CVP. In general, rural agricultural counties have smaller minority populations than urban counties.

Poverty levels for both individuals and children decreased slightly between 2000 and 2005. This trend would not be expected to continue indefinitely. Instead, the percentage of people below the poverty level would be expected to follow national and statewide economic trends. Generally, poverty rates tend to be higher in rural counties than in urban counties. Despite these differences, each of California's major urban areas has pockets of low-income neighborhoods with high poverty (and unemployment) rates. Minority and low-income communities that might be affected by the project include communities adjacent to construction projects, gateway and service communities providing support to construction-related activities, and low-income customers of water and power utilities who might experience higher rates as a result of costs of project-related system improvements.

These residents and workers may be most vulnerable to increases in CVP water and power costs and, conversely, would benefit from improved flood protection and CVP water and power supply reliability. Central Valley farm workers and other workers employed by businesses in the region that supply goods and services to agricultural operations also could benefit.

24.2 Regulatory Framework

24.2.1 Federal

Executive Order 12898

The purpose of Executive Order 12898 (part of which is excerpted in the introduction to this chapter) is to identify and address the disproportionate placement of adverse environmental, economic, social, or health impacts from Federal actions and policies on minority and/or low-income communities. This order requires lead agencies to evaluate impacts on minority or low-income populations during preparation of environmental and socioeconomic analyses of projects or programs that are proposed, funded, or licensed by Federal agencies.

In addition to the direction referenced above, Executive Order 12898 includes the following requirements:

- Each Federal agency shall conduct its programs, policies, and activities that substantially affect human health or the environment, in a manner that ensures that such programs, policies, and activities do not have the effect of excluding persons (including populations) from participation in, denying persons (including populations) the benefits of, or subjecting persons (including populations) to discrimination under, such programs, policies, and activities, because of their race, color, or national origin. *(Section 2-2)*

- Each Federal agency shall work to ensure that public documents, notices, and hearings relating to human health or the environment are concise, understandable, and readily accessible to the public. *(Section 5-5(c))*

In addition, the presidential memorandum accompanying the executive order states that "(e)ach Federal agency shall analyze the environmental effects, including human health, economic and social effects, of Federal actions, including effects on minority communities and low-income communities, when such analysis is required by the NEPA of 1969."

Two documents provide some measure of guidance to agencies required to implement Executive Order 12898. The first is *Environmental Justice Guidance Under the National Environmental Policy Act* (December 1997), published by CEQ. The second document, the *Final Guidance for Incorporating Environmental Justice Concerns* (April 1998) published in the U.S. Environmental Protection Agency's NEPA Compliance Analysis, serves as a guide for incorporating environmental justice goals into preparation of the Environmental Impact Statement under NEPA. These documents provide specific guidelines for assessing environmental justice effects associated with a proposed Federal project.

24.2.2 State

There are no State plans, policies, regulations, or laws related to environmental justice applicable to the project. However, Senate Bill 115 (Chapter 690, Statutes of 1999), signed into law in 1999, defined environmental justice in statute and established the Governor's Office of Planning and Research as the coordinating agency for State environmental justice programs (California Government Code, Section 65040.12). This law further required the California Environmental Protection Agency to develop a model environmental justice mission statement for boards, departments, and offices within the agency by January 1, 2001 (Public Resources Code, Sections 72000 to 72001). The purpose of this program is to inform decision-makers by providing guidance on environmental justice issues.

24.2.3 Regional and Local

There are no regional or local plans, policies, regulations, or laws related to environmental justice applicable to the project.

24.3 Environmental Consequences and Mitigation Measures

This section describes the potential environmental consequences of the project alternatives as they relate to environmental justice. This analysis relies on demographic data provided in the *Socioeconomics, Population, and Housing Technical Report* and incorporates that information as necessary to describe potential effects on minority and low-income communities.

24.3.1 Methods and Assumptions

According to CEQ and U.S. Environmental Protection Agency guidelines established to assist Federal and State agencies, a minority population is present in a project area if (1) the minority population of the affected area exceeds 50 percent, or (2) the minority-population percentage of the affected area is meaningfully greater than the minority-population percentage in the general population or other appropriate unit of geographic analysis. By the same rule, a low-income population exists if the project area consists of 50 percent or more people living below the poverty threshold, as defined by the U.S. Census Bureau, or is meaningfully greater than the poverty percentage of the general population or other appropriate unit of geographic analysis.

The CEQ guidance indicates that when agencies determine whether environmental effects are disproportionately high and adverse, they are to consider whether there is or would be an impact on the natural or physical environment (as defined by NEPA) that would adversely affect a minority population or low-income population.

None of the published guidelines define the term "disproportionately high and adverse," but CEQ includes a nonquantitative definition stating that an effect is

disproportionate if it appreciably exceeds the risk or rate to the general population (CEQ 1997).

The following population characteristics are considered in this analysis:

- Race and ethnicity
- Per-capita income as it relates to the poverty level

The relevant demographic data were obtained from the U.S. Census Bureau and the California Department of Finance. Data are presented at the county level to accommodate the geographic size of each portion of the study area.

In this analysis, a county is considered to have a minority population if its nonwhite population is greater than 50 percent or is meaningfully larger than the general (statewide) nonwhite population. Low-income areas are defined as counties in which the percentage of the population below poverty status exceeds 50 percent, or is meaningfully greater than the general population (average statewide poverty level).

Native American Outreach

Public and stakeholder coordination meetings were conducted on behalf of Reclamation with Native American tribal groups whose traditional territories overlap the primary study area. Seven tribal groups were invited to an information meeting held on April 4, 2007, in Redding, California. The purpose of the meeting was to provide general information about the project, initiate Section 106 consultation with groups desiring to participate in the project, and introduce Elena Nilsson as the Native American Tribal Coordination study lead. Invitations were sent to the Grindstone Rancheria, Paskenta Rancheria, Pit River Tribe, Redding Rancheria, Shasta Nation, Winnemem Wintu, and the Wintu Tribe and Toyon-Wintu Center. The meeting was attended by representatives from the Winnemem Wintu and the Madesi Band of the Pit River Tribe.

Between August 2007 and March 2008, nine meetings were held with Native American groups whose traditional territories overlap with the primary study area. These included meetings and/or workshops with groups and individuals representing major tribes and/or extended family groups in the Shasta/Redding area regarding potential effects on cultural resources from a plan to enlarge Shasta Dam. The purposes of the meetings were to solicit, clarify, and document major concerns and issues regarding the project, and to establish a preferred method/approach to maintaining effective communication during the remainder of the project study and in future endeavors. Five groups participated in these meetings: Grindstone Indian Rancheria (one meeting), Paskenta Band of Nomlaki Indians (one meeting), Pit River Tribe (three meetings), Shasta Nation (one meeting), and Winnemem Wintu (three meetings).

24.3.2 Criteria for Determining Disproportionately High and Adverse Effects

To make a finding that disproportionately high and adverse effects would likely fall on minority or low-income populations, three conditions must be met simultaneously:

- There must be a minority or low-income population in the impact zone.
- A high and adverse impact must exist.
- The impact must be disproportionately high and adverse on the minority or low-income population.

24.3.3 Topics Eliminated from Further Consideration

No topics related to environmental justice that are included in the significance criteria listed above have been eliminated from further consideration. All relevant topics are analyzed below.

Effects on sites considered sacred by local Native American communities in the upper Sacramento River portion of the primary study area and the lower Sacramento River and Delta and CVP and SWP service areas have been eliminated from further discussion. No impacts are anticipated to these resources as a result of changes in Shasta Dam operations (i.e., storage and release scenarios). Furthermore, any construction activities near sites considered sacred by local Native American communities would require mitigation as stated in Chapter 14, including compliance with Section 106 of the NHPA. As a result, no disproportionately high and adverse effects on Native American populations would be expected; therefore, potential effects related to this topic in these geographic regions are not discussed further in this PDEIS.

24.3.4 Direct and Indirect Effects

No-Action Alternative

Shasta Lake and Vicinity

Impact EJ-1 (No-Action): Potential Disproportionate Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake Communities at Shasta Lake and in the vicinity would remain below minority and low-income thresholds as they relate to environmental justice. Adverse construction-related impacts would be avoided, and construction-related employment opportunities and gains within local economies would not be realized. Existing adverse effects on minority or low-income populations do not constitute a disproportionately high and adverse impact. No disproportionately high and adverse effects on minority or low-income populations would occur.

Shasta County would maintain its steady population growth under the No-Action Alternative. Since 1990, the population has increased by 22.3 percent, with total population projected to reach 224,000 by 2020 (DOF 2007). The

minority (nonwhite) population, including the Winnemem Wintu Tribe and other Native Americans, is projected to account for 16.6 percent of the total population in Shasta County in 2020, slightly more than the current 14.3 percent representation, but less than the 62.5 percent minority population projected statewide for 2020 (DOF 2007; U.S. Census Bureau 2006a).

As described in Table 24-1, the poverty level in Shasta County decreased by 2.2 percent during 2000 to 2005, and unemployment rates in Shasta County were mostly steady during 2000 to 2005, fluctuating between 6.0 and 7.5 percent. This trend should continue as long as statewide trends continue and strong employment opportunities continue to be provided in the region by major employment sectors such as trade, transportation, and utilities; government; educational, and health services; and leisure and hospitality industries (see Chapter 16, "Socioeconomics, Population, and Housing"). Professional and business services and education and health services are projected to be the leading growth industries in Shasta County; these are also the top two anticipated growth industries statewide. No disproportionately high or adverse impacts on minority or low-income communities are anticipated under the No-Action Alternative. Mitigation is not required for the No-Action Alternative.

Impact EJ-2 (No-Action): Potential Disproportionate Effect on Native American Populations from Disturbance or Loss of Sacred Locations in the Vicinity of Shasta Lake Shasta Dam would not be enlarged; no infrastructure would be removed, modified, or relocated; and no changes in Reclamation's Shasta Lake operations would occur. No disproportionately high and adverse effects on Native American populations would occur.

Under the No-Action Alternative, Shasta Dam would not be enlarged; no infrastructure would be removed, modified, or relocated; and no changes in Reclamation's Shasta Lake operations would occur. Therefore, there would be no effect on several locations in the vicinity of Shasta Lake that are considered sacred by local Native American communities. No disproportionately high and adverse effects on Native American populations would occur. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact EJ-3 (No-Action): Potential Disproportionate Effect on Minority and Low-Income Populations in the Upper Sacramento River Area Communities in the upper Sacramento River portion of the primary study area would remain below minority and low-income thresholds for environmental justice. The No-Action Alternative would not cause long-term operational changes; therefore, communities adjacent to the Sacramento River would not be affected by long-term changes to environmental and recreational conditions. Construction-related gains within this area would not be realized. Existing adverse effects on minority or low-income populations would not be disproportionately high and adverse. No disproportionately high and adverse effects on minority or low-income populations would occur.

Tehama County would maintain its steady population growth under the No-Action Alternative. Since 1990, the population has increased by 22.9 percent, with total population projected to reach 79,000 by 2020 (DOF 2007). The minority (nonwhite) population is projected to account for 31 percent of the total population in Tehama County in 2020, an increase of nearly 7 percent from the current 23.9 percent level, but less than the 62.5 percent minority population projected statewide for 2020 (DOF 2007).

As described in Chapter 16, "Socioeconomics, Population, and Housing," during 2000 to 2005, the poverty level in Tehama County decreased by 2.8 percent and unemployment rates in Tehama County fluctuated between 6.4 and 7.6 percent. Tehama County is similar to neighboring Shasta County in employment and income trends, and dominant employment sectors. Projected growth industries differ between the two counties, however; Tehama County is projected to experience strong economic growth in construction and information services (see Chapter 16, "Socioeconomics, Population, and Housing"). These sectors are the third and fifth largest anticipated growth areas statewide.

Because the No-Action Alternative would not change existing or projected future conditions, it would not have a disproportionately high or adverse effect on minority or low-income communities. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta

Impact EJ-4 (No-Action): Potential Disproportionate Effect on Minority and Low-Income Populations in the Lower Sacramento River and Delta Area

Some communities within the lower Sacramento River and Delta portion of the extended study area contain minority and low-income populations above environmental justice thresholds; however, continuing the existing and projected future conditions under the No-Action Alternative would not affect those populations. No disproportionately high and adverse effects on minority or low-income populations would occur.

The lower Sacramento River and Delta portion of the extended study area includes Butte, Colusa, Contra Costa, Glenn, Sacramento, San Joaquin, Solano, Sutter, and Yolo counties. In 2006, the population of the nine-county region was 4,056,430. This number is expected to grow by 24.8 percent to 5,063,392 by 2020 (DOF 2007; U.S. Census Bureau 2006b, 2006c, 2007a, 2007b, 2007c, 2007d, 2007e, 2007f). The minority (nonwhite) population is projected to account for 63.8 percent of the total population in the lower Sacramento River and Delta area by 2020, with minority populations exceeding 50 percent in Colusa, Sacramento, San Joaquin, Solano, Sutter, and Yolo counties. Although the minority population in the lower Sacramento River and Delta area is projected to exceed 50 percent by 2020, the 63.8 percent representation would not be meaningfully greater than the statewide minority population, which is projected to be 62.5 percent.

In 2006, poverty levels in the nine-county region ranged from 7 percent to 18 percent, with low-income populations exceeding the 13.3 percent statewide poverty level in Butte, Glenn, San Joaquin, and Yolo counties (U.S. Census Bureau 2006b, 2006c, 2007a, 2007d, 2007g). Employment and labor trends in the lower Sacramento River and Delta portion of the extended study area are generally consistent with statewide trends. In 2005, approximately 5.3 percent of the labor force was classified as unemployed, compared to a statewide total of 5.4 percent. Butte, San Joaquin, Glenn, Sutter, and Colusa counties registered higher unemployment rates than the state as a whole in 2005. Generally, the counties with the highest unemployment rates in 2005 were characterized by greater dependence on the agricultural industry and less industrial diversity. Four of the five counties with unemployment rates above the statewide average maintained more than 60 percent of their land mass in agricultural production. Unemployment rates tend to be higher in rural areas than in urban areas because farm work is typically seasonal or temporary.

The lower Sacramento River and Delta portion of the extended study area has some low-income populations and some counties with a higher unemployment rate than the statewide average. However, the No-Action Alternative would not change the existing or projected future conditions. Therefore, the No-Action Alternative would not have disproportionately high and adverse effects on minority or low-income populations. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas

Impact EJ-5 (No-Action): Potential Disproportionate Effect on Minority and Low-Income Populations in the CVP/SWP Service Areas Some communities within the CVP and SWP service areas contain minority and low-income populations above environmental justice thresholds; however, adverse effects on CVP and SWP customers within these communities do not constitute a disproportionately high and adverse impact. Continuing the existing and projected future conditions under the No-Action Alternative would not affect these populations. No disproportionately high and adverse effects on minority or low-income populations would occur.

The CVP and SWP service areas are so expansive that they may be considered synonymous with the entire state of California for environmental justice purposes. Together, the CVP and SWP service areas include 36 of California's 58 counties, accounting for 91 percent (37,444,385 residents) of California's population in 2006. The state's population has increased by almost 25 percent since 1990 and is projected to increase by approximately 17 percent to more than 44 million people by 2020 (DOF 2007). Continued ethnic diversification is expected. Minority groups have been steadily increasing their proportion of the state population. Almost all minority groups (except African Americans) experienced double-digit population growth between 2000 and 2005 (U.S. Census Bureau 2002a, 2006b). Hispanics are the most numerous minority group in California, and many members of this ethnic group work on farms that

receive some or all of their water from the CVP. In general, rural agricultural counties have smaller minority populations than urban counties.

Poverty levels for both individuals and children in California decreased slightly between 2000 and 2005. This trend would not be expected to continue indefinitely. Instead, the percentage of people below the poverty level would be expected to follow national and statewide economic trends. Generally, poverty rates tend to be higher in rural counties than in urban counties. Despite these overall differences, each of the state's major urban areas has pockets of low-income neighborhoods with high poverty rates.

California's total labor force increased just over 2 percent from 2002 to 2005, adding between 100,000 and 200,000 individuals each year. Between 2004 and 2005, the labor force increased by approximately 188,000 individuals. This was the largest annual increase over the 4-year period. California's total labor force exceeded 17.7 million in 2005. The state's unemployment rate was lowest in 2000 (5.0 percent), and has been increasing since 2003. Unemployment in 2005 registered at 5.4 percent, equal to the state's 2001 unemployment rate. This observed decrease in the unemployment rate at the state level has coincided with similar national employment trends. Like poverty, unemployment rates tend to be lower in urban areas than in rural areas of the state; however, high unemployment rates are often found in low-income neighborhoods of major urban centers.

Although the CVP and SWP service areas have some low-income populations, the No-Action Alternative would not change the existing or projected future conditions. Therefore, no disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity

Impact EJ-1 (CP1): Potential Disproportionate Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake Communities adjacent to the project construction site may experience temporary or short-term adverse environmental effects because of construction activities and changes in project conditions and operations. However, neither construction-related nor operational effects would disproportionately affect minority or low-income populations in the vicinity of Shasta Lake. Increased employment and income opportunities could also result from project construction activities, and would not be disproportionately distributed among minority and low-income populations. No disproportionately high and adverse effects on minority or low-income populations would occur.

Under this alternative, the dam would be raised by 6.5 feet over a 36-month construction period. Residents near Shasta Dam, as well as others who may

commute or otherwise travel near construction sites, would be exposed to a range of potentially adverse environmental and public health effects over a 36-month construction period (Reclamation 2007). Temporary and/or short-term adverse noise, visual, and air quality effects could result; in addition, motorists could be delayed, and access to recreation opportunities or local businesses could be temporarily reduced. Negative health effects could also result if hazardous materials were to be accidentally released into the environment during construction.

Nonwhite individuals, including the Winnemem Wintu Tribe and other Native Americans, accounted for 14.3 percent of Shasta County's total population in 2005, well below the 50 percent threshold for a minority population. This percentage is also substantially less than the 2005 statewide nonwhite population of 55.6 percent. Likewise, the poverty rate in Shasta County was 13.2 percent in 2005, well below the 50 percent threshold and slightly less than the 13.3 percent statewide poverty rate. Therefore, the percentages of minority and low-income individuals in populations in Shasta County are well below threshold levels for a minority or low-income population. Therefore, minority and low-income populations would not be disproportionately affected by these adverse effects.

Increased employment and income opportunities may result from construction under CP1, which could benefit minority and low-income populations. Project construction under CP1 could increase the number of jobs available, or could improve business conditions and incomes for workers who are already employed by businesses that would directly or indirectly benefit from project-related construction spending. The project would require a labor force of 350 people drawn directly from the Shasta Lake area. Most (85 percent) of the construction materials and supplies would be purchased in the vicinity; these materials and supplies would constitute 60 percent of total construction costs (Reclamation 2007). As described above, the percentages of minority and low-income individuals in Shasta County populations are well below threshold levels for minority and low-income populations, and employment effects would not be disproportionately distributed among these groups. Selected minority and low-income individuals may be potentially affected. Such economic and job-related impacts would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact EJ-2 (CP1): Potential Disproportionate Effect on Native American Populations from Disturbance or Loss of Sacred Locations in the Vicinity of Shasta Lake The local Native American community has identified several locations in the vicinity of Shasta Lake that they consider to be sacred. Notable among these locations are the Winnemem Wintu's Puberty Rock and the doctoring pools near Nawtawaket Creek and the Pit River Madesi Band's ethnographic villages, associated burial grounds, and several TCPs. CP2 would have a substantial adverse effect on several of these locations in the vicinity of Shasta Lake. Because the Winnemem Wintu and Pit River Madesi Band

members attach religious and cultural significance to these locations, the disturbance or loss of resources associated with these locations would result in a disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

Two tribes, the Winnemem Wintu and the Pit River Madesi Band, live within the vicinity of Shasta Lake, where they continue to actively practice many aspects of their traditional culture. Both groups have related that a complex cultural landscape of village sites, ceremonial areas, sacred sites, burial sites, and resource areas would be affected directly by CP1.

Two particularly important Winnemem Wintu locations that would be affected by CP1 are Puberty Rock and the doctoring pools near Nawtawaket Creek. CP1 could submerge Puberty Rock, restricting the Winnemen Wintu from holding the puberty ceremony at this important location. Relocating the rock to higher ground is not possible; in the Winnemem worldview, its location is preordained and connected with the nearby "two sisters" mountain (Bolliboka Mountain). Puberty Rock also marks the location of an extensive village with housepits and burials, situated at Kabyai Creek, west of the McCloud River near the McCloud Campground. CP1 would inundate additional burials at this location, which would require removal and relocation. The Winnemem Wintu have estimated that 120 ancestral villages are still accessible above the current high-water line of Shasta Lake and would be adversely affected by CP1.

The Pit River Madesi Band members state that 22 ethnographic villages, associated burial grounds, and several TCPs are located within the existing reservoir and proposed inundation or fluctuation areas.

The Winnemem Wintu and Pit River Madesi Band members attach religious and cultural significance to several locations in the vicinity of Shasta Lake; therefore, the disturbance and loss of resources associated with these locations would result in a disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake. Mitigation for this impact is not proposed because no feasible mitigation is available.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact EJ-3 (CP1): Potential Disproportionate Effect on Minority and Low-Income Populations in the Upper Sacramento River Area Effects from project-related construction are not anticipated in the upper Sacramento River area downstream from Shasta Dam. In the long term, operational changes resulting from CP1 could reduce the risk of flooding and enhance environmental and recreational conditions in this area. These operational effects would not constitute a disproportionately high and adverse impact on minority and low-income populations. No disproportionately high and adverse effects on minority or low-income populations would occur.

In Tehama County, nonwhite individuals accounted for 23.9 percent of the total population in 2005. This is roughly half of the 50 percent threshold for a minority population. This level also is substantially less than the statewide nonwhite population of 55.6 percent. The poverty level in Tehama County was 14.5 percent in 2005, also well below the 50 percent threshold and slightly higher than the 13.3 percent statewide poverty rate. From 2000 to 2004, poverty levels in Tehama County decreased at a rate of 2.8 percent, outpacing the statewide poverty reduction rate (0.9 percent) by 1.9 percent over approximately the same time. If this trend continues, poverty levels will soon be lower than statewide levels (if they are not already). Based on this trend, and the comparatively consistent poverty rates between Tehama County and the statewide population, poverty levels in Tehama County are not meaningfully greater than poverty levels statewide. Therefore, the percentages of minority and low-income individuals in populations in Tehama County are well below threshold levels for minority and low-income populations. Thus, disproportionately high and adverse effects on minority or low-income populations would not occur.

Communities along the upper Sacramento River portion of the primary study area would not be exposed to direct construction-related impacts associated with CP1.

Raising Shasta Dam would add 256,000 acre-feet of cold-water storage to the overall capacity of the reservoir. This operational change would be beneficial for two reasons. CP1 would reduce the risk of flooding downstream from Shasta Dam and consequently reduce potentially adverse social, economic, and environmental effects because of flooding for property owners, businesses, and workers. In addition, CP1 would improve environmental and recreational conditions by enhancing habitat for fish and wildlife, benefiting anglers, hunters, and wildlife viewers.

These beneficial impacts would not be disproportionately distributed among minority and low-income populations, because representation of these groups in the population of Tehama County is well below threshold levels. Selected minority and low-income individuals may be potentially affected; however, these environmental and recreational effects would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact EJ-4 (CP1): Potential Disproportionate Effect on Minority and Low-Income Populations in the Lower Sacramento River and Delta Area

Operational effects of CP1 would be similar to those described for the upper Sacramento River portion of the primary study area under Impact EJ-2 (CP1). However, because the beneficial effects (reduction of flooding risk and improved environmental and recreational conditions) would diminish with distance from the project site, the benefits in this area would be less. No

disproportionately high or adverse effects on minority or low-income populations would occur.

Operational effects of CP1 on minority and low-income populations in the lower Sacramento River and Delta portion of the extended study area would be similar to those described for the upper Sacramento River portion of the primary study area under Impact EJ-2 (CP1). However, benefits in the lower Sacramento River and Delta area resulting from the reduced risk of flooding and improved environmental and recreational conditions would be less than described for the upper Sacramento River area because the lower Sacramento River and Delta is located at a greater distance from the project site. Minority and low-income populations would not be disproportionately affected. No disproportionately high or adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact EJ-5 (CP1): Potential Disproportionate Effect on Minority and Low-Income Populations in the CVP/SWP Service Areas Direct construction-related impacts are not anticipated in the CVP and SWP service areas. The project could result in adverse indirect impacts because of water and power rate increases for customers within the CVP and SWP service areas. Employment opportunities and personal incomes may increase because of operational changes that improve the reliability of the water supply and power for businesses and others. Minority and low-income populations would not be disproportionately affected. No disproportionately high and adverse effects on minority or low-income populations would occur.

Utility customers in communities within the CVP and SWP service areas may experience indirect, adverse effects through rate increases as a result of CP1. Project-related water storage and hydroelectric facility improvements may be funded partly through increased rates for water and power services. However, such adverse effects would not disproportionately affect minority or low-income populations.

Operational changes resulting from CP1 may increase employment opportunities and water and power reliability in the CVP and SWP communities, which would be beneficial for individual utility customers and businesses. Selected minority and low-income individuals may be beneficially affected by increased employment opportunities. Such beneficial employment-related impacts would not disproportionately affect minority and low-income populations. Thus, no disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity

Impact EJ-1 (CP2): Potential Disproportionate Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake Communities adjacent to the project construction site may experience temporary and/or short-term adverse environmental effects because of construction activities and changes in project conditions and operations. However, neither construction-related nor operational effects would disproportionately affect minority or low-income populations in the vicinity of Shasta Lake. Therefore, no disproportionately high and adverse effects on minority or low-income populations would occur.

Effects on minority and low-income populations would be similar to those described above for Impact EJ-1 (CP1), except that the dam would be raised by 12.5 feet and the construction period likely would extend for up to 6 additional months. The beneficial effects and less than significant adverse impacts would be similar to those described under Impact EJ-1 (CP1) because the types of work and the predicted workforce would be similar under each alternative. As described under Impact EJ-1 (CP1), the percentages of minority and low-income individuals in populations in Shasta County are well below threshold levels for a minority or low-income population. Therefore, disproportionately high and adverse effects on minority or low-income populations would not occur. Mitigation for this impact is not needed, and thus not proposed.

Impact EJ-2 (CP2): Potential Disproportionate Effect on Native American Populations from Disturbance or Loss of Sacred Locations in the Vicinity of Shasta Lake The local Native American community has identified several locations in the vicinity of Shasta Lake that they consider to be sacred. Notable among these locations are the Winnemem Wintu's Puberty Rock and the doctoring pools near Nawtawaket Creek and the Pit River Madesi Band's ethnographic villages, associated burial grounds, and several TCPs. CP2 would have a substantial adverse effect on several of these locations in the vicinity of Shasta Lake. Because the Winnemem Wintu and Pit River Madesi Band members attach religious and cultural significance to these locations, the disturbance or loss of resources associated with these locations would result in a disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

This impact would be similar to but slightly greater than Impact EJ-2 (CP1) because the inundation area under CP2 would be slightly greater than under CP1. A disproportionately high and adverse effect on Native American populations would occur. Mitigation for this impact is not proposed because no feasible mitigation is available.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact EJ-3 (CP2): Potential Disproportionate Effect on Minority and Low-Income Populations in the Upper Sacramento River Area Effects from project-

related construction are not anticipated in the upper Sacramento River area downstream from Shasta Dam. In the long term, operational changes resulting from CP2 could reduce the risk of flooding and enhance environmental and recreational conditions in this area. These operational effects would not constitute a disproportionately high and adverse impact on minority and low-income populations. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-3 (CP1). CP2 would provide 187,000 acre-feet more cold-water storage capacity than CP1. Greater storage capacity would reduce the risk of flooding and, along with increased cold water, would benefit downstream fisheries and recreation resources and users. Also, as described under Impact EJ-3 (CP1), the percentages of minority and low-income individuals in populations in Tehama County are well below threshold levels for minority and low-income populations. Thus, disproportionately high and adverse effects on minority or low-income populations would not occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact EJ-4 (CP2): Potential Disproportionate Effect on Minority and Low-Income Populations in the Lower Sacramento River and Delta Area

Operational effects of CP2 would be similar to those described for the upper Sacramento River portion of the primary study area under Impact EJ-4 (CP2). However, because the beneficial effects (reduction of flooding risk and improved environmental and recreational conditions) would diminish with distance from the project site, the benefits in this area would be less. No disproportionately high or adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-4 (CP1). Under CP2, reduced flooding and beneficial effects on fisheries and recreation resources also would occur in the lower Sacramento River and Delta portion of the extended study area. However, the beneficial effects would be less than along the upper Sacramento River because benefits would diminish with increasing distance from the project site. As in the upper Sacramento River portion of the primary study area, the additional 187,000 acre-feet of reservoir storage would provide somewhat greater benefits under CP2 than under CP1. Minority and low-income populations would not be disproportionately affected. No disproportionately high or adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact EJ-5 (CP2): Potential Disproportionate Effect on Minority and Low-Income Populations in the CVP/SWP Service Areas Direct construction-related impacts are not anticipated in the CVP and SWP service areas. The project could result in adverse indirect impacts because of water and power rate

increases for customers within the CVP and SWP service areas. Employment opportunities and personal incomes may increase because of operational changes that improve the reliability of the water supply and power for businesses and others. Minority and low-income populations would not be disproportionately affected. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-5 (CP1). Construction costs under CP2 would be greater than under CP1, because of the increased need for construction materials and an additional 12 months of construction. These increased costs would result in slightly greater increases in water and power rates than under CP1. However, such adverse effects would not disproportionately affect minority and low-income populations. Operational benefits would be similar to those of CP1, and minority or low-income populations would not be disproportionately affected. Therefore, no disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

Shasta Lake and Vicinity

Impact EJ-1 (CP3): Potential Disproportionate Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake Communities adjacent to the project construction site may experience temporary and/or short-term adverse environmental effects because of construction activities and changes in project conditions and operations. However, neither construction-related nor operational effects would disproportionately affect minority or low-income populations in the vicinity of Shasta Lake. No disproportionately high or adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-1 (CP1). Under CP3, the effects on minority and low-income populations would be similar to those described above for Impact EJ-1 (CP1), except that the dam would be raised by 18.5 feet and the construction period would extend for at least 12 additional months. The beneficial impacts and less than significant adverse impacts would be similar to those described under CP1 because the types of work and the predicted workforce would be similar under each alternative. As described under Impact EJ-1 (CP1), the percentages of minority and low-income individuals in populations in Shasta County are well below threshold levels for a minority or low-income population. Therefore, disproportionately high effects on minority or low-income populations would not occur (nor would disproportionately high and beneficial effects). Mitigation for this impact is not needed, and thus not proposed.

Impact EJ-2 (CP3): Potential Disproportionate Effect on Native American Populations from Disturbance or Loss of Sacred Locations in the Vicinity of Shasta Lake The local Native American community has identified several

locations in the vicinity of Shasta Lake that they consider to be sacred. Notable among these locations are the Winnemem Wintu's Puberty Rock and the doctoring pools near Nawtawaket Creek and the Pit River Madesi Band's ethnographic villages, associated burial grounds, and several TCPs. CP3 would have a substantial adverse effect on several of these locations in the vicinity of Shasta Lake. Because the Winnemem Wintu and Pit River Madesi Band members attach religious and cultural significance to these locations, the disturbance or loss of resources associated with these locations would result in a disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

This impact would be similar to but slightly greater than Impact EJ-2 (CP2) because the inundation area under CP3 would be slightly greater than under CP2. A disproportionately high and adverse effect on Native American populations would occur. Mitigation for this impact is not proposed because no feasible mitigation is available.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact EJ-3 (CP3): Potential Disproportionate Effect on Minority and Low-Income Populations in the Upper Sacramento River Area Effects from project-related construction are not anticipated in the upper Sacramento River area downstream from Shasta Dam. In the long term, operational changes resulting from CP3 could reduce the risk of flooding and enhance environmental and recreational conditions in this area. These beneficial operational effects would not be disproportionately distributed among minority and low-income populations. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-3 (CP1). CP3 would provide 378,000 acre-feet more cold-water storage capacity than CP1. Greater storage capacity would reduce the risk of flooding and, along with increased cold water, would benefit downstream fisheries and recreation resources and users. Also, as described under Impact EJ-3 (CP1), the percentages of minority and low-income individuals in populations in Tehama County are well below threshold levels for minority and low-income populations. Thus, disproportionately high and adverse effects on minority or low-income populations would not occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact EJ-4 (CP3): Potential Disproportionate Effect on Minority and Low-Income Populations in the Lower Sacramento River and Delta Area
Operational effects of CP3 would be similar to those described for the upper Sacramento River portion of the primary study area under Impact EJ-3 (CP3). However, because the beneficial effects (reduction of flooding risk and improved environmental and recreational conditions) would diminish with distance from the project site, the benefits in this area would be less. No

disproportionately high or adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-4 (CP1). Under CP3, reduced flooding and beneficial effects on fisheries and recreation resources also would occur in the lower Sacramento River and Delta portion of the extended study area. However, the beneficial effects would be less than along the upper Sacramento River because benefits would diminish with increasing distance from the project site. As in the upper Sacramento River portion of the primary study area, the additional 378,000 acre-feet of reservoir storage would provide somewhat greater benefits under CP3 than under CP1. Minority and low-income populations would not be disproportionately affected. No disproportionately high or adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact EJ-5 (CP3): Potential Disproportionate Effect on Minority and Low-Income Populations in the CVP/SWP Service Areas Direct construction-related impacts are not anticipated in the CVP and SWP service areas. The project could result in adverse indirect impacts because of water and power rate increases for customers within the CVP and SWP service areas. Employment opportunities and personal incomes may increase because of operational changes that improve the reliability of the water supply reliability and power for businesses and others. Minority and low-income populations would not be disproportionately affected. No disproportionately high or adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-5 (CP1). Construction costs under CP3 would be greater than under CP1 because of the increased need for construction materials and an additional 12 months of construction. These increased costs would result in slightly greater increases in water and power rates than under CP1. However, such adverse effects would not disproportionately affect minority and low-income populations. Operational benefits would be similar to those of CP1, and minority and low-income populations would not be disproportionately affected. Therefore, no disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Shasta Lake and Vicinity

Impact EJ-1 (CP4): Potential Disproportionate Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake Communities adjacent to the project construction site may experience temporary and/or short-term adverse environmental effects because of construction activities and changes in

project conditions and operations. However, neither construction-related nor operational effects would be disproportionately distributed among minority or low-income populations in the vicinity of Shasta Lake. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-1 (CP1). Under CP4, the effects on minority and low-income populations would be similar to those described above for Impact EJ-1 (CP1), except that the dam would be raised by 18.5 feet and the construction period would extend for at least 12 additional months. The beneficial effects and less than significant adverse impacts would be similar to those described under CP1 because the types of work and the predicted workforce would be similar under each alternative. As described under Impact EJ-1 (CP1), the percentages of minority and low-income individuals in populations in Shasta County are well below threshold levels for a minority or low-income population. Therefore, adverse and beneficial effects would not be disproportionately distributed among minority or low-income populations. No disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact EJ-2 (CP4): Potential Disproportionate Effect on Native American Populations from Disturbance or Loss of Sacred Locations in the Vicinity of Shasta Lake The local Native American community has identified several locations in the vicinity of Shasta Lake that they consider to be sacred. Notable among these locations are the Winnemem Wintu's Puberty Rock and the doctoring pools near Nawtawaket Creek and the Pit River Madesi Band's ethnographic villages, associated burial grounds, and several TCPs. CP2 would have a substantial adverse effect on several of these locations in the vicinity of Shasta Lake. Because the Winnemem Wintu and Pit River Madesi Band members attach religious and cultural significance to these locations, the disturbance or loss of resources associated with these locations would result in a disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

This impact would be similar to Impact EJ-2 (CP3), but the frequency and timing of inundation may vary. Disproportionately high and adverse effects on Native American populations would occur. Mitigation for this impact is not proposed because no feasible mitigation is available.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact EJ-3 (CP4): Potential Disproportionate Effect on Minority and Low-Income Populations in the Upper Sacramento River Area Effects from project-related construction are not anticipated in the upper Sacramento River area downstream from Shasta Dam. In the long term, operational changes resulting from CP4 could reduce the risk of flooding and enhance environmental and recreational conditions in this area. These beneficial operational effects would not constitute a disproportionately high and adverse impact on minority and

low-income populations. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-3 (CP1). CP4 would provide 378,000 acre-feet more cold-water storage capacity than CP1. Greater storage capacity would reduce the risk of flooding and, along with increased cold water, would benefit downstream fisheries and recreation resources and users. Also, as described under Impact EJ-3 (CP1), the percentages of minority and low-income individuals in populations in Tehama County are well below threshold levels for minority and low-income populations. Minority and low-income populations would not be disproportionately affected. No disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact EJ-4 (CP4): Potential Disproportionate Effect on Minority and Low-Income Populations in the Lower Sacramento River and Delta Area

Operational effects of CP4 would be similar to those described for the upper Sacramento River portion of the primary study area under Impact EJ-3 (CP4). However, because the beneficial effects (reduction of flooding risk and improved environmental and recreational conditions) would diminish with distance from the project site, the benefits in this area would be less. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-4 (CP1). Under CP4, reduced flooding and beneficial effects on fisheries and recreation resources also would occur in the lower Sacramento River and Delta portion of the extended study area. However, the beneficial effects would be less than along the upper Sacramento River because benefits would diminish with increasing distance from the project site. As in the upper Sacramento River portion of the primary study area, the additional 378,000 acre-feet of reservoir storage would provide somewhat greater benefits under CP4 than under CP1. Minority and low-income populations would not be disproportionately affected. No disproportionately high or adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact EJ-5 (CP4): Potential Disproportionate Effect on Minority and Low-Income Populations in the CVP/SWP Service Areas Direct construction-related impacts are not anticipated in the CVP and SWP service areas. The project could result in adverse indirect impacts because of water and power rate increases for customers within the CVP and SWP service areas. Employment opportunities and personal incomes may increase because of operational changes that improve the reliability of the water supply and power to businesses and others. Minority and low-income populations would not be

disproportionately affected. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-5 (CP1). Construction costs under CP4 would be greater than under CP1 because of the increased need for construction materials and an additional 12 months of construction. These increased costs would result in slightly greater increases in water and power rates than under CP1. However, such adverse effects would not disproportionately affect minority and low-income populations. Operational benefits would be similar to those under CP1, and minority and low-income populations would not be disproportionately affected. Therefore, no disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Shasta Lake and Vicinity

Impact EJ-1 (CP5): Potential Disproportionate Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake Communities adjacent to the project construction site may experience temporary adverse environmental effects because of construction activities and changes in project conditions and operations. However, the construction activity in any specific area would be short-term, and neither construction-related nor operational effects would constitute a high and adverse impact on minority or low-income populations in the vicinity of Shasta Lake. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-1 (CP1). Under CP5, the effects on minority and low-income populations would be similar to those described above for Impact EJ-1 (CP1), except that the dam would be raised by 18.5 feet and the construction period would extend for at least 12 additional months. The beneficial effects and less than significant adverse impacts would be similar to those described under CP1 because the types of work and the predicted workforce would be similar under each alternative. As described under Impact EJ-1 (CP1), the percentages of minority and low-income individuals in populations in Shasta County are well below threshold levels for a minority or low-income population. Therefore, minority and low-income populations would not be disproportionately affected. No disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact EJ-2 (CP5): Potential Disproportionate Effect on Native American Populations from Disturbance or Loss of Sacred Locations in the Vicinity of Shasta Lake The local Native American community has identified several locations in the vicinity of Shasta Lake that they consider to be sacred. Notable among these locations are the Winnemem Wintu's Puberty Rock and the doctoring pools near Nawtawaket Creek and the Pit River Madesi Band's

ethnographic villages, associated burial grounds, and several TCPs. CP2 would have a substantial adverse effect on several of these locations in the vicinity of Shasta Lake. Because the Winnemem Wintu and Pit River Madesi Band members attach religious and cultural significance to these locations, the disturbance or loss of resources associated with these locations would result in a disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

This impact would be the same as Impact EJ-2 (CP3). Disproportionately high and adverse effects on Native American populations would occur. Mitigation for this impact is not proposed because no feasible mitigation is available.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact EJ-3 (CP5): Potential Disproportionate Effect on Minority and Low-Income Populations in the Upper Sacramento River Area Effects from project-related construction are not anticipated in the upper Sacramento River area downstream from Shasta Dam. In the long term, operational changes resulting from CP5 could reduce the risk of flooding and enhance environmental and recreational conditions in this area. These operational effects would not constitute a disproportionately high and adverse impact on minority and low-income populations. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-3 (CP1). CP5 would provide 378,000 acre-feet more cold-water storage capacity than CP1. Greater storage capacity would reduce the risk of flooding and, along with increased cold water, would benefit downstream fisheries and recreation resources and users. Also, as described under Impact EJ-3 (CP1), the percentages of minority and low-income individuals in populations in Tehama County are well below threshold levels for minority and low-income populations. Therefore, minority and low-income populations would not be disproportionately affected. No disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact EJ-4 (CP5): Potential Disproportionate Effect on Minority and Low-Income Populations in the Lower Sacramento River and Delta Area
Operational effects of CP5 would be similar to those described for the upper Sacramento River portion of the primary study area under Impact EJ-3 (CP5). However, because the beneficial effects (reduction of flooding risk and improved environmental and recreational conditions) would diminish with distance from the project site, the benefits in this area would be less. No disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-4 (CP1). Under CP5, reduced flooding and beneficial effects on fisheries and recreation resources also would occur in the lower Sacramento River and Delta portion of the extended study area. However, the beneficial effects would be less than along the upper Sacramento River because benefits would diminish with increasing distance from the project site. As in the upper Sacramento River portion of the primary study area, the additional 378,000 acre-feet of reservoir storage would provide somewhat greater benefits under CP5 than under CP1. Minority and low-income populations would not be disproportionately affected. No disproportionately high or adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact EJ-5 (CP5): Potential Disproportionate Effect on Minority and Low-Income Populations in the CVP/SWP Service Areas Direct construction-related impacts are not anticipated in the CVP and SWP service areas. The project could result in adverse indirect impacts because of water and power rate increases for customers within the CVP and SWP service areas. Employment opportunities and personal incomes may increase because of operational changes that improve the reliability of the water supply and power for businesses and others. Minority and low-income populations would not be disproportionately affected. Therefore, no disproportionately high and adverse effects on minority or low-income populations would occur.

This impact would be similar to Impact EJ-5 (CP1). Construction costs under CP5 would be greater than under CP1 because of increased materials and an additional 12 months of construction. These increased costs would result in slightly greater increases in water and power rates than under CP1. However, such adverse effects would not disproportionately affect minority and low-income populations. Operational benefits would be similar to those under CP1, and minority and low-income populations would not be disproportionately affected. Therefore, no disproportionately high and adverse effects on minority or low-income populations would occur. Mitigation for this impact is not needed, and thus not proposed.

24.3.5 Mitigation Measures

Table 24-2 presents a summary of effects and mitigation measures for environmental justice.

Table 24-2. Summary of Mitigation Measures for Environmental Justice

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact EJ-1: Potential Disproportionate Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake	Effect before Mitigation	NDHA	NDHA	NDHA	NDHA	NDHA	NDHA
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	Effect after Mitigation	NDHA	NDHA	NDHA	NDHA	NDHA	NDHA
Impact EJ-2: Potential Disproportionate Effect on Native American Populations in the Vicinity of Shasta Lake	Effect before Mitigation	NDHA	DHA	DHA	DHA	DHA	DHA
	Mitigation Measure	None required.	None available.				
	Effect after Mitigation	NDHA	DHA	DHA	DHA	DHA	DHA
Impact EJ-3: Potential Disproportionate Effect on Minority and Low-Income Populations in the Upper Sacramento River Area	Effect before Mitigation	NDHA	NDHA	NDHA	NDHA	NDHA	NDHA
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	Effect after Mitigation	NDHA	NDHA	NDHA	NDHA	NDHA	NDHA
Impact EJ-4: Potential Disproportionate Effect on Minority and Low-Income Populations in the Lower Sacramento River and Delta Area	Effect before Mitigation	NDHA	NDHA	NDHA	NDHA	NDHA	NDHA
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	Effect after Mitigation	NDHA	NDHA	NDHA	NDHA	NDHA	NDHA
Impact EJ-5: Potential Disproportionate Effect on Minority and Low-Income Populations in the CVP/SWP Service Areas	Effect before Mitigation	NDHA	NDHA	NDHA	NDHA	NDHA	NDHA
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	Effect after Mitigation	NDHA	NDHA	NDHA	NDHA	NDHA	NDHA

Key:
DHA = Disproportionately high and adverse
NDHA = Not disproportionately high and adverse

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are needed for Impacts EJ-1 (CP1), EJ-3 (CP1), EJ-4 (CP1), or EJ-5 (CP1). No feasible mitigation is available for Impact EJ-2 (CP1). The disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance would result in an unmitigable disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are needed for Impacts EJ-1 (CP2), EJ-3 (CP2), EJ-4 (CP2), or EJ-5 (CP2). No feasible mitigation is available for Impact EJ-2 (CP2). The disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance would result in an unmitigable disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation measures are needed for Impacts EJ-1 (CP3), EJ-3 (CP3), EJ-4 (CP3), or EJ-5 (CP3). No feasible mitigation is available for Impact EJ-2 (CP3). The disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance would result in an unmitigable disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

CP4 – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation measures are needed for Impacts EJ-1 (CP4), EJ-3 (CP4), EJ-4 (CP4), or EJ-5 (CP4). No feasible mitigation is available for Impact EJ-2 (CP4). The disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance would result in an unmitigable disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation measures are needed for Impacts EJ-1 (CP5), EJ-3 (CP5), EJ-4 (CP5), or EJ-5 (CP5). No feasible mitigation is available for Impact EJ-2 (CP5). The disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance would result in an unmitigable disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake.

24.3.6 Cumulative Effects

In the primary study area (i.e., Shasta Lake and vicinity and the upper Sacramento River from Shasta Dam to Red Bluff), minority and low-income populations are not disproportionately represented. Identified construction effects would be less than significant, and minority and low-income populations would not be disproportionately affected.

Some communities within the extended study area (i.e., the lower Sacramento River and Delta and the CVP and SWP service areas) exceed minority and low-income thresholds. These communities, along with the general population, would benefit from project effects that would reduce future water shortages by improving water supply reliability for both average and drought years. The greatest benefit would be provided by CP3, CP4, and CP5, which would provide an additional 634,000 acre-feet of storage capacity. CP1 and CP2 would provide only 256,000 and 443,000 acre-feet of increased storage capacity, respectively, with correspondingly reduced benefits.

Alternatives that would incorporate the greatest increase to dam height would result in the greatest project cost because of higher costs for construction materials and longer construction periods. These increased costs may be reflected in increased utility rates that could be combined with other utility rate increases. Such rate increases would be incremental and would be experienced by the general population, along with minority and low-income communities.

Therefore, the project would not contribute to disproportionate placement of environmental impacts on low-income and minority populations or communities, and no cumulatively considerable impacts would result.

The disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance would result in a disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake. Therefore, the project would contribute to disproportionate placement of environmental impacts on Native American populations and would result in a cumulatively considerable incremental contribution to a significant and unavoidable cumulative impact.

Chapter 25
Wild and Scenic River Considerations for McCloud River

This chapter describes the effects of the dam and reservoir modifications proposed under the SLWRI on the wild and scenic river values of the lower McCloud River, one of the major tributaries to Shasta Lake.

This chapter differs from the other chapters in this PDEIS in that it concerns only the McCloud River and does not discuss other portions of the primary study area nor the extended study area. The study area for this chapter consists of the lower McCloud River from the McCloud River Bridge to the confluence with Little Bollibokka Creek (Figure 25-1).

The primary focus of this chapter is the wild and scenic river values of the lower McCloud River, particularly the reach that would periodically be newly inundated if Shasta Dam and Shasta Lake were enlarged. The discussion and analysis concentrate on the values for which the McCloud River has been determined eligible for listing under the Federal Wild and Scenic Rivers Act (Federal WSRA; Public Law 90-542, as amended; 16 U.S. Code 1271-1287) and for which a portion of the river is protected under the California Public Resources Code, Section 5093.542 (State PRC). Section 5093.542 was established through enactment of the California Wild and Scenic Rivers Act, as amended (Sections 5093.50 – 5093.70).

This chapter also differs from the other chapters in that it first provides background information and then discusses the regulatory framework to provide context for the affected environment section.

25.1 Background

Segments of the McCloud River have been determined eligible for listing under the Federal WSRA and are protected under the State PRC. The river has not been formally listed as wild and scenic under either the Federal WSRA or State PRC.

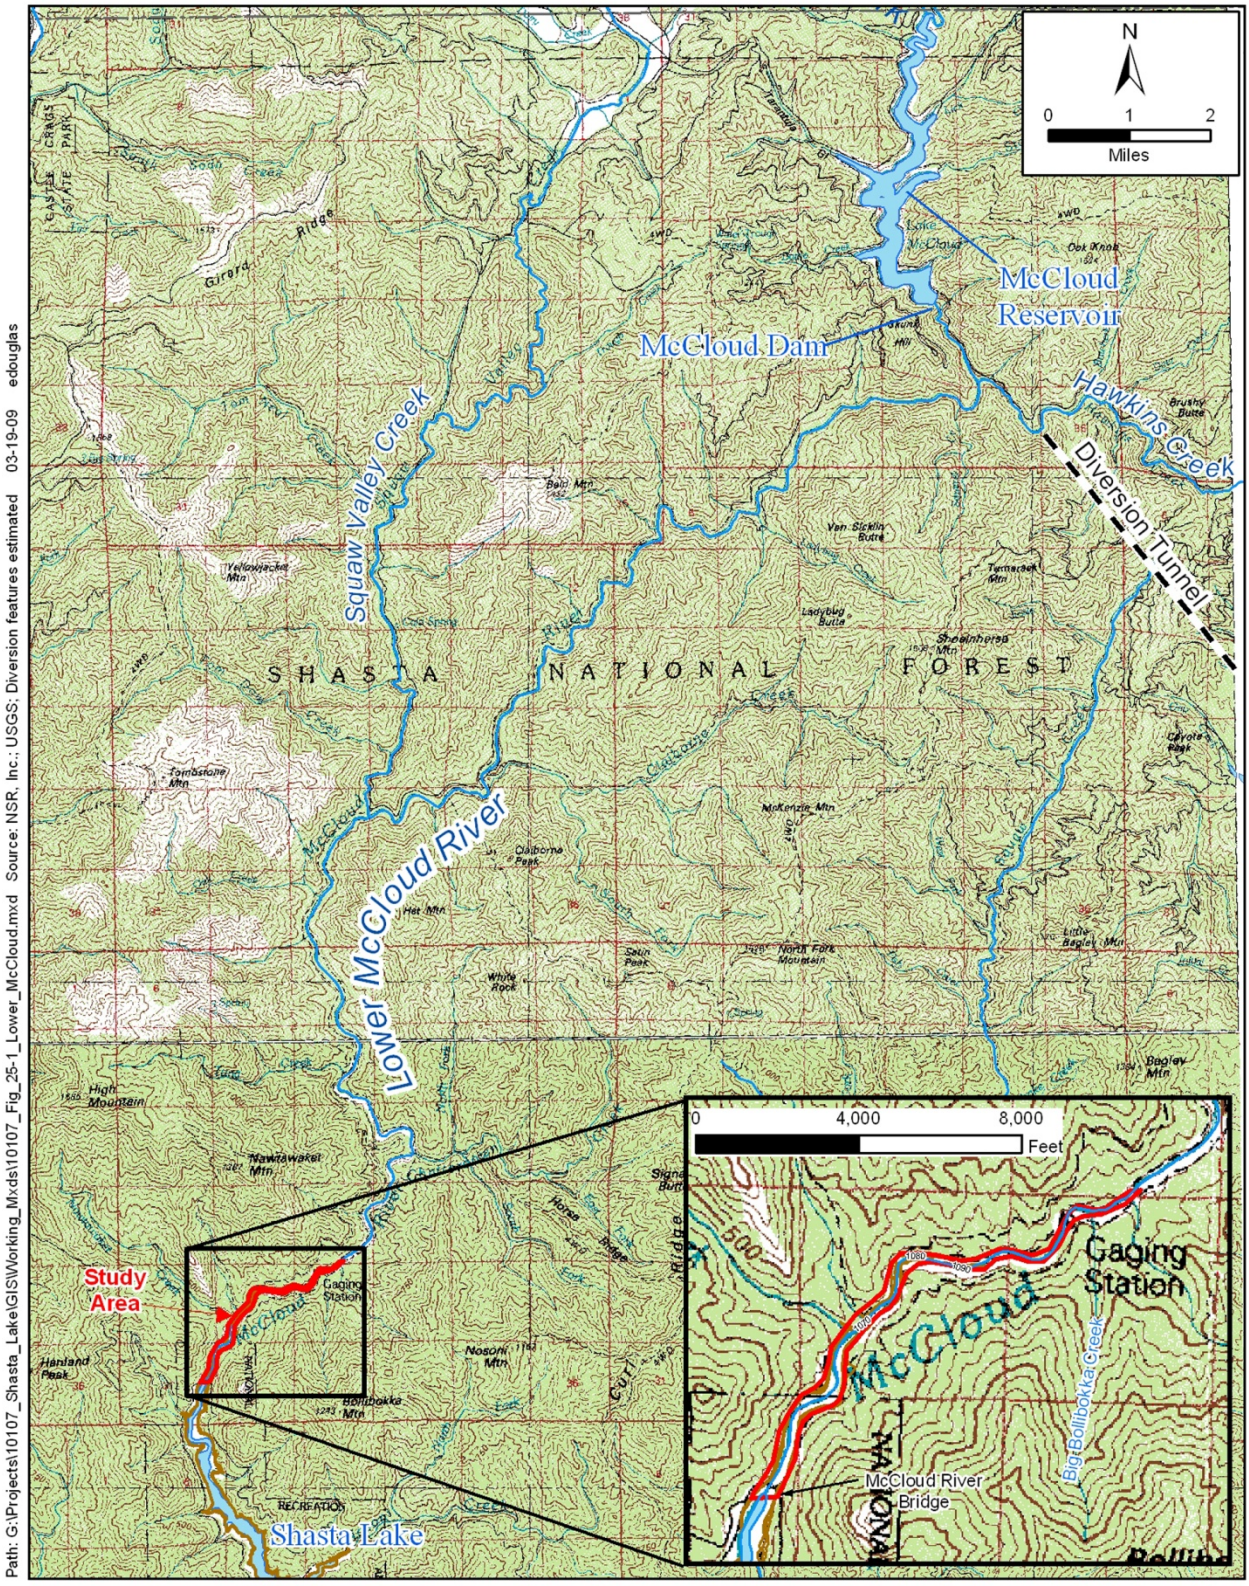

Figure 25-1. Lower McCloud River Study Area

The USFS evaluated the eligibility of the McCloud River for listing as wild and scenic under the Federal WSRA during preparation of the Shasta-Trinity National Forest (STNF) Land and Resource Management Plan (LRMP) in 1994 (USFS 1994). Although the LRMP found the McCloud River eligible for listing, the LRMP direction was to not formally designate any reach of the river as wild and scenic. Instead, the direction was to manage the lower McCloud River under a Coordinated Resource Management Plan (CRMP; USFS 1995a). The coordinated resource management plan (CRMP) is a coordinated effort between landowners and stakeholders with a vested interest in the river. The CRMP requires its signatories to protect the values that make it eligible for Federal designation as wild and scenic and contains a provision stating that the USFS reserves the right to pursue designation if the CRMP is terminated or fails to protect these values.

The California Resources Agency (Resources Agency) evaluated the McCloud River in the late 1980s (Jones & Stokes Associates 1988) to determine whether it was eligible for listing under the State PRC. The Resources Agency study found it eligible, but the California legislature declined to add the river to the California wild and scenic river system. The legislature instead passed an amendment to the California Wild and Scenic Rivers Act to protect the river's free-flowing condition and the river's fishery below McCloud Dam through the State PRC.

As described in more detail under "Regulatory Framework," the State PRC and Federal WSRA share several similar components: the establishment of a wild and scenic rivers system; the purpose of protecting certain rivers in their "free-flowing" condition; the identification of extraordinary or outstandingly remarkable values (ORV) that make such rivers eligible for protection; a study process and procedure for including rivers in the system; and classifications of "wild," "scenic," and "recreational." Both the Federal WSRA and State PRC prohibit new water impoundments on designated rivers, and both contain directives to government agencies to use their powers to further the policies of the legislation.

The Federal WSRA establishes a larger wild and scenic river corridor—typically at least 0.25 mile on each side of the river—than the State PRC and requires Federal agencies to manage the public lands in the corridor to protect the river's free-flowing character and ORVs. In addition, the managing Federal agency for rivers that are Federally designated as wild and scenic is required to develop and implement a management plan that will ensure the river's protection. In contrast, the State PRC provides protection only to the first line of permanent riparian vegetation and does not require a management plan.

The length of the lower McCloud River determined eligible for wild and scenic river status was different in the Federal and State evaluations. The USFS defined the lower McCloud River more narrowly than the Resources Agency, considering the portion of the river that is currently periodically inundated by

Shasta Lake – referred to in this chapter as the *transition reach* – as part of the lake rather than part of the river. The USFS defined the lower river as extending from McCloud Dam downstream to an elevation of 1,070 feet mean sea level (msl) (approximately 22 total river miles), which corresponds to the current full-pool elevation of Shasta Lake. The Resources Agency's study report included approximately 5,400 feet of the transition reach (down to the McCloud River Bridge) as part of the lower river's segments (approximately 23 total river miles).

In its evaluation, the USFS divided the McCloud River into 10 segments encompassing 46 total river miles: three segments along the upper McCloud River (24 river miles above McCloud Reservoir) and seven segments along the lower McCloud River (22 river miles below McCloud Dam). Numbering of the upper McCloud River segments began at the headwaters and counted downstream, but numbering of the lower McCloud River segments began at the downstream extent and counted upstream. The USFS concluded that all 10 segments of the McCloud River were eligible for listing as a Federal wild and scenic river because they are free flowing, possess good water quality, and exhibit ORVs in the areas of cultural and historical resources, fisheries, geology, and scenic resources. Part of the lowermost segment – Segment 4 – would be periodically inundated if Shasta Lake is expanded. Segment 4 extends from about 5,400 feet upstream from the McCloud River Bridge, beginning at an elevation of 1,070 feet msl, to about Little Bollibokka Creek. The lower extent of this segment corresponds with the current full-pool elevation of Shasta Lake based on Reclamation geographic information system data. Figure 25-2 shows the downstream extent of Segment 4.

The Resources Agency's report also identified 10 segments, but its evaluation encompassed only 43 total river miles and the numbering of segments began at the headwaters and counted downstream along the entire river. The segments included six along the upper river (20 river miles above McCloud Reservoir) and four along the lower river (23 river miles below McCloud Dam). Eight of the 10 segments were determined eligible for State wild and scenic river status. Segment 10 extends from the McCloud River Bridge to the northern border of Section 9, Township 36 North, Range 3 West, which is just upstream from the river's confluence with Tuna Creek. Approximately 5,400 feet of the transition reach is included in Segment 10; the portion of the transition reach downstream from the bridge was determined ineligible. The downstream extent of Segment 10 is shown on Figure 25-2.

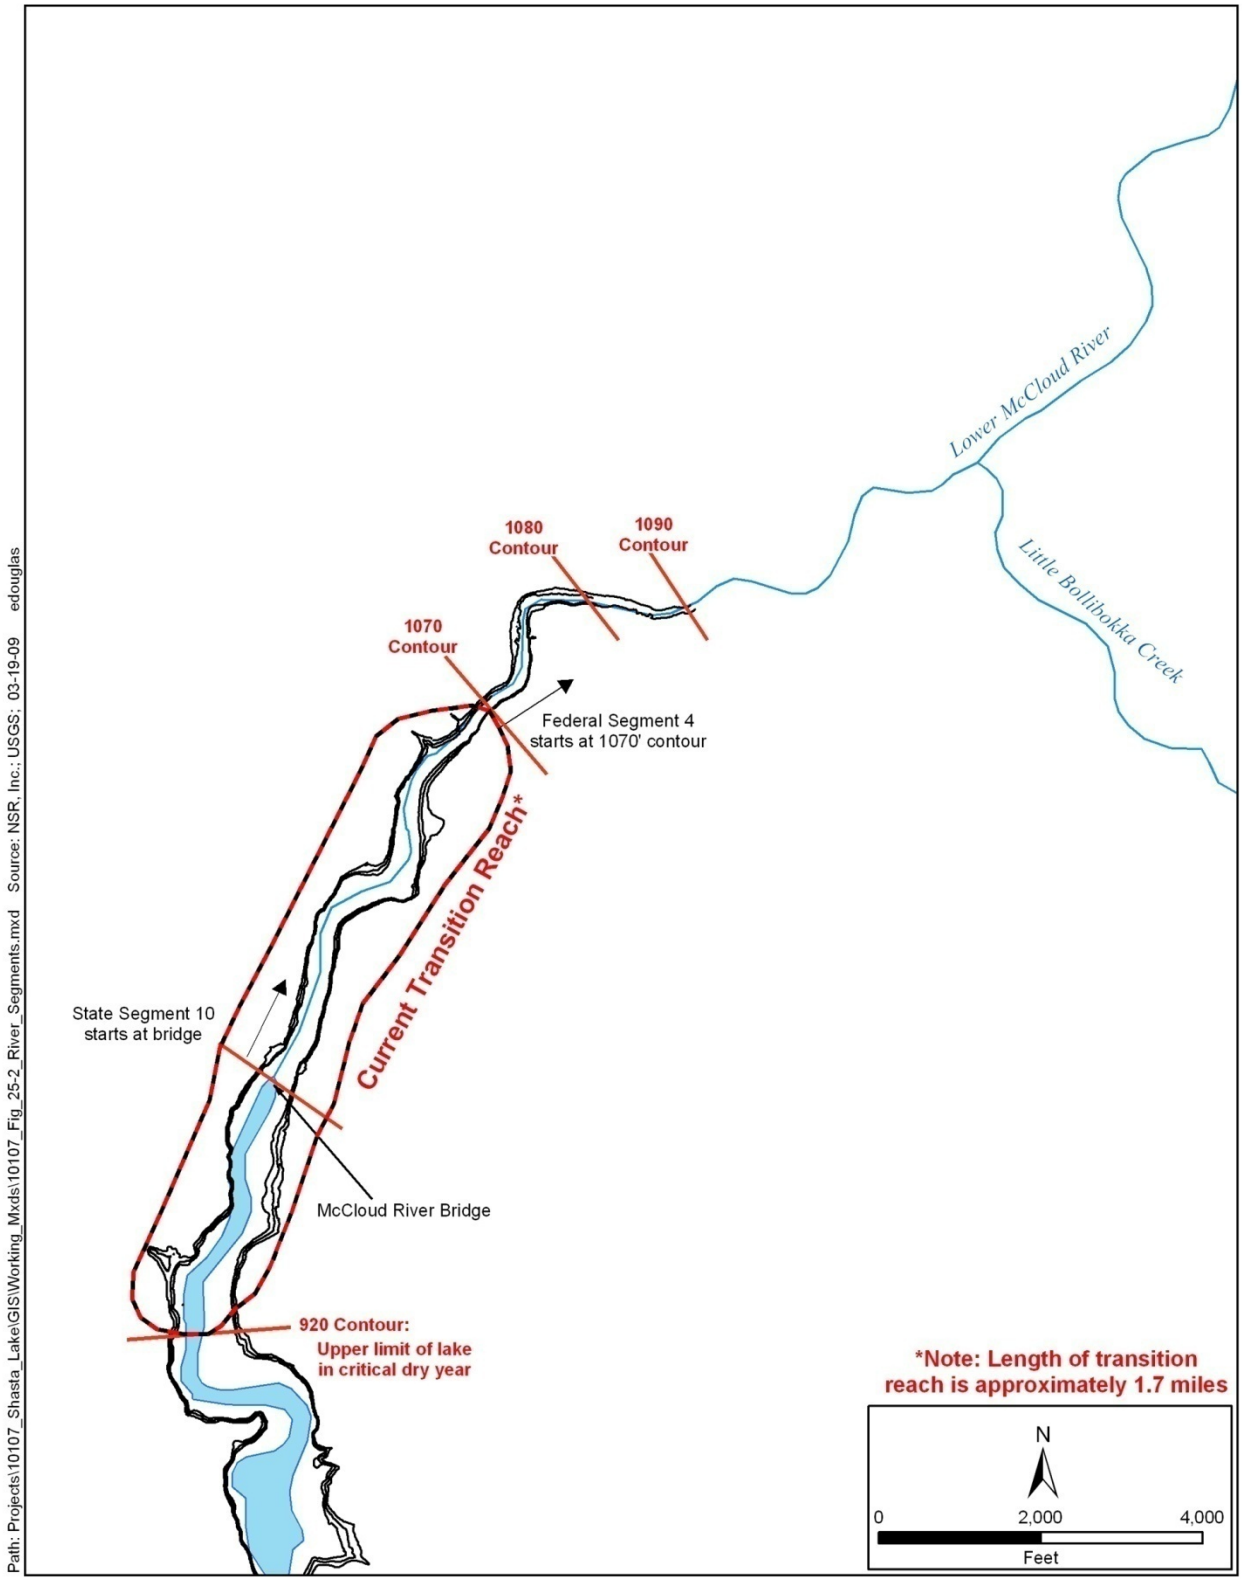

Figure 25-2. Differences in State and Federal Segments and Transition Reach

25.2 Regulatory Framework

25.2.1 Federal

Federal Wild and Scenic Rivers Act

The Federal WSRA, enacted in 1968, established the National Wild and Scenic Rivers System "to preserve rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations." To be eligible for inclusion in the system, a river must be free-flowing and exhibit ORVs. Free-flowing means "existing or flowing in a natural condition without impoundment, diversion, straightening, rip-rapping, or other modification of the waterway" (16 USC Section 1286). ORVs are scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values (16 USC Section 1271). Depending on the specific conditions of a river, it may be designated as "wild," "scenic," or "recreation." Different segments of a single river can receive different designations; in other words, some segments can be designated wild, some scenic, and some recreation or combinations of these designations.

Through the development and approval of the STNF LRMP, the USFS determined that segments of the McCloud River are eligible for inclusion in the national system; however, the river has not been formally designated and thus is not afforded protections under the Federal WSRA. Instead, the McCloud River CRMP was developed "to protect the [river's] unique and outstandingly remarkable features," thereby maintaining its eligibility.

The USFS evaluation concluded that the lower McCloud River, from McCloud Dam downstream about 22 miles to the river's transition to Shasta Lake at about 1,070 feet msl, provides outstanding cultural, fisheries, and geologic values, and its corridor has been classified as a highly sensitive visual area by the USFS (USFS 1994 and 1995b). The entire river corridor contains prehistoric and historic sites from past use by Indian tribes, late 1800 and early 1900 resorts, and logging activities. The lower river provides habitat for trout species (bull trout/Dolly Varden, which is believed to be extinct, and rainbow trout, which has been transplanted all over the world) and is considered a "blue ribbon trout fishery" (USFS 1994). Outstanding geologic values include rock outcrops, cascades, and pools. Based on the ORVs, the STNF determined that the lower McCloud River meets the eligibility requirements for designation under the Federal WSRA.

Shasta-Trinity National Forest Land and Resources Management Plan

The STNF LRMP is a forest-wide land use plan developed to guide resource management within the forest (USFS 1995b). For planning purposes, the STNF is divided into six land allocations for which specific management prescriptions are identified. The land allocations include Congressionally Reserved Areas, Late-Successional Reserves, Administratively Withdrawn Areas, Riparian Reserves and Key Watersheds, Matrix Lands, and Adaptive Management Areas.

Management areas were identified within the STNF to establish management direction in response to the issues and resources of each distinct area. The Management Area defined for the McCloud River provides resource direction for recreational use, specifically fishing and viewing waterfalls, and management of old-growth habitat. Management of the wild and scenic river ORVs of the McCloud River is deferred to the CRMP.

Coordinated Resource Management Plan

In 1990, certain public agencies and private parties with interests in the management of lands adjacent to the McCloud River executed a memorandum of understanding to pursue preparation of a CRMP. The memorandum was signed by representatives of the USFS, DFG, The Nature Conservancy, Pacific Gas and Electric Company (PG&E), the Bollibokka Land Company, Crane Mills, McCloud River Co-Tenants, Sierra Pacific Industries, and the Hearst Corporation. In 1991, the same signatories, along with California Trout Inc., signed another memorandum of understanding to establish the framework for and approve the CRMP. The CRMP was adopted in July 1991. In 2007, the property owned by the Bollibokka Land Company was sold to Westlands Water District, which is not a party to the CRMP.

The CRMP provides a framework for the coordination of management activities among the participants to ensure that the characteristics of the river that make it eligible for Federal wild and scenic river designation are protected. The CRMP provides specific conditions for the USFS' management of the river and states that the USFS "reserves the right to pursue [Federal wild and scenic river] designation" if the CRMP is terminated or significantly impaired or if the CRMP fails to protect the values that make the river suitable for such designation.

25.2.2 State

California Public Resource Code, Sections 5093.50-5093.70

Sections 5093.50–5093.70 were added to the State PRC in 1972, through enactment of the California Wild and Scenic Rivers Act, to preserve certain rivers that possess extraordinary scenic, recreational, fishery, or wildlife values in their free-flowing state. The State PRC identifies, classifies, and provides protection for specific rivers or river segments, as approved by the legislature. Rivers or river segments that are specifically identified and classified in the PRC comprise the State Wild and Scenic Rivers System. As described in Section 5093.50, rivers or river segments included in the State system must possess "extraordinary scenic, recreational, fishery, or wildlife values"; the PRC does not define what constitutes "extraordinary."

Various amendments to the California Wild and Scenic Rivers Act have been passed, adding related legislation to the PRC. In 1986, Assembly Bill (AB) 3101 (Statutes 1986, Chapter 894) established a study process to help determine eligibility for potential additions to the State system (PRC Section 5093.547 and

Section 5093.548). Additionally, protection for river segments can be provided without formally identifying them as part of the State system.

In 1989, an amendment to the California Wild and Scenic Rivers Act was passed, adding Section 5093.542 to the PRC to protect the McCloud River fishery, which it describes as "one of the finest wild trout fisheries in the state." It further declares that "The continued management of river resources in their existing natural condition represents the best way to protect the unique fishery of the McCloud River" and that "maintaining the McCloud River in its free-flowing condition to protect its fishery is the highest and most beneficial use of the waters of the McCloud River." The amendment provides protection to the McCloud River fishery and its "natural" and "free-flowing" condition from Algoma to the confluence with Huckleberry Creek (upper McCloud River), and 0.25 mile downstream from the McCloud Dam to the McCloud River Bridge (lower McCloud River). Although the Legislature declared that the McCloud River possessed "extraordinary resources" in the context of the State PRC, the Legislature's action stopped short of formally designating the river as wild and scenic.

25.3 Affected Environment

This section defines "affected environment" as the wild and scenic characteristics of the lower McCloud River that could be affected by the proposed modifications to Shasta Dam and Shasta Lake. It briefly describes the McCloud River from its headwaters to the McCloud Arm of Shasta Lake. It then describes the wild and scenic values of Segment 4 identified in the USFS evaluation and the values provided protection in the State PRC.

Descriptions of the river and its characteristics were derived primarily from the following sources:

- Wild and Scenic Rivers Evaluation, Appendix E to the Environmental Impact Statement for the Shasta-Trinity National Forest Land and Resources Management Plan (USFS 1994)
- Lower McCloud River and McCloud Arm Watershed Analyses (USFS 1998a and 1998b)
- McCloud River Wild and Scenic River Report (Jones & Stokes Associates 1988)
- Lower McCloud River Wild Trout Area Fishery Management Plan, 2004 through 2009 (Rode and Dean 2004)
- Lower McCloud River Habitat Typing Report (USFS 2001)

25.3.1 The McCloud River

McCloud River Basin

The McCloud River basin drains an area of approximately 800 square miles (USFS 1998a) in northern Shasta County and southern Siskiyou County, southeast of Mount Shasta. The river originates in an area of the STNF near Colby Meadows at approximately 4,250 feet above msl (Rode and Dean 2004). From its headwaters to Shasta Lake, the river is approximately 59 miles long. McCloud Reservoir, part of PG&E's McCloud-Pit Hydroelectric Project, separates the upper river from the lower river. The lower McCloud River transitions into the McCloud Arm of Shasta Lake upstream from the McCloud River Bridge (Figure 25-3).

Upper McCloud River

The upper McCloud River is an approximately 36-mile reach from the river's origins at Colby Meadows downstream to the transition with McCloud Reservoir. The river basin above the reservoir drains an area of approximately 403 square miles. Mean monthly flows in the upper McCloud River range from 766 cubic feet per second (cfs) in October to over 1,000 cfs in March, April, and May (PG&E 2006).

McCloud Reservoir

The McCloud Reservoir is a major component of PG&E's McCloud-Pit Hydroelectric Project, which was constructed in 1965 and operates under license from the Federal Energy Regulatory Commission (FERC). The McCloud Reservoir is approximately 5 miles long and has a storage capacity of approximately 35,200 acre-feet of water. The McCloud-Pit Hydroelectric Project diverts approximately 75 percent of the upper McCloud River's flow through a pipeline to Iron Canyon Reservoir, then conveys it downslope and discharges it into the Pit River at the Pit 6 powerhouse, upstream from the Pit River Arm of Shasta Lake (PG&E 2006). The remaining 25 percent of flows provide base flow for the lower McCloud River, a considerable reduction from historic flow volumes (Jones & Stokes Associates 1988).

Lower McCloud River

The lower McCloud River flows southwesterly through a deep canyon with steep slopes approximately 22 miles from McCloud Dam downstream to the transition with Shasta Lake. Vegetation along the lower river is predominately mixed-conifer and Douglas-fir forest. This stretch of river receives runoff from a 404-square-mile area of the lower McCloud River basin and the 95-square-mile Squaw Valley Creek basin. It provides exceptional fishing opportunities and includes two long-established fishing clubs, the Bollibokka Club and the McCloud River Club. The Nature Conservancy's McCloud River Preserve also encompasses a portion of the lower McCloud River.

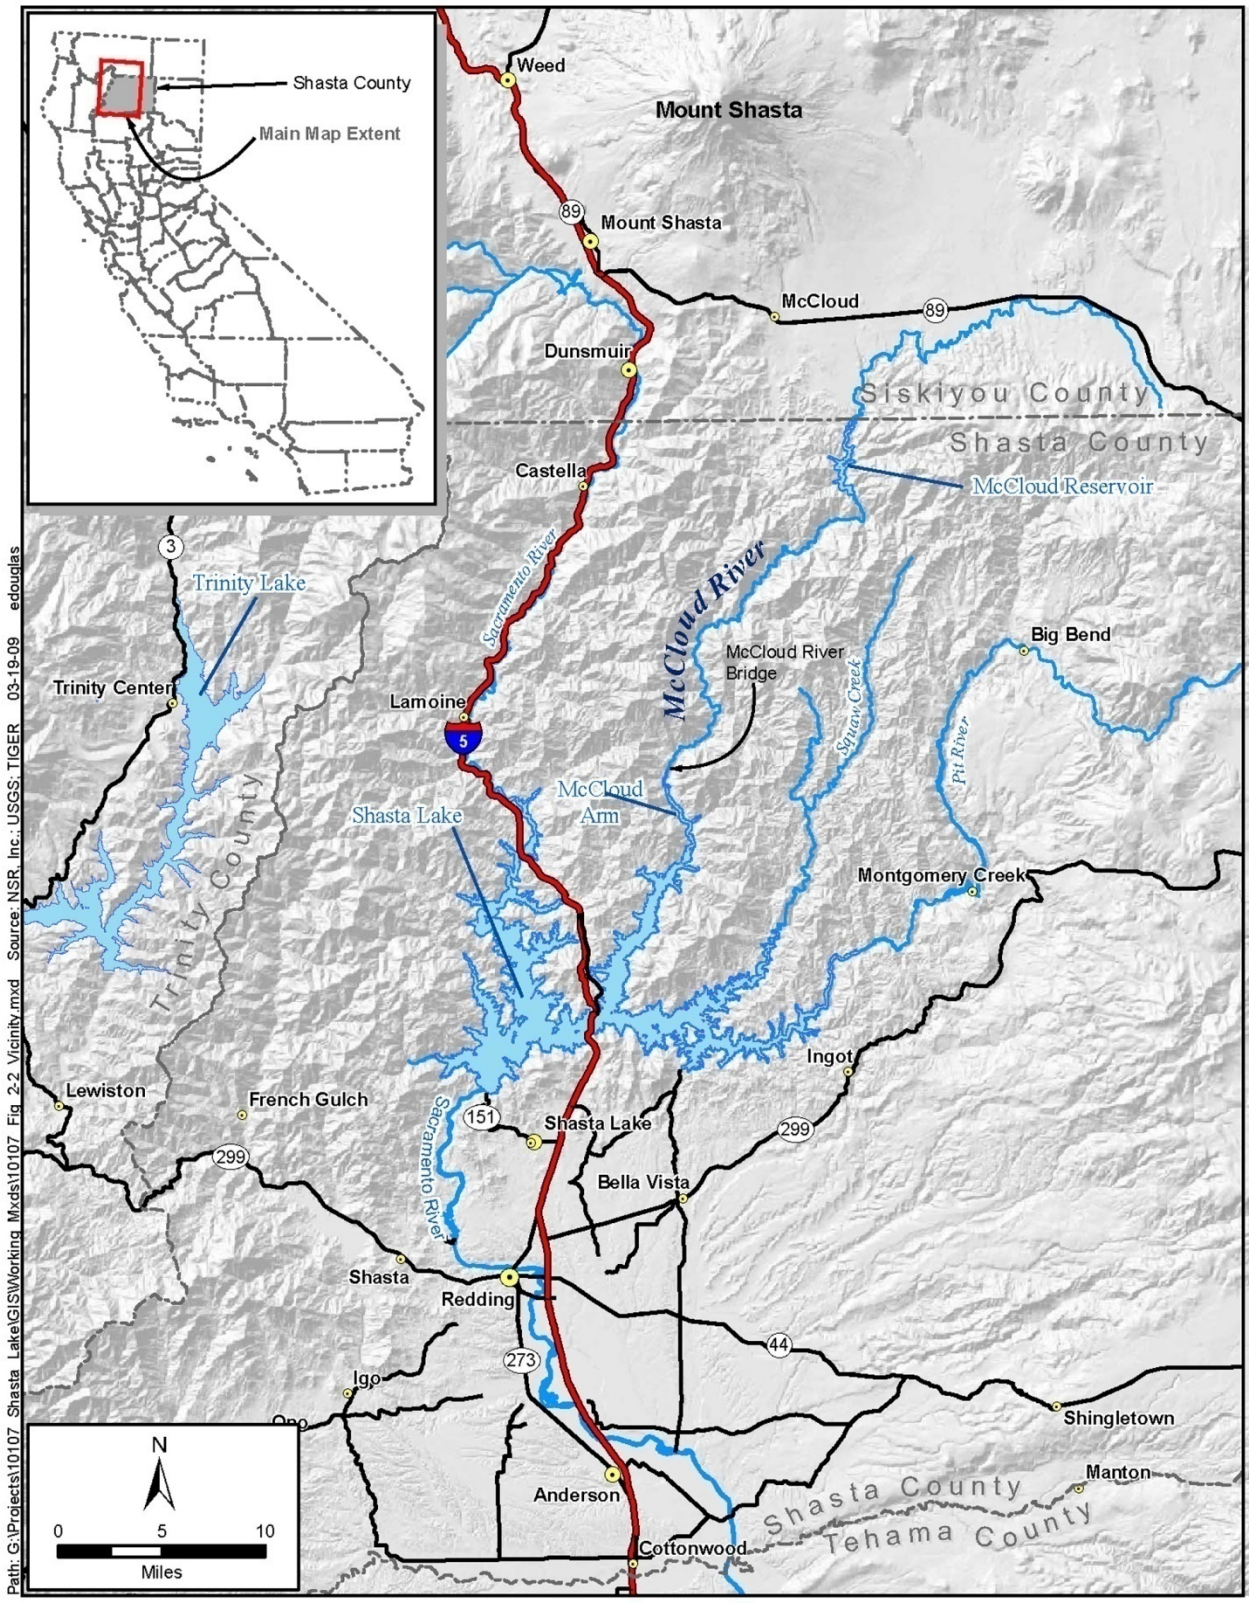

Figure 25-3. Regional Location

Flows in the lower McCloud River have been controlled by releases from McCloud Dam since 1965 (PG&E 2006). Under its current FERC license, PG&E's McCloud-Pit Hydroelectric Project maintains a minimum instream flow of 50 cfs from May through November and 40 cfs from December through April through controlled releases. Accordingly, flows in the lower McCloud River are highly regulated, and annual flows in the river below McCloud Dam do not follow a pattern typical of an unimpaired mountain river in northern California. Prior to dam construction, flows in the lower river were considerably higher, estimated to be in the range of 924 to 1,245 cfs (mean monthly flows) from June to October (Jones & Stokes Associates 1988, citing U.S. Geological Survey (USGS) for the period of 1967 to 1985).

McCloud Arm of Shasta Lake

The construction of Shasta Dam between 1938 and 1945 converted part of the lower McCloud River into the McCloud Arm of Shasta Lake. The McCloud Arm is more than 16 miles long, with approximately 70 miles of shoreline. It drains an area of approximately 41,000 acres (USFS 1998b). Water levels in the arm fluctuate with the lake's water levels, and during periods of lower water levels, a water line, known as the "bathtub ring," is evident along the banks. During extended periods of lower water levels, vegetation may become established on the exposed banks.

The upper extent of the lake encompasses the transition reach, which varies between about 920 and 1,070 feet msl. Because of the effects of Shasta Lake on the McCloud Arm, the STNF determined that the transition reach did not meet the eligibility requirements of a wild and scenic river (USFS 1994). The USFS defined the upper limit of the McCloud Arm as an elevation of 1,070 feet, or approximately 5,400 feet above the McCloud River Bridge. This elevation corresponds to the lower limit of Segment 4. A portion of the transition reach – from the McCloud River Bridge to the 1,070-foot elevation – is included in the segments of the river provided protection under the State PRC.

The transition reach provides a corridor for fish migrating between Shasta Lake and the lower McCloud River and contributes to the unique fishery of the river. Common fish in the McCloud Arm include rainbow trout, spotted bass, riffle sculpin, and speckled dace (North State Resources, Inc. 2008).

Water temperatures in the McCloud Arm become warmer as the river transitions to Shasta Lake. The warmer temperatures associated with Shasta Lake support warmwater fish, but the cooler temperatures of the transition reach may prevent some fish from migrating upstream into the lower river. Water temperatures in the transition reach may be suitable for warmwater species.

25.3.2 The McCloud River's Wild and Scenic Values

This section focuses on the wild and scenic river characteristics and ORVs of the lower McCloud River identified by the USFS in the wild and scenic river evaluation performed for the STNF LRMP (USFS 1994) and the wild and

scenic river characteristics and extraordinary value protected under the State PRC.

The McCloud River's fishery and its free-flowing condition are identified in both the USFS evaluation and the State PRC. These characteristics are discussed first, followed by a discussion of the wild and scenic characteristics and values – water quality, geology, cultural/historical resources, and visual quality/scenery – that are identified only in the USFS evaluation.

Specific information is lacking concerning the river reach that could periodically be inundated if Shasta Dam and Shasta Lake were enlarged because the lands along this part of the river are privately owned and access for biological and other surveys has been limited; therefore, general information concerning the lower McCloud River as a whole is provided for some resource areas. This section also includes a brief description of the current transition reach (see Figure 25-1) because the reach of the river that would be newly inundated would likely take on the characteristics of the existing transition reach.

Fishery

The fishery of the lower McCloud River is unique; the river is considered a premier trout fishery, despite the ongoing effects of McCloud Dam and Shasta Lake on the river's flows and water quality. To characterize the fishery, this section includes descriptions of the aquatic habitat in USFS Segment 4, the Resources Agency's Segment 10, and the transition reach as well as the fish species that inhabit the study area.

Aquatic Habitat The lower McCloud River is characterized as a series of alternating riffles, pools, and cascading pocket water occurring along a broad, boulder-studded river channel within a confined, heavily timbered valley. A narrow band of montane riparian vegetation (typically less than 25 feet wide) dominated by willows, white alders, and Oregon ash occurs along the river banks adjacent to steep hill slopes with mixed conifer-Douglas-fir forest (USFS 2001).

In 2001, the USFS prepared a Habitat Typing Report to characterize aquatic habitats in the lower McCloud River from the McCloud River Bridge to McCloud Dam. The report divided the lower river into four reaches: McCloud Dam to Ladybug Creek, Ladybug Creek to Clairborne Creek, Clairborne Creek to Tuna Creek, and Tuna Creek to McCloud River Bridge. The reach from Tuna Creek to McCloud River Bridge includes all of Segment 4 and nearly all of Segment 10, including the portion of the transition reach that is part of Segment 10. Data are not available for the transition reach below the McCloud River Bridge downstream to Shasta Lake.

The dominant aquatic habitat in the reach of the lower river from Tuna Creek to McCloud River Bridge includes runs (20 percent), mid-channel pool (18

percent), low-gradient riffles (18 percent), lateral scour pool from bedrock (11 percent), and pocket water (10 percent) (USFS 2001). This reach provides most of the corner pool (100 percent), glide (89 percent), and cascade (50 percent) habitats in the lower river.

The portion of the transition reach upstream from McCloud River Bridge is dominated by low-gradient riffles and mid-channel pools, with some pocket water, glides, runs, and lateral scour pools. Glide habitat is the dominant aquatic habitat between the 1,070-foot and 1,080-foot elevations, and pocket water is the dominant aquatic habitat between the 1,080-foot and 1,090-foot elevations. The habitat within the current transition reach represents a fraction of the total available aquatic habitat within the lower McCloud River and provides a small portion of the habitats within the reach from the McCloud River Bridge to Tuna Creek.

The diversity of riffles, flatwater habitat, and pools is influenced by the presence of boulders and cobble substrate and variations in flow conditions. The lower river is dominated by boulders with pockets of gravel present at pool tailouts and in velocity breaks behind large boulders. The riffles are generally higher gradient channel sections with turbulent surface flow and uniform cobble and boulder substrates. While swift pocket water in the lower McCloud River often appears more like a riffle than a run, the habitable eddies, or pockets, created behind the boulders that characterize this habitat type make it functionally more similar to the other flatwater habitats (USFS 2001). Typically, flatwater and pools are the principal habitats used by the trout in the McCloud River for rearing and feeding (Wales 1939, Rode and Dean 2004, USFS 2001).

The USFS (2001) reported that the aquatic habitat within the transition reach has undergone type conversions caused by aggradation and scour of sediments for about 3,700 feet upstream from the McCloud River Bridge. When Shasta Lake is drawn down, large, wide, low-gradient riffles with channel braiding dominate in this reach. When the lake is at full pool and at intermediate levels of drawdown, the transition reach becomes inundated, but a unidirectional current created by the lower McCloud River's inflow is detectable throughout the inundation zone, slowing as it approaches the flat water of Shasta Lake. To varying degrees, this fluctuating backwater effect converts this reach to a deep, wide, slow-moving riverine habitat transitioning to lacustrine habitat near the bottom of the transition reach.

Fish Species The current composition and distribution of fish species inhabiting the lower McCloud River and Shasta Lake reflect the historic fishery, the operational effects of Shasta Dam and McCloud Dam, and the introduction of nonnative fish species into the river and Shasta Lake. The completion of Shasta Dam in 1945 eliminated all runs of anadromous fish in the river (Rode and Dean 2004). The historic fishery included Chinook salmon (*Oncorhynchus tshawytscha*), steelhead (*O. mykiss irideus*), rainbow trout (*O. mykiss*), and the

only known California occurrence of the bull trout (*Salvelinus confluentus*). The bull trout is believed to have been extirpated from the lower McCloud River and is possibly extinct in California. Today, the fishery is dominated by rainbow trout and brown trout (*Salmo trutta*), an introduced species that migrates between Shasta Lake and the lower McCloud River. Other nonnative species also migrate up the lower McCloud River, including spotted bass (*Micropterus punctulatus*), but bass have not been confirmed upstream from Tuna Falls, a high-gradient rapid at the confluence with Tuna Creek. Despite the change in fish species in this 22-mile reach, the lower McCloud River is still considered one of California's premier trout streams.

Fish observed in the river downstream from the Tuna Creek confluence during a survey conducted in summer 2007 included rainbow trout, spotted bass, speckled dace (*Rhinichthys osculus*), sculpin spp. (*Cottus* spp.), Sacramento sucker (*Catostomus occidentalis*), and Sacramento pikeminnow (*Ptychocheilus grandis*) (North State Resources, Inc. 2008). Other fish that occur in this reach include brown trout, brook trout (*Salvelinus fontinalis*), hardhead (*Mylopharodon conocephalus*), and smallmouth bass (*Micropterus dolomieui*). The status of the riverine fish species of the lower McCloud River is identified in Table 25-1.

Rainbow Trout Fluvial and adfluvial populations of rainbow trout use the habitat available throughout the lower McCloud River. The McCloud River rainbow trout became known as "the rainbow of the fish culturist" because eggs from that population accounted for transplants of rainbow trout in the 1880s to the eastern states and several other countries.

The rainbow trout that inhabit the McCloud River are a vigorous, active fish that primarily inhabit swifter portions of pool and pocket water habitats. Adults migrate into the lower McCloud River from Shasta Lake in the spring and fall months, presumably to spawn. Suitable spawning habitat in the study area is limited, and the trout likely migrate further upstream to spawn (North State Resources, Inc. 2008).

Although the genetic origin of these fish has not been evaluated, the numerous strains of rainbow trout planted in Shasta Lake over the years have likely resulted in some introgression among migratory rainbow trout in the lower McCloud River. The degree to which this migratory population of rainbow trout contributes to the native trout fishery of the river is not specifically known; however, available data do not indicate that it is substantial.

Rainbow trout typically mature in their second to third year and move upstream to spawn in the lower McCloud River and its tributaries from February to June. The eggs typically hatch in 3 to 4 weeks, depending on water temperature, and fry emerge 2 to 3 weeks later. The fry remain in quiet waters close to shore, among cobbles, or under overhanging vegetation for several weeks. As the fish grow, they move into swifter water habitats.

Table 25-1. Riverine Fish Species of the Lower McCloud River

Species	Current Status	Comments
Sacramento sucker (Catostomus occidentalis)	Common	Native, non-game species, observed during 2007 surveys
Riffle sculpin (Cottus gulosus)	Common	Native, non-game species, observed during 2007 surveys
Smallmouth bass (Micropterus dolomieui)	Uncommon	Introduced sport species in Shasta Lake, moves into lower river from lake, warmwater species
Spotted bass (Micropterus punctulatus)	Uncommon	Introduced sport species in Shasta Lake, moves into lower river from lake, observed during 2007 surveys, warmwater species
Hardhead (Mylopharodon conocephalus)	Uncommon	Native, non-game species
Rainbow trout (Oncorhynchus mykiss)	Abundant	Native trout species, subject to special angling regulations, coldwater species, observed during 2007 surveys
Sacramento squawfish (=pikeminnow) (Ptychocheilus grandis)	Common	Native, non-game species, observed during 2007 surveys
Speckled dace (Rhinichthys osculus)	Common	Observed during 2007 surveys
Brown trout (Salmo trutta)	Common	Introduced sport species found throughout the river, migrates from Shasta Lake to spawn in lower river, subject to special angling regulations, coldwater species
Bull trout (Salvelinus confluentus)	CE; Extinct	Native, believed extirpated from entire river by mid-1970s, a few restoration experiments performed in upper river tributaries, coldwater species
Brook trout (Salvelinus fontinalis)	Rare	Introduced sport species, stocking in upper river and tributaries discontinued, very rarely observed in lower river, coldwater species

Sources: Wales 1939, Tippets and Moyle 1978, Rode and Dean 2004, Moyle 2002, DFG, unpublished data, North State Resources, Inc. 2008

Key:

CE = California Endangered

In the river, this species forms feeding station hierarchies, which they aggressively defend, and prey on aquatic and terrestrial insects drifting in the current. They also eat active bottom invertebrates. It has been reported that McCloud River rainbow trout tend to be more bottom-oriented when feeding than rainbow trout elsewhere.

In reservoirs, rainbow trout form loose schools and feed on both invertebrates and other fish, although fish dominate their diet as they grow larger. Preferred prey in Shasta Lake is the threadfin shad. Trout growth in Shasta Lake is more rapid than for fluvial trout. The optimum temperature range for growth and for completion of most life stages of rainbow trout is between 50 and 70 degree Fahrenheit (°F), though they seem to prefer and thrive at temperatures in the lower two-thirds of this range. Rainbow trout in lakes and streams seldom live for more than 6 years.

Brown Trout Like the rainbow trout, fluvial and adfluvial populations of brown trout use habitat throughout the lower McCloud River, but this species migrates more between the lake and river. It is not as abundant as the rainbow trout. DFG biologists suggest that this species occupies an ecological niche previously occupied by bull trout in the lower McCloud River (Rode and Dean 2004).

Only some of the brown trout migrating from Shasta Lake that passed a lower river counting weir were observed upstream in the Wild Trout Management Area (segments 7, 8, 9, and 10), so the actual extent of the spawning grounds of migratory brown trout is not fully known.

Brown trout mature in their second or third year. Some fish may mature in the river while others may migrate to Shasta Lake to feed, returning to spawn on a recurring basis. The stimulus for upstream migration is often a rise in stream flow or changing lake temperatures. Spawning takes place from November through December when water temperatures fall below 50°F. Eggs typically hatch within 7 to 8 weeks, depending on water temperature. Fry emerge from the gravel 3 to 6 weeks later. The habitats used by juvenile brown trout are similar to those used by rainbow trout; however, as brown trout grow, they tend to select habitats with slower water and more cover. In the riverine environment, brown trout prefer slow, deep pools with abundant boulder and bedrock ledge cover. The timing of emigration of juvenile brown trout to Shasta Lake is not known.

Fluvial brown trout have diets similar to those of rainbow trout, but appear to feed more on the stream bottom for benthic prey than rainbows. As brown trout grow, their diet expands to include larger invertebrate prey and fish. Larger brown trout are voracious predators, especially on fish, including young salmonids. In Shasta Lake, adult brown trout prefer threadfin shad as a staple prey.

Brown trout growth in the lower McCloud River appears to increase after age 3, which has been attributed to their migration to Shasta Lake to exploit the forage fish populations. Brown trout growth is best at temperatures ranging from 45 to 69°F, though they seem to prefer and dominate other trout species near the upper half of this range.

Spotted Bass and Smallmouth Bass Black basses and other sunfishes dominate in the littoral zones of Shasta Lake. Spotted bass and smallmouth bass are now the most common black basses in Shasta Lake, with spotted bass having become most frequent over the past 20 years. Both spotted and smallmouth bass occupy shallow, low-gradient habitat offered by Shasta Lake and its tributaries. They can be found throughout Shasta Lake and in the lower ends of the main tributary streams, including the lower McCloud River. However, the extent to which black bass have colonized the lower McCloud River is not currently known.

Smallmouth bass and spotted bass share similar life histories, and these similarities may account for their persistence in Shasta Lake compared to that of largemouth bass, which have declined in numbers. Both smallmouth and spotted bass mature in their second or third year and spawn in the late spring. Smallmouth will spawn at cooler temperatures (55 to 61°F) than spotted bass (greater than or equal to 65°F). Both species seek quiet shallow areas over mud, sand, gravel, and rocky, debris-littered bottoms to spawn in both lakes and streams. This type of spawning habitat is available in the transition reach of the lower McCloud River, especially when lake levels are high.

Juvenile bass feed on small invertebrates until they are large enough to prey on small fish and large invertebrates. Temperature preferences and optimal growth for both species of black basses is attained in the range from 68 to 81°F. Because of the year-round cool temperatures (less than or equal to 68°F) of the lower McCloud River, temperatures preferred by bass only occur during the late summer and early fall months upstream from the transition reach. Therefore, the temperature regime of the lower McCloud River may limit intrusions of bass from the lake. However, spotted bass were observed in the lower river below the confluence of Tuna Creek during summer fish surveys (North State Resources, Inc. 2008).

Free-Flowing Condition

The Federal WSRA defines *free flowing* as "existing or flowing in natural condition without impoundment, diversion, straightening, rip-rapping, or other modification of the waterway" (16 USC Section 1286). The State PRC defines free-flowing as "existing or flowing without artificial impoundment, diversion, or other modification of the river." It states, however, that the "presence of low dams, diversion works, and other minor structures does not automatically bar a river's inclusion in the system."

Base flows in the lower McCloud River are partially controlled by releases from McCloud Reservoir in accordance with PG&E's FERC license and include precipitation and inflow from tributaries. The lower McCloud River experiences seasonal fluctuations and large variations in base flows (USFS 1998a). Releases from McCloud Reservoir into the lower river are heavily regulated, with a minimum release requirement of 50 cfs from May through November and 40 cfs from December through April; the releases are typically well above these minimum requirements and tend to stay above 100 cfs (USFS 1998a). Tributary contributions are the most noticeable flows during storm events, but are substantially reduced during low-flow conditions. Because of the minimum release requirements from McCloud Reservoir, spring and summer flows are considerably more stable than they would be under unregulated conditions.

PG&E monitors lower McCloud River flows in accordance with its FERC license at a gaging station in Segment 4 upstream from Shasta Lake (0.2 mile downstream from Big Bollibokka Creek); the most recent available water data record covers the water year October 2006–September 2007 (USGS 2007). For

this period, measured mean monthly flows ranged from 235 cfs in August to a high of 1,185 cfs in February, with maximum flows as high as 5,010 cfs.

Over the course of the year, the transition from lake to river expands and contracts over a distance of about 1.7 miles due to changing water levels in Shasta Lake (Figure 25-2). During April and May of wet years, the transition reach extends about 1 mile (5,400 feet) upstream from the McCloud River Bridge to the full pool elevation of 1,070 feet msl, the downstream boundary of Segment 4. As described in Chapter 6, "Hydrology, Hydraulics, and Water Management" Shasta Lake reaches full-pool elevation about one year in five.

Despite upstream and downstream dams and diversions, the lower McCloud River meets the definition of a free-flowing river under both the Federal WSRA and State PRC.

Water Quality

The water quality of the lower McCloud River is influenced by natural processes and land use activities, including PG&E's McCloud-Pit Hydroelectric Project, timber management activities, and roads. Overall, the water quality of the river is rated as good (USFS 1998). Glacial silt gives the river "a beautiful turquoise color typical of rivers draining glacial valleys in British Columbia and Alaska" (Jones & Stokes Associates 1998).

Turbidity and water temperature are two important factors that influence the water quality of the river and affect aquatic habitat. Turbidity is caused by suspended sediment transported from upstream waters and in surface runoff, particularly from disturbed landscapes, such as timber harvest areas or roads. Water temperature is affected by a variety of conditions, such as river flows, solar radiation, and density of vegetation along the river, but is closely tied to the temperature of the flows released from the McCloud Reservoir.

The turbidity of the lower McCloud River is influenced by the water quality and water levels of the McCloud Reservoir and runoff from upland areas throughout the basin. Turbidity levels are generally low during most of the year, ranging from 5–10 nephelometric turbidity units, but can spike to more than 900 units during periods of intense rainfall and flood flows (PG&E 2006).

Sediment becomes trapped at McCloud Dam and is released into the lower river during large storm events, temporarily increasing turbidity levels, especially in the upper segments of the lower river. Testing of the McCloud Dam bypass valve can cause high turbidity for a short period when sediment is discharged from the reservoir into the lower McCloud River. Surface runoff, especially after the first storms of the wet season, can contribute large amounts of turbid runoff from upland areas.

The length of the transition reach depends on the water year type. As the transition reach moves upstream, sediment within the reach is remobilized and

turbidity levels respond accordingly. Periodic fluctuations in water levels can result in erosion along the banks and localized increases in turbidity levels in the transition reach and the McCloud Arm.

The year-round cool water temperature regime of the lower McCloud River inhibits the productivity of its fishery, but provides high-quality holding habitat for salmonids, contributing to the river's unique value as a tributary to Shasta Lake. The controlled releases from McCloud Dam appear to have a direct bearing on the water temperatures downstream. Water temperatures tend to be higher in Segment 4 than immediately below McCloud Dam. Data recorded at PG&E's monitoring station on the river just upstream from Shasta Lake (0.2 mile downstream from Big Bollibokka Creek) indicate that water temperature ranges from the high 30s to the upper 60s (°F), with lower temperatures in the winter and higher temperatures in the summer (PG&E 2006).

The infusion of cooler water from the lower McCloud River influences water temperatures in the transition reach throughout the year. The degree of influence depends on the amount of discharge from the river and Shasta Lake levels. The temperatures throughout the lower McCloud River also control to some degree the distribution of the warmwater fishery known to occupy the river below Tuna Falls.

Outstandingly Remarkable Values Identified in USFS Evaluation

Cultural/Historical Resources Cultural resources include archaeological sites, historical structures and sites, and areas of religious or cultural significance to Native Americans. Significant resources that provide important information on the prehistory and history of an area or that are considered sacred to Native Americans can contribute to wild and scenic river values.

The McCloud River basin was part of a major center of occupation by the Wintu people, who occupied the McCloud River area at the time of Euro-American contact in the 1800s. Although much of the Wintu territory was overrun with miners and other opportunistic Euro-Americans, the lower McCloud River was left largely untouched due in part to a lack of easily mined materials and the ruggedness of the terrain (Yoshiyama and Fisher 2001), but also because of the resistance of the Wintu to incursions into their territory. Because of its generally undisturbed nature, the significance of the lower McCloud River to prehistoric and ethnographic records of this area of California's history is considered to be great (Jones & Stokes Associates 1988).

Within the 0.25-mile corridor deemed eligible by the USFS, three formally recorded sites and other known sites contribute to the lower river's ORVs because they provide important information on the use of the area from before the Late Archaic Period (1300 to 150 before present, calibrated using radiocarbon dating) to the Historic Era (1840 to present). Three Wintu villages, called Tsekerenwaitsogi, Klolwakut, and Boloibaki, are thought to have been located in the general area of the present-day Bollibokka Club headquarters

(Guilford-Kardell 1980), which is part of the former Wintu territory. These villages likely represent the typical lifestyle of the Wintu at the time of Euro-American contact, when they lived in permanent villages near rivers and streams and were semi-sedentary, foraging people (DuBois 1935). As part of the Wintu occupation of this area, prehistoric, historic, and modern Traditional Cultural Properties, sacred locations, and important use areas are located throughout the lower McCloud River basin (outside of the 0.25 mile corridor), including features such as mountains, unique landforms, caves, distinctive rock outcrops, waterfalls, pools, springs, and resource gathering areas.

Point McCloud Bridge (known as McCloud River Bridge in this chapter) is a historical resource that was constructed in 1940 and altered in 1986; the bridge would be subject to relocation in conjunction with SLWRI activities. The Bollibokka Club is a historical resource located on the north bank of the river between the confluence of Big Bollibokka Creek on the east and Wittawaket Creek on the west. Buildings associated with the club were built between the 1860s and 1920s by Austin and Rueben Hills, the founders of Hill's Brothers Coffee, and previous owners (Lucas and Stienstra 2007). A log cabin dates from the 1860s, and other structures date from the ownership of the Hills Family, including the clubhouse built in 1924 and a structure built of river cobble in 1915 (Whitney 2004). Although these resources could be eligible for listing on the National Register of Historic Places, they have not been formally evaluated.

The fishery of the lower McCloud River was also very important to prehistoric and historic uses of the area. The Native Americans in the lower McCloud River basin conducted communal fish drives of salmon or steelhead at night, which brought together many communities and provided opportunities for trade and social networking, including the parsing out of the catch among the people and villages involved (DuBois 1935). Fish, including salmon, steelhead, Sacramento sucker, freshwater shellfish, and lamprey, were an important part of the Native American diet in this area. When the northern mines opened in the 1800s, settlers moved into the area, and the McCloud River and other rivers' fisheries provided important sources of food. In the early years of settlement, fish and game in the area were used for subsistence; however, this changed with the formation of the State of California and increased fishery management and recreational fishing.

Geology The lower McCloud River flows through a number of geologic formations, including the McCloud Limestone formation. This formation contains fossilized remains of invertebrate and vertebrate fauna that provide important scientific information on the history of California, and it has a high potential for research. According to the USFS (1998b), the limestone features exposed at a number of locations around Shasta Lake are unique and contribute to worldwide paleontological knowledge. The McCloud Limestone contains 36 species of corals, some of which may form the basis of a new taxonomic group.

Because of its very diverse fossil faunas, the mountainous terrain between the McCloud and Pit arms of Shasta Lake is perhaps California's single most important area for paleontological research (Munthe and Hirschfield 1978, cited in USFS 1998b). The limestone outcrops on the ridge immediately northwest of McCloud River Bridge (several hundred vertical feet above Shasta Lake) have produced several large Mississippian and Pennsylvanian invertebrate faunas. Because this period is poorly represented on the West Coast, this fossiliferous limestone is important to understanding the late Paleozoic evolution in this part of the country (USFS 1998b). Limestone outcrops adjacent to the McCloud Arm also provide habitat for several special-status species, such as Shasta salamander, Shasta eupatorium, Howell's cliff-maids, and Shasta snow-wreath (Reclamation 2003).

Exposed outcrops of the limestone formation are visible from the lower McCloud River in and upslope of the transition reach and contribute to its scenic values.

Visual Quality/Scenery The visual setting of the lower McCloud River upstream from Shasta Lake includes views of the river, limestone rock outcrops, adjacent coniferous and oak forests, and infrastructure associated with the Bollibokka and McCloud River clubs. A USGS stream gage has also been in place for a number of years. The pristine nature of the lower river provides for high-quality scenic views. However, the scenic views of the lower McCloud River are enjoyed by only a limited number of viewers, consisting primarily of private landowners, club members, and their guests.

Views of the river include "picturesque cascading whitewater, and deep, long, green- or turquoise-colored pools," with Douglas-fir and black and canyon oaks dominating the steep slopes and hillsides along the river (Jones & Stokes Associates 1988). Several buildings are present at the Bollibokka Club headquarters, but these structures blend in with the visual setting. The transition reach exhibits some evidence of fluctuating surface water elevations associated with changes in water levels of Shasta Lake. Areas that are noticeably affected by the reservoir levels exhibit "a bathtub ring of steep, treeless slopes with occasional deposits of alluvium."

The scenic views make most of the lower McCloud River, including Segment 4, eligible as a scenic river under the Federal WSRA (USFS 1994). To be classified as a scenic river, the river must be free of impoundments, be accessible in places by roads, and have a river basin/shoreline that is largely undeveloped. Segment 4 does not contain any human-made or other impoundments that affect its free-flowing conditions. Roads to the Bollibokka Club provide access to portions of Segment 4 for members of the club and their guests. Currently, public access is limited to pedestrians on USFS lands along the shoreline of Shasta Lake. For these reasons, the USFS has determined that this segment meets the eligibility requirements of a scenic river under the Federal WSRA.

25.4 Environmental Consequences and Mitigation Measures

This section identifies how the characteristics of the lower McCloud River that make it eligible for listing under the State PRC and Federal WSRA could be affected by each alternative and whether the alternatives would conflict with the provisions of the STNF LRMP and the CRMP.

25.4.1 Methods and Assumptions

This analysis of environmental consequences focuses on the effects of proposed modifications to Shasta Dam and Shasta Lake on the McCloud River's free-flowing conditions, its water quality, and the ORVs (cultural resources, fisheries, geology, and scenery) that make it eligible for listing as a wild and scenic river under the Federal WSRA. In large part, the environmental effects are based on computer modeling of water levels and the anticipated changes in the environment due to fluctuations in water levels and expansion of the transition reach. Physical effects to the free-flowing conditions, water quality, and ORVs are analyzed in terms of their effects on the eligibility of the river for wild and scenic river designation. While aquatic habitat data are used to quantify the relative impact to fishery values, a qualitative analysis is provided for most resources because of a lack of quantitative data and the subjective nature of the values. Information to support the analysis was generated from available literature and planning documents and technical studies prepared as part of the SLWRI as well as other chapters in this PDEIS.

CalSim Modeling

The CalSim-II computer model was used to assist in the evaluation of the potential impacts of the project alternatives on water-related resources. The model used historical data on California hydrology to represent the variety of weather and hydrologic patterns, including wet periods and droughts, under which water storage and conveyance facilities would be operated. Two scenarios (base cases) of demands for, and storage and conveyance of, water were used in model runs: 2005 facilities and demands ("existing conditions") and forecasted 2030 demands and reasonably foreseeable projects and facilities ("future conditions"). A model run was conducted for each of these base cases combined with each alternative so that the effects of the No-Action Alternative and the action alternatives could be evaluated for both existing and future conditions.

The analysis focuses on the environmental effects in the portion of segment 4 that would periodically be inundated. These effects are discussed in the following section.

Gage Data

PG&E, in coordination with USGS, monitors McCloud River flows in accordance with its FERC license for the McCloud-Pit Hydroelectric Project at a gaging station just upstream from the McCloud River Bridge, approximately 0.2 mile downstream from Big Bollibokka Creek (USGS 11368000 McCloud

River above Shasta Lake, California). The station measures mean, minimum, and maximum monthly flows in the lower McCloud River. The most recent available water data record covers the water year of October 2006 to September 2007 (USGS 2007). Data from the 2006 to 2007 water year were used to describe flow conditions in the lower river.

Water Quality Monitoring

Current and historical water quality monitoring data for the McCloud River have been collected by federal and state agencies as well as PG&E and The Nature Conservancy. The California Department of Water Resources maintains water quality information on the McCloud River in the California Data Exchange Center database. The Nature Conservancy monitors water quality at the McCloud River Preserve. Water quality monitoring of the lower McCloud River includes measures of water temperature, dissolved oxygen, pH, specific conductance, and turbidity, as well as correlated data on weather, air temperature, and debris movement. PG&E monitors water quality in compliance with its FERC license. Available information on water quality was used to describe the setting of the lower river and assess changes in water quality that would occur as a result of the Shasta Dam modification alternatives.

Habitat Typing

The USFS stream habitat typing performed in 1999 and 2000 (STNF, December 2001 unpublished data report, as found in USFS 2001) was used to describe aquatic habitat in the lower McCloud River and to assess the changes in aquatic habitat from implementation of the Shasta Dam modification alternatives. The habitat typing data were used in conjunction with the CalSim-II modeling results, digitized orthophotographs, and high-resolution topographic data to provide habitat maps and graphic depictions of the distribution of aquatic habitat in the lower river below Little Bollibokka Creek. A longitudinal profile, using water surface elevations, was generated to illustrate habitats; it does not provide an accurate representation of channel geometry.

A quantitative evaluation of the aquatic habitats was performed using digital images and the USFS habitat typing data in an integrated geographic information systems environment. Longitudinal habitat delineation was determined from the habitat typing data, with minor adjustments to match photo-interpreted habitat, and incorporated into the geographic information systems in conjunction with water surface elevations generated through the CalSim-II modeling results. Estimates of aquatic habitat areas were generated from digitized wetted stream perimeters. These measurements were based on orthophotographs taken April 25, 2001. While the absolute amount of riverine habitat can vary with flow, the relative proportions of different types of habitat remain relatively constant. Therefore, we used the relative proportions of aquatic habitat types to compare impacts to the transition reach with the entire lower river.

25.4.2 Criteria for Determining Significance of Effects

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, other Federal and State guidance, and consider the context and intensity of the environmental effects as required under NEPA. (Please see Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences) for an explanation of the distinction between significance under NEPA and significance under CEQA.) Impacts of an alternative on the wild and scenic river values of the lower McCloud River would be significant if project implementation would:

- Affect the eligibility for Federal listing as a wild and scenic river of any portion of the lower McCloud River above the 1,070-foot elevation
- Conflict with the Shasta-Trinity National Forest Land and Resource Management Plan or with management of the McCloud River under the Coordinated Resource Management Plan
- Conflict with the protection provided the lower McCloud River under the State PRC

25.4.3 Direct and Indirect Effects

No-Action Alternative

Under the No-Action Alternative, Reclamation would not pursue an action to enlarge Shasta Dam to help increase anadromous fish survival in the upper Sacramento River and address the growing water supply reliability issues in California. Water levels in Shasta Lake and the transition reach would continue to fluctuate similar to current conditions. USFS Segment 4 and the Resources Agency's Segment 10 would not be affected by this alternative.

Impact WASR-1 (No-Action): Effect on McCloud River's Eligibility for Listing as a Federal Wild and Scenic River Under the No-Action Alternative, the current maximum elevation of water levels in the transition reach would not be increased, and Segment 4 would not be affected. Fluctuations in water levels would continue to be similar to current conditions, with water levels reaching the maximum elevation of 1,070 feet msl – the downstream boundary of Segment 4 – in the transition reach for a brief period (typically a few days in May) during wet years.

The average monthly water surface of Shasta Lake would continue to fluctuate based on the water year, with a maximum elevation of 1,053 feet msl in April of an average water year and 1,070 feet msl in April and May of a wet year. These fluctuations would not affect the free-flowing conditions and water quality of Segment 4. The ORVs that make the river eligible for designation as a Federal wild and scenic river would continue to be affected only by ongoing natural processes and land use activities, and all of Segment 4 would remain eligible for

listing under the Federal WSRA. Therefore, there would be no impact. Mitigation is not required for the No-Action Alternative.

Impact WASR-2 (No-Action): Conflict with Shasta-Trinity National Forest Land and Resource Management Plan or Coordinated Resource Management Plan Under the No-Action Alternative, the STNF LRMP and CRMP would continue to be implemented as they have in the past, with no changes in the management of the McCloud River's free-flowing condition, water quality, and ORVs. Therefore, there would be no impact. Mitigation is not required for the No-Action Alternative.

Impact WASR-3 (No-Action): Conflict with the California Public Resources Code, Section 5093.542 Under the No-Action Alternative, the protections afforded the McCloud River by the State PRC would not be affected. River conditions would not be modified, and the provisions of the PRC would continue to protect the river. Therefore, there would be no impact. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 would involve a 6.5-foot raise of Shasta Dam, which would increase the lake's gross pool by 8.5 feet and enlarge the total storage space in the lake by 256,000 acre-feet. This increase would equate to an increase of about 1,100 acres of surface area occupied by Shasta Lake when the lake is full. CP1 also includes measures to increase water supply reliability while contributing to increased survival of anadromous fish. Under CP1, operational guidelines for Shasta Dam would continue unchanged, with the additional storage retained for water supply reliability and increased survival of anadromous fish.

Impact WASR-1 (CP1): Effect on McCloud River's Eligibility for Listing as a Federal Wild and Scenic River Under CP1, the increased gross pool of Shasta Lake would expand the current transition reach up to the 1,078-foot elevation, resulting in adverse effects on the characteristics of approximately 1,470 feet of Segment 4. The rest of the McCloud River would remain eligible for designation as a Federal wild and scenic river.

Under CP1, approximately 1,470 feet, or 11 percent, of Segment 4 would be periodically inundated. This increase in the transition reach to a maximum elevation of 1,078feet msl would equate to a 16 percent increase over the current transition reach. The length of time during the year when the transition reach is inundated and the maximum elevation of the inundation area would vary by the type of water year (wet, above normal, below normal, average, dry, or critical).

Within the expanded transition reach, flow conditions and fisheries would periodically be affected, with the timing and duration of the effects similar to those that occur in the current transition reach. Over time, the expansion of the

bathtub ring would affect water quality, geology, and visual quality/scenery in the affected portion of Segment 4. Erosion of soils along the river could expose buried cultural resources, and periodic inundation could permanently alter cultural resource values and features in the transition reach important to Native Americans. These effects could reduce the total length of the lower McCloud River that is eligible for wild and scenic river designation by about 1,470 feet (approximately 1.2 percent of the total length of the lower river).

Free-Flowing Conditions Under CP1, the currently free-flowing section of the lower McCloud River would be reduced by about 1,470 feet or about 1.2 percent. The flow characteristics of the affected portion of Segment 4 would periodically be modified, resulting in slower moving waters and a wider river channel. When inundated, the affected portion would retain some current, but flow velocities would decrease with distance downstream. This modification would not meet the definition of a free-flowing river under the WSRA.

Because free-flowing conditions are a fundamental requirement for wild and scenic river eligibility, the 1,470-foot reach of Segment 4 that would be affected by CP1 would become ineligible for listing under the WSRA.

Water Quality As Shasta Lake's water levels rise, vegetation and soils along the banks of the affected portion of Segment 4 would become inundated. Most or all of the vegetation that is inundated would eventually die and be washed or fall into the river, bringing with it sediment and other materials that could affect water quality. Soils in the affected portion of Segment 4 would erode as water levels rise and fall, causing an increase in turbidity. These effects would likely be most noticeable during the initial inundation periods, since the river corridor is likely to eventually stabilize as the soil is eroded to bedrock.

Within the approximately 1,470-foot reach of Segment 4 that would be affected under CP1, water temperatures would fluctuate relative to temperatures immediately upstream. Similar to flow, these changes would vary by water year type. Increased turbidity and warmer water temperatures would be most noticeable along the affected portion of Segment 4 because this area has not been previously exposed to periodic inundations.

Adverse effects on water quality would be associated with the periodic fluctuations in the water levels of Shasta Lake. Because water quality is a fundamental requirement for wild and scenic river eligibility, the 1,470-foot reach of Segment 4 that would be affected by CP1 would become ineligible for listing under the WSRA.

Outstandingly Remarkable Values As described above under Affected Environment, the ORVs that make Segment 4 of the McCloud River eligible for listing as a wild and scenic river are cultural/historical resources, fisheries, geology, and visual quality/scenery.

Cultural/Historical Resources Under CP1, erosion of rock outcrops and expansion of the bathtub ring in an approximately 1,470-foot reach of Segment 4 could expose buried or previously undiscovered prehistoric cultural resources associated with Wintu occupation of the area and historic recreational uses of the area. As this reach becomes inundated, any exposed resources would be susceptible to the effects of water, which could damage or otherwise alter their values, affecting their eligibility for listing on the National Register of Historic Places and reducing their importance for providing information on past use within the corridor. As the water recedes, exposed resources would be susceptible to wind and rain and could be visible, potentially exposing them to theft or vandalism. These adverse effects would be localized along the corridor of the affected portion of Segment 4 and would likely only affect a small portion of the cultural resources that may be associated with the lower McCloud River basin.

The historic structures associated with the Bollibokka Club occur outside of the area that would be affected by the expanded transition reach and would not be affected. However, unrecorded resources associated with the Wintu village locations may occur within the corridor along the river and could be subjected to periodic inundation, deposition, and scour within the upper portions of the expanded transition reach. Portions of three other recorded sites could also be subject to similar impacts within the expanded transition reach, which could result in damage to resources within the sites. Although these sites may provide information on the area's history or prehistory, none of these sites has been formally listed on the National Register of Historic Places.

Sacred sites important to Native Americans have not been specifically identified, and access to lands adjacent to the reach that would be periodically inundated under CP1 is limited because all of these lands are privately owned.

The cultural resources located along the 1,470-foot reach of Segment 4 that would be affected under CP1 would be subject to the effects of periodic inundation.

Fisheries Aquatic habitat in the 1,470-foot expansion of the transition reach would be affected during periodic inundations, resulting in potential adverse effects on the fish that occur in the river. Potential adverse effects on fish could include a reduction in spawning habitat for trout in the expanded transition reach and an increase in the range of warmwater fish in the lower McCloud River. Fishing opportunities would not be affected more than they are now with the periodic fluctuations in river levels.

Under CP1, the transition reach would be extended by about 1,470 feet to the 1,078-foot elevation, resulting in a larger inundation area when Shasta Lake water levels are the highest. Aquatic habitat in the affected portion of Segment 4 consists primarily of flatwater habitat (52 percent glide, 19 percent mid-channel pool, and 13 percent run), with pocket water (11 percent) and a small, low-

gradient riffle (5 percent) in the lower portion of the segment. With the periodic inundations, sediment deposition could cause flatwater habitat to convert to riffle habitat, resulting in a reduction in flatwater habitat of less than 3 percent of the total lower McCloud River's flatwater habitat. During the inundation period, riffle and pool habitat (approximately 1.2 percent of the total lower McCloud River) would be converted to flatwater habitat. Also, riparian vegetation along the newly inundated banks of the affected portion of Segment 4 would be expected to die, which could affect water temperatures and reduce cover for fish in this reach. The extent of these effects would depend on the frequency, duration, and surface elevation of the inundation, which would vary depending on the type of water year and water levels of Shasta Lake.

The migration of fish, especially trout, between the lower McCloud River and Shasta Lake is an important attribute of the unique trout fishery. Many of the rainbow and brown trout that occupy the lower McCloud River spend part of their lives rearing in Shasta Lake, feeding on the abundant prey in the lake and attaining large sizes that would not be possible if they reared only in the river. Upon returning to the river to spawn, these lake-reared fish provide the trophy-sized trout, particularly brown trout, for which the lower McCloud River is renowned (Rode and Dean 2004). Based on a survey that extended up to Tuna Falls (North State Resources, Inc. 2008), the reach of Segment 4 that would periodically be inundated does not contain any barriers or impediments to fish movement or migration, and CP1 would not create any. Consequently, trout migration through the transition reach to upstream spawning areas would not be impaired.

Conversely, warmwater fish movement between the lake and river is not likely to be facilitated by the expanded transition reach. Warmwater fish from Shasta Lake, such as spotted bass, have been observed throughout the lower McCloud River, at least up to the confluence with Tuna Creek (North State Resources, Inc. 2008). Nonnative warmwater species inhabiting Shasta Lake (e.g., smallmouth bass and spotted bass) are known to exploit riverine and transitional habitats and are effective predators of juvenile trout. No barriers have been observed in the transition reach that could prevent warmwater fish from moving upstream, and no barriers would be created by the expansion of the transition reach. Warmwater fish would continue to be able to move between the lake, the transition reach, and lower McCloud River (Segment 4).

Aquatic habitat changes could affect how fluvial resident trout use habitat within the affected portion of Segment 4. General effects may range from temporary displacement of trout to upstream habitats at high water levels to degraded riverine habitat suitability within the transition reach.

Suitable spawning habitat for rainbow and brown trout in the expanded transition reach is limited because of the few pools and riffles available during the spring and fall when these species spawn. Based on the USFS habitat data and more recent reconnaissance surveys, the amount of spawning gravels in the

expanded transition reach represents only a small percentage of the suitable spawning habitat in the lower McCloud River. However, any effect on spawning habitat would be considered adverse.

Geology During periods of maximum inundation in the 1,470-foot portion of Segment 4 that would be affected under CP1, some rock outcrops may become inundated and could erode, but the overall geologic value of the McCloud Limestone features would not be adversely affected.

Visual Quality/Scenery The visual quality of the affected portion of Segment 4 would decrease as the vegetation along the banks becomes inundated and eventually dies, the bathtub ring expands, and evidence of flow is reduced. These conditions would be similar to those in the current transition reach. The affected portion of Segment 4 would no longer have the qualities that contributed to its classification by the USFS as "scenic."

CP1 would result in making approximately 1,470 feet of the lower McCloud River ineligible for listing as wild and scenic. This impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

Impact WASR-2 (CP1): Conflict with Shasta-Trinity National Forest Land and Resource Management Plan or Coordinated Resource Management Plan The inundation of approximately 1,470 feet of Segment 4 would conflict with the provisions in the STNF Land and Resource Management Plan and the CRMP to protect the ORVs that make the McCloud River eligible for listing under the WSRA. The raising of Shasta Dam would have an adverse impact on the ORVs of the lower McCloud River, as discussed under Impact WASR-1 (CP1). Effects on the ORVs would not affect the overall eligibility of the river for designation as a wild and scenic river, although the total length of the river that could be recommended for listing could decrease by approximately 1,470 feet (approximately 1.2 percent of the total lower river). Management of the river's ORVs under the STNF LRMP and CRMP would not be affected. No land use changes would occur along the river, and the USFS and signatories to the CRMP would be able to continue implementing provisions of their plans that apply to the river. Nonetheless, this impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

Impact WASR-3 (CP1): Conflict with the California Public Resources Code, Section 5093.542 The State PRC includes provisions that protect the McCloud River fishery and its "natural" and "free-flowing" condition. Implementation of proposed modifications to Shasta Dam and Shasta Lake could conflict with these provisions.

The proposed modifications to Shasta Dam and Shasta Lake would result in temporary and periodic fluctuations in water levels within the expanded transition reach, affecting about 1.2 percent of the lower McCloud River. Under CP1, the transition reach would be extended by about 1,470 feet, a 16 percent increase over the current transition reach; this entire area would be inundated only during peak water levels in the spring of wet years. The free-flowing conditions of the river would not be adversely affected beyond the upstream extension of the transition reach. The primary impact of the expansion of the transition reach would be conversion of aquatic habitat in a manner similar to that described under Impact WASR-1 and Impact WASR-2 and comparable to the habitat conversion that can be observed in the current transition reach downstream. While the overall impacts to the existing natural condition, particularly hydrology and aquatic/riparian ecology, are small in the context of the entire lower McCloud River, the impacts would conflict with the PRC. This impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP2 would involve a 12.5-foot raise of Shasta Dam, which would increase the lake's gross pool by 14.5 feet and enlarge the total storage space in the lake by 443,000 acre-feet. This increase would equate to an increase of about 1,850 acres of surface area when the lake is full. CP2 also includes measures to increase water supply reliability while contributing to increased survival of anadromous fish. Under CP2, operational guidelines for Shasta Dam would continue unchanged, with the additional storage retained for water supply reliability and increased survival of anadromous fish.

Impact WASR-1 (CP2): Effect on McCloud River's Eligibility for Listing as a Federal Wild and Scenic River Impact WASR-1 (CP2) would be similar to Impact WASR-1 but would affect 1270 feet more of Segment 4 than CP1. Implementation of CP2 would reduce the total length of the McCloud River that is eligible for wild and scenic river designation by about 2,740 feet (approximately 2.3 percent of the total length of the lower river). The rest of the lower McCloud River would remain eligible for listing.

Under CP2, approximately 2,740 feet, or 21 percent, of Segment 4 would be periodically inundated. The transition reach would increase to a maximum elevation of 1,084 feet msl, which would extend it by about 2,740 feet (a 30 percent increase over the current transition reach), inundating a larger portion of the lower McCloud River within the study area and Segment 4. The inundated area would increase to approximately 51 total acres (an increase of 18 acres over existing conditions and 9 acres more than CP1 conditions), with a maximum width of approximately 530 feet (an increase of 60 feet over existing conditions) and a total length of approximately 11,740 linear feet (2.22 miles). The extension of the transition reach by approximately 2,740 feet would affect

approximately 21 percent of Segment 4. Additional impacts under CP2 compared with CP1 would be minimal and would be limited to the additional 440-foot extension of the transition reach and about 15 additional feet on both sides of the river.

During a wet year, the maximum average water surface elevation of Shasta Lake would be 1,080 feet msl, with a peak elevation of 1,084 feet msl during May. This is an increase of 15 feet above the existing maximum average. During an average water year, the maximum average water surface elevation would increase to 1,051 feet msl, an increase of 11 feet above existing conditions. During dry and critical water years, the change would be on the order of 5 to 9 feet in elevation.

The increased gross pool of Shasta Lake would expand the current transition reach up to the 1,084-foot elevation, a 30 percent increase. Flow conditions and fisheries in the 2,740-foot reach of Segment 4 would periodically be affected, with the timing and duration of the effects similar to those in the current transition reach. Over time, the expansion of the bathtub ring would adversely affect water quality, geology, and visual quality/scenery. Erosion of soils along the river could expose buried cultural resources, and periodic inundation could permanently alter cultural resource values and features in the transition reach important to Native Americans.

Free-Flowing Conditions As discussed under Impact WASR-1 (CP1), the flow characteristics of the extended transition reach under CP2 would be periodically modified, resulting in slower moving waters and a wider river channel. This modification would not meet the definition of a free-flowing river under the WSRA. The width of the transition reach would be increased by approximately 30 feet on both sides of the river. Flow conditions and the river's free-flowing nature upstream from the expanded transition reach would remain similar to current conditions.

Because free-flowing conditions are a fundamental requirement for wild and scenic river eligibility, the 2,740-foot reach of Segment 4 that would be affected by CP2 would become ineligible for listing under the WSRA.

Water Quality Under CP2, increased turbidity and warmer water temperatures would be most noticeable along the expanded 2,740 feet of the transition reach and in the 30-foot corridor on either side of the transition reach because these areas have not been previously exposed to periodic inundations. As discussed under Impact WASR-1 (CP1), effects on water quality would be associated with the periodic increases in water levels of Shasta Lake.

Because water quality is a fundamental requirement for wild and scenic river eligibility, the 2,740-foot reach of Segment 4 that would be affected by CP2 would become ineligible for listing under the WSRA.

Outstandingly Remarkable Values As described above under Affected Environment, the ORVs that make Segment 4 of the McCloud River eligible for listing as a wild and scenic river are cultural/historical resources, fisheries, geology, and visual quality/scenery.

Cultural/Historical Resources Impacts would be the same as discussed under Impact WASR-1 (CP1); however, a slightly larger portion of the three recorded sites and possible resources associated with the known Wintu villages would be inundated.

The cultural resources located along the 2,740-foot reach of Segment 4 that would be affected under CP2 would be subject to the effects of periodic inundation.

Fisheries Aquatic habitat in the affected 2,740-foot segment consists of pocket water and a lateral scour pool. The potential conversion of flatwater habitat to riffle habitat in the 2,740-foot segment would be similar to but greater than under WASR-1 (CP1), and overall impacts to aquatic habitat and fish would be similar to those discussed under Impact WASR-1 (CP1).

Geology Impacts would be the same as discussed under Impact WASR-1 (CP1); the geologic values of the lower McCloud River would not be adversely affected.

Visual Quality/Scenery Impacts would be the same as discussed under Impact WASR-1 (CP1). The affected portion of Segment 4 would no longer have the qualities that contributed to its classification by the USFS as "scenic."

CP2 would result in making approximately 2,740 feet of the lower McCloud River ineligible for listing as wild and scenic. This impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

Impact WASR-2 (CP2): Conflict with Shasta-Trinity National Forest Land and Resource Management Plan or Coordinated Resource Management Plan The inundation of approximately 2,740 feet of Segment 4 would conflict with the provisions in the STNF Land and Resource Management Plan and the CRMP to protect the ORVs that make the McCloud River eligible for listing under the WSRA. This impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

Impact WASR-3 (CP2): Conflict with the California Public Resources Code, Section 5093.542 The impact would be similar to WASR-3 (CP1) but the magnitude of the impact would be greater under CP2 because of the longer transition reach. Under CP2, the proposed modifications to Shasta Dam and Shasta Lake would result in temporary and periodic fluctuations in water levels

within the expanded transition reach, affecting about 2.3 percent of the lower McCloud River. Under CP2, the reach affected by Shasta Lake water levels would be extended by about 2,740 feet, a 30 percent increase over the current transition reach; this entire area would be inundated only during peak water levels in the spring of wet years. The free-flowing conditions of the river would not be adversely affected beyond the upstream extension of the transition reach. The primary impact of the expansion of the transition reach would be conversion of aquatic habitat in a manner similar to the habitat conversion that can be observed in the current transition reach downstream. While the overall impacts to the existing natural condition, particularly hydrology and aquatic/riparian ecology, are small in the context of the lower McCloud River, the impacts would conflict with the PRC. This impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

CP3, 4, 5 – 18.5-Foot Dam Raise, with Variations

CP3, CP4, and CP5 would involve an 18.5-foot raise of Shasta Dam, which would increase the lake's gross pool by 20.5 feet and enlarge the total storage space in the lake by 634,000 acre-feet. This increase would equate to an increase of about 2,500 acres of surface area when the lake is full. CP3, CP4, and CP5 include variations in measures to increase water supply reliability while contributing to increased survival of anadromous fish. CP3 involves measures to increase water supply reliability and survival of anadromous fish. The primary function of CP4 is to address the survival of anadromous fish by increasing the volume of cold water available to the temperature control device through lake reoperations, while still improving water supply reliability. CP5 involves (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing either additional or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience.

Impacts associated with CP3, CP4, and CP5 would be very similar to those described for CP1 and CP2, but the increased water levels of Shasta Lake would affect a longer reach of the lower McCloud River. Because of their similarities, and in an effort to reduce redundancy, only the differences between the plans are described below.

Impact WASR-1 (CP3,4,5): Effect on McCloud River's Eligibility for Listing as a Federal Wild and Scenic River Implementation of CP3, CP4, and CP5 would reduce the total length of the McCloud River that is eligible for wild and scenic river designation by about 3,550 feet (less than 3 percent of the total length of the lower river). The rest of the lower McCloud River would remain eligible for listing.

Under CP3, 4, and 5, the extent of the transition reach would increase to a maximum elevation of 1,090 feet msl, which would extend the current transition reach by about 3,550 feet (a 39 percent increase over the current transition reach), inundating a larger portion of the lower McCloud River within the study area and Segment 4. The inundated area would increase to approximately 60 total acres (an increase of 27 acres over existing conditions, and 9 acres more than CP2 conditions), with a maximum width of approximately 610 feet (an increase of 140 feet over existing conditions) and a total length of approximately 12,550 linear feet (2.38 miles). The extension of the transition reach by approximately 3,550 feet would affect approximately 26 percent of Segment 4. Additional impacts under CP3, 4, and 5 compared with CP1 and CP2 would be minimal and would be limited to the additional 810-foot extension of the transition reach and about 20 additional feet on either side of the river.

During a wet year, the maximum average water surface elevation of Shasta Lake would be 1,086 feet msl, with a peak elevation of 1,090 feet msl during May. This is an increase of 21 feet above the existing maximum average. During an average water year, the maximum average water surface elevation would increase to 1,054 feet msl, an increase of 14 feet above existing conditions. During dry and critical water years, the change would be on the order of 6 to 13 feet in elevation.

The increased gross pool of Shasta Lake would expand the current transition reach by approximately 3,550 feet (810 feet beyond CP2's effects) up to the 1,090-foot elevation, resulting in a 39 percent increase in the transition reach. Within the expanded transition reach, flow conditions and fisheries would periodically be affected, with the timing and duration of the effects similar to those in the current transition reach. Over time, the expansion of the bathtub ring would affect water quality, geology, and visual quality/scenery. Erosion of soils along the river could expose buried cultural resources, and periodic inundation could permanently alter cultural resource values and features in the transition reach important to Native Americans.

Free-Flowing Conditions As discussed under Impact WASR-1 (CP1), the flow characteristics of the extended transition reach under CP3, CP4, and CP5 would be temporarily modified, resulting in slower moving waters and a wider river channel. This modification would not meet the definition of a free-flowing river under the WSRA. The width of the transition reach would be increased by approximately 70 feet on either side of the river. Flow conditions and the river's free-flowing nature upstream from the expanded transition reach would remain similar to current conditions.

Because free-flowing conditions are a fundamental requirement for wild and scenic river eligibility, the 3,550-foot reach of Segment 4 that would be affected by CP1 would become ineligible for listing under the WSRA.

Water Quality Under CP3, 4, and 5, increased turbidity and warmer water temperatures would be most noticeable along the expanded 3,550-foot reach of the transition reach and in the 70-foot corridor on either side of the transition reach because these areas have not been previously exposed to periodic inundations. Under these plans, the wider affected river corridor could result in greater temporary effects on water quality because more vegetation would be temporarily inundated and more soils would be exposed. As discussed under Impact WASR-1 (CP1), effects on water quality would be associated with the periodic increases in water levels of Shasta Lake.

Because water quality is a fundamental requirement for wild and scenic river eligibility, the 3,550-foot reach of Segment 4 that would be affected by CP3, CP4, and CP5 would become ineligible for listing under the WSRA.

Outstandingly Remarkable Values As described above under Affected Environment, the ORVs that make Segment 4 of the McCloud River eligible for listing as a wild and scenic river are cultural/historical resources, fisheries, geology, and visual quality/scenery.

Cultural/Historical Resources Impacts would be similar to those discussed under Impact WASR-1 (CP1). Under CP3, CP4, and CP5, the wider affected river corridor could result in greater effects on cultural resources because of the wider inundated area and increased erosion. Larger portions of the three recorded sites and known Wintu villages would become inundated.

The cultural resources located along the 3,550-foot reach of Segment 4 that would be affected under CP3, CP4, and CP5 would be subject to the effects of periodic inundation.

Fisheries Aquatic habitat in the additional 810-foot segment under CP3, CP4, and CP5 consists of a mid-channel pool and a lateral scour pool. The potential conversion of flatwater habitat to riffle habitat in the 3,550-foot reach of Segment 4 that would be affected under these plans be similar to but greater than under WASR-1 (CP1), and overall impacts to aquatic habitat and fish would be similar to those discussed under Impact WASR-1 (CP1).

Geology Impacts would be the same as discussed under Impact WASR-1 (CP1), except additional rock outcrops could become inundated because of the wider affected corridor.

Visual Quality/Scenery Impacts would be similar to those discussed under Impact WASR-1 (CP1). Under these plans, the wider affected river corridor could result in greater effects on the visual setting because of the wider inundated area and increased impacts on vegetation. The water line would also be visible at a higher elevation and could be more noticeable. The affected portion of Segment 4 would no longer have the qualities that contributed to its classification by the USFS as “scenic.”

CP3, 4, and 5 would result in making approximately 3,550 feet of the lower McCloud River ineligible for listing as wild and scenic. This impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

Impact WASR-2 (CP3,4,5): Conflict with Shasta-Trinity National Forest Land and Resource Management Plan or Coordinated Resource Management Plan The inundation of approximately 3,550 feet of Segment 4 would conflict with the provisions in the STNF Land and Resource Management Plan and the CRMP to protect the ORVs that make the McCloud River eligible for listing under the WSRA. This impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

Impact WASR-3 (CP3,4,5): Conflict with the California Public Resources Code, Section 5093.542 The impact would be similar to WASR-3 (CP1) but the magnitude of the impact would be greater under CP3, CP4, and CP5 because of the longer transition reach. Under CP3, CP4, and CP5, the proposed modifications to Shasta Dam and Shasta Lake would result in temporary and periodic fluctuations in water levels within the expanded transition reach, affecting about 3 percent of the lower McCloud River. Under CP3, CP4, and CP5, the reach affected by Shasta Lake water levels would be extended by about 3,550 feet, a 39 percent increase over the current transition reach; this entire area would be inundated only during peak water levels in the spring of wet years. The free-flowing conditions of the river would not be adversely affected beyond the upstream extension of the transition reach. The primary impact of the expansion of the transition reach would be conversion of aquatic habitat in a manner similar to the habitat conversion that can be observed in the current transition reach downstream. While the overall impacts to the existing natural condition, particularly hydrology and aquatic/riparian ecology, are small in the context of the lower McCloud River, the impacts would conflict with the PRC. This impact would be significant and unavoidable. Mitigation for this impact is not currently available. Additional studies will be conducted to determine if feasible mitigation measures could be developed.

25.4.4 Mitigation Measures

Table 25-2 presents a summary of mitigation measures for wild and scenic rivers.

No mitigation measures are proposed because none are available that would reduce the impacts to a less than significant level.

Table 25-2. Summary of Mitigation Measures for Wild and Scenic Rivers

Impact		No-Action Alternative	CP1	CP2	CP3	CP4	CP5
Impact WASR-1: McCloud River's Eligibility for Listing as a Federal Wild and Scenic River	LOS before Mitigation	NI	SU	SU	SU	SU	SU
	Mitigation Measure	None required.	No feasible mitigation available to reduce impact.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact WASR-2: Conflict with STNF LRMP or CRMP	LOS before Mitigation	NI	SU	SU	SU	SU	SU
	Mitigation Measure	None required.	No feasible mitigation available to reduce impact.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact WASR-3: Conflict with California Public Resources Code, Section 5093.542	LOS before Mitigation	NI	SU	SU	SU	SU	SU
	Mitigation Measure	None required.	No feasible mitigation available to reduce impact.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU

Key:
LOS = level of significance
NI = no impact
SU = significant and unavoidable

25.4.5 Topics Eliminated from Further Consideration

No topics related to the eligibility of the McCloud River for listing under the Federal WSRA, the compatibility of the alternatives with the STNF LRMP or the CRMP, or their compatibility with the State PRC providing protection to the McCloud River were eliminated from further consideration.

25.4.6 Cumulative Effects

Significant effects were identified related to the compatibility of the project with the State PRC, Section 5093.542. The potential effects would be of greater magnitude and duration with the larger dam raises (i.e., CP3 through CP5 would have greater potential effects than CP1 and CP2). These impacts may also be associated with one other reasonably foreseeable action that could affect the McCloud River, the relicensing of PG&E's McCloud-Pit Project. However, the relicensing process is ongoing; until it is completed, its potential effects on the McCloud River are unknown. Therefore, the potential for project-related impacts to be cumulatively considerable would be less than significant.

This page left blank intentionally.

Chapter 26
Other Required Disclosures

26.1 Significant Adverse Effects that Cannot be Avoided If a Project is Implemented

Section 21100(b)(2)(A) of CEQA provides that an environmental impact report (EIR) will include a detailed statement setting forth "any significant effect on the environment that cannot be avoided if the project is implemented." Chapters 4–25 of this PDEIS analyze in detail all of the project's potentially significant environmental impacts, including cumulative impacts; list feasible mitigation measures that could reduce or avoid the project's significant impacts; and specify whether these mitigation measures would reduce these impacts to a less than significant level. If there is no feasible mitigation measure available to reduce a significant impact to a less than significant level, then the impact is considered to be a significant and unavoidable impact. The SLWRI would have the following significant and unavoidable environmental impacts (direct, indirect, and cumulative):

- Loss or diminished availability of known mineral resources.
- Loss or diminished soil biomass productivity.
- Soil erosion or loss of topsoil due to shoreline processes.
- Conversion of forest land to nonforest uses in the vicinity of Shasta Lake.
- Conflict with existing land use goals and policies of affected jurisdictions (Shasta Lake and vicinity and upper Sacramento River).
- Disruption of existing land uses (Shasta Lake and vicinity and upper Sacramento River).
- Loss of sensitive plant communities and special-status plant species resulting from induced growth (cumulative).
- Effects on air quality with respect to short-term construction emissions: temporary emissions of reactive organic gases, oxides of nitrogen, and particulate matter with an aerodynamic resistance diameter of 10 micrometers or less (commonly known as PM_{10}).

- Effects on prehistoric and historic-era cultural resources.
- Consistency with guidelines for visual resources in the *Shasta-Trinity National Forest Land and Resource Management Plan*.
- Degradation and/or obstruction of a scenic view from key observation points.
- Generation of increased daytime glare and/or nighttime lighting.
- Effect on the McCloud River's eligibility for listing as a Federal Wild and Scenic River.
- Conflict with the California Public Resources Code, Section 5093.542.
- Effects on power and energy with respect to decreases in Shasta, CVP and SWP, and Pit 7 powerplant energy generation.
- Effects on power and energy with respect to increases in CVP and SWP pumping plant energy.
- Cumulative effects on south Delta water levels, X2 position, and Delta outflow.

Where feasible mitigation exists, it has been included to reduce these impacts; however, the application of all feasible mitigation would not be sufficient to reduce these impacts to a less than significant level.

26.2 Relationship of Short-Term Uses and Long-Term Productivity

NEPA requires consideration of "the relationship between short-term uses of man's environment and the maintenance and enhancement of long-term productivity" (40 Code of Federal Regulations 1502.16). This involves using all practicable means and measures, including financial and technical assistance, in a manner calculated to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans.

All action alternatives analyzed in this PDEIS involve new construction such as raising Shasta Dam, constructing seismic and static retrofits, replacing bridges, and relocating/reconstructing recreational facilities adversely affected by higher reservoir levels. Specific activities would modify the Pit River Bridge, replace seven other bridges, relocate 45-130 structures, and inundate numerous small segments of existing paved and unpaved roads. Approximately 20 buildings

associated with marinas or resorts would be affected directly, and about 25 other buildings associated with ancillary facilities could be affected indirectly because of their proximity to the new water surface at full pool.

All of the action alternatives would result in indirect and induced employment, which may be to support hiring in businesses that provide materials to the construction effort; in service-related industries that provide food, beverages, and other goods to construction workers; or in more technical industries, such as consulting firms and other businesses (see Chapter 16, "Socioeconomics, Population, and Housing"). Sales and profits for businesses that support the construction industry in the primary study area would result in increased profits over the 36- to 60-month construction period.

Potential habitat- and recreation-related losses caused by enlarging the dam and reservoir would irreversibly affect habitats and developments near the dam inundation area. Impacts on habitat areas within the dam inundation area would be mitigated by preservation of habitats elsewhere. Construction activities would include short-term uses of capital, labor, fuels, and construction materials, habitats, and recreation areas. General commitments of construction materials are largely irreversible, because most of the construction materials are unsalvageable.

Potential benefits of the action alternatives include an increase in the reliability of the water supply and a reduction in the probability of experiencing a potential flood-related loss of resources, property, and human life. Environmental uses and habitat for a variety of aquatic and terrestrial species along the Sacramento River and waterways within the primary and extended study areas would be maintained, and potentially enhanced with proposed mitigation. There are no adverse effects that would pose a long-term risk to health and safety.

26.3 Irreversible and Irretrievable Commitments of Resources

The State CEQA Guidelines require a discussion of the significant irreversible environmental changes that would be caused by a proposed action should it be implemented. In addition, an Environmental Impact Statement (EIS) prepared under NEPA must analyze irreversible and irretrievable commitments of resources such as soils, wetlands, waterfowl habitat, and cultural resources (40 Code of Federal Regulations 1502.16).

The irreversible and irretrievable commitment of resources is the permanent loss of resources for future or alternative purposes. Irreversible and irretrievable resources are those that cannot be recovered or recycled, or those that are consumed or reduced to unrecoverable forms. The action alternatives would result in the irreversible and irretrievable commitment of the following energy and material resources during project construction and maintenance:

- Construction materials, including such resources as soil and rocks
- Land area committed to new/expanded project facilities and water inundation areas
- Energy expended in the form of electricity, gasoline, diesel fuel, and oil for equipment and transportation vehicles that would be needed for project construction and maintenance

Nonrenewable resources are expected to account for a minimal portion of the region's resources; the project's use of nonrenewable resources would not affect the availability of these resources for other needs within the region. Construction activities would not result in inefficient use of energy or natural resources. Construction contractors selected would use best available engineering techniques, construction and design practices, and equipment operating procedures. Further, mitigation would be provided to offset any loss of habitat areas and other land uses within the proposed dam inundation areas. Long-term project operation would not result in substantial long-term consumption of energy and natural resources, and increased energy production would result from the additional storage capacity.

26.4 Growth-Inducing Impacts

CEQA requires that an EIR discuss how a project may induce growth. NEPA requires that an EIS consider indirect effects of a project, which are often the result of growth inducement. A project is considered potentially growth inducing if it is reasonably foreseeable that the project may foster economic or population growth or may result in the construction of additional housing (California Code of Regulations, Section 15126.2(d)). The increase in water supply reliability that would result from the construction of any of the project's action alternatives is considered potentially growth inducing because it would foster economic growth and potentially remove an obstacle to development.

The purpose of this section is to disclose how the action alternatives analyzed in this PDEIS could be growth inducing and to describe how the potential resulting environmental effects would be addressed. In *Napa Citizens for Honest Government v. Napa County Board of Supervisors* (2001) 91 Cal.App.4th 342, 367–371 [110 Cal.Rptr.2d 579], the California Court of Appeal, Fourth District, provided clear direction on the standards for disclosure of growth-inducing effects in an EIR that is also relevant to an EIS. The lead agency may also consider mitigation measures for the anticipated effects. Growth-inducing impacts are evaluated for the project alternatives in accordance with the California Court of Appeal finding in *Napa Citizens for Honest Government v. Napa County Board of Supervisors* (2001):

> *Neither CEQA itself, nor the cases that have interpreted it, require an EIR to anticipate and mitigate the effects of a particular project on growth on other areas. In circumstances such as these, it is sufficient that the final EIR (FEIR) warns interested persons and governing bodies of the probability that additional housing will be needed so that they can take steps to prepare for or address that probability. The FEIR need not forecast the impact that the housing will have on as yet unidentified areas and propose measures to mitigate that impact. That process is best reserved until such time as a particular housing project is proposed.*

The increase in water supply reliability resulting from the proposed action would make additional water resources available for municipal, industrial, and agricultural uses in the CVP and SWP service areas. The additional water resources could be used for actions that sustain and support growth.

Project construction is not growth inducing because new housing would not be required. Growth-inducing effects resulting from the increase in water supply reliability caused by the action alternatives would be indirect, and the ability of Reclamation to forecast the extent and location of these effects is extremely limited. More than likely, the effects would be spread throughout the CVP and SWP service areas, would change annually, and would depend on how the additional water supply stored in Shasta Lake is ultimately used. Because the potential indirect growth-inducing effects are speculative and amorphous, no feasible mitigation measures are available or proposed. Direct impacts on traffic and air quality and changes to the jobs/housing balance will be evaluated and mitigated by the local land use agency during general plan updates and project-specific application review. The following potential effects of an increase in the reliability of the water supply are discussed:

- Existing fallow agricultural land and rangeland may be converted to irrigated row crops or irrigated orchard. This land use change could increase effects of local economic growth on farmers and could result in more local employment opportunities.

- If water supply is an obstacle to expansion of industrial facilities, this obstacle may be removed. Increased industrial capacity could result in economic growth and provide more local employment opportunities.

- If water supply is an obstacle to residential development, this obstacle may be removed, and local land use authorities may be encouraged to approve residential development projects on currently zoned agricultural land:

  - Residential development would result in the construction of houses.

- Residential development may cause economic growth through the collection of development fees.

The project analysis includes a primary study area and an extended study area. The primary study area encompasses Shasta Dam and Shasta Lake; inflowing rivers and streams consisting of the Sacramento River, McCloud River, Pit River, and Squaw Creek; and the Sacramento River downstream to about Red Bluff Diversion Dam. Because of the potential influence of Shasta Dam modification on natural resources along the Sacramento River, and on programs and projects in the Central Valley, the project also evaluates an extended study area that includes the Sacramento River basin downstream from Red Bluff Diversion Dam, the American River basin, the Delta, the San Joaquin River basin, and the CVP and SWP service areas.

The extended study area includes CVP and SWP reservoirs and the portions of tributaries that are downstream from these reservoirs and that affect Sacramento River, San Joaquin River, Trinity River, and Delta flows. These reservoirs and tributaries include Lake Oroville, Folsom Lake, Millerton Lake, San Luis Reservoir, New Melones Reservoir, and Trinity Lake, and portions of the Trinity, Feather, American, and Stanislaus rivers. The CVP and SWP service areas include much of the Sacramento and San Joaquin valleys, and substantial portions of the Bay Area and Southern California.

26.4.1 Increased Construction Work

The action alternatives analyzed in this PDEIS would create new construction jobs in the primary study area, but this temporary effect would not be growth inducing. Concrete workers, workers with large-scale construction experience, general laborers, and others would be drawn from the existing local construction industry. These jobs represent a relatively small increase (i.e., less than 0.5 percent) in the total labor force in the two counties of the primary study area, but would represent a substantial increase in employment for many of the cities surrounding the project, where employment has consistently been below the state average (EDD 2010, 2011). Therefore, jobs created by the action alternatives would be serviced largely by the local workforce and would not be growth inducing (see Chapter 16, “Socioeconomics, Population, and Housing”).

26.4.2 Increased Flood Protection

The action alternatives are also anticipated to provide some flood protection benefits, but these benefits are not growth inducing. The added capacity would give Reclamation greater flexibility in using the reservoir for flood management purposes, thereby increasing the threshold at which seasonal heavy-rain events produce flood conditions downstream from Shasta Dam. The benefits of this increase in capacity and related flood management options would be most evident along the upper Sacramento River in the primary study area, and would decrease downstream as other major tributaries join the Sacramento River. Structures in and inhabitants of this floodplain experience the most direct effects from storage releases during flood events. The action alternatives would

reduce the frequency, magnitude, and duration of some potential future flood events, like those that have affected structures and residents in this part of the primary study area in the past.

As a result of the added reservoir capacity, the overall risk of flooding and its related consequences below Shasta Dam is expected to be reduced. Although heavy-rain events would continue to occur in the region, enlarging the dam is intended to provide greater flexibility in flood management in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures in or near the lower Sacramento River and Delta floodplains would be expected over time. However, the flood management benefits of the dam enlargement would not be expected to change the existing floodplain or Federal Emergency Management Agency flood zone designations, so the action alternatives would not remove an obstacle to development; therefore, flood protection benefits are not considered growth inducing.

26.4.3 Increased Water Supply Reliability

Implementing any of the action alternatives would improve the reliability of the water supply in both the primary and extended study area. This improved water supply reliability would better accommodate existing water contracts by increasing the water supply in some years. The environmental consequences of these contracts have been (and in the future will be) evaluated in separate environmental review processes. The improvement in water supply reliability would not change long-term contract amounts or deliveries from within their existing historical ranges.

A variety of factors indirectly influence business, residential, and population growth in the region. Among these are city and county general plans and policies, and the availability of utility services, public schools, and transportation services. Water is one of the primary public services needed to support urban development, including businesses, industry (including agriculture), and housing; a deficiency in water service capacity could constrain future development.

Implementing any of the action alternatives would also increase water yield, which has the potential to be growth inducing. The expected increase in water yield relative to the entire CVP and SWP service areas would be small (i.e., less than 1 percent), and this new yield would likely be provided to a number of geographic areas within the CVP and SWP service areas. Also, a substantial portion of this water would substitute for groundwater pumping, allow for changes in agricultural irrigation practices, or return idle cropland to production. For this reason, implementing any of the action alternatives would result in beneficial effects on agricultural resources, which would intrinsically benefit the economies in the affected localities. An increase in the reliability of water provided to agricultural areas would not necessarily lead to a direct increase in population, because the water would service primarily existing agricultural

lands and would not be expected to foster expansion into undeveloped natural communities. However, the cumulative effect of a more reliable water source would be to increase agricultural effectiveness, a key economic sector in the region, which could indirectly result in growth-inducing impacts by bringing more money into the local economies.

Agriculture is the most important segment of the economy below Shasta Dam and throughout California's Central Valley. Beneficial effects of improved water supply reliability are predicted by an economic analysis applying the "change in net income" method as estimated by the Central Valley Production Model. The average annual benefits to agriculture from the improvement in water supply reliability for CVP irrigation deliveries, based on weighted values, range from $9 million to $14.6 million (see the Economic Valuation Appendix).

Benefits from an increase in the reliability of the municipal and industrial (M&I) water supply are estimated based on SWP deliveries. The economic benefit of average M&I deliveries is calculated using a conservative value of $500 per acre-foot for M&I supplies. The estimated average annual benefits from the increase in M&I water supply reliability range from $3.9 million to $7.6 million (see the Economic Valuation Appendix).

Total water supply benefits are the sum of weighted-average benefits to the reliability of agricultural and M&I water supplies. Total benefits from increased water supply reliability range from $13.3 million to $18.1 million (see the Economic Valuation Appendix). Therefore, the action alternatives would result in positive economic effects related to growth of the agricultural and M&I sectors by potentially increasing the available water supply. This would be a potentially growth-inducing effect.

If residential development is constrained by water supply, then increased reliability of the water supply may remove an obstacle to residential development. Therefore, the action alternatives would be potentially growth inducing. Local land use authorities are required to demonstrate sufficient water supply reliability pursuant to Senate Bill 610 (Chapter 643, Statutes of 2001), in addition to an evaluation required by CEQA. Water supply reliability may be demonstrated with surface water, water contracts, groundwater, and combinations thereof. Impacts on the physical environment would be evaluated and mitigated at a project level. Because the locations of potential residential development on existing agricultural or rangeland cannot be predicted, and because of the speculative and amorphous nature of potential impacts, no mitigation for impacts of the action alternatives is required.

Increased reliability of the water supply could reduce a limitation on growth throughout the primary and extended study areas; however, projects that could affect natural resources or otherwise accommodate growth in the study area would have to comply with existing planning documents and would be subject to project-specific public environmental analysis and review. The effects of

subsequent growth would be analyzed in general plan EIRs and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these effects would be the responsibility of these local jurisdictions, not Reclamation.

The expected increase in water yield relative to the entire CVP would be small; however, this new yield could be provided to any number of geographic areas within the CVP service area (and in part would substitute for ongoing groundwater pumping). Further, it would be speculative to identify specific areas where growth could occur or the indirect effects on specific community service facilities in a particular service area.

26.5 Identification of Environmental Preferences for Alternatives

Each alternative was ranked similarly based on evaluation criteria. The primary distinguishing factors are related to water supply reliability, anadromous fish survival, and other project objectives. CP1, CP2, and CP3 primarily address water supply reliability; however, each of these plans would also contribute to other project objectives, with the exception of ecosystem restoration. Further, the likelihood that each of these three plans would meet its intended objectives is very high because the plans would not significantly rely on any other actions. However, CP4 further emphasizes anadromous fish survival through an increase in the storage dedicated to cold-water supply each year and gravel augmentation, and CP5 specifically addresses environmental restoration and gravel augmentation. With both CP4 and CP5, overall water supply reliability would be reduced, primarily because in each case ongoing future actions would be required that are not directly related to operation and maintenance of the enlarged reservoir. With the survival of increased numbers of anadromous fish, operational considerations are required to ensure a high degree of success. For environmental restoration, success would depend on the continued effectiveness of the environmental restoration facilities/features proposed as part of the SLWRI – enhanced lake area spawning and rearing habitat, increased native vegetation, and new riparian rehabilitation areas – well past completion of construction.

26.5.1 Least Environmentally Damaging Practicable Alternative

The Least Environmentally Damaging Practicable Alternative will be determined on the basis of the entire environmental review and identified in the Record of Decision, consistent with the Federal Clean Water Act, Section 404, which requires that only the Least Environmentally Damaging Practicable Alternative may be approved and implemented by a Federal agency.

26.5.2 Environmentally Preferable Alternative/Environmentally Superior Alternative

Construction-related impacts would be similar for all of the action alternatives, and the significance determinations for each of the action alternatives are

largely the same. Varying magnitudes of impacts would be related largely to the height of the dam raise because additional construction resources would be required for the larger raise and more land would be affected within the larger inundation area. All of the action alternatives would provide additional opportunities for flood management; they also would provide greater water supply reliability during extremely dry years, which would benefit all water users. CP1 and CP2 would have less of an impact on land uses within the reservoir area than the other action alternatives because they would raise the dam by 6.5 feet and 12.5 feet, respectively, compared to an 18.5-foot increase proposed under CP3, CP4, and CP5. However, water supply reliability and anadromous fish survival would be maximized with the larger raise.

CP4 would increase water supply reliability for agricultural, M&I, and environmental purposes; provide the greatest net increase in hydropower generation; maintain recreation capacity with modernized facilities; and provide water quality benefits to the upper Sacramento River and the Delta. In addition, CP4 would dedicate 378,000 acre-feet of the additional water from increased storage to maintain cold-water volume or augment flows as part of an adaptive management plan for anadromous fish survival, would augment gravel in the upper Sacramento River, and would restore riparian, floodplain, and side channel habitat.

At this time, based on analyses to date, alternatives involving an 18.5-foot raise of Shasta Dam appear to have the greatest environmental benefits, although no environmentally preferable alternative has been selected. It is recognized that additional refinement and changes may occur to the alternatives after performing further analyses and receiving input from agencies, stakeholders, and the public. Any such changes will be addressed as appropriate into the Draft EIS and other future SLWRI documents.

26.6 Compliance with Applicable Laws, Policies, and Plans

For more detailed descriptions of the laws, policies, and plans listed below see Section 3.4, “Regulatory Framework.”

26.6.1 Federal Requirements

National Environmental Policy Act

NEPA requires that an appropriate document be prepared to ensure that Federal agencies accomplish the law’s purposes. The Council on Environmental Quality has adopted regulations and other guidance that provide detailed procedures that Federal agencies follow to implement NEPA. Once finalized, Reclamation would use this EIS to comply with Council on Environmental Quality regulations and document NEPA compliance.

Clean Water Act

Section 404 A Section 404(b)(1) alternatives information package will be prepared for the proposed action and submitted to USACE and the U.S. Environmental Protection Agency. In addition, if construction is authorized, Reclamation will obtain a Section 404 permit prior to filling any waters of the United States. USACE will issue a Record of Decision that addresses pertinent consideration and implementation requirements. Section 404 also requires that a Least Environmentally Damaging Practicable Alternative is identified and must be implemented by an implementing Federal agency.

Section 401 Water quality certification requires evaluation of potential impacts in light of water quality standards and Clean Water Act (CWA) Section 404 criteria governing discharge of dredged and fill materials into waters of the United States. The Federal government delegates water pollution control authority under Section 401 of the CWA to the states. Refer to the "Porter-Cologne Water Quality Control Act" section below.

Federal Endangered Species Act

Reclamation has coordinated with USFWS and NMFS regarding potential project effects on Federally listed species. The potential effects of the SLWRI on endangered and threatened species are described in Chapter 11, "Fisheries and Aquatic Ecosystems"; Chapter 12, "Botanical Resources and Wetlands"; and Chapter 13, "Wildlife Resources." Reclamation will prepare the appropriate biological assessments to address potential impacts on Federally listed species and will consult with USFWS and NMFS regarding impacts of the proposed action.

Magnuson-Stevens Fishery Conservation and Management Act

Chapter 11, "Fisheries and Aquatic Ecosystems," discusses impacts on fisheries and fisheries habitat. Reclamation will coordinate with NMFS to ensure that recommended measures be put into the proposed action that would minimize adverse modifications to Essential Fish Habitat. The proposed action's specific implementation plan will analyze the significance of modifications to Essential Fish Habitat and will support the habitat assessments included for restoration-specific actions during the Section 7 Endangered Species Act consultations.

Fish and Wildlife Coordination Act

Compliance with the Fish and Wildlife Coordination Act (FWCA) involves assessing the impacts of a proposed action on preservation, conservation, and enhancement of fish and wildlife habitat. Reclamation will be required to include recommendations for preserving affected habitats, mitigating their loss, and enhancing such habitats, in its documentation of compliance. Documentation of compliance with the FWCA is a separate analysis of habitats of concern to USFWS, NMFS, and DFG, and does not replace the analysis required by Section 7 of the Federal Endangered Species Act.

Bald and Golden Eagle Protection Act

USFWS has proposed new permit regulations to authorize the take of bald and golden eagles under the Bald and Golden Eagle Protection Act, generally when the take to be authorized is associated with otherwise lawful activities (72 *Federal Register* 31141–31155, June 5, 2007). With delisting of the bald eagle in 2007, the Bald and Golden Eagle Protection Act is the primary law that protects bald eagles, as well as golden eagles. As discussed in Chapter 13, "Wildlife Resources," suitable habitat is not present for golden eagle in the study area; however, the proposed action would have a significant and unavoidable impact on the bald eagle. Therefore, Reclamation will consult with USFWS to implement the reasonable and prudent alternative and conservation measures to reduce impacts on the bald eagle.

Federal Clean Air Act

As discussed in Chapter 5, "Air Quality and Climate," the SLWRI would not result in long-term effects on air quality. Because the effects of the proposed action on air quality have been evaluated and mitigated to the extent possible, the proposed action would comply with the Federal Clean Air Act.

Federal Water Project Recreation Act

Compliance with the Federal Water Project Recreation Act is achieved by documenting the consideration of recreation opportunities in USACE reports and NEPA documents. Within this PDEIS, Reclamation has taken into consideration, and addressed, outdoor recreation and fish and wildlife enhancement in the primary and extended study areas.

Safe Drinking Water Act

Water used for domestic purposes must be treated by the local or regional water supply in accordance with Federal and State standards. Reclamation is in compliance with the Safe Drinking Water Act because the proposed action would not change existing license requirements or impede enforcement of primary drinking water standards.

National Historic Preservation Act

Studies of the area of potential effect and consultation with the Winnemem Wintu and the California State Historic Preservation Officer determined that sites of cultural significance exist in and around Shasta Lake, including sites related to historic activities of Native Americans. These sites could be inundated should the proposed action be implemented. A representative of the Winnemem Wintu has been involved in reviewing previous study findings, the results of the archival and field research, and conditions for preservation designed to reduce potential impacts on cultural resources. The FEIS will be sent to the California State Historic Preservation Officer for use in consultation between Reclamation and the California State Historic Preservation Officer to confirm that adverse effects on resources that are listed in or eligible for listing in the National Register of Historic Places are avoided or mitigated. For these reasons, the

project would comply with Section 106 of the National Historic Preservation Act.

Farmland Protection Policy Act

As a Federal agency preparing environmental compliance documents, Reclamation must include in its analysis a farmland assessment designed to minimize adverse impacts on prime and unique farmlands and provide for mitigation as appropriate. Chapter 10, "Agriculture and Important Farmland," evaluates potential effects of the proposed action on Important Farmland.

Rivers and Harbors Act

In the USACE Sacramento District, navigable waters of the United States in the project area that are subject to the requirements of the Rivers and Harbors Act include the Sacramento River, and all waterways in the Sacramento–San Joaquin drainage basin affected by tidal action. Sections of the River and Harbors Act applicable to the proposed action are described below.

Section 9 All of the action alternatives for the proposed action would include construction of dikes. A Section 9 approval would be required before construction of any dikes. Reclamation would obtain approval from the Chief of Engineers and by the Secretary of the Army before construction of any dikes in navigable waters of the United States.

Section 10 A Section 10 permit would be required before any activity that would alter waters of the United States. To comply with the Rivers and Harbors Act, Reclamation would apply for a permit from USACE's Sacramento District before construction, and that application would be processed simultaneously with the CWA Section 404 permit application. This PDEIS evaluates the environmental effects that the proposed action would have on waters of the United States, including navigable waters.

Section 13 Within the primary study area, the Central Valley Regional Water Quality Control Board has jurisdiction. The Federal government delegates water pollution control authority under Section 402 of the CWA to the states. Refer to the "Porter-Cologne Water Quality Control Act" section below.

Migratory Bird Treaty Act

As discussed in Chapter 13, "Wildlife Resources," this PDEIS evaluates potential impacts on migratory bird species and identifies mitigation measures to reduce impacts on birds, nests, and eggs. In addition, Reclamation would implement all feasible measures included in the FWCA Report. Reclamation would comply with the Migratory Bird Treaty Act by implementing mitigation measures described herein and in the FWCA Report before and during implementation of the proposed action.

National Forest Management Act

As discussed in Chapter 1, "Introduction," USFS is a cooperating agency in this PDEIS. Under the National Forest Management Act, any decision emanating from a NEPA process must comply with the Land and Resource Management Plan (LRMP) in order to authorize an action on lands managed by the Shasta-Trinity National Forest (STNF). Significant impacts on lands and resources managed by the STNF are disclosed in Chapter 4, "Geology, Geomorphology, Minerals, and Soils"; Chapter 12, "Botanical Resources and Wetlands"; Chapter 13, "Wildlife Resources"; Chapter 17, "Land Use and Planning"; Chapter 18, "Recreation and Public Access"; and Chapter 19, "Aesthetics and Visual Resources," of this PDEIS. These impacts may require nonsignificant, project-specific amendments to the LRMP.

The National Forest Management Act also requires that USFS maintain viable populations of existing native and desired nonnative species in the planning area. This requirement will be met by preparing a biological evaluation and associated management indicator species assessment. Those documents will be used by USFS to make a finding that the actions disclosed in the record of decision issued by Reclamation will be consistent with the LRMP.

Federal Land Policy and Management Act

As described in Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," the Federal Land Policy Management Act directs USFS and the U.S. Bureau of Land Management to manage public lands under the principles of multiple use and sustained yield. Under the Federal Land Policy and Management Act, the use and occupancy of public lands requires authorization by a land management agency, typically under the auspices of a special-use permit. As the principal land management agency for the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area, USFS and, to a lesser degree, the U.S. Bureau of Land Management will need to use this EIS, when finalized, to support issuance of authorizations to various parties pursuant to the Federal Land Policy and Management Act.

Wild and Scenic Rivers Act

Section 7 of the Federal Wild and Scenic Rivers Act requires the STNF to manage the outstandingly remarkable values of the McCloud River consistent with the objectives and standards and guidelines of its LRMP. The evaluation in the STNF LRMP concluded that the lower McCloud River, from McCloud Dam downstream about 22 miles to the river's transition to Shasta Lake at about 1,070 feet mean sea level, provides outstanding cultural, fisheries, and geologic values, and its corridor has been classified as a highly sensitive visual area by USFS (USFS 1995). Based on the outstandingly remarkable values, the STNF determined that the lower McCloud River meets the eligibility requirements for designation under the Federal Wild and Scenic Rivers Act. Chapter 25, "Wild and Scenic River Considerations for McCloud River," evaluates potential effects of the SLWRI on the McCloud River.

Indian Trust Assets

When adverse impacts on Indian Trust Assets (ITA) cannot be avoided, appropriate mitigation or compensation will be provided. ITAs consist of lands that have been deeded to tribes or upon which tribes have a historical legal claim. However, there are no such lands within the primary study area; for this reason, it was determined that the SLWRI would have no impact on ITAs. Because ITAs have been evaluated and the SLWRI would have no impact on these resources, the SLWRI would comply with ITAs.

Executive Order 11988 (Flood Hazard Policy)

As discussed in Chapter 6, "Hydrology, Hydraulics, and Water Management," all of the action alternatives would have an effect on floodplains in the study area. However, the proposed action would not increase flood flows, and feasible mitigation would be implemented to compensate for the impact of altered flow on riparian and wetland communities.

Executive Order 11990 (Protection of Wetlands)

As discussed in Chapter 12, "Botanical Resources and Wetlands," a wetland delineation will be prepared for the proposed action and a USACE Section 404 permit will be obtained before construction. The project would identify the location of sensitive habitats by conducting a wetland delineation, avoid and minimize impacts to the extent feasible, and compensate for any losses. However, implementation of any of the action alternatives would result in significant and unavoidable impacts on wetlands.

Executive Order 12898 (Environmental Justice Policy)

As discussed in Chapter 24, "Environmental Justice," the disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance would result in a disproportionately high and adverse effect on Native American populations in the vicinity of Shasta Lake. Therefore, the project would contribute to disproportionate placement of environmental impacts on Native American populations and would result in a cumulatively considerable incremental contribution to a significant and unavoidable cumulative impact. No feasible mitigation is available to reduce this high and adverse effect. Compliance with Executive Order 12898 occurs through the identification of this effect and the lack of feasible mitigation measures available to reduce it.

Executive Order 13007 (Indian Sacred Sites) and April 29, 1994, Executive Memorandum

The Native American Heritage Commission was contacted to identify whether any recorded sacred sites were situated within the primary study area and to obtain a recommended list of Native Americans to contact regarding the proposed action. Potential impacts of the proposed action on Indian sacred sites are addressed in Chapter 14, "Cultural Resources." Reclamation will continue to coordinate with the Native American Heritage Commission and Native American contacts to address potential impacts on sacred sites.

Executive Order 13112 (National Invasive Species Management Plan)

A weed management plan is within the scope of the proposed action and would include methods for managing the spread of invasive plant species. Because the details of the weed management plan have not been finalized at the time of this writing, this PDEIS identifies preparation and implementation of a weed management plan as a mitigation measure. Developing and implementing the weed management plan as a mitigation measure demonstrates compliance with Executive Order 13112. Reclamation would demonstrate continued compliance with this executive order by implementing the methods described in the weed management plan.

Federal Transit Administration

This PDEIS evaluates potential groundborne-vibration impacts on sensitive receptors, including the maximum sensitivity of 65 vibration decibels for hospitals, high-technology manufacturing, and laboratory facilities. Some construction activities associated with the action alternatives could result in groundborne vibrations exceeding 65 vibration decibels. However, sensitive receptors would need to be within 250 feet of the activities to be affected and there are no sensitive receptors within this distance. Reclamation has demonstrated consistency with this policy by evaluating the construction activities that would generate the maximum possible groundborne vibration at the highest sensitive uses.

Federal Energy Regulatory Commission

Changes to hydroelectric facilities on the Pit River, including instream flow releases or modifications to downstream structures, may necessitate a license amendment from the Federal Energy Regulatory Commission. Reclamation will support Pacific Gas and Electric Company in any application to the Federal Energy Regulatory Commission for necessary license amendments before implementing any proposed actions that would affect Pit River flows.

U.S. Coast Guard

The SLWRI has the potential to affect several bridges over inflows to Shasta Lake. Coordination with the U.S. Coast Guard will be maintained in respect to these potential impacts.

26.6.2 State Requirements

California Environmental Quality Act

This document has been prepared in accordance with CEQA and may be used by State permitting agencies that would be involved in review and approval of the project.

California Endangered Species Act

Evaluations have been conducted for State-listed endangered and threatened species, and have determined that the proposed action would affect several State-listed species. Effects on those species are discussed in Chapter 11,

"Fisheries and Aquatic Ecosystems"; Chapter 12, "Botanical Resources and Wetlands"; and Chapter 13, "Wildlife Resources." Reclamation will prepare appropriate biological assessments to address potential impacts on Federally listed species, and will consult with DFG regarding impacts of the proposed action on State-listed species.

California Fish and Game Code—Fully Protected Species

This PDEIS identifies potential actions that could result in take of fully protected species, and Reclamation will work closely with DFG to evaluate methods to avoid impacts on fully protected species.

California Fish and Game Code Section 1602—Streambed Alteration

A DFG streambed alteration agreement must be obtained for any project that would result in an impact on a river, stream, or lake. This PDEIS identifies potential actions within the proposed action that would require the alteration of stream features subject to Section 1602 of the California Fish and Game Code. This document requires Reclamation to secure an approved streambed alteration agreement before performing any actions subject to Section 1602.

California Fish and Game Code Sections 5900–5904, 5930–5948, 7261, and 7370 —Fish Passage

This PDEIS identifies potential actions that could result affect fish passage, and Reclamation will work closely with DFG to evaluate methods to avoid impacts on sturgeon, fish passage, and designated "Heritage Trout Waters." Potential impacts on fisheries are described in Chapter 11, "Fisheries and Aquatic Ecosystems."

Central Valley Flood Control Act of 2008

Reclamation has developed the proposed action in a manner that is consistent with the Central Valley Flood Control Act, and that would not inhibit development of the *Central Valley Flood Protection Plan*.

Central Valley Flood Protection Board Encroachment Permit

Certain proposed actions will require work along the Sacramento River in areas that may be subject to Title 23 because the river is managed for flood control and thus contains features subject to the jurisdiction of the Central Valley Flood Protection Board. Reclamation will secure encroachment permits, as needed, to satisfy Title 23 before performing any work along relevant reaches of the Sacramento River that contain flood control features subject to Central Valley Flood Protection Board jurisdiction.

Water Rights

The proposed action would not include any actions that would require acquisition, use, or modification of water rights. Therefore, the proposed action would comply with all existing water rights in the study areas.

California Public Resources Code

The Legislature has declared that the McCloud River, which is within the study area, possessed "extraordinary resources" in the context of the California Public Resources Code, Section 5093.542, established through enactment of the Wild and Scenic Rivers Act, as amended (Sections 5093.50 – 5093.70); however, the Legislature's action stopped short of formally designating the river as wild and scenic. Chapter 25, "Wild and Scenic River Considerations for McCloud River," evaluates potential effects of the proposed action on the McCloud River. New legislation may be required for State support and/or participation in the proposed action.

The California Public Resources Code also contains several other sections relevant to the project. Compliance with provisions of the California Public Resources Code is achieved in this PDEIS by analyzing the impact of proposed actions on recreation opportunities. Chapter 18, "Recreation and Public Access," of this PDEIS discusses effects on Shasta Lake and the surrounding recreation areas under the alternatives.

California Harbors and Navigation Code

Significant modifications to the facilities of Shasta Lake may necessitate coordination with the California Department of Boating and Waterways and/or the U.S. Coast Guard. Reclamation will conduct such coordination as necessary.

Porter-Cologne Water Quality Control Act

Proposed actions that have the potential to adversely affect water quality are identified in this PDEIS. Measures necessary for compliance with the act would need to achieve consistency with implementation programs under the water quality control plan for the Sacramento River basin, and with the Central Valley Regional Water Quality Control Board's waste discharge requirements. Other necessary actions would likely include application for and finalization of National Pollutant Discharge Elimination System permits and Section 401 water quality certifications.

California Land Conservation Act of 1965 (Williamson Act)

Approximately 51 percent of Shasta County's farmland is under Williamson Act contracts (Shasta County 2004). Williamson Act lands affected by the proposed action are discussed in Chapter 10, "Agriculture and Important Farmland."

California Clean Air Act

This PDEIS evaluates the contribution of the proposed action to any violation of air quality standards and identifies mitigation measures to help achieve consistency with the State implementation plan's attainment goal before implementation of any proposed actions.

California Native Plant Protection Act

All proposed actions are evaluated in this PDEIS for consistency with this act. Mitigation measures are provided, as necessary, to minimize potential take of listed and special-status plants under the California Native Plant Protection Act.

California Native Plant Society Species Designations

This PDEIS identifies plants of concern on California Native Plant Society lists that may be affected by proposed actions, using these lists as a method of identifying species of concern. Mitigation and minimization measures will be implemented, as necessary, to reduce the significance of potential impacts on these species of concern.

California Scenic Highway Program

On the south side of Shasta Lake, portions of State Route 151 are an officially designated State Scenic Highway. County Road A18 is an officially designated County Scenic Highway, and is also located on the southern banks of Shasta Lake. Portions of Interstate 5, as it approaches Shasta Lake and crosses the Pit River Bridge, are considered eligible for designation as a State Scenic Highway. Impacts on scenic highways are discussed in Chapter 19, "Aesthetics and Visual Resources."

State Lands Commission Land Use Lease

In the primary study area, the lands under the jurisdiction of the California State Lands Commission include areas along the Sacramento River, north of Red Bluff. Work on the Sacramento River would require a lease from the CLSC. Reclamation will coordinate with the California State Lands Commission and obtain a State Lands Lease before starting work in areas under California State Lands Commission jurisdiction.

California Surface Mining and Reclamation Act

In general, the Surface Mining and Reclamation Act of 1975 (SMARA) requires that the lead agency approve a permit and a reclamation plan and that an approved financial assurance be posted for the reclamation of the mined land. If borrow is required from borrow site(s), not previously permitted under SMARA, Reclamation will either obtain a SMARA permit or an exemption from SMARA for all borrow sites before beginning borrow activities.

State of California General Plan Guidelines

Chapter 8, "Noise and Vibration," evaluates long-term effects on noise levels in the study area. Long-term changes in noise levels associated with any proposed actions would be less than significant. Because Reclamation has evaluated long-term compatibility of noise levels, the proposed action would comply with these guidelines.

California Department of Transportation

Highway improvements or modifications such as may be required under this project may require an encroachment permit as issued through the California

Department of Transportation (Caltrans). The project may involve modifications to roadways that Caltrans considers "complex" and require extensive communication with the Caltrans Department of Engineering Services and/or structure-specific encroachment permits. These are detailed in the *Caltrans Encroachment Permits Manual*, which is available at the Caltrans Web site.

26.6.3 Local Plans and Policies

Shasta County Air Quality Management District's Authority to Construct and Permit to Operate

Reclamation would obtain an Authority to Construct permit before building or installing any new emissions unit or modifying any existing emissions unit that requires a permit, if necessary. Reclamation would also obtain a Permit to Operate after all construction is completed and the emission unit is ready for operation, if needed.

Other Local Permits and Requirements

Several other local permits and requirements may apply to the proposed action. Shasta and Tehama counties and their public works departments will require compliance with local plans and ordinances, such as the county general plan, zoning ordinances, grading plan, and various use permits. Utility easements and various encroachments also may be required.

Chapter 27
Public Involvement, Consultation, and Coordination

This chapter summarizes completed, ongoing, and anticipated public outreach and agency involvement efforts related to development of the SLWRI, including activities that satisfy NEPA requirements for public scoping and agency consultation and coordination. Chapter 29, "EIS Distribution List," lists the entities receiving a copy of the PDEIS. Reclamation encourages review of this PDEIS and will continue to solicit public and agency input on the proposed action.

27.1 Public Involvement Through Project Scoping

Public scoping activities are conducted as part of compliance with both NEPA and CEQA, but are more formalized under NEPA. Scoping allows agencies, stakeholders, organizations, and other interested parties to identify resources to be evaluated, issues that may require environmental review, reasonable alternatives to consider, and potential mitigation if significant adverse effects are identified. The scoping process helps with early identification of problems to be studied, and also helps to eliminate from detailed study issues that are not critical to the decision at hand. Scoping also provides decision makers with insight on the issues and concerns that the public believes should be considered as part of the feasibility study. Public scoping activities performed for the SLWRI environmental documentation process are described below.

27.1.1 Notice of Intent to Propose an Environmental Impact Statement

Reclamation initiated the scoping process by publishing a notice of intent to prepare an Environmental Impact Statement (EIS) and a notice of public scoping meetings pursuant to NEPA on October 7, 2005, in the *Federal Register* (Volume 70, pages 58744–58746). The opportunity for submitting written comments on the notice of intent extended through December 6, 2005.

On the same day that the notice of intent and notice of meetings were published in the *Federal Register*, Reclamation announced the scoping meetings to be held in a news release posted on the project Web site and distributed via e-mail to media in the extended study area. The release was also distributed to agencies, stakeholders, organizations, and other interested parties. A second news release on October 20, 2005, announced an additional scoping meeting to be held in Red Bluff, and was published in display advertisements that

Reclamation purchased in newspapers within the immediate study area in Redding, Red Bluff, and Dunsmuir.

27.1.2 Public Scoping Meetings

In 2005, seven public scoping meetings were conducted in an "open house" format throughout California to update the public on the status of the proposed action and to solicit and receive input on alternatives, project related concerns, and issues to be addressed in the environmental review process (see Table 27-1 for meeting locations and dates). Project team members from Reclamation and its consultants staffed informational workstations and interacted with meeting participants to provide information and answer questions. Attendance ranged from very light at the Fresno and Concord meetings to strong participation at the Dunsmuir, Redding, and Red Bluff meetings (Table 27-1). The proximity to the projects, and advertisements in three local newspapers, likely contributed to a stronger attendance in the northern cities.

Table 27-1. Scoping Meeting Locations and Attendance

Meeting Location	Date	Attendees Signed In
Sacramento	October 24, 2005	10
Concord	October 24, 2005	2
Los Angeles	October 26, 2005	4
Fresno	November 1, 2005	2
Dunsmuir	November 2, 2005	11
Redding	November 3, 2005	39
Red Bluff	November 3, 2005	20
Total		**88**

Source: Reclamation 2006

The meetings were attended by private citizens, Federal and State agency personnel, local government representatives, political representatives, members of the media, Native American groups, and business owners, and representatives of private industry, utilities, environmental interest groups, and nongovernmental organizations.

Displays of information were presented at each meeting on large-scale panels at a series of four workstations. Information included on these panels is summarized as follows:

Background

This workstation described Shasta Dam and Shasta Lake, authorization of the Federal feasibility study and other pertinent guidance, the CALFED Bay-Delta Program Record of Decision (ROD) relating to enlarging Shasta Dam and Shasta Lake, and the primary and extended study areas.

Environmental Overview

This workstation summarized the major resource areas to be evaluated, defined the biological, socioeconomic, physical, and cultural environments, and identified potential impacts on those environments. The workstation also included information on the Federal environmental review process and Federal and State regulatory requirements and processes.

Study Process

This workstation presented information on water resources problems and needs being addressed in the SLWRI environmental documents. The primary and secondary study objectives were identified along with the overall study mission. The workstation also included information about the Federal plan formulation process, including the development of the SLWRI initial alternatives and the formulation of comprehensive alternatives.

Initial Alternatives

This workstation described the initial alternatives formulated, potential major features associated with potential enlargement of Shasta Dam and Shasta Lake that are likely to be considered in future studies, and potential environmental restoration features to be included in the alternatives.

The *Environmental Scoping Report* (Reclamation 2006) describes the scoping process, comments received during scoping, and how these comments would be addressed as part of the SLWRI and in support documentation (e.g. Feasibility Report and EIS).

27.2 Other Public Outreach

In addition to scoping activities, other public outreach activities have included the following:

- Presentations to the Water Education Foundation (multiple years)
- Project update meetings with marina owners in the Shasta Lake area (multiple years)
- Bay-Delta Public Advisory Committee presentations (multiple years)
- Briefings to resource management groups and stakeholders (multiple years)
- Briefing to the Association of California Water Agencies
- Project Web site for the SLWRI (www.usbr.gov/mp/slwri/index.html)

Future meetings will focus primarily on public outreach related to the release of this PDEIS and the subsequent Draft EIS.

27.3 Consultation and Coordination

Reclamation has consulted various public agencies and organizations during the public outreach process and throughout development of the SLWRI PDEIS to obtain feedback on the investigation. Consultations have assisted Reclamation in determining the scope of the PDEIS, developing project components and objectives, identifying the range of alternatives, and defining potential environmental impacts, impact significance, and mitigation measures.

27.3.1 Consultation and Coordination with Agencies

Reclamation conducts ongoing consultation and coordination efforts with agencies. The SLWRI study management structure includes the active participation of numerous cooperating agencies and other stakeholders on a Project Coordination Team (PCT) and Study Management Team and in Technical Working Groups. Cooperating agencies for the SLWRI, pursuant to NEPA, include USFS, Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians, USACE, and U.S. Department of the Interior, Bureau of Indian Affairs. Other participants in the PCT include USFWS, NMFS, U.S. Department of the Interior, Bureau of Land Management, DWR, DFG, and other Federal and State agencies. These groups were active contributors to the ongoing development and/or review of the alternative plans that are addressed herein and in supporting documentation.

The PCT is among the most effective means of communication between agencies, continuing to provide for regular participation by numerous cooperating agencies. Regularly scheduled bimonthly meetings have been held and continue to be held, for the purpose of project coordination and decision making, with invitations extended to all cooperating agencies and other CALFED Bay-Delta Program agencies and the Central Valley Regional Water Quality Control Board.

Key elements of these coordination activities are the *Planning Aid Memorandum* and *Coordination Act Report*, documents to be issued by USFWS. A draft *Planning Aid Memorandum* outlining areas of potential concern was circulated among the resource agencies in the first quarter of 2007. Development of the *Coordination Act Report* began in summer 2007, with circulation of a draft in 2008.

27.3.2 Consultation and Coordination with Tribal Governments

Consistent with a memorandum from the President on April 29, 1994, Reclamation and the cooperating agencies will continue to actively engage Federally recognized tribal governments in planning and developing the investigation, and will consult with each tribe on a government-to-government basis before taking actions that could affect such tribal governments. Under Federal Trust responsibility, Reclamation will provide full disclosure (benefits and negative impacts) of the project, allow time for tribal review/consultation, and receive comments and/or suggestions for alternatives.

The PCT held several coordination meetings with Federally recognized tribes during 2007 and 2008. Tribes were invited to an informal meeting held on April 4, 2007, in Redding, California, to provide general information about the SLWRI and determine tribal participation interests. Additionally, from August 2007 to November 2008, members of the PCT held six separate meetings with four Federally recognized tribes whose traditional territories overlap with the SLWRI project area. The purposes of the meetings were to solicit, clarify, and document major concerns and issues regarding the SLWRI, and to establish a preferred method or approach for maintaining effective communication with each tribe during the remainder of the feasibility study and in future endeavors.

27.3.3 Coordination with Native American Tribal Groups

In accordance with Executive Order 12898, Native Americans – including Federally-recognized and non-Federally recognized tribes – are considered minority populations, and are encouraged as stakeholder groups to participate in the ongoing investigation. Several groups, such as the Winnemem Wintu and Shasta Nation, have expressed significant interest in the SLWRI. In response, the PCT conducted 10 meetings and dialogues in 2007 and 2008 with Native American groups whose traditional homelands overlap with the SLWRI study area; four of these meetings engaged non-Federally recognized tribes. Groups were invited to an April 4, 2007, informal meeting to receive general information about the SLWRI and to identify their interests for project participation. As with Federally recognized tribes, meetings were held with Native American groups to solicit, clarify, and document major concerns and issues regarding the SLWRI, and to establish each group's preferred method or approach for receiving communications about the SLWRI during the remainder of the study.

27.4 Major Topics of Interest

The focus of interest varied among the outreach activities, but a common theme centered on potential impacts on the Shasta Lake area that could result from enlargement of the reservoir.

The public, stakeholders, and other Federal agencies, and State and local agencies identified several areas of concern during SLWRI meetings and workshops. Key topics included potential adverse effects on cultural resources in the Shasta Lake area; recreation and recreation providers in the Whiskeytown-Shasta-Trinity National Recreation Area; terrestrial special-status species around Shasta Lake, including State-designated fully protected species, aquatic special-status species in the Sacramento River and Sacramento-San Joaquin Delta (including delta smelt); the lower McCloud River and its special designation under California Public Resources Code 5093.542(c); Delta water quality; south Delta water levels; Central Valley hydrology below CVP and SWP facilities and resulting effects on water supplies for water contractors and other water users; and consistency with the CALFED Bay-Delta Program ROD.

These topics are described in more detail in Section 1.6, "Areas of Controversy/Issues to Be Resolved."

27.5 Additional Steps in the Environmental Review Process

This PDEIS will be published for public, stakeholder, and agency review. During this period, stakeholder workshops will be held to present key findings and solicit input.

A Draft EIS will be prepared considering input from stakeholders and the public and results of updated modeling studies. In accordance with NEPA review requirements, the Draft EIS will be circulated for public and agency review and comment for at least 60 days following the date when the U.S. Environmental Protection Agency publishes the notice of availability of weekly receipt of environmental impact statements in the *Federal Register*. Similar to the approach to public scoping, public meetings will be held at that time at various locations statewide to solicit and receive public input on the DEIS. These meetings will be held during the public comment period so that any comments received at the meetings can be addressed in the FEIS. In addition, written comments from the public, reviewing agencies, and stakeholders will be accepted during the public comment period.

An FEIS will be prepared and circulated in accordance with NEPA requirements and will include responses to all comments. When the FEIS is complete, Reclamation will publish the document, and the notice of availability will be printed in the *Federal Register*, which will mark the start of a 60-day waiting period before Reclamation issues its ROD on the investigation. In the ROD, which is the final step in the EIS process, Reclamation will document its decision on which actions, if any, to take to address the primary objectives. It will also describe other risk reduction plans it considered, identify any mitigation plans, and describe factors and comments taken into consideration when making its decision.

To date, CEQA scoping has not been initiated. This process will commence after a State lead agency is identified.

Chapter 29
PDEIS Distribution List

This chapter provides an overview of the locations where this PDEIS is available for review and lists the agencies and organizations that received copies of this PDEIS. This list includes agencies and organizations that were involved in the scoping process for the proposed action, requested a copy of the PDEIS, or that may use the PDEIS for discretionary or informational purposes.

29.1 Document Availability

The public distribution of this PDEIS emphasizes the use of electronic media to ensure cost-effective, broad availability to the public and interested parties. This PDEIS is available on the Internet at Reclamation's Web site, <http://www.usbr.gov/mp/slwri/>. The PDEIS is also available for review at the following location:

U.S. Department of the Interior,
Bureau of Reclamation
2800 Cottage Way
Sacramento, CA 95825

29.2 Agencies and Organizations Receiving Copies of the PDEIS

All persons, agencies, and organizations listed in this chapter have been informed of the availability of and locations to obtain the PDEIS. Parties listed below have received an electronic copy of the entire PDEIS and appendices.

29.2.1 Federal and State Agencies

- U.S. Army Corps of Engineers
- U.S. Environmental Protection Agency
- U.S. Fish and Wildlife Service
- U.S. Forest Service
- National Marine Fisheries Service
- California Water Commission

- California Department of Boating and Waterways
- California Department of Conservation
- California Department of Fish and Game
- California Department of Public Health
- California Department of Parks and Recreation
- California Department of Toxic Substances Control
- California Department of Transportation
- California Department of Water Resources
- California Department of Food and Agriculture
- California Department of Forestry and Fire Protection
- California Environmental Protection Agency
- California Highway Patrol
- California Air Resources Board
- California Central Valley Flood Protection Board
- Central Valley Regional Water Quality Control Board
- State Water Resources Control Board
- California Energy Commission
- Delta Protection Commission
- Delta Stewardship Council
- Native American Heritage Commission
- State Lands Commission
- Office of Historic Preservation

29.2.2 Regional and Local Entities

- Shasta County
- Tehama County
- Shasta County Air Quality Management District
- Tehama County Air Quality Management District
- City of Redding
- City of Red Bluff

29.2.3 Other Interested Parties

- California Trout
- Environmental Defense
- Friends of the River
- Natural Heritage Institute
- Natural Resources Defense Council
- Pacific Coast Federation of Fishermen's Association
- Planning and Conservation League
- Sierra Club
- The Bay Institute
- The Nature Conservancy
- Winnemem Wintu
- Association of California Water Agencies
- California Urban Water Agencies
- Central Valley Project Water Association
- Friant Water Authority
- Kern County Water Agency
- Metropolitan Water District of Southern California

- San Luis-Delta Mendota Water Authority
- State Water Contractors
- Westlands Water District

Chapter 30
List of EIS Preparers

Following is a list of persons who contributed to preparation of this PDEIS.

This list is consistent with the requirements set forth in NEPA and CEQA (40 CFR 1502.17 and Section 15129 of the State CEQA Guidelines).

30.1 Federal

Reclamation (NEPA Lead Agency)	
Ron Ganzfried	Senior Reviewer
Katrina Chow	Project Manager
Janice Pinero	Environmental Resources
Carolyn Bragg	Environmental Resources
Jared Vauk	Geology
Russ Yaworsky	Water Operations
Steve Lloyd	Engineering
Buford Holt	Environmental Resources
Bill Taylor	Economics
Tom Hepler	Engineering
Bob Gee	Planning
Craig Stroh	Economics
Omid Rowhani	Economics
Julie Bowen	Real Estate
Chuck Johnson	Recreation
Scott Springer	Recreation
John Hannon	Fisheries Biologist
Patricia Rivera	Indian Trust Assets
Anastasia Leigh	Cultural Resources
Laureen Perry	Cultural Resources
David Hansen	GIS

30.2 Non-Federal

30.2.1 Consultants

Name	Qualifications	Participation
MWH		
Mary Paasch	B.S., Agricultural Engineering; M.S., Agricultural Engineering; 15 years experience.	Project Manager
Craig Wallace	B.S., Civil Engineering; 6 years experience.	Assistant Project Manager
Nicole Smith	B.S., Wildlife, Fisheries, and Conservation Biology; 6 years experience.	Project Planner; Document Coordination
Stefani Harrison	B.S., Environmental Engineering and Sciences; B.S., Urban Studies and Planning; M.S., Civil Engineering; 10 years experience.	Project Planner
Danelle Bertrand	B.S., Civil Engineering; M.S., Civil Engineering; 4 years experience.	Project Planner
Ian Buck	B.S., Civil Engineering; 1 year experience.	Engineering and Cost Estimating
Andy Draper	B.S., General Engineering; M.S., Irrigation Engineering; Ph.D., Water Resources; 32 years experience.	Water Quality; Hydrology, Hydraulics, and Water Management
Stephanie Theis	B.S., Fisheries Ecology; 20 years experience.	Fisheries and Aquatic Ecosystems
Erica Bishop	B.S., Geography; M.S., Water Resources/ Geography; 7 years experience.	Recreation and Public Access
Anna Fock	B.S., Civil Engineering; M.S., Civil Engineering; 12 years experience.	Power and Energy
Rajaa Hassan	B.S., Civil Engineering; M.S., Civil and Environmental Engineering; 10 years experience.	Power and Energy
Heather Shannon	B.S., Geology; M.S., Hydrology; 7 years experience.	Geology, Geomorphology, Minerals, and Soils
Barbara McDonnell	B.A., Biology; M.A., Biology; 37 years of experience.	NEPA/CEQA Specialist
Eric Clyde	B.S., Civil Engineering; M.S., Civil Engineering; 35 years experience.	Engineering; Hydrology, Hydraulics, and Water Management.

Name	Qualifications	Participation
Shankar Parvathinathan	B.E., Chemical Engineering; M.S., Environmental Engineering; Ph.D., Environmental Engineering; 10 years experience.	Engineering and Hydraulics
Josh Cowden	B.S., Zoology/Physiology and Environment and Natural Resources; M.S., Environmental Engineering; Ph.D., Environmental Engineering; 8 years experience.	Engineering
James Loucks	B.S., Construction Engineering; 30 years experience.	Cost Estimating
Don Crone	B.S., Civil Engineering; 36 years experience.	Cost Estimating
Paul Smith	B.S., Civil Engineering; 44 years experience.	Cost Estimating
Roger Schiller	41 years experience.	Cost Estimating
Elmer Cabero	B.S., Civil Engineering; M.A., Business Administration; 30 years experience.	Cost Estimating
Puja Mohandas	B.A., Architecture; M.A., Architecture; M.S., Civil Engineering; 7 years experience.	Cost Estimating
Craig Moyle	B.A., Journalism; 18 years experience.	Public Involvement
Maricela Leyva	10 years experience.	Administrative Assistant
Emily McAlister	B.A., Liberal Studies; 30 years experience.	Technical Editing
Mary Pat Smith	B.S., Animal Science; 20 years experience.	Technical Editing
Jim Darke	B.F.A., Liberal Arts; 24 years experience.	GIS
Steve Irving	B.A., Philosophy; 19 years experience.	GIS
Chisa Nishii	B.S., Environmental Biology and Management; M.S., Geographic Information Systems; 9 years experience.	GIS
Mimi Reyes	B.F.A., Graphic Design; 21 years experience.	Graphics
Jasmine Gerber	A.S., General Education; B.S. Graphic Design; 7 years experience.	Graphics

Name	Qualifications	Participation
Nora Antonio	A.A., Universal Studies; 17 years experience.	Word Processing
Amy Lehman	19 years experience.	Word Processing
AECOM		
Phil Dunn	B.S., Zoology; M.S., Fisheries Biology; 29 years experience.	EIS Principal-in-Charge
John Hunter	B.A., Environmental Studies; M.A., Ecological and Systematic Biology; Ph.D., Plant Biology; 22 years experience.	EIS Project Manager; ASIP Project Manager
Stephanie Rasmussen	B.S., Environmental Biology and Management; 7 years experience.	EIS Assistant Project Manager
Kerry McWalter	B.S., Environmental Engineering; M.E., Aquatic Ecology; 9 years experience.	Water Quality
Vick Germany	B.A., Ecology and Systematics; M.A., Resource Management and Environmental Planning; 21 years experience.	Water Quality
Samantha Salvia	B.S., Civil Engineering; B.A., Philosophy, Politics, and Economics; M.S., Civil and Environmental Engineering; 11 years experience.	Water Quality
Kara Baker	B.A., Political Science and Environmental Science; M.S., Civil and Environmental Engineering; 6 years experience.	Water Quality
Alice Berg	B.S., Biology; M.S., Natural Resources: Fisheries, Concentration in freshwater ecology and fisheries; 17 years experience.	Fisheries and Aquatic Ecosystems
Chris Fitzer	B.A., Geography (Environmental Concentration); MURP, Environmental Planning (Watershed/Water Resource Concentration); 14 years experience.	Fisheries and Aquatic Ecosystems
Dave Epstein	B.S., Environmental Biology and Management; 5 years experience.	Fisheries and Aquatic Ecosystems
Leo Edson	B.S., Biological Sciences; 22 years experience.	Wildlife Resources

Name	Qualifications	Participation
Linda Leeman	B.S., Wildlife and Fisheries Biology; M.S., Natural Resources (with distinction); 17 years experience.	Wildlife Resources
Kelly Holland	B.A., Environmental Studies; M.S., Environmental Science; 14 years experience.	Wildlife Resources
Petra Unger	M.S., Botany (minors in Soil Science and Zoology); 16 years experience.	Botanical Resources and Wetlands
Tammie Beyerl	B.A. (Cum Laude), Plant Biology; M.S., Plant Biology (Ecology); 7 years experience.	Botanical Resources and Wetlands
Honey Walters	B.S., Environmental Science; M.S., Atmospheric Science; 10 years experience.	Air Quality and Climate; Noise
Jim Kurtz	B.S., Atmospheric Science (concentration in Meteorology); M.S., Atmospheric Science (concentration in Environmental Sustainability); 4 years experience.	Air Quality and Climate
Jake Weirich	B.S., Sound Engineering; 4 years experience.	Noise and Vibration, Air Quality and Climate
Jim Vogel	B.S., Forest Recreation Resource Management; M.S., Forest Recreation Resource Management; Ph.D., Natural Resource Recreation and Tourism; 13 years experience.	Recreation and Public Access
Anne Ferguson	B.S., Natural Resource Recreation and Tourism; M.S., Environmental Sustainability; 7 years experience.	Recreation and Public Access
Rudy Calderon	B.A., Anthropology; M.A., Urban Planning; 10 years experience.	Geology, Geomorphology, Minerals, and Soils; Public Involvement
Jan Mulder	B.A., Geology; Graduate Studies, Planning; 27 years experience.	Socioeconomics, Population, and Housing; Environmental Justice
Jeff Caudill	B.A., Environmental Studies and Biology; M.U.R.P., Urban and Regional Planning; 5 years experience.	Socioeconomics, Population, and Housing; Environmental Justice
Peter Sullivan	B.A., Environmental Studies, Emphasis on Land Use, Natural Resources, and Parks; M.S., Urban Planning; 6 years experience.	Socioeconomics, Population, and Housing; Environmental Justice

Name	Qualifications	Participation
Jayni Allsep	B.A., Social Ecology - Environmental Analysis and Planning; 22 years experience.	Transportation and Traffic
Andrew Bayne	B.A., Health and Human Performance; 9 years experience.	Transportation and Traffic
Jenifer King	B.S., Biology; 16 years	Socioeconomics, Population, and Housing; Environmental Justice; Agriculture and Important Farmlands
Yanna Badet	M.S., Environmental Sciences; 8 years experience.	Agriculture and Important Farmlands
Matt Jacobs	B.S., Environmental Economics and Policy; 6 years experience.	Other Required Disclosures
Julie Nichols	B.A., Political Science (with honors); M.S., Journalism; 20 years experience.	Technical Editing
Lisa Clement	B.S., Environmental and Resource Sciences; 10 years experience.	GIS
Peter Jonas	B.A., Biology and Geography; M.S., Environmental Science; 23 years experience.	GIS
Brian Perry	27 years experience.	Lead Graphics
Christy Anderson	B.A., Fine Art; 24 years experience.	Graphics
Lorrie Jo Williams	B.S., Design; 22 years experience.	Graphics
Debby Jew	A.A., Liberal Arts; 22 years experience.	Word Processing
Amber Giffin	16 years experience.	Word Processing
Gayiety Lane	A.A., Liberal Arts; 11 years experience.	Word Processing
Roni Olaizola	A.A., Sociology (in progress); 24 years experience.	Word Processing
North State Resources		
Paul Uncapher	B.A., Geology; 32 years experience.	Project Manager
Keith Marine	B.S., Wildlife and Fisheries Biology; M.S., Ecology; 27 years experience.	Fisheries and Aquatic Ecosystems
Amy Carl	B.S., Wildlife Ecology and Conservation; 10 years experience.	Fisheries and Aquatic Ecosystems

Name	Qualifications	Participation
Scott Goebl	B.A., Geography; 20 years experience.	Land Use and Planning, Utilities and Service Systems, Public Services
Mike Gorman	B.S., Fisheries; 8 years experience.	Fisheries and Aquatic Ecosystems
Wirt Lanning	B.S., Ecology and Systematic Biology; 17 years experience.	Land Use and Planning, Public Services, Utilities and Service Systems
Kathleen Hitt	B.S., Environmental Studies and Psychology; J.D., Natural Resource Law; 6 years experience.	Land Use and Planning, Public Services, Utilities and Service Systems, Hazards and Hazardous Materials and Waste
Jim Fitzgerald	B.S., Geoscience; M.S., Geoscience; 13 years experience.	Geology, Geomorphology, Minerals, and Soils; Water Quality
Duncan Drummond	B.S., Geology; 7 years experience.	Geology, Geomorphology, Minerals, and Soils; Water Quality
Ginger Bolen	B.S., Wildlife Science; Ph.D., Integrative Biology; 17 years experience.	Botanical Resources and Wetlands, Wildlife Resources, Public Services, Utilities and Service Systems
Heather Kelley	B.S., Biology; 15 years experience.	Botanical Resources and Wetlands, Wildlife Resources
Len Lindstrand III	B.S., Wildlife Management; Minors in Fisheries Management and Forestry; 19 years experience.	Botanical Resources and Wetlands, Wildlife Resources
Constance Carpenter	B.A., History; B.S., Range Resources with emphasis in Fire Ecology; M.S., Forest Resources; 21 years experience.	Aesthetics and Visual Resources
Kathryn McDonald	B.A., English; 32 years experience.	Writing and Technical Editing
Sylvia Cantu	A.A., Court Reporting; 30 years experience.	Word Processing
Charles Shoemaker	B.S., Wildlife Biology (currently enrolled in M.S. program); 11 years experience.	GIS
Edward Douglas	B.A., Geography (with emphasis on GIS); 4 years experience.	GIS

Name	Qualifications	Participation
Hanson Environmental, Inc.		
Chuck Hanson	B.S., Fisheries Biology; M.S., Fisheries Biology; Ph.D., Ecology and Fisheries Biology; 32 years of experience.	Fisheries and Aquatic Ecosystems
Kristie Karkanen	B.A., Communications; 7 years experience.	Fisheries and Aquatic Ecosystems
Far Western Anthropological Research Group, Inc.		
Brian Byrd	B.A., Anthropology; M.A., Anthropology; Ph.D., Anthropology; 35 years experience.	Cultural Resources
William Hildebrandt	B.A., Anthropology; M.A., Anthropology; Ph.D., Anthropology; 35 years experience.	Cultural Resources
Kelly McGuire	B.A., Cultural Anthropology; M.A., Cultural Anthropology; 35 years experience.	Cultural Resources
Melissa Cascella	B.A., History; B.S., Anthropology; M.A., Cultural Resources Management; 8 years experience.	Cultural Resources
Wendy Masarweh	A.A., Anthropology and Art; UC Berkeley Extension Graphic Design Certificate Program; 22 years experience.	Cultural Resources
Anna Starkey	B.A., Anthropology; 4 years experience.	Cultural Resources
Aaron Buehring	B.A., Anthropology; 5 years experience.	Cultural Resources
Ryan Mitchell	B.S., Evolution and Ecology; B.S., Anthropology; 5 years experience.	Cultural Resources
Kathleen Montgomery	A.A., General Education; B.A., Communications, Graphic Arts; 6 years experience.	Cultural Resources
Daniel Troglin	B.A., Anthropology; 9 years experience.	Cultural Resources
Paul Brandy	B.S., Wildlife and Conservation Biology; M.S., Natural Resources Management (Wildlife); 10 years experience.	GIS
Tammara Norton	B.A., Anthropology; B.A., Art; 30 years experience.	Word Processing
